Notes:

[A] These top samples were analysed multiple times, first by a reinjection of the initial extracts and then by using aliquots from a fresh weighing of sample material. The mean result is shown. The results suggest that the untreated control sample, having a residue of 2.10 mg/kg, was switched with the treated sample. The result for the control sample is presumed to pertain to the treated sample.

[B] Applications were separated by 14 days, rendering the trials independent.

Subgroup of Cereal grains (including pseudocereals) feed products with high water (≥20 percent) content (forage and silage)

FATE OF RESIDUES IN STORAGE AND PROCESSING

Effects on the nature of the residue during processing

Radiolabelled [triazole-3(5)-^{14}C]-mefentrifluconazole and [chlorophenyl-U-^{14}C]-mefentrifluconazole were incubated in aqueous citrate-NaOH buffer solutions at concentrations of about 1 mg/L under three sets of conditions, each designed to simulate an appropriate process: 90 °C (pH 4, 20 minutes) to simulate pasteurisation, 100 °C (pH 5, 60 minutes), to simulate boiling, baking and brewing, and 120 °C (pH 6, 20 minutes in the dark) to simulate sterilisation (Hassink et al., 2014, BASF DocID 2014_1170665).

Total recovered radioactivity was measured for each test solution by LSC. Radioactive components were characterised by HPLC. Chiral analysis of mefentrifluconazole was also conducted using HPLC.

Under conditions representative of industrial and household processing procedures such as pasteurisation (pH 4, 90 °C, 20 min), baking, boiling, brewing (pH 5, 100 °C, 60 minutes) and sterilisation (pH 6, 120 °C, 20 minutes), mefentrifluconazole is shown to be stable. In addition, no degradation product exceeding 2 percent of total radioactivity was detected. Also, no change in the isomer ratio was observed. In conclusion, as mefentrifluconazole can be regarded as stable to hydrolysis, the nature of the residue is not affected by processing operations (Tables 150 and 151).

Residues after processing

Oranges

Three processing trials were carried out in the United States during the 2016 growing season (Bledsoe, 2017, BASF Reg. Doc. No. 2017_7008040) where oranges received three foliar airblast applications each at a rate of 736-754 g ai/ha, at 14-day intervals, of an EC formulation containing 100 g/L mefentrifluconazole. A nonionic surfactant (NIS) was added to the spray mixture for all applications. Mature oranges were harvested on the day of the last application (0 DALA) and transported to the processing facility under ambient conditions. At the processing facility, samples were processed within three days of receipt into juice, wet pomace, dried pomace, pulp, dried pulp, peel, peel after oil extraction, oil and marmalade according to commercial practices.

Washed oranges (6 kg) were hand peeled to generate the washed peel sample. A separate sample of washed oranges (190 kg) were then abraded for 45 seconds to scarify the flavedo for oil recovery. The scarified fruit was hand peeled to generate the peel after oil extraction sample. The remaining peeled, scarified fruit was used to make wet and dried pulp. To make wet and dried pulp, the peeled and scarified fruit (22 kg) was chopped using a food processor and fed through a pulper finisher.

The juice from the finisher was used to make marmalade. The pulp recovered from the finisher was pressed using a fruit press to form the wet pulp. A portion of the wet pulp was dried in an air dryer to < 10 percent moisture and the dried pulp was milled to a finished moisture content of 2.62–4.52 percent.

For the juice, scarified oranges (26 kg) were transferred to a juice extractor for juice removal. The collected juice was transferred to a pulper finisher and screened to remove the vesicular membranes, seeds, segment membranes, and peel fragments.

To make the oil, the collected oil-water emulsion from the scarification process was transferred to a sifter and screened to separate any flavedo fractions from the oil-water emulsion. The scarified flavedo fraction was used to make pomace. The oil-water emulsion was processed through a cream separator and centrifuged to separate the oil from the emulsion.

For pomace, peel from the juicing process was shredded using a food processor. The shredded peel was combined with the rag and seed from the juicing process and the scarified flavedo, lime (~95 percent CaO) was added and mixed, and then the limed pomace was pressed to generate the wet pomace sample. A portion of the wet pomace was dried in an air dryer to < 10 percent moisture and the dried pomace was milled to a finished moisture content of 2.62–4.36 percent.

To make the marmalade, orange rind was removed with a vegetable peeler and cooked for 20 minutes. An aliquot of juice from the pulp processing was cooked on a stove with 20 percent water added by weight. The cooked rind and juice were combined with lemon juice (3 tablespoons juice per kg fruit) and sugar (1.5 times the total weight of the fruit mixture) and boiled for 3 minutes. Pectin was added and the mixture was boiled for an additional 2 minutes to produce the finished marmalade which was packed into sterilized jars.

Residues of mefentrifluconazole in oranges and all processed commodities were determined using LC-MS/MS method D1511/01. The LOQ was 0.01 mg/kg for the RAC and all processed commodities. The maximum duration between sampling of the oranges and processed commodities and analysis was 138 days. Adequate storage stability data are available to support the storage conditions and durations for the samples in the present study. Processing factors are shown in Table 152.

Apples

Three processing trials were carried out in the United States during the 2014 and 2015 growing seasons (Hummel, 2017, BASF DocID 2017_7000414) where apples received three foliar airblast applications each at a rate of 296-304 g ai/ha, at 6 to 8-day intervals, of an SC formulation containing 400 g/L mefentrifluconazole. An adjuvant was added to the spray mixture for all applications. Mature apples were harvested on the day of the last application (0 DALA) and transported to the processing facility under ambient conditions. At the processing facility, samples were processed within 4–9 days of receipt into

apple sauce, dried applies, canned apple, wet pomace, washed whole apples, apple juice, dried pomace, wash water, and fruit syrup according to commercial practices.

To produce washed whole apples and wash water, the fruit (25 kg) were first washed in a wire basket that was submerged multiple times in 19 L buckets of water. The wash water sample was collected directly from each water bucket.

For apple juice, wet and dry pomace, and fruit syrup, washed whole fruit samples were passed through a hammer mill to produce apple mash. The mash was separated into juice and wet pomace using a hydraulic press. A portion of the juice was heated in a kettle for 4 hours at 68–74 °C to produce fruit syrup. To pasteurize the juice, the juice sample was microwaves for 12 minutes at 100 percent power (equivalent to 85 °C on a 1200-watt microwave). To generate the dry pomace samples, a portion of the wet pomace was dried on a tray in a dehydrator for 18–20 hours at 57–63 ºC to a moisture content of approximately 10 percent.

To produce apple sauce, canned apple, and dried apple slices, washed whole apples were peeled, cut into quarter-inch slices, and cored. The quarter-inch slices were further cut in half. A portion of the apple slices were placed in a kettle with about 473 mL of water, heated to 71 °C for 20 minutes, and stirred to generate slices in syrup for canned fruit. Another portion of the apple slices was similarly placed in a kettle with about 473 mL of water, heated to 71 °C for 45 minutes, and mashed to generate apple sauce. The remaining apple slices were placed on dehydrator trays and dried at 66–71 °C for 20–24 hours to produce the dried apple slices with a moisture content of approximately 10 percent.

Residues of mefentrifluconazole in apples and all processed commodities were determined using LC-MS/MS method D1511/01. The LOQ was 0.01 mg/kg for the RAC and all processed commodities. The maximum duration between sampling of the apples and processed commodities and extraction for analysis was 428 days. Adequate storage stability data are available to support the storage conditions and durations for the samples in the present study. Processing factors are shown in Table 153.

Plums

Three processing trials were carried out in the United States during the 2014 and 2015 growing seasons (Hummel, 2017, BASF DocID 2017_7000415) where plums received three foliar airblast applications each at a rate of 298-307 g ai/ha, at 7-day intervals, of an SC formulation containing 400 g/L mefentrifluconazole. An adjuvant was added to the spray mixture for all applications. Mature plums were harvested on the day of the last application (0 DALA) and transported to the processing facility under ambient conditions. At the processing facility, samples were processed within 3 days of receipt into dried prunes, de-pitted plums, juice, puree, washed whole plums and wash water according to commercial practices.

To produce washed whole plums and wash water, the fruit (27 kg) were first washed in a wired basket that was submerged multiple times in 19L buckets of water. The wash water sample was collected directly from each water bucket. The remaining fruit was pitted to generate the de-pitted plum sample.

To make juice, puree, and prunes, portions of the washed pitted fruit (21 kg) was passed through an electric juice processor, passed through an electric food strainer/sauce maker, or dried on a tray in a dehydrator for 14-18 hours at 54-66 ºC to a moisture content of 15-18 percent, respectively.

Residues of mefentrifluconazole in plums and all processed commodities were determined using LC-MS/MS method D1511/01. The LOQ was 0.01 mg/kg for the RAC and all processed commodities. The maximum duration between sampling of the plums and processed commodities and extraction for analysis was 603 days. Adequate storage stability data are available to support the storage conditions and durations for the samples in the present study. Processing factors are shown in Table 154.

Peach

Two processing trials were carried out in the United States during the 2017 growing season (Crawford, 2018, BASF DocID. No. 2018_7003950) where peaches received three foliar airblast applications each at a rate of 148–153 g ai/ha, at 7-day intervals, of an SC formulation containing 400 g/L mefentrifluconazole, applied either as a concentrated spray volume (591–764 L/ha) or dilute spray volume (1956–2304 L/ha). An adjuvant was added to the spray mixture for all applications. Mature peach (3.4 kg) were harvested on the day of the last application (0 DALA), frozen within 2.5 hours of collection, and shipped frozen by freezer truck to the processing facility ≤ 27 days later. At the processing facility, samples were processed by peeling whole peaches into peel and pulp sample.

Residues of mefentrifluconazole in peach fruit, peach pulp, and peach peel were determined using LC-MS/MS method D1511/01. The LOQ was 0.01 mg/kg for the RAC and all processed commodities. The maximum duration between sampling of the peach and processed commodities and extraction was 250 days. Adequate storage stability data are available to support the storage conditions and durations for the samples in the present study. Processing factors are shown in Table 155.

[2] RAC = raw agricultural commodity.

Grapes

Three processing trials were carried out in Germany during 2014 (Plier et al., 2016, BASF DocID 2014_1315284) where wine grapes received two foliar applications each at a rate of 430–460 g ai/ha, at 21–36-day intervals, of an EC formulation containing 100 g/L mefentrifluconazole. Mature grapes were harvested on the day of the last application (0 DALA, not discussed further) and 21 DALA and transported to the processing facility under ambient conditions. At the processing facility, grape samples were processed into must (naturally cloudy, deposit, separated), pomace, pasteurized juice, yeast deposit, wine, stalks, crush, and raisins according to commercial practices.

For grapes used to make rosé wine, juice was prepared by crushing unwashed grapes (51 kg) in a grape mill. The mash (stalks, flesh, skin, seed and juice) was pressed to extract the liquid. Samples of must naturally cloudy and pomace were taken. Subsequently, $K_2S_2O_5$ (SO_2) was added to the must as a preservative prior to clarification (natural sedimentation). After clarification, samples of must deposit and must were separated and collected. The raw juice was then pasteurized (83–87 °C for 2 minutes), bottled and sampled.

For grapes used to make red wine, juice was prepared by crushing red grape bunches (51 kg) in a stalk separator mill which removed the stalks from the rest of the mash. Stalks and crush were sampled. Subsequently, $K_2S_2O_5$ (SO_2) was added. Following crushing, the mash was heated up to 60 °C for two minutes and stirred. After cooling down, the mash was pressed to extract the liquid. Samples of must naturally cloudy and pomace were taken. After clarification must deposit and must were separated and sampled. The raw juice was then pasteurized (83–87 °C for 2 minutes), bottled and sampled.

For the vinification process (both rosé and red wine), raw juice was poured into glass vessels and pure culture yeast and nutrient salt was added to begin fermentation. After fermentation and clarification with $K_2S_2O_5$ (SO_2), the intermediate liquid was transferred to a new vessel and the yeast deposit was sampled. Bentonite was added to liquid to absorb proteins and $K_2S_2O_5$ (SO_2) was added. The resultant young wine was filtered after clarification and then bottled for maturation and stored at approximately 8 ºC. After maturation, the wine was sampled.

For the production of raisins, washed grape bunches were put in boiling water and then manually washed with cold tap water in a vessel. The bunches were dried in an oven (70 °C) for 23:20–26:00 hours until a moisture content of 10.08–10.90 percent was achieved. After drying, raisins were manually

removed from the stalks. Raisins and stalks were sampled.

Residues of mefentrifluconazole in grapes and all processed commodities were determined using LC-MS/MS method L0076/09. The LOQ was 0.01 mg/kg for the RAC and all processed commodities. The maximum duration between sampling of the grapes and processed commodities and extraction was 518 days. Adequate storage stability data are available to support the storage conditions and durations for the samples in the present study. Processing factors are shown in Table 156.

Notes:

[1] DALA = days after last application.

[2] The processing factors were calculated by dividing the residue in the processed fraction by the residue for the RAC sample (processor RAC).

[3] RAC = raw agricultural commodity.

Strawberries

Three processing trials were carried out in Germany during the 2020 growing season (Plier *et al*., 2021, BASF DocID 2020/2108050) where strawberries received three foliar applications each at a rate of 315–342 g ai/ha, at 7 day intervals, of a suspension concentrate with 75 g/L mefentrifluconazole. Mature strawberries (BBCH 87) were harvested on the final day of application (0 DALA) and one day after the last application (1 DALA). Strawberry RAC samples were shipped at ambient temperature by car from the test facilities to the processing facility where they were stored under cooled conditions until processing. Samples were processed according to commercial practices into washed strawberries, wash water, canned strawberries, fruit syrup, jam before cooking, and jam after cooking.

Strawberry fruits without stems were manually washed in tap water for 3 minutes. Samples of wash water and washed strawberries were collected and placed into frozen storage until analysis.

For the production of jam, sugar (400 g) and glucose-syrup (800 g) were mixed with washed strawberries (900 g) and boiled for ~ 8–14 minutes until a dry substance of 63–65 percent was reached. Citric acid (8 g) and a 5 percent pectin solution (8 g pectin in 0.16 L water) were then added and the mixture was boiled until a dry substance of 60–62 percent was achieved. The jam was left to cool down for 120 minutes. The pH of the final product was 2.99–3.07. Samples of jam before cooking and jam after cooking (after cool down period) were taken and placed into frozen storage until analysis.

For the production of canned strawberries and fruit syrup, water (0.90 L), ascorbic acid (3.81 g), citric acid (2.25 g), and sugar (540–600 g) were mixed with washed strawberries (3000 g) and boiled for 30 seconds. The mixture was poured into jars and then filled with the water used for cooking until 2 cm below the rim. The jars were closed and placed into an autoclave at 91 °C for 2 minutes. Following pasteurization, the jars were allowed to cool for 120 minutes. The pH of the final product was 3.31–3.58. Samples of fruit syrup and canned strawberries were collected and placed into frozen storage until analysis.

Residues of mefentrifluconazole in strawberries and all processed commodities were determined using LC-MS/MS method L0076/09 (Plier *et al*., 2021, BASF DocID 2020/2108050). The limit of quantification (LOQ) was 0.01 mg/kg for the RAC and all processed commodities. The maximum duration between sampling of the strawberries and processed commodities and extraction was 166 days. All samples were analysed within 7 days of extraction. Processing factors are shown in Table 157.

Notes:

[1] DALA = Days after last application.

[2] Mefentrifluconazole residues values of the Processor RAC (i.e. strawberry samples analysed prior to processing) were used for the calculation of the processing factors.

[3] RAC = raw agricultural commodity, representative sub-samples were collected prior to processing.

Cucumbers

Three processing trials were carried out in Germany during the 2020 growing season (Plier et al., 2021, BASF DocID 2020/2108051) where cucumbers received three foliar applications each at a rate of 317–365 g ai/ha, at 6–7 day intervals, of a suspension concentrate with 75 g/L mefentrifluconazole. Fruits (BBCH 74–79) were harvested on the final day of application (0 DALA) and three days after the last application (3 DALA). Cucumber RAC samples were shipped at ambient temperature by car from the test facilities to the processing facility where they were processed immediately. Samples were processed according to commercial practices into canned gherkins, vegetable stock, wash water, washed gherkins, pickled gherkins, and brine.

Cucumber fruits without stems were manually washed in tap water for 3 minutes. Samples of wash water and washed gherkins were collected and placed into frozen storage until analysis.

For the production of pickled gherkins, a 5 percent (w/w) sodium chloride solution mixed with 1 percent (w/w) sugar was briefly boiled and then cooled down. This solution was filled into earthenware crocks containing washed cucumbers, which were weighted down. The crocks were closed and stored for 3 days at room temperature and subsequently 42–43 days at cooled conditions of 5–11 °C. Samples of brine and pickled gherkins were taken and placed into frozen storage until analysis.

For the production of canned gherkins and vegetable stock, water (2000 g), vinegar (800 g of 10 percent acid), salt (200 g), and sugar (400 g) were mixed and boiled for 30 seconds. The mixture was filled into jars containing washed cucumbers until 2 cm below the rim. The jars were closed and placed into an autoclave at 118–120 °C for 8–15 minutes. Following sterilization, the jars were allowed to cool for 60 minutes. Samples of vegetable stock and canned gherkins were collected and placed into frozen storage until analysis.

Residues of mefentrifluconazole in cucumbers and all processed commodities were determined using LC-MS/MS method L0076/09 (Plier et al., 2021, BASF DocID 2020/2108051). The limit of quantification (LOQ) was 0.01 mg/kg for the RAC and all processed commodities. The maximum duration between sampling of the cucumbers and processed commodities and extraction was 140 days. All samples were analysed within 7 days of extraction. Processing factors are shown in Table 158.

[3] RAC = raw agricultural commodity, representative sub-samples were collected prior to processing.

Tomatoes

Three processing trials were carried out in the United States during the 2016 growing season (Reeves, 2018, BASF DocID 2018/7005677) where tomatoes received three foliar applications each at a rate of 445–462 g ai/ha, at 6 to 8 day intervals, of an emulsifiable concentrate with 100 g/L mefentrifluconazole. An adjuvant (non-ionic surfactant) was added to the spray mixture for all applications. Tomato RAC samples and a single tomato fruit bulk sample were harvested on the final day of application (0 DALA) at the fruit ripening to full maturity growth stages (BBCH 82-89). Bulk tomato samples were shipped at ambient temperature within 24 hours of collection by overnight courier from the test facilities to the processing facility where they were stored under refrigerated conditions until processing. Samples were processed according to commercial practices into blanched tomatoes, blanching water, canned tomatoes, ketchup after pasteurization, paste, peeled tomatoes, puree, raw juice, sun-dried tomatoes, tomato peel, vegetable stock, wash water, washed tomatoes, and wet pomace.

Tomatoes were sorted by culling unsuitable fruits. Tomatoes to be processed were placed in water at temperatures of ~ 52–57 °C for 3–5 minutes and then rinsed with water. Defects and off-coloured areas were trimmed off prior to processing. Samples of wash water and washed tomatoes were collected and placed into frozen storage until analysis.

For the production of juice, paste, and puree, washed tomatoes were chopped in a Hobart food chopper and passed over a 6/64" screen. Material passing through the screen was pumped through a heat exchanger at ~ 90–97 °C and then passed through a 0.033" screen. Pulp material that did not pass through both screens was combined and collected as the representative sample of wet pomace. Tomato juice filtering through the 0.033" screen was checked for percent solids and acidity, and then adjusted accordingly to a pH of 4.5 or less with a 0.5 percent citric acid solution. Samples of raw juice were collected and placed into frozen storage until analysis. Tomato juice was used to produce puree and paste. Puree was generated by evaporating water from the tomato juice under heat and vacuum until a Brix range of 8–24 percent. Paste was produced using the same method but was concentrated to a Brix range of 24–30 percent. Both puree and paste were heated to ~ 85–91 °C and placed into metal cans and sealed. Cans were cooled in a 16–32 °C water bath for 28–32 minutes, and subsequently placed into frozen storage until analysis.

Tomato juice was also used in the production of ketchup. Tomato juice was evaporated to a solids content of 30–35 percent, and then vinegar (1.0–2.9 percent), sugar (4.5–5.5 pervent), and salt (0.9–1.2 percent) were added to the evaporated juice and stirred for 15 minutes. The mixture was screened through a sieve to remove large particles. Material passing through the screen was collected as ketchup, and placed into frozen storage until analysis.

Sun-dried tomatoes were produced by slicing cleaned tomatoes to ¼–3/8" thickness and put into a dehydrator, which dried the slices at ~ 49–54 °C for 24–26 hrs. The sun-dried tomatoes were placed into frozen storage until analysis.

For the production of canned tomatoes, washed tomatoes were blanched with 18–22 psi steam in a kettle for 1–3 minutes. Blanched tomatoes were placed into water to remove the skin. Blemishes were trimmed off following skin removal. The tomatoes were then put into cans with heated tomato juice, sealed, and cooked in a pressure cooker at 121–124 °C for 50–60 minutes. Canned tomatoes were cooled in a 16–32 °C water bath for 28–32 minutes, and subsequently placed into frozen storage until analysis.

Blanched tomatoes were produced by slicing an "X" on the bottom of each washed tomato and then placing into 98–101 °C water for 30–60 seconds. Tomatoes were removed from the boiling water and placed in cold water or a cold water bath. Tomato skins were removed and then the blanched tomatoes were cored. Samples of blanching water and blanched tomatoes were collected and placed into frozen storage until analysis.

Cleaned tomatoes were peeled by hand and representative samples of tomato peels and peeled tomatoes were collected and placed into frozen storage until analysis.

For the production of vegetable stock, cleaned tomatoes were cored and diced. The diced tomatoes were placed into 82–100 °C water for 45–60 minutes. The mixture was sieved after cooking to remove solids. Liquid passing through the sieve was collected as vegetable stock and placed into frozen storage until analysis.

Residues of mefentrifluconazole in tomatoes and all processed commodities were determined using LC-MS/MS method D1511/01 (Reeves, 2018, BASF DocID 2018/7005677). The limit of quantification (LOQ) was 0.01 mg/kg for the RAC and all processed commodities. The maximum duration between sampling of the tomatoes and processed commodities and extraction was 675 days. All samples were analysed within 15 days of extraction. Processing factors are shown in Table 159.

Notes:

[1] DALA = Days after last application.

[2] Mefentrifluconazole residues values of the Processor RAC (i.e. tomato samples analysed just prior to processing) were used for the calculation of the processing factors.

[3] RAC = raw agricultural commodity, representative RAC sub-samples of the tomato bulk sample were collected prior to processing.

Soya beans

Three processing trials were carried out in the United States during the 2014 and 2015 growing seasons (Crawford, 2016, BASF DocID 2015_7005934) where soya beans received two foliar broadcast applications each at a rate of 148–155 g ai/ha, at 6 to 7 day intervals, of an SC formulation containing 100 g/L mefentrifluconazole. A second plot at each trial site was treated with two foliar broadcast applications each at a rate of 299–308 g ai/ha, at 14 to 15-day intervals, using the same formulation. An adjuvant (non-ionic spreader/sticker/surfactant) was added to the spray mixture for all applications. Mature soya bean seed was harvested 21–23 days after the last application (DALA) from the first plot and

77–91 DALA from the second plot. Samples were frozen and transported to the processing facility by freezer truck within 13 days of harvest or kept at ambient temperature and hand delivered to the processing facility within 1 day of harvest. At the processing facility, samples were processed into aspirated grain fraction, hulls, untoasted meal, toasted meal, crude oil, refined oil, defatted soy flour, soy milk, tofu, pollards, soya sauce, and miso according to commercial practices.

To generate aspirated grain fractions (AGF), whole soya bean seed samples (530 kg) that were harvested from the first treated plots were placed in a dust generation room containing a holding bin, two bucket conveyors, and a screw conveyor. Samples were moved into the system and aspirated for 75–120 minutes to remove light impurities (grain dust). Light impurities were classified using sieves. Impurities that went through the 2360 micron sieve were recombined to produce the AGF sample.

Whole soya bean seed samples (91 kg) harvested from the second treated plots with a moisture content > 13.5 percent were dried in an oven at 54–71 ºC until the moisture content was 10.0–13.5 percent. After drying, samples were cleaned by aspiration and screening. For production of hulls, untoasted meal, toasted meal, defatted soy flour, crude oil, and refined oil, whole soya beans were hulled using a roller mill and aspirated to separate the sample into hull and kernel. The kernel moisture content was adjusted to 13.5 percent, heated to 71–79 ºC in a mixer, and then flaked using a flaking roll. A portion of the flakes was removed for direct solvent extraction (no extrusion). The remaining flakes were extruded in a continuous processor where they were turned into collets by direct steam injection and compression. After extrusion, the collets were ground in a disc mill and dried in an oven at 66–82 ºC for 30–40 minutes. Ground collets and flakes were placed in stainless steel extractors and submerged in 49–60 ºC hexane for 30 minutes, drained, and repeated two more times for 15 minutes each. The miscella (crude oil and hexane) from each extraction were combined. The extracted flakes were desolventized with warm air and fractions of untoasted meal were collected. The remaining desolventized flakes were ground in a mill and sieved with a 62 mesh screen on a sifter. The resulting fraction passing through the screen was the defatted soy flour sample. Extracted collets were toasted by steam injection, heated to 104–116 ºC for 30–60 minutes, and then screened. The collected material passing through the screen was the toasted meal sample. The crude oil and hexane from the miscella were separated by vacuum evaporation. The crude oil was heated to 91–96 ºC, filtered, and fractions were then collected for analysis. Crude oil was neutralized by adding sodium hydroxide and mixing at a high rotations per minute (RPM) in a water bath for 90 minutes (at 20–24 ºC) and then mixed at a low RPM for 20 minutes (at 63–67 ºC). The neutralized oil was centrifuged, the refined oil was decanted and filtered, and the resultant fractions were alkali refined oil and soapstock (the latter was discarded). The alkali refined oil was heated and bleached by the addition of activated bleaching earth (1 percent by weight of oil). After vacuum filtration the resulting fractions were bleached oil and spent bleaching earth (the latter was discarded). Bleached oil was deodorized by steaming under vacuum for 28–32 minutes (at 220–230 ºC), followed by the addition of 0.5 percent citric acid solution (1 mL/100 g oil). The resulting fractions were deodorized oil and deodorizer distillates (the latter was discarded).

For soya milk and tofu production, whole cleaned soya beans (0.8 kg) were washed, soaked in water for at least 12 hours, ground and filtered. The filtered liquid (soya milk) was heated for 9–11 minutes at 91–96 ºC. A portion of the soya milk was then mixed and heated to 75–85 ºC. Calcium sulfate solution was added until the liquid (whey) became transparent and curd formed, upon which they were separated by centrifugation and the curds (tofu) were collected.

For the production of soya sauce and miso, cleaned whole soya beans (2 kg) were washed and soaked in reverse osmosis water for 10–14 hours and then pressure cooked at 220–230 ºC for 57–63 minutes. After cooling, the pressure-cooked soya bean kernel material was mixed slowly with ground roasted wheat, distilled water, and *Aspergillus oryzae* starter culture (0.1–0.2 percent by weight) for

approximately 5 minutes. The mixture was incubated in a forced air chamber at 29–36 ºC with a relative humidity (RH) of 55–75 percent for 24–72 hours and then lowered to 20–26 ºC at the same RH for another 24–72 hours to develop mature Koji. The mature Koji was mixed with 22–28 percent sea salt/distilled water brine solution and placed back into the chamber at an RH of 55–75 percent and incubated at temperatures of 15–20 ºC for the first 30 days, 25–30 ºC for the next 120 days, and 15–20 ºC for the last 30 days. After the fermentation process, raw soya bean sauce was separated from the spent Koji (miso) using a hydraulic press and filter paper. The raw soya sauce was filtered by cotton and vacuum and then pasteurized for 20–30 minutes at 70–80 ºC.

Pollard was produced by drying cleaned whole soya beans at 54-71 ºC until a moisture content <10 percent. The material was then milled in a mill and sieved with a 100 mesh screen twice. The material passing through the sieve was full-fat soy flour (which was discarded) while the material remaining in the sieve was collected as pollard.

Residues of mefentrifluconazole in soya bean and all processed commodities were determined using LC-MS/MS method D1511/01. The LOQ was 0.01 mg/kg for the RAC and all processed commodities. The maximum duration between sampling of the soya beans and processed commodities and analysis was 539 days. Adequate storage stability data are available to support the storage conditions and durations for the samples in the present study. Processing factors are shown in Table 160.

Notes:

[1] DALA = Days after last application.

[2] Mefentrifluconazole residue values of the Processor RAC (i.e. soya beans analysed just prior to processing) were used for the calculation of the processing factors. n/a = not applicable, because both RAC and processed commodity were below the LOQ.

[3] RAC = raw agricultural commodity.

[4] Since the RAC contained residues <LOQ, no reliable PF can be calculated. However, a concentration of the residue can be observed.

Sugar beets

Three processing trials were carried out in Germany during the 2015 growing season (Plier et al., 2016, BASF DocID 2015_1220032) where sugar beets received two foliar applications each at a rate of 740–800 g ai/ha, at 13 to 14-day intervals, of an EC formulation containing 100 g/L mefentrifluconazole. Tops and roots were harvested 0 and 20–21 days after the last application (DALA). Only 20–21 DALA root samples were sent for processing by car at ambient temperature and were processed 4–7 days after harvest. At the processing facility, samples were processed into washed beets, wash water, cossettes, pressed pulp, press water, raw juice, thin juice, thick juice, molasses, raw sugar, affinated syrup, refined sugar, dried pulp, and ensiled pulp according to commercial practices.

Sugar beet roots (289 kg) were washed in a cylindrical beet-washer and the wash water and washed beets were sampled. Washed beets were then sliced in a slicer set at a distance of 7 mm. The resulting cossettes were sampled. Cossettes were counter-current extracted with warm tap water in an extraction trough. After extraction the raw juice was sampled. The raw juice was purified by two-stage liming (cold pre-liming at 34.5–39.9 ºC with 250 CaO/L of lime milk up to a pH of 11.2 for 15-16 minutes followed by heating of the juice to 84.8–84.9 ºC for 15–48 minutes) and two-stage carbonatation (CO_2 was added until a pH of 11.0–11.2 was reached at a carbonatation temperature of 84.8–85.4 ºC and then filtered; for the second carbonatation, the filtrate was heated up to 94.8–95.0 ºC and CO_2 was added until the lime content in the juice reached a minimum pH of 9.0 to 9.2 and filtered). The resultant thin juice was sampled. The thin juice was concentrated in a single-stage evaporating plant at a temperature of 80–84

ºC (pressure of 0.45–0.55 bar) to a dry substance content of 60.6–66.5 percent. After evaporation the thick juice was sampled. The thick juice was concentrated at a pressure of 0.25 bar into a metastable supersaturation state and powdered sugar was injected as seed. Once crystallisation was finished, the massecuite was brought into the cooling crystalliser where the massecuite was cooled down to 19.6–36.4 ºC and then centrifuged (at approximately 3500 min^{-1}) to separate the molasses and raw sugar (air dried) which were both sampled. The raw sugar was mixed with distilled water for 25–45 minutes and then centrifuged (at approximately 3500 min^{-1}) to separate affinated syrup and pure sugar (air dried after centrifugation) which were both sampled. The wet pulp from the counter-current juice extraction was pressed and separated into press water and pressed pulp which were both sampled. An aliquot of the pressed pulp was dried in a drying chamber at 35 ºC until a moisture content of <10 percent was reached. The dried pulp was sampled. Another aliquot of the pressed pulp was fermented in a silage glass container under pressure at 20.0–22.2 ºC for 6 weeks to produce ensilage pulp that was sampled.

Residues of mefentrifluconazole in sugar beet roots and all processed commodities were determined using LC-MS/MS method L0076/09. TheLOQ was 0.01 mg/kg for the RAC and all processed commodities. The maximum duration between sampling of the sugar beet roots and processed commodities and analysis was 175 days. Adequate storage stability data are available to support the storage conditions and durations for the samples in the present study. Processing factors are shown in Table 161.

Potatoes

Three processing trials were carried out in the United States during the 2015 growing season (Schreier, 2016, BASF DocID 2016_7006672) where potatoes received three foliar broadcast applications each at a rate of 745–757 g ai/ha, at 6 to 7–day intervals, of an EC formulation containing 100 g/L mefentrifluconazole. Potato tubers were harvested 6–7 days after the last application (DALA). An adjuvant was added to the spray mixture for all applications. Potato tubers were shipped at ambient temperatures to the processing facility within 2 days of harvest. At the processing facility, samples were processed into peeled potato, wet peel, boiled potatoes, microwave/boiled potatoes, baked potato, fried potato, crisps (potato chips in the United States), chips (French fries), granules/flakes, process waste, ensiled potato, starch, dried pulp, and potato protein according to commercial practices.

Potatoes were washed in a tub for 5 minutes and culled by hand. Culled potatoes were sampled as the process waste fraction. Washed potatoes (36 kg) were batch steamed for 45–60 seconds at 100–120 psi and then batch scrubbed for 15–30 second with a peeler. The peels were collected. Peeled potatoes were further inspected to remove additional peel, rot, green or otherwise damaged potatoes. The trim waste was retained. A fraction of the steamed peeled potatoes were collected for anlaysis. The collected potato peels were hydraulically pressed and blended with the trim waste and the combined fraction was sampled as the wet peel. The remaining peeled potatoes were cut into slabs using a slicer, batch spray-washed in cold tap water, precooked at 70–77 ºC for 20 minutes in a kettle, and then cooled to <32 ºC for 20 minutes. The precooked potato slabs were then steam cooked at 94–100 ºC for 40–42 minutes in a steam cabinet. The cooked potato slabs were mashed in a modified meat grinder and mixed for 37 seconds in a mixer with an emulsion of food additives. The cooked mash was dried in a drum dryer into a thin sheet and broken into large flakes by hand. The flakes were then fed into a fruit press hammermill for uniform milling of the potato flakes which were sampled for analysis.

For the production of potato starch, washed potatoes (36 kg) were batch steamed for 45–60

seconds at 100–120 psi and then batch scrubbed for 15–30 second with a peeler. The water from the scrubber and peels were collected. The collected potato peels were hydraulically pressed and the collected starch water was combined with the water from the scrubber and filtered using a series of sieves. The filtered star water was centrifuged and the starch sample was collected for analysis.

For the production of potato crisps (chips) and fried potatoes, washed potatoes (14 kg) were batch peeled using a restaurant style Hobart peeler for 30 seconds. The peeled potatoes were cut into ~0.16 cm slices for crisps or ~0.5 cm slices for fried potatoes using a restaurant style slicer. The sliced potatoes were placed in a tub of hot water, drained over a screen, and fried in oil at 163–191 ºC for 90–145 seconds (crisps) or 3–3.5 minutes (fried potatoes). The fried potato crisps and fried potatoes were drained, salted (crisps), and sampled for analysis.

To generate boiled potatoes, washed potatoes (5 kg) were hand-peeled (stove-boiled potatoes only) and cut into quarters (stove-boiled and microwave-boiled potatoes). Unpeeled, quartered potatoes were placed in water and microwaved until an internal temperature of 88–92 ºC was attained. The microwaved-boiled potatoes were removed from the water and sampled for analysis. The peeled, quartered potatoes were boiled in water on a stove until an internal temperature of 88–92 ºC was attained. The stove boiled potatoes were removed from the water and sampled for analysis. For the production of baked potatoes, washed potatoes were baked in an oven at 210 ºC until an internal temperature of 88–92 ºC was reached. The baked potatoes were sampled for analysis. French fries were produced by slicing washed unpeeled potatoes into 0.5 cm strips using a fry cutter and then frying the strips in a fat fryer at 177–191 ºC got 2.5–3.0 minutes. After frying, the fresh French fries were drained and cooled and then sampled for analysis.

To generate potato pulp, protein, and ensiled potato, washed potatoes (40 kg) were chopped in a fruit press and hammermill and milled with a food processor. The collected pulp was hydraulically pressed in a fruit press and the pressed wet pulp was dehydrated in a tray dryer. The dried pulp was sampled for analysis. The collected potato water after pressing was centrifuged, filtered, and thermal processed at ~90 ºC while adjusting the pH to ~4.0 using H_2SO_4. The precipitated protein was recovered from the water using a filter. The potato protein was sampled for analysis. An aliquot of potato pulp (milled potatoes) was placed in a bag silo, sealed, and allowed to ferment for a minimum of 3 weeks at room temperature after which time the bag was opened, the pH of the ensiled potatoes was measured, and a sample was collected for analysis.

Residues of mefentrifluconazole in potatoes and all processed commodities were determined using LC-MS/MS method D1511/01. The LOQ was 0.01 mg/kg for the RAC and all processed commodities. The maximum duration between sampling of the potatoes and processed commodities and analysis was 216 days. Adequate storage stability data are available to support the storage conditions and durations for the samples in the present study. Processing factors are shown in Table 162.

Notes:

[1] DALA = Days after last application.

[2] RAC = raw agricultural commodity.

[3] Since the RAC contained residues <LOQ, no reliable PF can be calculated. However, a concentration of the residue can be observed in baked potato, dried pulp, and potato protein from Trial ID R150062.

Wheat

Three processing trials were carried out in Germany during the 2014 growing season (Plier et al., 2015, BASF DocID 2014_1315283) where wheat received two foliar applications each at a rate of 420–490 g ai/ha, at 14 to 39-day intervals, of an EC formulation containing 100 g/L mefentrifluconazole. Wheat

whole plant no roots were harvested at 0, and 7–9 days after the last application (DALA). Wheat grain was harvested 45–60 DALA. Only samples collected at the 7–9 DALA and 45–60 DALA were sent for processing. Wheat samples for processing were shipped by car at ambient temperature from the field to the processing facility. Grain specimens were stored at room temperature until the start of processing (77–98 days after harvest). Whole plant no roots specimens were processed on the day of sampling. At the processing facility, samples were processed into wet silage, wilted silage, bran, flour, germ, middlings, shorts, gluten, gluten feed meal, starch, whole meal flour, whole grain bread, milled byproducts, and aspirated grain fraction, according to commercial practices.

For silage production, fresh harvested whole plants (5 kg) were dried in the field or in a dry oven at 35 ºC until a dry matter content of 35–55 percent was reached. Fresh wheat for wet silage production (dry matter content of 5–35 percent) and the dried wheat for wilted silage production were filled in special silage glass containers (under pressure) and stored closed at 20–25 ºC for about 6 weeks. Wet silage and wilted silage were sampled for analysis.

Wheat grain samples (61 kg) were cleaned and the aspirated grain fraction was sampled for analysis. Cleaned grain samples were moistened with tap water until a moisture content of 15–16 percent was reached (if necessary). Cleaned wheat grain (10 kg) was then milled in a closed system with different pairs of smooth rollers and sifter passages into straight flour, bran, and middlings. Samples of flour, bran and middlings were taken for analysis. Bran and middlings were further processed by mixing them together and then separating the mixture into shorts and low grade meal using a centrifuge/scouring machine. Samples of shorts were taken for analysis.

For the production of whole-meal flour and whole-meal bread, the same milling procedure used for the production of flour was used. After milling, the shorts were cracked into smaller pieces using an impact mill. All milling products of the process were used completely for the whole-meal and were mixed homogenously in a special flour mixer. Samples of whole-meal flour were taken for analysis. For baking whole meal bread, whole meal flour, yeast, salt, and water were mixed. The resulting dough was kneaded for 7 minutes, fermented for 20 minutes, reprocessed for 5 minutes, fermented a second time in a baking tin for 40 minutes, and then baked at 210–230 ºC for 50 minutes. A sample of whole-grain bread was taken for analysis.

To generate wheat germs, wheat grain (20 kg) was broken in a roller mill with 0.5 mm roller distance. The 400–1000 µm fraction was collected while the fraction > 1000 µm was broken again with a 0.3 mm roller distance. This procedure was repeated three times with a final roller distance of 0.2 mm. The fractions < 400 µm and the last fraction > 1000 µm were not processed further but were retained for the generation of milled byproducts. The 400–1000 µm fraction was fed through a special separator to obtain middlings/germ and bran. The bran was retained for the generation of milled byproducts. The middlings/germ mixture was milled into flour, bran, and small wheat germ discs in a mill with smooth rollers. The mixture was then sieved to separate the fractions. The flour was retained for the generation of milled byproducts. The bran/germ fraction was sieved again into fine bran/germ and coarse bran/germ fractions. From the separated germ discs, small parts of bran were removed manually and samples of germ were taken for analysis. The bran was mixed with the other fractions which were retained to generate milled byproducts. Milled byproducts were sampled for analysis.

For the production of starch and gluten, wheat grain (5 kg) was milled into straight flour, bran, and middlings. Straight flour and water were mixed to form hydrated dough which was then separated by centrifugation into wet starch, process water, and gluten (containing starch). The starch was washed with water and separated by centrifugation into starch, process water, and gluten twice. The gluten (containing starch) was also washed with water and centrifuged several times resulting in gluten after washing and process water fractions. Process water fractions were separated by centrifugation into starch and fibre.

Fibre was dried at 60 ºC. Wet starch fractions were dried at 60 ºC while wet gluten was dried by freeze drying. After the drying process, the dried products were milled. The milled starch fractions were combined. Starch and gluten samples were collected for analysis. The dried and milled fractions of fibre, starch, and gluten were then mixed to form gluten feed meal which was sampled for analysis.

Residues of mefentrifluconazole in wheat and all processed commodities were determined using LC-MS/MS method L0076/09. The LOQ was 0.01 mg/kg for the RAC and all processed commodities. The maximum duration between sampling of the wheat and processed commodities and analysis was 305 days. Adequate storage stability data are available to support the storage conditions and durations for the samples in the present study. Processing factors are shown in Table 163.

Notes:

[1] DALA = Days after last application.

[2] Mefentrifluconazole residue values of the Processing RAC (i.e. wheat samples analysed just prior to processing) were used for the calculation of the processing factors. n/a = not applicable.

[3] RAC = raw agricultural commodity.

Barley

Three processing trials were carried out in Germany during the 2014 growing season (Plier et al., 2015, BASF DocID 2014_1315282) where barley received two foliar applications each at a rate of 440–490 g ai/ha, at 15 to 24-day intervals, of an EC formulation containing 100 g/L mefentrifluconazole. Barley grain, harvested 43–56 days after the last application (DALA), were shipped by car at ambient temperature from the field to the processing facility. Grain specimens were stored at room temperature until the start of processing (116–140 days after harvest). At the processing facility, samples were processed into pearled (pot) barley, flour, bran, brewing malt, malt sprouts, beer, brewers grain (dried), and brewers yeast according to commercial practices.

Barley grain samples (49 kg) were cleaned and sieved through a 2.5 mm mesh and then combined wet and dry steeping was conducted to begin the malting process. After steeping, the malt sample underwent still germination (continuous turning for 166 hours at 14.5 °C, with a relative humidity of > 90 percent) and was kiln dried to a water content of 5.30–5.45 percent in a dry chamber. After kiln-drying, the germs were removed mechanically by a trimmer and brewing malt and malt sprouts were sampled for analysis.

To brew the malt, the malt sample (12 kg) was milled with a malt-mill, mashed in a heatable tun, and lautered in a refining vat for 2–3 hours to separate the wort from the insoluble malt components (brewer's grain). After separation, the brewers grain was dried at 50 °C until a dry matter content of <10 percent was attained, and then dried brewers grain was sampled for analysis. Hop pellets were added to the wort and the mixture was boiled for 1.5 hours at normal pressure. After boiling the flocs (hops draff) were separated in a whirlpool system for 20 minutes using intra-plant circulation. Fermentation was carried out in bottom fermentation containers at approximately 9 °C for 9–11 days. The yeast deposited on the tank bottom was sampled as brewers yeast prior to maturation. After fermentation, the beer was

matured by under warm conditions (room temperature) for 2 days, followed by cold maturation (under pressure at approximately 0.7–1.0 bar, 2 °C) for 21 days. The resultant rack beer was filtered and the final beer product was sampled for analysis.

For the production of pearled (pot) barley, the grain (5 kg) was cleaned and the moisture content was adjusted by drying or dampening to approximately 16 percent. The samples were then hulled until an abrasion of 20–25 percent was reached. The abrasion was sieved into bran and flour. Pot barley, bran, and flour were sampled for analysis.

Residues of mefentrifluconazole in barley and all processed commodities were determined using LC-MS/MS method L0076/09. The LOQ was 0.01 mg/kg for the RAC and all processed commodities. The maximum duration between sampling of the barley grain and processed commodities and analysis was 254 days. Adequate storage stability data are available to support the storage conditions and durations for the samples in the present study. Processing factors are shown in Table 164.

Notes:

[1] DALA = Days after last application.

[2] Mefentrifluconazole residue values of the Processing RAC (i.e. barley grain samples analysed just prior to processing) were used for the calculation of the processing factors.

[3] RAC = raw agricultural commodity.

Rice

Three processing trials were carried out in the United States during the 2014 growing season (Reeves, 2019, BASF DocID 2015_7005931) where rice received two foliar applications each at a rate of 449–547 g ai/ha, at 14 day intervals, using an EC formulation containing 100 g/L mefentrifluconazole. An adjuvant was added to the spray mixture for all applications. Rice grain were harvested 21 days after the last application (DALA). Rice grain samples were stored ambient for durations less than 48 hours or stored frozen and shipped by freezer truck to the processing facility. At the processing facility, samples were stored frozen until processed into hulls, polished rice, and bran according to commercial practices.

Rice gain (60 kg) were cleaned by aspiration and screening using an aspirator to remove light impurities and then screened to separate foreign particles from the cleaned rough rice. The cleaned rough rice was then milled in a rice mill where the hull was removed in the hulling portion of the mill by rubber rollers. The hull material was separated from the brown rice by aspiration. After dehulling, the brown rice was milled in the milling chamber into white milled rice and bran by friction. Bran was separated from the white milled rice by air injection into the milling chamber. After exiting the milling chamber, bran was sieved to remove broken pieces of brown and white milled rice and small amounts of hull material from bran. Fractions of hull material, white milled rice (polished rice) and bran were collected for analysis.

Residues of mefentrifluconazole in rice and all processed commodities were determined using LC-MS/MS method D1511/01. The LOQ was 0.01 mg/kg for the RAC and all processed commodities. The maximum duration between sampling of the rice and processed commodities and analysis was 723 days for the RAC and 437 days for the processed fractions. Adequate storage stability data are available to support the storage conditions and durations for the samples in the present study. Processing factors are shown in Table 165.

DALA = Days after last application.

[2] In the United States study, mefentrifluconazole residue values of the Processing RAC (i.e. rice grain samples analysed just

prior to processing) were used for the calculation of the processing factors.

[3] RAC = raw agricultural commodity.

Maize

Three processing trials were carried out in the United States during the 2014 and 2015 growing seasons (Delinsky, 2016, BASF DocID 2016_7009425) where maize received two foliar applications each at a rate of 296–301 g ai/ha or 443–446 g ai/ha, at 14 to 22-day intervals, of an EC formulation containing 100 g/L mefentrifluconazole. An adjuvant was added to the spray mixture for all applications. Forage was harvested 13–17 days after the last application (DALA) from corn treated at the higher application rate. Maize grain was harvested 20–21 DALA from corn treated at the lower application rate and 52–69 DALA from corn treated at the higher application rate. Forage samples for processing were shipped under chilled conditions the day of harvest to the processing facility where they were stored at ambient temperature until processing. Grain samples for processing were either stored at ambient temperature for 2 days after harvest (R140861), shipped frozen on the day of harvest (R140862), or frozen for 4 days after harvest until being shipped frozen to the processing facility where all grain samples were stored frozen until processing. At the processing facility, samples were processed into silage, aspirated grain fractions, flour (wet milling), flour (dry milling), bran, gluten, gluten feed meal, starch (wet milling), germ, refined oil (wet milling), meal (dry milling), grits (dry milling), milled byproduct, and refined oil (dry milling) according to commercial practices.

Maize forage samples (55 kg) were fed into a chipper/shredder. The chopped material was placed in a container (micro-silo) and sealed for 21 days. Ensiled samples (silage) were collected for analysis.

Maize grain samples (300 kg) from the lower application were dried in an oven to a moisture content of 10.0–13.0 percent. Samples were then aspirated to remove light impurities (grain dust). Light impurities were classified using sieves of varying microns. The material passing through the 2360 micron sieve was recombined to produce one aspirated grain fraction (AGF).

Maize grain samples from the higher application (248 kg) were dried in an oven to a moisture content of 10.0–15.0 percent. Samples were then cleaned by aspiration and screening. Large and small screenings and light impurities were combined to produce milled byproducts.

In dry milling processes, cleaned whole maize grain (102 kg) was adjusted to a moisture content of 20.0–22.0 percent and then fed into a disc mill to crack the kernel. Corn stock from the mill was dried for 30 minutes at approximately 54–71 °C. Dried cornstock was screened with 0.31 cm screen to separate bran, germ, and large grits from grits, meal and flour. The latter three were separated using 14 mesh (~0.14 cm) and 62 mesh (~0.025 cm) sieves. The fraction on top of the 14 mesh sieve was grits; the fraction on top of the 62 mesh sieve was meal and the fraction through the 62 mesh sieve was flour. Bran, germ, and large grits were screened again to separate hull, germ, and grits using 0.51 cm and 0.48 cm screens. Germ fractions were dried to a final moisture content of 14.0–16.0 percent and processed fraction samples of grits, meal, flour, bran, and germ were collected for analysis.

Germ material (13 kg) was heated in a mixer for 10 minutes. Following heating, the material was flaked in a flaking roll with a gap setting of 0.018–0.025 cm. After flaking, some samples were sieved to remove any remaining endosperm from the germ flakes. Flaked material was placed in stainless steel batch extractors and after 30 minutes the miscella (crude oil and hexane) was drained and hexane was added to repeat the cycle two more times. Final two washings were at the same temperature range for 15– 30 minutes each. Following the final draining, the spent flakes were desolventized with ambient air to remove residual hexane. The resulting fractions were miscella and solvent extracted germ flakes. The

miscella was passed through a laboratory vacuum evaporator to separate the crude oil from the hexane. Crude oil was heated for hexane removal, filtered, and collected for refining. For alkali refining, the free fatty acid (FFA) of the crude oil was determined. Based on the FFA, weighed amounts of crude oil and 16 degree sodium hydroxide were placed in a water bath and mixed for 15 minutes on high RPM and then for 12 minutes on low RPM. Neutralized oil and soapstock were separated using centrifugation. Alkali refined oil samples were decanted and filtered prior to bleaching (by the addition of activated bleaching earth, 1.0 percent by weight of oil). The bleached oil was filtered. The resulting fractions were bleached oil and spent bleaching earth/filter aid. Bleached oil was steam bathed under vacuum. The oil was allowed to cool. During the cooling period a 0.5 percent citric acid solution was added to the oil. Resulting fractions were refined-bleached-deodorized oil (RBD oil) and deodorizer distillates. The RBD oil samples were collected for analysis.

In the wet milling processes, dried and cleaned maize grain (79 kg) were steeped in water containing 0.1–0.2 percent sulfurous acid for 22–48 hours. Steeped whole corn was passed through a disc mill and a majority of the germ and hull was removed using a hydroclone (water centrifuge). Germ and hull were dried to obtain a final moisture content between 5–10 percent. After drying, the germ and hull were separated using aspiration and screening. Cornstock (without germ and hull) ground in the disc mill was passed over a separator equipped with a 325 mesh (50 micron) screen. Process water passing through the screen was separated into starch and gluten using batch centrifugation. Starch was dried in an oven until the moisture content was less than 15.0 percent. The remainder of the gluten was dried utilizing a steam-heated drum dryer. The processed fraction samples of starch, gluten and gluten feed meal were collected for analysis.

Germ fractions (6 kg) were adjusted to a moisture content of 12 percent, heated in a mixer, flaked in the flaking roll and pressed in an expeller to liberate part of the crude oil. Resulting fractions are expelled crude oil and presscake with residual crude oil. The presscake was placed in stainless steel batch extractors and submerged for 30 minutes. The miscella was dried and fresh hexane added to repeat the cycle two more times. Following the final draining, the spent presscake was desolventized with ambient air to remove residual hexane. Resulting fractions from solvent extraction were miscella and solvent extracted presscake (germ cake). Miscella was passed through a laboratory vacuum evaporator to separate the crude oil from hexane. Crude oil was then heated for hexane removal. Crude oils from expelling and solvent extraction were filtered and combined for refining. Crude oil samples from the wet milling process were alkali refined, bleached, and deodorized utilizing the same methods used during the dry milling procedure.

For the production of wet milled flour, cleaned whole corn sample was boiled in solution of calcium hydroxide and water for 28–32 minutes and then steeped overnight. The liquid was drained and the corn was rinsed to remove fiber. The remaining corn was ground in a mill and the ground material was pressed into thin pieces and dried for 2–2.5 hours. The dried material was ground again in a pin mill and sieved with a 40 mesh screen. Material passing through the screen was wet milled flour, which was collected for analysis.

Residues of mefentrifluconazole in corn and all processed commodities were determined using LC-MS/MS method D1511/01. The LOQ was 0.01 mg/kg for the RAC and all processed commodities. The maximum duration between sampling of the maize and processed commodities and analysis was 577 days. Adequate storage stability data are available to support the storage conditions and durations for the samples in the present study. Processing factors are shown in Table 166.

Notes:

[1] DALA = Days after last application.

[2] Mefentrifluconazole residue values of the Processing RAC (i.e. corn samples analysed just prior to processing) were used for the calculation of the processing factors. n/a = not applicable. Since the corn grain processing RACs contained residues <LOQ, no processing factors could be calculated. However, a concentration of the residue was observed in several processed commodities (e.g. AGF, bran, gluten feed meal, milled byproducts).

[3] RAC = raw agricultural commodity.

Cotton

Three processing trials were carried out in the United States during the 2017 growing season (Moore and Phillips, 2019, BASF DocID 2018/7007471) where cotton received three foliar applications at a rate of 734–767 g a.i./ha, at 7 day intervals, of an emulsifiable concentrate containing 100g/L mefentrifluconazole. An adjuvant (non-ionic surfactant) was added to the spray mixture for all applications. Undelinted cottonseed and bulk seed cotton were collected from the untreated plot and treated approximately 30 days after last application (DALA). Undelinted cottonseed samples were placed into frozen storage within 3 hours of collection and transported to the processing facility by freezer truck. Bulk seed cotton samples were stored ambient for durations less than 55 hours, stored frozen and then shipped to the processing facility by freezer truck. At the processing facility, bulk seed cotton samples were processed into cottonseed hulls, cottonseed meal and refined oil according to commercial practices.

To produce undelinted cottonseed (RAC) fractions, seed cotton was cleaned with a stick extractor to remove the gin byproducts (gin trash) and ginned to separate ginned cottonseed (undelinted cottonseed) and lint in a Continental cotton gin. The resulting products were ginned cottonseed, lint, and gin trash. Undelinted cottonseed (RAC) fractions were collected and placed into frozen storage. The ginned cottonseed samples were mechanically delinted to produce delinted cottonseed.

To produce hull fractions, delinted cottonseed was cracked in a roller mill and the kernel and hull material were separated with a screen cleaner equipped with 10/64-inch and/or 12/64-inch screens. The hull material fractions were collected and the moisture content of the kernel was determined with an electronic moisture analyser. The moisture content of the kernel was adjusted to 13.5 percent by adding water and mixing. The samples were then allowed to equilibrate for a minimum of 2 hours.

For production of meal and refined oil, kernel material was heated in a steam heated mixer to 79–91 °C and held for 28–32 minutes. After heating, the material was flaked in a flaking roll with a gap setting of 0.008–0.013 inch. The flakes were extruded in a continuous processor (extruder) where they were turned into collets by direct steam injection. After extrusion, the material (collets) were ground and dried in an oven at 66–82 °C for 30–40 minutes. Ground collets were placed in stainless steel batch extractors and submerged in 49–60 °C hexane for 30 minutes, drained, and repeated two more times for 15 minutes each. The extracted solvent meal was toasted by steam injection, heated to 102–104 °C,

stopped at 104–116 °C and held there for 45 minutes. After cooling, the toasted meal samples were passed through a screen cleaner equipped with a 1/8-inch sieve. Toasted cottonseed meal was collected and placed into frozen storage. The crude oil and hexane from the miscella were separated by vacuum evaporation. The crude oil was heated to 91–96 °C, filtered and fractions were then collected for analysis. Crude oil was neutralized by adding sodium hydroxide and mixing at a high RPM in a water bath for 14–16 minutes (at 21–24 °C), followed by a low RPM for 11–13 minutes (at 63–67 °C). The neutralized oil was centrifuged, the refined oil was decanted and filtered and the resultant fractions were alkali refined oil and soapstock (the latter was discarded). The refined oil was heated to 40–50 °C and bleached by the addition of activated bleaching earth (1 percent by weight of oil). The temperature was increased to 85–100 °C and held for 10–15 minutes. After vacuum filtration, the resulting fractions were bleached oil and spent bleaching earth (the later was discarded). Bleach oil was deodorized by steaming under vacuum for 28–32 minutes (at 220–230 °C), followed by the addition of 0.5 percent citric acid solution (1 mL/100 g oil). The resulting fractions were alkali refined, bleached, and deodorized (RBD) oil. RBD oil was collected and placed in frozen storage.

Residues of mefentrifluconazole in cotton and all processed commodities were determined using LC-MS/MS method D1511/01. The limit of quantification (LOQ) was 0.01 mg/kg for the RAC and all processed commodities. The maximum duration between sampling of the cotton and processed commodities and extraction for analysis was 364 days. All samples were analysed within 0 to 8 days of extraction. Processing factors are shown in Table 167.

Table 167 Concentration of mefentrifluconazole residues in cotton processed fractions and processing factors

Notes:

[1] DALA = Days after last application.

[2] The processing factor was calculated by dividing the residue in the processed fraction by the residue for the RAC sample (processor RAC).

[3] RAC = Raw agricultural commodity.

Coffee

Four processing trials were carried out in Brazil during the 2017 and 2018 growing seasons (José, 2019, BASF DocID 2019_2041531) where coffee received three foliar applications each at a rate of 783–

860 g ai/ha, at 60 day intervals, of an SC formulation containing 200 g/L each of mefentrifluconazole and pyraclostrobin. Pyraclostrobin residues were not investigated in this study. Coffee fruit were harvested 45 days after the last application (DALA). After sampling, coffee fruits were dried at ambient temperature. For the dried coffee samples, the dried fruits were sifted to remove leaves and branches. For the coffee bean samples, the dried fruits were peeled using a small processing machine to generate the dried coffee cherry samples. Samples were shipped frozen to the processing facility and remained frozen until processing. At the processing facility, samples were processed into concentrated liquor, instant coffee, and roasted ground coffee according to commercial practices.

Green coffee beans were roasted for 20 minutes at 200 °C to obtain a medium-strong roasted coffee. Distilled water was used to stop the roasting process. After roasting, the coffee beans were stored at room temperature for at least 18 hours to expel the CO_2 generated during roasting and to equilibrate its moisture content. Coffee beans were then ground in a cone mill.

To produce concentrated liquor, green coffee beans were roasted at 180 °C for 80–90 minutes and then stored at room temperature for at least 18 hours. The roasted coffee beans were then broken in a cone mill and sieved to remove the "fines". The coffee was then extracted using a coffee extraction pilot equipment containing seven columns of extraction. Filtered heated water (92 ± 4 °C) was pumped into the columns (water flow was 0.48 mL/minute) through the base and percolated the column in contact with the coffee. The extract was collected from the column. To generate instant coffee, coffee extract was left at room temperature for one hour and then dried in a spray dryer (air flow of 0.8 L/min, temperature of 175–180 °C).

Residues of mefentrifluconazole in coffee beans and processed commodities were determined using LC-MS/MS method L0076/09. The LOQ was 0.01 mg/kg for the RAC and all processed commodities. The maximum duration between sampling of the coffee and processed commodities and analysis was 253 days. Adequate storage stability data are available to support the storage conditions and durations for the samples in the present study. Processing factors are shown in Table 168.

Livestock feeding studies

Dairy cow feeding study

Mefentrifluconazole was administered orally once daily to five groups of three lactating Holstein/Friesian/Ayrshire cross dairy cattle (2–14 years of age; 496–752 kg bw) by gelatine capsule for 28 days (Bancroft, 2015, BASF DocID 2016_1190690). Mean daily feed consumption for the dose groups during the exposure period were 7.71–20.13 kg dry matter/day. Mean daily milk yields for the dose groups during the dosing period were 6.7 to 16.9 kg/cow/day. Based on mean daily feed consumption, the dosing levels were equivalent to 1.5, 7.5, 50 and 150 ppm in the feed. Milk was collected twice daily (am and pm sampling pooled) throughout the 28 days of dosing. On day 21, milk was also separated into cream and skimmed milk. Muscle (loin, hindleg), liver, kidney and fat (peri-renal, mesenterial and subcutaneous) samples were collected at sacrifice 22–24 hours after the final dose, except for three of the six cows from the highest dose tested group which were sacrificed three, seven and fourteen days after the final dose to monitor the decline of residue levels post dosing. The maximum frozen storage intervals were 49 days for milk while the maximum storage intervals for tissues were 97, 110, 35 and 90 days for liver, kidney, muscle and fat, respectively. Samples were analysed for the parent compound using the LC-MS/MS analytical method L0272/01 and for the metabolite M750F022 using the GC-MS method L0309/01. The LOQ for each analyte was 0.010 mg/kg.

The methods were concurrently validated by fortifying samples of milk, cream, skimmed milk, muscle, liver, kidney and fat, with known amounts of mefentrifluconazole and M750F022. Mean

recoveries of the parent compound in milk (whole and skimmed), cream and tissues ranged from 70 percent to 92 percent with relative standard deviations of 3 percent to 11 percent. Likewise, mean recoveries of the metabolite in milk and tissues ranged from 73 percent to 105 percent with relative standard deviations of 5 percent to 14 percent. The validation results demonstrated the acceptability of the methods used in this study. The results of the study are shown in Tables 170 and 171.

Laying hen feeding study

Mefentrifluconazole was administered orally once daily to 4 groups of 12 *Gallus domesticus* hens per group (each group further divided into 3 subgroups of 4 hens per subgroup) (22 weeks of age; 1.3–2.4 kg bw) by gelatine capsule for 34 days (Schatz, 2015, BASF DocID 2015_1106667). Mean daily feed consumption for the dose groups during the exposure period was 0.13 kg dry matter/day. Average egg production during the dosing period ranged from 5–7 eggs/week. Based on mean daily feed consumption, the dose levels were equivalent to 1.5, 4.5 and 15 ppm in the feed. Eggs were collected twice daily (am and pm sampling pooled) throughout the 34 days of dosing. On day 24, egg samples from the 15 ppm

dosing level were separated into egg yolk and egg white. Muscle, liver, skin with fat and abdominal fat samples were collected at sacrifice 6 hours after the final dose, except for 12 hens from the 15 ppm group which were sacrificed two, seven and fourteen days after the final dose to monitor the decline of residue levels post dosing. The maximum frozen storage intervals were 86 days for eggs while the maximum storage intervals for tissues were 88, 88, 97 and 60 days for muscle, liver, fat and skin with fat, respectively.

Samples were analysed for the parent compound using the LC-MS/MS analytical method L0272/01 and for the metabolite M750F022 using the GC-MS method L0309/01. The LOQ reported for each method was 0.010 mg/kg. The methods were concurrently validated by fortifying samples of eggs, muscle, liver, skin with fat and abdominal fat, with known amounts of mefentrifluconazole and M750F022. Mean recoveries of the parent compound in eggs, muscle, liver, skin with fat and abdominal fat samples ranged from 84 percent to 102 percent with relative standard deviations of 2 percent to 11 percent. Likewise, mean recoveries of the metabolite in eggs and tissues ranged from 71 percent to 90 percent with relative standard deviations of 11 percent to 15 percent. The validation results demonstrated the acceptability of the methods used in this study. The results of the study are shown in Table 172 and 173.

APPRAISAL

Mefentrifluconazole, (2RS)-2-[4-(4-chlorophenoxy)-2-(trifluoromethyl)phenyl]-1-(1*H*-1,2,4-triazol-1-yl) propan-2-ol, is a triazole fungicide belonging to the group of the sterol biosynthesis inhibitors.

Mefentrifluconazole was scheduled at the Fifty-first Session of the CCPR for Evaluation for Residues and Toxicology by the 2020 JMPR, which was postponed to the 2021 JMPR Meeting, where an ADI of 0–0.04 mg/kg bw and an ARfD of 0.3 mg/kg bw were established. The Residue evaluation was rescheduled to the 2022 JMPR Meeting.

The Meeting received information from the manufacturer on physical and chemical properties, metabolism studies on plants and animals, environmental fate in soil, analytical method and stability in stored analytical samples, use patterns and supervised residue trials, processing studies and livestock feeding studies. A summary of metabolites found in metabolism studies are shown in Table 174.

Table 174 Summary information on mefentrifluconazole and its metabolites mentioned in this appraisal

Based on its physical chemical properties, mefentrifluconazole is slightly soluble in water and moderately soluble in non-polar solvents. It is likely to sequester to fatty matrices based on its Log Kow. It has low potential for volatilization. Hydrolysis and aqueous photolysis are unlikely to be important routes of degradation at environmentally relevant pH levels.

Plant metabolism

Mefentrifluconazole metabolism data were provided for grape, soya bean and wheat.

Grape

Three grapevines (variety *Müller-Thurgau*), grown outdoors, received three foliar treatments with either a 1:1 mixture of [^{14}C-U-chlorophenyl:^{13}C-U-chlorophenyl]-mefentrifluconazole or a 2:1 mixture of [^{14}C-3(5)-triazole:^{13}C-3(5)-triazole]-mefentrifluconazole at a rate of 150 g ai/ha with re-treatment intervals of 10–11 days. Grape leaves and clusters were harvested 12 days following the last application.

Total radioactive residues (TRR) in grape berries, leaves and stalks following combustion were 0.40–0.44 mg eq/kg, 7.24–8.86 mg eq/kg and 0.67–1.21 mg eq/kg, respectively.

Extraction of grape berries, leaves, and stalk samples with methanol (3×) and water (2×) released 87–90 percent TRR, 89–91 percent TRR, and 93–94 percent TRR, respectively. Hydrolysis of the post-extraction solids (PES) following various enzymatic treatments released an additional 2–5 percent TRR, which were not further analysed.

Mefentrifluconazole was the major identified residue in all matrices, accounting for 64–70 percent TRR (0.22–0.30 mg/kg) in berries, 60–70 percent TRR (4.43–5.11 mg eq/kg) in leaves, and 86–92 percent TRR (0.56–1.04 mg eq/kg) in stalks. Metabolite M750F019 was identified in berries, leaves, and stalks at 6–7 percent TRR (0.024–0.026 mg eq/kg), 14–21 percent TRR (1.068–1.55 mg eq/kg), and 2 percent TRR (0.015 mg eq/kg), respectively. The chlorophenyl-label-specific metabolite M750F026 was identified as a minor metabolite in leaves only at 1 percent TRR (0.10 mg eq/kg).

Soya bean

Ten containers of soya bean plants (variety *Sultana*, 13 plants/container), cultivated indoors in a vegetation hall and subsequently moved into climatic chambers, received three foliar treatments with either a 1:1 mixture of [^{14}C-U-chlorophenyl:^{13}C-U-chlorophenyl]-mefentrifluconazole or a 2:1 mixture of [^{14}C-3(5)-triazole:^{13}C-3(5)-triazole]-mefentrifluconazole at a rate of 125 g ai/ha with re-treatment intervals of 17–19 days. Soya bean forage was harvested 19 days after the first application (just before the second application; BBCH growth stage of 71–72). At harvest, 47–48 days after the final application at BBCH growth stage 89, the mature pods were collected and manually opened in order to separate seeds from hulls. In addition green pods were also harvested and the remaining stems and leaves (matrix: rest of plant) were collected.

TRRs reported were highest in the rest of plant (16.0–19.9 mg eq/kg), followed by the green pods (8.86–16.0 mg eq/kg), forage (4.4–6.5 mg eq/kg), hulls (3.74–3.89 mg eq/kg) and seed (0.11–2.6 mg eq/kg).

Radioactivity released following extraction with methanol (3×) and water (2×) ranged between 91–93 percent, 69–74 percent, and 87–88 percent in soya bean forage, hull, and rest of plant, respectively. When extracted using acetonitrile:isohexane (1:1) and water, between 56–76 percent TRR were released from soya bean seeds and 78–83 percent from green pods. PES of forage, hulls, rest of plant and seeds were solubilized using various enzymatic treatments releasing 4–38 percent TRR.

Unextracted residues of green pods were not hydrolysed.

Mefentrifluconazole (free and conjugated) was a major residue in forage, hulls and rest of plant, accounting for 60–83 percent TRR (3.18–13.70 mg/kg). The minor metabolites, M750F012 and M70F018/M750F020 (both free and conjugated), were identified at levels ranging from 0.03–6 percent TRR (0.01–0.97 mg eq/kg).

In green pods, mefentrifluconazole represented 69 percent TRR (5.98 mg/kg) while M750F012 and M70F018/M750F020 were each ≤4 percent (≤0.33 mg eq/kg).

Mefentrifluconazole (free) was a minor residue in seed, accounting for only 0.4–4 percent TRR (0.005–0.013 mg/kg). Triazole alanine (free and conjugated) was a major metabolite, accounting for 48 percent TRR (1.46 mg eq/kg). 1,2,4-Triazole and triazole lactic acid (both free) were identified at levels of 0.3 percent TRR (0.008 mg eq/kg) and 1 percent TRR (0.04 mg eq/kg), respectively.

Chiral analysis of forage, hull and rest of plant samples (C-label and T-label) confirmed that the racemic mixture (1:1 ratio of S-enantiomer and R-enantiomer) is essentially maintained, and hence that there is no significant change in the ratio of the mefentrifluconazole enantiomers. Chiral analysis was not conducted for seed/green pod since mefentrifluconazole was not present in quantifiable amounts.

Wheat

Twenty containers of spring wheat (variety *Thassos*, 10 containers per label), cultivated indoors in a vegetation hall/greenhouse, received two foliar treatments with either a 1:1 mixture of [^{14}C-U-chlorophenyl:^{13}C-U-chlorophenyl]-mefentrifluconazole or a 2:1 mixture of [^{14}C-3(5)-triazole:^{13}C-3(5)-triazole]-mefentrifluconazole at a rate of 150 g ai/ha with a re-treatment interval of 21 days. Wheat forage was harvested 15 days after the first application (just before the second application; BBCH growth stage 61). Straw and grain were harvested 35 days after the final application at BBCH growth stage 89.

Total radioactive residues (TRR) were highest in straw (14.3–24.3 mg eq/kg), followed by forage (2.5–2.6 mg eq/kg) and grain (0.06–0.07 mg eq/kg).

Forage and straw samples were extracted with methanol (3×) and water (2×). Wheat grain was extracted with acetonitrile:isohexane (1:1) and water. Solvent extracted radioactivity ranged between 95–96 percent TRR, 44–78 percent TRR, and 83–86 percent TRR in wheat forage, grain, and straw, respectively. The acetone precipitate of grain and the forage and straw post-extraction solids were subjected to solvent and enzymatic treatments releasing an additional 20–40 percent TRR for grain and 2–9 percent TRR for forage and straw.

In forage, mefentrifluconazole (free) accounted for 84–89 percent TRR (2.01–2.06 mg/kg). The minor metabolites, M750F009, M750F012, M750F019 and M750F018/M750F020, all present in the free form, collectively represented 3–4 percent TRR (0.06–0.09 mg eq/kg). In straw, mefentrifluconazole (free and conjugated) accounted for 59–68 percent TRR (9.6–14.3 mg/kg). The total concentration of the same metabolites ranged from 19–21 percent TRR (2.7–5.1 mg eq/kg), accounting for up to 0.4-fold the concentrations of mefentrifluconazole (free and conjugated). Mefentrifluconazole was not found in grain, and triazole alanine and triazole acetic acid were major metabolites accounting for 46 percent TRR (0.28 mg eq/kg) and 22 percent (0.13 mg eq/kg), respectively. 1,2,4-triazole was present at 1 percent TRR (0.006 mg eq/kg).

In summary, the unchanged parent is the predominant residue (>60 percent TRR) in mefentrifluconazole treated plants, notably in forage (wheat, soya bean), leaf/stalks (grapes), straw/hulls (wheat, soya bean), green pods (soya bean) and grapes. The enantiomer ratio of the two mefentrifluconazole isomers remained unchanged (racemic mixture). In wheat grain and soya bean seed,

the unchanged parent is present at very low levels, and the predominant component of the residue is the group of triazole derived metabolites (triazole alanine [TA], triazole acetic acid [TAA], triazole lactic acid [TLA] and 1,2,4-triazole), formed via cleavage of the triazole bridge, with triazole alanine the most abundant compound. The metabolic pathway of mefentrifluconazole in plants is largely based on two main transformation steps: hydroxylation followed by conjugation and cleavage of the triazole bridge followed by conjugation.

Animal metabolism

The Meeting received animal metabolism studies with mefentrifluconazole in lactating goats, laying hens and rats.

Rats

Metabolism of mefentrifluconazole in rats was evaluated by the 2021 JMPR Meeting. Metabolism in the rat was extensive and complex with a total of 68 identified metabolites resulting from phase I and phase II reactions. Main metabolic pathways comprised hydroxylation, methylation and cleavage of the ether group or of the triazole ring from the parent molecule, often followed by conjugations. Most metabolites occurred at low concentrations and only very few of them, observed in the faeces, accounted for more than 30 percent of the dose. In urine, the most abundant metabolite was 1,2,4-triazole with a maximum abundance of 10 percent. In bile, the five main metabolites were all glucuronides which had been formed subsequent to hydroxylation. In faeces, there was a 1:1 ratio of the two isomers of mefentrifluconazole, whereas a shift towards the R-enantiomer was observed in methanolic liver and kidney extracts.

Lactating goats

The metabolism of chlorophenyl-U-^{14}C-labelled, triazole-3-(5)-^{14}C-labelled or trifluoromethylphenyl-ring-U-^{14}C-labelled mefentrifluconazole was investigated in lactating goats. Animals were dosed orally once daily for 12–14 consecutive days. The nominal daily doses were equivalent to 12 ppm in the diet. During the dosing period, urine and faeces were sampled once daily, while milk was collected twice daily. Liver, kidney, muscle and fat samples were collected after animal sacrifice, approximately 23 hours after administration of the last dose.

Most of the radioactivity was recovered in the excreta with urine containing 26–40 percent of the administered dose (AD) and faeces containing 34–50 percent of the AD. The radioactivity recovered in milk and tissues was low, each accounting for ≤ 2.2 percent of the AD. Plateau levels of radioactive residues in milk were reached within 5–6 days after administration of the first dose.

The calculated total radioactive residues (TRRs) in the pooled milk samples (144–288 h) ranged from 0.029–0.273 mg eq/kg for whole milk, 0.016–0.270 mg eq/kg for skimmed milk and 0.207–0.521 mg eq/kg for cream. For tissues, TRRs were highest in liver (0.650–1.332 mg eq/kg), followed by kidney (0.352–0.422 mg eq/kg), composite fat sample (0.213–0.532 mg eq/kg) and composite muscle sample (0.047–0.223 mg eq/kg). In general, levels of radioactivity were lower in milk and muscle.

Extraction of whole milk with acetonitrile released the majority of the radioactivity (86–96 percent TRR). Mefentrifluconazole was the major residue, accounting for 44.5–47.5 percent TRR (0.014–0.028 mg/kg) as were 1,2,4-triazole (78 percent TRR; 0.214 mg eq/kg) and the metabolite M750F043 (14–25 percent TRR; 0.004–0.016 mg eq/kg). Three additional minor metabolites were identified: M750F022 (1–2 percent TRR; 0.001 mg eq/kg), M750F041 (6–7 percent TRR; 0.002–0.004 mg eq/kg) and M750F072 (6–11 percent TRR; 0.002–0.004 mg eq/kg). A similar metabolic profile was observed in skimmed milk and cream.

Isohexane extraction of the composite fat samples released the majority of the radioactivity (> 91 percent TRR) for all three labels. Mefentrifluconazole was the main component of the residues (85–88 percent TRR; 0.18–0.47 mg/kg). Metabolite M750F022 and 1,2,4-triazole were the only other metabolites detected in fat, at up to 6 percent TRR (0.031 mg eq/kg) and 5 percent TRR (0.01 mg eq/kg), respectively.

Extraction of composite muscle samples with methanol released greater than 92 percent TRR. Mefentrifluconazole and the 1,2,4-triazole were the predominant residues, accounting for 12–96 percent TRR (0.03–0.09 mg/kg) and 87 percent TRR (0.19 mg eq/kg), respectively. Metabolite M750F022 was observed at much lower levels (7 percent TRR; 0.003 mg eq/kg).

EThe remaining unextracted radioactivity (up to 9 percent TRR) was subjected to protease hydrolysis which released an additional 2–3 percent TRR (0.01–0.04 mg eq/kg). Mefentrifluconazole represented one of the main components of the residue (26–50 percent TRR; 0.17–0.62 mg/kg), together with the metabolite M750F016 (10–15 percent TRR; 0.065–0.20 mg eq/kg) and 1,2,4-triazole (32 percent TRR; 0.21 mg eq/kg). Metabolite M750F068, resulting from glucuronidation of the parent compound, was also observed in liver but at lower levels (3–4 percent TRR; 0.03–0.06 mg eq/kg). In addition, the minor metabolite M750F022 and its glucuronide derivative M750F038 accounted for 5–11 percent TRR (0.05–0.15 mg eq/kg).

Methanol extraction of kidney released greater than 96 percent TRR. Mefentrifluconazole accounted for 10–46 percent TRR (0.04–0.20 mg/kg). Major predominant metabolites included 1,2-4-triazole (68 percent TRR; 0.27 mg eq/kg), M750F038/M750F064 (co-eluting in one peak, sum: 27 percent TRR; 0.09 mg eq/kg; present in a 1:1 ratio), M750F068 (18 percent TRR; 0.06 mg eq/kg), M750F022 (6–14 percent TRR; 0.02–0.06 mg eq/kg) and M750F038 (11 percent TRR; 0.05 mg eq/kg). The metabolites M750F003, M750F015, M750F016 and M750F072 were also observed but none represented greater than 4 percent TRR (0.02 mg eq/kg).

While the ratio of both mefentrifluconazole isomers was approximately 50:50 in the doses administered to the animals and in the extracts of faeces, the relative amount of the (S)-isomer was lower compared to the (R)-isomer in cream, liver, fat, kidney and muscle, ranging from 20 percent:80 percent to 30 percent:70 percent. These findings demonstrated that matrix-specific differences were observed. This shift towards the R-enantiomer was also observed in the methanol extracts of liver and kidney in the rat metabolism study.

Laying hens

The metabolism of chlorophenyl-U-^{14}C-labelled, triazole-3-(5)- ^{14}C-labelled or trifluoromethylphenyl-ring-U-^{14}C-labelled mefentrifluconazole was investigated in laying hens. The test item was administered once daily by gavage (ten animals per label) for 14 consecutive days at a nominal dose of 12 ppm feed. During the dosing period, excreta were collected once daily, while eggs were collected twice daily after which they were separated into egg whites and egg yolks. Liver, kidney, muscle and fat samples were collected after animal sacrifice, 3–6 hours after administration of the last dose.

The radioactive residues in excreta accounted for 75–89 percent AD. Only ≤ 0.3 percent AD was retained in edible tissues and < 1 percent AD in egg. ^{14}C-residues in egg yolk reached a plateau concentration within 7 days of dosing for all radiolabels. In egg white, ^{14}C-residues reached a plateau within 3–7 days depending on the radiolabel.

Total radioactivity was highest in composite fat samples (0.21–1.1 mg eq/kg), followed by kidney (0.42–0.64 mg eq/kg), liver (0.31–0.58 mg eq/kg) and composite muscle samples (0.053–0.36 mg eq/kg).

Following sequential extractions of egg yolks with methanol and water, greater than 89 percent TRR was released. Mefentrifluconazole (6–44 percent TRR; 0.03–0.12 mg/kg), M750F022 (39–47 percent TRR; 0.19–0.29 mg eq/kg) and 1,2,4-triazole (41 percent TRR; 0.11 mg eq/kg) represented the major residues. The fatty acid conjugates of the metabolite M750F022 (sum of M750F023, M750F024 and/or M750F025) were also present but at lower levels (6–15 percent TRR; 0.03–0.09 mg eq/kg).

The radioactivity in egg whites following administration of the C- and TFMP- radiolabelled-mefentrifluconazole was ≤ 0.009 mg/kg eq, therefore, these were not subjected to further analysis. Egg whites from the T-label study were extracted with methanol and water which, released almost all of the radioactivity (98 percent TRR; 0.350 mg eq/kg). 1,2,4-Triazole was the only metabolite identified, accounting for the majority of the radioactivity (83 percent TRR; 0.297 mg eq/kg).

Methanol and/or methanol/water extraction of muscle samples released greater than 85 percent TRR. M750F022 (C/TFMP-labels: 50–77 percent TRR; 0.02–0.05 mg/kg) and 1,2,4-triazole (T-label: 91 percent TRR; 0.322 mg eq/kg) represented the main components. Mefentrifluconazole and the fatty acid conjugates of M750F022 (sum of M750F023, M750F024 and/or M750F025) were present in lower amounts, accounting for 6–7 percent TRR (0.003–0.005 mg eq/kg) and 10–20 percent TRR (0.007–0.010 mg eq/kg), respectively.

Sequential extraction of liver with methanol/water released 83–100 percent TRR. The predominant metabolites observed included M750F022 (29–37 percent TRR; 0.12–0.17 mg eq/kg), the glutathione conjugate, M750F034 (up to 20 percent TRR; 0.12 mg eq/kg), and the 1,2,4-triazole (85 percent TRR; 0.41 mg eq/kg). Mefentrifluconazole and the fatty acid conjugates of M750F022 (sum of M750F023, M750F024 and/or M750F025) accounted for 6–7 percent TRR (0.03 mg/kg) and 7–12 percent TRR (0.02–0.07 mg eq/kg), respectively.

Extraction of kidney with methanol released 79–99 percent TRR, with limited radioactivity released following subsequent extractions using isohexane or water. M750F022 (20 percent TRR; 0.09–0.12 mg eq/kg) and 1,2,4-triazole (66 percent TRR; 0.37 mg eq/kg) were identified as major metabolites. Conversely, the parent and the fatty acid conjugates of M750F022 (sum of M750F023, M750F024 and/or M750F025) were present in low amounts, each accounting for 4 percent TRR (0.017 mg/kg).

Extraction of fat (C- and TFMP label) using acetonitrile released 83–112 percent TRR, while extraction using methanol (T-label) released 102 percent TRR, with limited radioactivity released following subsequent extractions with isohexane or water. 1,2,4-Triazole (73 percent TRR; 0.14 mg eq/kg), the fatty acid conjugates of M750F022 (sum of M750F023, M750F024 and M750F025) (~42 percent TRR; 0.287–0.380 mg eq/kg) and the metabolite M750F022 (25–41 percent TRR; 0.18–0.37 mg eq/kg) accounted for the majority of the radioactivity. Mefentrifluconazole was present at lower levels (5–20 percent TRR; 0.04–0.10 mg/kg).

In summary, the metabolism of mefentrifluconazole in livestock and rats was qualitatively similar, based on two main transformation steps: hydroxylation followed by conjugation and cleavage followed by conjugation. Most of the radioactivity was eliminated via excreta. In goat and poultry matrices, mefentrifluconazole and 1,2,4-triazole were the predominant components of the residue. Metabolite M750F022 (and its fatty acid conjugates) was also a major component in poultry matrices.

Environmental fate in soil

The Meeting received information on soil aerobic metabolism, hydrolysis and photolysis properties of mefentrifluconazole. Studies were also received on the nature of [^{14}C]-mefentrifluconazole in confined rotational crops and the magnitude of mefentrifluconazole in field rotational crops.

Aerobic soil metabolism (laboratory studies)

Mefentrifluconazole is persistent in soil with DT_{50} ranging from 156 to >1000 days. However, the Meeting noted that the predicted DT_{50} values were extrapolated well beyond the study duration (120 days) and should be treated with caution.

The metabolites 1,2,4-triazole and M750F003 were detected, reaching maximum amounts of 5.2 percent of the total applied radioactivity (TAR) and 2 percent TAR, respectively. A number of additional metabolites were detected, however, none exceeded 1 percent TAR at any sampling time.

Hydrolysis

Mefentrifluconazole is stable in aqueous solutions at environmentally relevant pHs of 5, 7 and 9.

Soil photolysis

Limited degradation of the parent compound was observed in both irradiated and dark control soil samples, hence photolysis was not an important route of dissipation.

Field Dissipation

The dissipation of mefentrifluconazole under field conditions has been studied in the United States (bare ground and turf-cropped soil), Europe (bare soil) and (bare soil). Quantifiable residues of mefentrifluconazole were detected only in the first 20 cm of the soils. No residues above the LOQ were detected below 20 cm in any sample at any site. For bare soil, the overall geometric mean (non-normalised) DT_{50} was estimated to be 149 days, indicating mefentrifluconazole is non-persistent to moderately persistent. Therefore, the Meeting decided that mefentrifluconazole shows limited potential to accumulate in soil following application in consecutive years.

Confined rotational crops

[Chlorophenyl-U-^{14}C] and [triazole-3(5)-^{14}C]-labelled mefentrifluconazole, formulated as EC formulations, were applied to bare sandy loam soil, in plastic containers maintained in either a glass roofed vegetation hall, phytotron or in a glass house, at an application rate of 300 g ai/ha. Spinach (variety *Corvette)*, white radish (variety *April Cross)* and spring wheat (*Thasos*) were sown 30/31, 120/122 and 364/365 days after the soil treatment. All crops were harvested at maturity and additional immature spinach samples as well as spring wheat forage samples (in part dried to hay) were collected 25–33 days and 49–55 days after planting (DAP), respectively.

Significant uptake and translocation of TRRs from soil into the secondary crops was observed over all plant-back intervals (PBI) and matrices (particularly spring wheat grain), which is due to the uptake and translocation of high amounts of triazole derivative metabolites (1,2,4-triazole, triazole alanine [TA], triazole acetic acid [TAA] and triazole lactic acid [TLA]). The highest levels of radioactive residues were found in spring wheat straw (30-day PBI) and in spring wheat grain, hay and straw after the 120/122–day PBI. The TRRs in spinach and white radish matrices were generally lower compared to those in wheat matrices. Overall, residues remained similar or decreased at longer PBIs, except for wheat grain where residues peaked at the 120-day PBI followed by a slight decrease by the 365-day PBI, yet still higher than the TRRs at the 30-day PBI.

In all tested matrices, except wheat grain, methanol released 26–96 percent TRR and water released an additional 1–34 percent TRR, while that released from wheat grain ranged from 7–49 percent and 8–53 percent TRR, respectively. PES underwent extensive hydrolysis using various solvents and enzymes, and analysis of the hydrolysates demonstrated that the radioactivity was associated with plant

constituents.

Mefentrifluconazole was the main component detected in all tested samples, except grain. At 30/31-day PBI, residues accounted for 14–91 percent TRR (0.008–0.013 mg/kg) in immature and mature spinach, and 4–70 percent TRR (0.006–0.101 mg/kg) in the other matrices. At 120/122-day PBI, residues of the parent were 36–61 percent TRR (0.006–0.055 mg/kg) in immature and mature spinach, wheat forage, hay and straw, and at 364/365-day PBI, accounted for 1–41 percent TRR (0.0008–0.018 mg/kg) in wheat samples. No parent or metabolites were detected in radish roots or tops beyond the 30-day PBI.

In spinach and wheat, metabolites accounting for 2–80 percent TRR (0.0003–0.018 mg eq/kg), 5–83 percent TRR (0.0004–0.032 mg eq/kg) and 22–65 percent TRR (0.004–0.022 mg eq/kg) at 30-, 120- and 365-day PBIs, respectively, were characterised based on their chromatographic properties.

At longer PBIs, the parent was only detected in wheat hay (122-day PBI: 1.3 percent TRR; [0.030 mg/kg]) and straw (122-day PBI; 1 percent TRR; [0.014 mg/kg] and 365-day PBI; 1 percent TRR [0.008 mg/kg]).

In most cases, the main metabolite in the crop matrices (T-label) was triazole alanine (13–94 percent TRR; 0.022–0.982 mg eq/kg), followed by triazole lactic acid 9–39 percent TRR (0.005–0.807 mg eq/kg). The only exceptions were spring wheat hay (122 DAT) and spring wheat straw (all PBIs), where, triazole lactic acid was the most abundant component among all the analytes identified. In spring wheat grain, triazole alanine (42–73 percent TRR; 0.98–2.36 mg eq/kg) was the main component followed by triazole acetic acid (20–24 percent TRR; 0.46–0.69 mg eq/kg). The sum of the triazole derivative metabolites and 1,2,4-triazole in all secondary crops ranged from 65–101 percent TRR.

In summary, when rotational crops were cultivated on mefentrifluconazole-treated soil, the residues included mainly two components, the parent and triazole derivative metabolites (1,2,4-triazole, TA, TAA, TLA), the latter being generated by cleavage of the parent molecule at the triazole bridge.

Field rotational crops

Field rotational crop studies were conducted in the United States and Europe during the 2014 and 2015 growing seasons. In the United States, treated plots received three broadcast soil directed spray applications, with a 7-day retreatment interval, for a total rate of 595 to 614 kg ai/ha/season. In Europe, a single application was made to bare soil at up to 327 kg ai/ha. At intervals of 1, 3 (Europe only), 4 and 11/12 months following the last application to the bare soil, wheat, lettuce or broccoli, and carrot or radish were planted.

In the United States, mefentrifluconazole residues in wheat forage/hay/straw reached 2.38/0.53/0.06, 0.69/0.87/< 0.01, 1.13/2.65/0.02, and 1.57/1.97/0.01 mg/kg at 1, 3, 4 and 11 month PBIs, respectively. In radish tops/root, the residues reached 0.07/0.03, 0.04/0.02, 0.02/0.02 and < 0.01/< 0.01 mg/kg at 1, 3, 4 and 12 month PBIs, respectively. Residues in wheat grain and lettuce were < 0.01 mg/kg at all PBIs.

In Europe, residues of mefentrifluconazole in all tested crops, including a cereal grain (wheat), root crop (carrot and radish), leafy (lettuce and spinach) and Brassica (broccoli and cauliflower) vegetables were consistently below the LOQ of 0.01 mg/kg at all PBIs of 1, 4 and 12 months.

In summary, the environmental fate data demonstrated that mefentrifluconazole is relatively persistent in soil and is stable in aqueous solutions at environmentally relevant pHs. Photolysis of mefentrifluconazole on the soil surface is not anticipated to be an important dissipation process. The metabolism in rotational crops showed to be similar to that in primary crops with no rotational crop specific metabolites. Uptake of mefentrifluconazole in food commodities and wheat straw was very

limited, however, measurable uptake into wheat forage and hay was observed.

No quantifiable residues of 1,2,4-triazole were observed in any of the tested crops. In general, residues of triazole alanine, triazole acetic acid and triazole lactic acid were higher in feed commodities than food commodities. In food commodities, triazole alanine was the highest among all triazole derivative metabolites, followed by triazole lactic acid and triazole acetic acid, all of which declined with increased PBI.

Methods of Analysis

The Meeting received descriptions and validation data for three analytical methods capable of quantifying residues of mefentrifluconazole in diverse plant matrices. The samples were extracted with methanol/water/2 mol/L HCl (70/25/5), acetonitrile or methanol/water (80/20), the samples with hexane, cleaned-up with salts and dispersive SPE (QuEChERs), or injected directly in the LC-MS/MS. Average recoveries were in the range of 70–120 percent (with a few isolated exceptions) with RSD of ≤ 20 percent. The methods were satisfactorily validated at LOQ of 0.01 mg/kg for all tested plant matrices, including cereals, citrus, coffee, soya beans, grapes and apple.

The Meeting also received descriptions and validation data for two method for analysis of mefentrifluconazole residues in animal matrices. In one method, samples were extracted with acetonitrile and iso-hexane (milk, cream, fat) or methanol/water/2N HCl (70/25/5) (muscle, kidney, liver and egg), and the other method uses QuEChERs. Residues were quantified by LC-MS/MS, and the methods were satisfactorily validated at a LOQ of 0.01 mg/kg.

Two methods to analyse the metabolite M750F022 and the fatty acid conjugate M750F025 (measured as M750F022) in hen matrices were provided. Samples were extracted with acetonitrile:isohexane, methanol/water/2 mol/L HCl (70/25/5) or methanol/water, the extracts cleaned up on SPE column, and residues quantified using GC-MS. The fatty acid conjugates of M750F022 were hydrolysed using NaOH (10 M). Recoveries of mefentrifluconazole and the metabolites M750F022 and M750F025 were acceptable, and the LOQ achieved for all animal commodities were 0.01 mg/kg for each analyte.

The methods for analysing mefentrifluconazole in plant matrices and mefentrifluconazole and the metabolites M750F022 and M750F025 in animal matrices were successfully validated by independent laboratories, demonstrating good reproducibility. Some of the plant-specific methods were also subjected to radiovalidation, where bioincurred residues of mefentrifluconazole were adequately recovered from samples of wheat forage, soya bean green pods and grapes collected from the metabolism studies, demonstrating the efficiency of the data collection analytical methods to extract incurred residues of mefentrifluconazole. The only exception was wheat straw, where the extraction efficiency was 59 percent likely due to the difference in extraction solvents between the metabolism study (methanol (3×) and water (2×)) and the analytical method (acetonitrile). For residues of mefentrifluconazole in animal matrices, extraction efficiencies were 80 percent or higher for milk, cream, muscle, kidney, fat, egg yolk and lower for liver (46 percent). For M750F022, extraction efficiencies were 90 percent or higher for milk, cream, kidney, fat and lower for egg yolk (66 percent), muscle (61 percent) and liver (46–50 percent). This was also likely due to the minor differences in extraction solvents between the metabolism study and the analytical method.

Stability of pesticide residues in stored analytical samples

Residues of mefentrifluconazole in samples fortified at 0.1 mg/kg were determined to be stable at ≤-18 ºC for at least 24 months in high water content commodities (tomato, apple, wheat whole plant), high oil

content commodities (rapeseed), high protein content commodities (dry bean seed, dry pea seed, dry soya bean seed), high starch content commodities (potato tuber), high acid content commodities (grape, lemon), and wheat straw.

Residues of mefentrifluconazole and M750F022 (at 0.1 mg/kg) were stable at ≤-18 ºC for at least 6 months in milk, cream, eggs and bovine and poultry tissues.

These demonstrated storage stability intervals covered the storage durations of the crop field trials, processing studies and animal feeding studies.

Definition of the residue

Plant commodities

The nature of the mefentrifluconazole residues was investigated in grapes (leaves, stalks and berries), soya beans (green pods, hulls, seed, and rest of plant) and wheat (forage, grain, straw) following foliar treatment.

Mefentrifluconazole was the major analyte in all tested plant matrices (60–92 percent TRR; 0.22–14.3 mg/kg), except wheat grain and soya bean seed where the predominant metabolite was triazole alanine (free and conjugated: 46–48 percent; 0.28–1.5 mg eq/kg), a common metabolite of several triazole fungicides. As suitable analytical methods are available to analyse the parent compound, the Meeting considered that mefentrifluconazole was a suitable marker for monitoring compliance.

In deciding which compounds should be included in the residue definition for risk assessment, the Meeting considered the likely occurrence and toxicological properties of M750F019, found in grapes, as well as the triazole derivative metabolites found in soya bean seed and wheat grain.

M750F019 was not observed in the rat, however, its toxicity was considered to be covered by the health based guidance value (HBGV) of the parent compound, as noted in the 2021 JMPR Report. Furthermore, in the grape metabolism study, the ratio of M750F019 to the parent compound in grapes was 0.1, demonstrating a low contribution to the dietary exposure, compared to the parent compound.

Triazole derivative metabolites (1,2,4-triazole, triazole alanine, triazole lactic acid and triazole acetic acid) were found in significant amounts in wheat grain and soya bean seed from primary plant metabolism studies. Moreover, these metabolites were also frequently detected in control and treated crops from supervised field trials. The Meeting noted that these metabolites can arise from other sources and have toxicities known to be different from mefentrifluconazole. The Meeting concluded that these metabolites should be assessed separately, and were not further considered in the current evaluation.

The Meeting decided the residue definition for dietary risk assessment for plant commodities should be mefentrifluconazole.

Animal commodities

The nature of the mefentrifluconazole residues was investigated in lactating goats and laying hens. The metabolism of mefentrifluconazole was qualitatively similar in both animals, yet more extensive in goats.

Mefentrifluconazole (free and/or conjugated) was a major component of the residue in the goat (milk 3–48 percent TRR; kidney 10–46 percent TRR; muscle 12–96 percent TRR; liver 31–53 percent TRR; fat 85–88 percent TRR), but a minor component in the hen (egg yolk 6–44 percent TRR; muscle 6–7 percent TRR; fat 5–20 percent TRR; liver 10–26 percent TRR and kidney 4 percent TRR). Nevertheless, mefentrifluconazole (free and/or conjugated) was present in all tested livestock matrices which would make it a suitable marker for monitoring compliance.

Validated analytical methods are available for the determination of mefentrifluconazole in tissues, milk and eggs. The Meeting agreed the residue for compliance monitoring for tissues, milk and eggs should be mefentrifluconazole (free and conjugated).

In deciding which compounds should be included in the residue definition for risk assessment, the Meeting considered the likely occurrence and toxicological properties of the metabolites potentially contributing to the dietary risk.

Specific toxicological studies reviewed at the 2021 JMPR Meeting were only available for the metabolite M750F022, which was considered to have equal or lower toxicity than the parent compound. The Meeting concluded that the HBGVs apply to mefentrifluconazole and its metabolites M750F015, M750F016, M750F017, M750F019, M750F022, M750F038, M750F043, and M750F068, expressed as mefentrifluconazole. The current Meeting also concluded that two additional livestock metabolites (M750F064 and M750F034) are not of concern from the genotoxicity perspective and the HBGVs for parent mefentrifluconazole are also applicable.

1,2,4-Triazole was found in measurable amounts in lactating goat and laying hen metabolism studies (32–87 percent TRR; ≤ 0.4 mg eq/kg). 1,2,4-Triazole and triazole alanine were also frequently detected in control and treated samples of milk, eggs and tissues in the animal feeding studies. The Meeting concluded that these metabolites can arise from other sources and have toxicities known to be different from mefentrifluconazole. These metabolites should be assessed separately, considering their source and respective toxicities, and were not further considered in the current evaluation.

Only the major metabolites, M750F016, M750F043, M750F064 and M750F068, identified in milk, liver and kidney of the lactating goat metabolism study are being considered for the residue definition for risk assessment as the nature of the residues in fat were not further elucidated considering the low TRRs.

In goat muscle and fat tissues, the majority of the TRR was identified as parent mefentrifluconazole (85–96 percent TRR; 0.03–0.47 mg/kg). In liver, kidney and milk, the sum of mefentrifluconazole and M750F022 (including their conjugates M750F068, M750F064 and M750F043) represent 60 percent, 64 percent and 70 percent of the TRR, respectively, which cover more than 80 percent of the total compounds for which the HBGVs apply. The less prominent metabolite M750F016 found in liver does not contribute significantly to the overall dietary exposure nor to the sum of mefentrifluconazole and M750F022 (free and conjugated) already taken into account for dietary risk assessment.

Only the major metabolites identified in the poultry metabolism study, M750F022 and its fatty acid conjugates (M750F023, M750F024 and M750F025) and M750F034 (sulfate conjugate of mefentrifluconazole) were considered.

The 2021 Meeting noted that the additional fatty acid side chains of the conjugates M750F023, M750F024 and M750F025 may cause differences in kinetics compared to the metabolite M750F022, and therefore, the Meeting concluded that the TTC approach for non-genotoxic compounds of Cramer Class III (1.5 µg/kg bw/day) should be considered for these metabolites.

For compounds covered by the parent HBGVs, metabolite M750F022 was the predominant component in all poultry tissues and eggs accounting for up to 10-fold the concentrations of the parent compound. In the laying hen feeding study, other than the parent compound, only M750F022 was investigated in eggs and tissues, where residues of this metabolite were equivalent to or higher than those of the parent compound at all feeding levels. Therefore, this metabolite will contribute to the overall dietary exposure to mefentrifluconazole and should be considered in combination with M750F034 (sulfate conjugate of mefentrifluconazole) in the residue definition for risk assessment.

The Meeting agreed that the suitable residue definition for risk assessment is the sum of mefentrifluconazole (free and conjugated) + M750F022 (free and conjugated), expressed as mefentrifluconazole.

Conclusions

Based on the above, the Meeting recommended the following residue definitions for mefentrifluconazole.

Definition of the residue for compliance with the MRL and for dietary exposure assessment for plant commodities: *Mefentrifluconazole*.

Definition of the residue for compliance with the MRL for animal commodities: *Mefentrifluconazole (free and conjugated).*

Definition of the residue for dietary exposure assessment for animal commodities: Sum of mefentrifluconazole (free and conjugated) + M750F022 (free and conjugated), expressed as mefentrifluconazole.

In deciding whether the residue for monitoring compliance is fat-soluble, the Meeting noted that the mean residues of mefentrifluconazole at the highest dose tested in the lactating cow feeding study were 0.16 mg/kg in muscle and 1.7 mg/kg in perirenal fat while residues were 5× higher in cream compared to whole milk. In the laying hen feeding study, total mefentrifluconazole residues at the highest dose tested were 0.05 mg/kg in muscle and 0.53 mg/kg in fat.

The Meeting considered the residue is fat-soluble.

Results of supervised residue trials in crops

Citrus fruits

The critical GAP for the citrus fruits crop group is from the United States: 3×146 kg ai/ha, 14-day RTI (days), 0-day PHI. The Meeting received supervised residue trials conducted on whole orange, grapefruit and lemon in the United States, as well as two trials on orange and one trial on lemon conducted in Mexico, all matching the critical GAP.

Mefentrifluconazole residues in whole oranges in ranked order were (n = 14); 0.15, 0.17, 0.18, 0.19 (2), 0.20 (2), 0.23, 0.24, 0.29, 0.33, 0.46, 0.66 and 0.70 mg/kg.

Noting that oranges are the representative crop of the subgroup of oranges, the Meeting estimated a maximum residue level of 1 mg/kg, an STMR of 0.215 mg/kg, and an HR of 0.70 mg/kg for the Subgroup of oranges, sweet, sour.

Mefentrifluconazole residues in whole grapefruits in ranked order were (n = 6); 0.10, 0.13, 0.16, 0.19, 0.20 and 0.24 mg/kg.

Noting that grapefruits are representative of the subgroup of pummelo and grapefruits, the Meeting estimated a maximum residue level of 0.5 mg/kg, an STMR of 0.16 mg/kg and an HR of 0.24 mg/kg for the Subgroup of pummelo and grapefruits.

Mefentrifluconazole residues in whole lemons in ranked order were (n = 7): 0.30, 0.33 (2), 0.37, 0.44, 0.60 and 0.98 mg/kg.

Noting that lemons are the representative crop of the subgroup of lemons and limes, the Meeting estimated a maximum residue level of 1.5 mg/kg, an STMR of 0.37 mg/kg, and an HR of 0.98 mg/kg for the Subgroup of lemons and limes.

The GAP covers the group of citrus fruits, including use on mandarins. Although trials were not provided for mandarins, the Meeting noted that residues in lemons/limes have been shown to be similar to or greater than residues in mandarins. Therefore, the Meeting decided to extrapolate the residues from lemon and estimated a maximum residue level of 1.5 mg/kg, an STMR of 0.37 mg/kg, and an HR of 0.98 mg/kg, for the Subgroup of mandarins.

Pome fruits

The critical GAP for pome fruits is from the United States; 3×146 g ai/ha, 7-day RTI (days) and a 0-day PHI. The Meeting received supervised residue trials conducted on apple and pear in Canada and the United States matching the critical GAP.

Mefentrifluconazole residues in apples in ranked order were (n = 13): < 0.01, 0.23, 0.26, 0.30 (2), 0.37, 0.39, 0.43 (2), 0.45, 0.46, 0.47 and 0.55 mg/kg.

Mefentrifluconazole residues in pears in ranked order were (n = 10): < 0.01, 0.30, 0.32, 0.34 (2), 0.40, 0.52, 0.68, 0.73 and 0.92 (highest 1.12) mg/kg.

The Meeting noted that the GAP covers the group of pome fruits except persimmon, Japanese and that median residues in apples and pears are within a 5-fold difference. The Mann-Whitney U-test also determined that the datasets were from the same population. Therefore, the Meeting decided to combine the two datasets of apples and pears.

Combined mefentrifluconazole residues in apples and pears were (n = 23): < 0.01 (2), 0.23, 0.26, 0.30 (3), 0.32, 0.34 (2), 0.37, 0.39, 0.40, 0.43 (2), 0.45, 0.46, 0.47, 0.52, 0.55, 0.68, 0.73 and 0.92 (highest 1.12) mg/kg.

The Meeting estimated a maximum residue level of 1.5 mg/kg, an STMR of 0.39 mg/kg, and an HR of 1.12 mg/kg (based on the highest residue of replicate samples) for the Group of pome fruits except persimmon, Japanese.

Stone Fruits

The critical GAP for stone fruits is from the United States; 3×146 g ai/ha, 7-day RTI (days) and a 0-day PHI. The Meeting received supervised residue trials conducted on whole peaches, cherries and plums in Canada and the United States matching the critical GAP.

Mefentrifluconazole residues in whole peaches in ranked order were (n = 12): 0.36, 0.41, 0.42, 0.47, 0.48, 0.52, 0.60, 0.70, 0.72, 0.81 and 0.96 (2) (highest 1.04) mg/kg.

Noting that peaches are the representative crop of the subgroup of peaches, the Meeting estimated a maximum residue level of 2 mg/kg, an STMR value of 0.56 mg/kg, an HR of 1.04 mg/kg (based on the highest residue of replicate samples) for the Subgroup of peaches.

Mefentrifluconazole residues in sweet and tart cherries in ranked order were (n = 7): 0.04, 0.94, 1.0, 1.1, 1.4, 2.0 and 2.2 (highest 2.4) mg/kg.

Noting that cherries are the representative crop of the subgroup of cherries, the Meeting estimated a maximum residue level of 5 mg/kg, an STMR of 1.1 mg/kg and an HR of 2.4 mg/kg (based on the highest residue of replicate samples) for the Subgroup of cherries.

Mefentrifluconazole residues in plums in ranked order were (n = 9): < 0.01, 0.03, 0.13, 0.21, 0.26, 0.30, 0.32, 0.37 and 0.98 (highest 1.0) mg/kg.

Noting that plums are the representative crop of the subgroup of plums, the Meeting estimated a maximum residue level of 1.5 mg/kg, an STMR value of 0.26 mg/kg and an HR of 1.0 mg/kg (based on the

highest residue of replicate samples) and for the Subgroup of plums.

Cane berries

The critical GAP for cane berries is from the United States; 3×146 g ai/ha, 7-day RTI (days) and a 0-day PHI. The Meeting received supervised residue trials conducted on blackberries in the United States matching the critical GAP.

Mefentrifluconazole residues in blackberries in ranked order were (n=6): 0.25, 0.35, 0.71, 1.2 and 1.3 (2) (highest of 1.62) mg/kg.

Noting that blackberries are the representative crop of the subgroup of cane berries, the Meeting estimated a maximum residue level of 3 mg/kg, an STMR value of 0.96 mg/kg and an HR of 1.62 mg/kg (based on the highest residue of replicate samples) for the Subgroup of cane berries.

Bush berries

The critical GAP for bush berries is from the United States; 3×146 g ai/ha, 7-day RTI (days) and a 0-day PHI. The Meeting received supervised residue trials conducted on blueberries in the United States matching the critical GAP.

Mefentrifluconazole residues in blueberries in ranked order were (n=9): 0.06, 0.18, 0.51, 0.56, 0.58, 0.68, 0.74, 0.77 and 3.16 (highest 3.24) mg/kg.

Noting that blueberries are the representative crop of the subgroup bush berries, the Meeting estimated a maximum residue level of 5 mg/kg, an STMR value of 0.58 mg/kg and an HR of 3.24 mg/kg (based on the highest residue of replicate samples) for the Subgroup of bush berries and extrapolated these values to elderberries and Guelder rose.

Grapes

The critical GAP for wine grapes is from the United States; 3×146 g ai/ha, 10-day RTI (days) and a 14-day PHI. The Meeting received supervised residue trials conducted on wine grapes in Canada and the United States matching the critical GAP.

Mefentrifluconazole residues in grapes in ranked order were (n = 8): 0.25, 0.33, 0.38, 0.41, 0.67, 0.83, 1.0 and 1.1 mg/kg.

The Meeting estimated a maximum residue level of 2 mg/kg, an STMR value of 0.54 mg/kg and an HR of 1.1 mg/kg for wine grapes.

The critical GAP for table grapes is from the United States; 2×112 g ai/ha, 10-day RTI (days) and a 14-day PHI. The Meeting received trials from the United States on table grapes where 3 foliar applications were made at 147–155 g ai/ha, 8–11-day RTI (days)s, seasonal application rates of 449–460 g ai/ha and 14–21-day PHIs.

As supervised field trials were conducted at rates 2-fold greater than the critical GAP and the RTI (days)s were longer, without suitable data to estimate half-lives, the Meeting concluded that the overall impact of these parameters on the residue was > 25 percent, and a maximum residue level could not be estimated for table grapes.

Low growing berries

The critical GAP for low growing berries is from the United States; 3×146 g ai/ha, 7-day RTI (days) and a 0-day PHI. The Meeting received supervised residue trials conducted on strawberries in the United States

matching the critical GAP.

Mefentrifluconazole residues in strawberries in ranked order were (n = 11): < 0.01 (2), 0.08, 0.15, 0.24, 0.29, 0.43, 0.44, 0.50, 0.62 and 1.1 mg/kg.

Noting that strawberries are the representative crop of the subgroup of low growing berries, the Meeting estimated a maximum residue level of 2 mg/kg, an STMR value of 0.29 mg/kg and an HR of 1.1 mg/kg for the Subgroup of low growing berries.

Assorted tropical and sub-tropical fruits – inedible peel

Avocado

The critical GAP for avocado is from El Salvador; 3×120 g ai/ha, 14-day RTI (days) and a 3-day PHI. The Meeting received supervised residue trials conducted on avocado in Brazil, Colombia and Mexico matching the critical GAP.

Mefentrifluconazole residues in pitted whole avocadoes, expressed as whole fruit, in ranked order were (n = 6): 0.10, 0.22, 0.32, 0.39, 0.42 and 0.50 mg/kg.

The Meeting estimated a maximum residue level of 1 mg/kg, an STMR value of 0.36 mg/kg and an HR of 0.50 mg/kg for avocadoes.

Banana

The critical GAP for bananas is from Ecuador; 4×140 g ai/ha, 14-day RTI (days) and a 0-day PHI. The Meeting received supervised residue trials, conducted on bagged and unbagged bananas in Brazil, Colombia and Ecuador, where 5 foliar applications were made at a target rate of 140 g ai/ha, RTI (days)s of 14 days, seasonal application rates of 700 g ai/ha and a DALA of 0 days.

The Meeting agreed that the first application in the trials made 70 days prior to harvest would not contribute significantly to residues at the time of harvest and considered suitable for estimating a maximum residue level.

Mefentrifluconazole residues in unbagged whole bananas in ranked order were (n=10): 0.04, 0.12, 0.16, 0.24, 0.35, 0.47, 0.54, 0.57, 0.65 and 0.74 mg/kg.

Mefentrifluconazole residues in the pulp of unbagged bananas in ranked order were (n=10): < 0.01, 0.01, 0.04, 0.05 (2), 0.06, 0.09, 0.14, and 0.21 (2) mg/kg.

The Meeting estimated a maximum residue level of 1.5 mg/kg, an STMR of 0.055 mg/kg and an HR of 0.21 mg/kg.

Mango

The critical GAP for mango is from China; 3×0.016 kg ai/hL, 10-day RTI (days) and a 14-day PHI. The Meeting received supervised residue trials conducted on mango in China approximating the critical GAP.

Mefentrifluconazole residues in whole mangoes in ranked order were (n = 6): 0.12, 0.16 (2), 0.20, 0.22 and 0.28 mg/kg. Residues in pulp were all < 0.01 m/kg (n=6).

The Meeting estimated a maximum residue level of 0.6 mg/kg and an STMR and HR of 0.01 mg/kg.

Papaya

The critical GAP for papaya is from El Salvador; 2×120 g ai/ha, 14-day RTI (days) and a 3-day PHI. The

Meeting received supervised residue trials conducted on papaya from Brazil, Colombia and Mexico, matching the critical GAP.

Mefentrifluconazole residues in whole papayas in ranked order were (n = 6): < 0.01, 0.04, 0.07 (2), 0.19 and 0.22 mg/kg.

The Meeting estimated a maximum residue level of 0.5 mg/kg, an STMR value of 0.07 mg/kg and an HR of 0.22 mg/kg for papayas.

Bulb vegetables

The critical GAP for bulb vegetables is from the United States; 3×146 g ai/ha, 7-day RTI (days) and a 7-day PHI. The Meeting received supervised residue trials conducted on bulb onions and green onions in Canada and the United States matching the critical GAP.

Mefentrifluconazole residues in bulb onions in ranked order were (n=13): < 0.01, 0.01(2), 0.03 (2), 0.05 (2), 0.08, 0.09 (3), 0.10 and 0.11 mg/kg.

The Meeting estimated a maximum residue level of 0.2 mg/kg, an STMR of 0.05 mg/kg and an HR of 0.14 mg/kg (based on the highest residue of replicate samples) for the Subgroup of bulb onions.

Mefentrifluconazole residues in green onions in ranked order were (n=5): 0.11, 0.28, 0.39, 0.42 and 2.1 mg/kg.

The Meeting estimated a maximum residue level of 4 mg/kg, an STMR of 0.39 mg/kg and an HR of 2.2 mg/kg (based on the highest residue of replicate samples) for the Subgroup of green onions.

Fruiting vegetables – Cucurbits

The critical GAP for fruiting vegetables-cucurbits is from the United States for "cucurbit vegetables"; 3×146 g ai/ha, 7-day RTI (days) and a 0-day PHI. The Meeting received supervised residue trials on cucumbers, summer squash and melons from Canada and the United States matching the critical GAP.

Mefentrifluconazole residues in cucumbers in ranked order were (n = 9): 0.01, 0.02, 0.03 (4), 0.04 (2) and 0.10 (highest 0.123) mg/kg.

Mefentrifluconazole residues in summer squashes in ranked order were (n = 8): 0.01(2), 0.04, 0.05 (3) and 0.09 (2) mg/kg.

The Meeting noted that the median residues of cucumbers and summer squashes were within 5-fold, and that the Mann-Whitney U-test determined the datasets were from the same population. Therefore, the Meeting decided to combine the two datasets of cucumbers and summer squashes.

The ranked order of the combined mefentrifluconazole residues in cucumbers and summer squashes were (n = 17): 0.01 (3), 0.02, 0.03 (4), 0.04 (3), 0.05 (3), 0.09 (2) and 0.10 (highest 0.123) mg/kg.

The Meeting estimated a maximum residue level of 0.15 mg/kg, an STMR of 0.035 mg/kg and an HR of 0.123 mg/kg (based on the highest residue of replicate samples) for the Subgroup of fruiting vegetables, cucurbits - cucumbers and summer squashes.

Mefentrifluconazole residues in whole muskmelons in ranked order were (n = 8): 0.11 (3), 0.14, 0.16, 0.17, 0.21 and 0.22 mg/kg.

Noting that melons is the representative crop of the melons, pumpkins and winter squashes crop subgroup, the Meeting estimated a maximum residue level of 0.5 mg/kg, an STMR of 0.15 mg/kg and an HR of 0.23 mg/kg (based on the highest residue of replicate samples) for the Subgroup of fruiting vegetables, cucurbits – melons, pumpkins and winter squashes.

Fruiting vegetables – Other than cucurbits

The critical GAP for fruiting vegetables-other than cucurbits is from the United States for "fruiting vegetables"; 3×146 g ai/ha, 7-day RTI (days) and a 0-day PHI. The Meeting received trials on cherry tomatoes, tomatoes, bell peppers and non-bell peppers from the United States matching the critical GAP.

Mefentrifluconazole residues in field tomatoes (including cherry tomatoes [CT]) in ranked order were (n= 19): 0.03, 0.04, 0.05 (2), 0.08, 0.09, 0.10, 0.11, 0.13[CT], 0.14, 0.15 (2), 0.17, 0.19, 0.23, 0.25, 0.36[CT], 0.37 and 0.41[CT] (highest 0.45) mg/kg.

The Meeting estimated a maximum residue level of 0.7 mg/kg, an STMR of 0.14 mg/kg and an HR of 0.45 mg/kg (based on the highest residue of replicate samples) for the Subgroup of tomatoes.

Mefentrifluconazole residues in field bell peppers and non-bell peppers [NB] in ranked order were (n= 14): 0.04, 0.05, 0.06 (2), 0.20, 0.22, 0.24[NB], 0.26 [NB], 0.30, 0.33[NB], 0.39[NB], 0.43, 0.60[NB] and 0.73 (highest 0.84) mg/kg.

The Meeting estimated a maximum residue level of 1.5 mg/kg, an STMR of 0.25 mg/kg and an HR of 0.84 mg/kg (based on the highest residue of replicate samples) for the Subgroup of peppers (excluding martynia, okra and roselle).

The critical GAP from the United States for fruiting vegetables, other than cucurbits, also covers eggplants. The Meeting decided the pepper data could be used to extrapolate the maximum residue level of 1.5 mg/kg, the STMR of 0.25 mg/kg and the HR of 0.84 mg/kg for peppers to the Subgroup of eggplants.

Chili peppers, dried

Based on the estimated maximum residue level of 1.5 mg/kg for the Subgroup of peppers (excluding martynia, okra and roselle) and applying a default processing factor of 10, the Meeting estimated a maximum residue level of 15 mg/kg for peppers, chili, dried, together with an STMR of 2.5 mg/kg (0.25 × 10) and an HR of 8.4 (0.84 × 10) mg/kg.

Leafy vegetables (including Brassica leafy vegetables)

The critical GAP for leafy vegetables (including Brassica leafy vegetables) is from the United States for "leafy vegetables"; 3 × 146 g ai/ha, 7 day-RTI (days), 0-day PHI. The Meeting received trials from Canada and the United States on head lettuce, leaf lettuce, cos lettuce, spinach, radish leaves and mustard greens. All trials matched the critical GAP, except those for radish leaves, which were harvested at a DALA of 7 days.

Mefentrifluconazole residues in head lettuce with wrapper leaves, in ranked order were (n = 8): 0.12, 0.27, 0.32, 0.89, 1.30, 1.50, 2.1 and 2.2 mg/kg. Residues in head lettuce without wrapper leaves were < 0.01, 0.05, 0.09 and 1.6 mg/kg.

Mefentrifluconazole residues in leaf lettuce in ranked order were (n = 7): 2.4, 2.7, 3.0, 4.2, 4.4, 6.4 and 7.2 mg/kg.

Mefentrifluconazole in one sample of cos lettuce was 2.3 mg/kg.

Mefentrifluconazole residues in spinach in ranked order were (n = 8): 3.8, 4.6, 4.9, 5.2, 11, 12 (2) and 17 (highest 18) mg/kg.

The Meeting noted that the GAP in the United States covers the subgroup of leafy vegetables and decided to explore the possibility of estimating a subgroup maximum residue level for mefentrifluconazole. The median residues in head lettuce with wrapper leaves, leaf lettuce and spinach

differed by more than 5-fold and from the Kruskal-Wallis test, the datasets were not shown to be from the same residue population.

Therefore, the Meeting used the spinach dataset to estimate a maximum residue level of 30 mg/kg, an STMR of 8.1 mg/kg and an HR of 18 mg/kg (based on the highest residue of replicate samples) for the Subgroup of leafy greens.

The Meeting noted that the acute dietary exposure assessment showed that residues in leafy greens exceeded the ARfD of 0.3 mg/kg bw, at 140 percent for each amaranth leaves, chicory leaves and edible leaved chrysanthemums for Belgian toddlers, 130 percent for raw endive for Dutch children, 240 percent for cooked/boiled endive for Dutch toddlers, 140 percent for head lettuce for Dutch children and 120 percent for leaf lettuce for Dutch children. No alternative GAP was available.

Mefentrifluconazole residues in mustard greens in ranked order were (n = 4): 4.1, 5.0, 8.3 and 12 mg/kg.

The Meeting noted that the GAP in the United States for the subgroup of leafy vegetables includes Brassica leafy vegetables. The Meeting estimated a maximum residue level of 30 mg/kg, an STMR of 6.65 mg/kg and an HR of 12 mg/kg for the Subgroup of Leaves of Brassicaceae.

For dietary burden calculation, the Meeting estimated a median residue of 6.65 mg/kg and highest residue of 12 mg/kg for mustard greens and extrapolated the median and highest residues to kale leaves and rape forage.

The Meeting noted that the acute dietary exposure assessment showed that exposure from the consumption of mustard greens exceeded the ARfD of 0.3 mg/kg bw, at 240 percent for Chinese cabbage for Chinese children, 110 percent for kale for German children and 200 percent for mustard greens for Chinese children. No alternative GAP was available.

Legume vegetables

The critical GAP for legume vegetables, except soya bean and edamame, is from the United States; 3×146 g ai/ha, 7-day RTI (days) and a 21-day PHI. The Meeting received trials on beans and peas with pods and succulent beans and peas without pods from Canada and the United States matching the critical GAP.

Beans with pods

Mefentrifluconazole residues in beans with pods in ranked order were (n=6): < 0.01 (5) and 0.03 mg/kg.

The Meeting estimated a maximum residue level of 0.05 mg/kg, an STMR of 0.01 mg/kg and an HR of 0.03 mg/kg for the Subgroup of beans with pods, except soya bean (succulent seeds in pods).

Peas with pods

In trials approximating the critical GAP, mefentrifluconazole residues in peas with pods in ranked order were (n=9): < 0.01 (5), 0.02, 0.03 (2) and 0.08 (highest 0.10) mg/kg.

The Meeting estimated a maximum residue level of 0.15 mg/kg, an STMR of 0.01 mg/kg and an HR of 0.10 (based on the highest residue of replicate samples) mg/kg for the Subgroup of peas with pods.

Succulent beans without pods

In trials approximating the critical GAP, mefentrifluconazole residues in succulent beans without pods in ranked order were (n=6): < 0.01 (5) and 0.02 mg/kg.

The Meeting estimated a maximum residue level of 0.03 mg/kg, an STMR of 0.01 mg/kg and an

HR of 0.02 mg/kg for the Subgroup of succulent beans without pods, except soya bean (succulent seeds).

Succulent peas without pods

In trials approximating the critical GAP, mefentrifluconazole residues in succulent peas without pods in ranked order were (n=9): < 0.01 (9) mg/kg.

The Meeting estimated a maximum residue level of 0.01* mg/kg, an STMR of 0.01 mg/kg and an HR of 0.01 mg/kg for the Subgroup of succulent peas without pods.

Pulses

The critical GAP for pulses, except dry soybeans, is from the United States; 3×146 g ai/ha, 7-day RTI (days) and a 21-day PHI. The Meeting received trials on dry beans, dry peas and dry lentils from Canada and the United States matching the critical GAP.

Dry beans

Mefentrifluconazole residues in dry beans in ranked order were (n=10): < 0.01 (7), 0.02 (2) and 0.05 mg/kg.

The Meeting estimated a maximum residue level of 0.07 mg/kg and an STMR of 0.01 mg/kg for the Subgroup of dry beans, except soya bean dry.

Dry peas

In trials approximating the critical GAP, mefentrifluconazole residues in dry peas in ranked order were (n=8): < 0.01, 0.01 (3), 0.02 (3) and 0.09 mg/kg.

The Meeting estimated a maximum residue level of 0.15 mg/kg and an STMR of 0.015 mg/kg for the Subgroup of dry peas, except lentil (dry).

Dry lentils

In trials approximating the critical GAP, mefentrifluconazole residues in dry lentils in ranked order were (n=6): 0.04, 0.06, 0.14, 0.30, 0.55 and 0.68 mg/kg.

The Meeting estimated a maximum residue level of 1.5 mg/kg and an STMR of 0.22 mg/kg for lentils.

Dry soya beans

The critical GAP for dry soya beans is from the United States; 2×146 g ai/ha, 7-day RTI (days), 21-day PHI. The Meeting received supervised residue trials conducted on dry soya bean seeds in the United States matching the critical GAP.

Mefentrifluconazole residues in dry soya beans in ranked order were (n=17): < 0.01 (12), 0.01 (2), 0.03, 0.06 and 0.31 mg/kg.

The Meeting estimated a maximum residue level of 0.40 mg/kg and an STMR of 0.01 mg/kg for soya bean, dry.

Root and tuber vegetables

Root vegetables

The critical GAP for root and tuber vegetables, except sugar beets, is from the United States; 3×146 g

ai/ha, 7-day RTI (days), 7-day PHI. The Meeting received supervised residue trials conducted on carrots and radish in the United States matching the critical GAP.

Mefentrifluconazole residues in carrot roots in ranked order were (n=11): < 0.01 (2), 0.05, 0.06, 0.10, 0.11, 0.12, 0.15, 0.16, 0.22 and 0.24 mg/kg.

Mefentrifluconazole residues in radish roots in ranked order were (n=7): < 0.01, 0.03 (2), 0.08, 0.11, 0.13 and 0.38 (highest 0.40) mg/kg.

The Meeting noted that the GAP covers the group of root vegetables, except sugar beets. The median residues in carrot roots and radish roots are within a 5-fold difference and the Mann-Whitney U-test also determined that the datasets were from the same population. Therefore, the Meeting decided to combine the datasets for carrot roots and radish roots.

Combined mefentrifluconazole residues in carrot roots and radish roots were (n = 18): < 0.01 (3), 0.03 (2), 0.05, 0.06, 0.08, 0.10, 0.11, 0.11, 0.12, 0.13, 0.15, 0.16, 0.22, 0.24 and 0.38 (highest 0.40) mg/kg.

The Meeting estimated a maximum residue level of 0.5 mg/kg, an STMR of 0.105 mg/kg and an HR of 0.40 mg/kg for the Subgroup root vegetables, except sugar beets.

Sugar beet

The critical GAP for sugar beet is from the United States; 2×146 g ai/ha, 14-day RTI (days), 7-day PHI. The Meeting received supervised residue trials conducted on sugar beet roots in Canada and the United States where the RTI (days) was 7 days and the sugar beet roots were harvested at DALAs of 14–21days. Therefore, a maximum residue level could not be estimated for sugar beet roots.

Tuberous and corm vegetables

The critical GAP for tuberous and corm vegetables is from the United States; 3×146 g ai/ha, 7-day RTI (days), 7-day PHI. The Meeting received supervised residue trials conducted on potatoes in Canada and the United States matching the critical GAP.

Mefentrifluconazole residues in potatoes in ranked order were (n = 19): < 0.01 (18) and 0.04 (highest 0.05) mg/kg.

Noting that potatoes are the representative crop of the subgroup tuberous and corm vegetables, the Meeting estimated a maximum residue level of 0.05 mg/kg, an STMR of 0.01 mg/kg and HR of 0.05 mg/kg for the Subgroup of tuberous and corm vegetables.

Wheat

The critical GAP for wheat, triticale and rye is from the United States; 2×146 g ai/ha, 14-day RTI (days), 21-day PHI. The Meeting received supervised residue trials conducted on wheat in Canada and the United States matching the critical GAP. The Meeting also received trials conducted in Europe, but none matched the critical GAP.

Mefentrifluconazole residues in wheat in ranked order were (n = 23): < 0.01, 0.02, 0.03 (3), 0.04 (2), 0.06, 0.08 (2), 0.09 (3), 0.10 (2), 0.11 (2), 0.12 (3), 0.13, 0.14, and 0.27 mg/kg.

The Meeting estimated a maximum residue level of 0.4 mg/kg and an STMR of 0.09 mg/kg for wheat grain.

Noting that the GAP covers triticale and rye, and wheat grain is the representative crop of the similar grains, and pseudocereals without husks crop subgroup, the Meeting decided to extrapolate the residues from wheat grain and estimated a maximum residue level of 0.4 mg/kg and an STMR of

0.09 mg/kg for triticale and rye.

Barley

The critical GAP for barley and oats is from the United States; 2×146 g ai/ha, 14-day RTI (days), 21-day PHI. The Meeting received supervised residue trials conducted on wheat in Canada and the United States matching the critical GAP. The Meeting also received trials conducted in Europe, but none matched the critical GAP.

Mefentrifluconazole residues in barley in ranked order were (n = 10): < 0.01, 0.20, 0.25, 0.34, 0.37, 0.48, 0.56, 0.71, 0.80, and 1.7 mg/kg.

The Meeting estimated a maximum residue level of 3 mg/kg and an STMR of 0.425 mg/kg for residues of mefentrifluconazole in barley grain.

Noting that the GAP covers oats, and barley grain is the representative crop of the similar grains, and pseudocereals with husks crop subgroup, the Meeting decided to extrapolate the residues from barley grain and estimated a maximum residue level of 3 mg/kg and an STMR of 0.425 mg/kg for oats.

Rice

The critical GAP for rice is from China; 2×12 g ai/ha, 5-day RTI (days), 21-day PHI. The Meeting received supervised residue trials conducted on rice in China matching the critical GAP. The Meeting also received trials conducted in Brazil and United States, but none matched the critical GAP.

Mefentrifluconazole residues in rice grain in ranked order were (n = 12): 0.029, 0.65 (2), 0.75, 1.0, 1.1, 1.3, 1.4, 1.8, 2.3, and 2.5 (2) mg/kg.

Mefentrifluconazole residues in husked rice in ranked order were (n = 12): < 0.01, 0.08, 0.09, 0.10 (2), 0.11 (2), 0.19, 0.24, 0.47, 0.50, and 0.79 mg/kg.

The Meeting estimated a maximum residue level of 5 mg/kg and an STMR of 1.2 mg/kg for residues of mefentrifluconazole in rice.

The Meeting also estimated a maximum residue level of 1.5 mg/kg and an STMR of 0.11 mg/kg for residues of mefentrifluconazole in husked rice.

Sorghum

The critical GAP for sorghum and millet is from the United States; 2×146 g ai/ha, 14-day RTI (days), 21-day PHI. The Meeting received supervised residue trials conducted on sorghum in the United States matching the critical GAP.

Mefentrifluconazole residues in sorghum in ranked order were (n = 9): < 0.01, 0.18, 0.24, 0.31, 0.41, 0.42, 0.52, 0.78, and 1.2 mg/kg.

The Meeting estimated a maximum residue level of 2 mg/kg and an STMR of 0.41 mg/kg for residues of mefentrifluconazole in sorghum grain.

Noting that the GAP covers millet, and sorghum grain is the representative crop of sorghum grain and millet crop subgroup, the Meeting decided to extrapolate the residues from sorghum grain and estimated a maximum residue level of 2 mg/kg and an STMR of 0.41 mg/kg for millet.

Maize

The critical GAP for maize and popcorn is from the United States; 2×146 g ai/ha, 14-day RTI (days), 21-day PHI. The Meeting received supervised residue trials conducted on maize in the United States

matching the critical GAP.

Mefentrifluconazole residues in maize in ranked order were (n = 17): < 0.01 (17) mg/kg.

The Meeting estimated a maximum residue level of 0.01* mg/kg and an STMR of 0.01 mg/kg for residues of mefentrifluconazole in maize.

Noting that the GAP covers popcorn, and maize is the representative crop of maize cereals crop subgroup, the Meeting decided to extrapolate the residues from maize and estimated a maximum residue level of 0.01(*) mg/kg and an STMR of 0.01 mg/kg for popcorn.

Sweet Corn

The critical GAP for sweet corn is from the United States; 3×146 g ai/ha, 14-day RTI (days), 21-day PHI. The Meeting received supervised residue trials conducted on sweet corn in the United States matching the critical GAP.

Mefentrifluconazole residues in sweet corn kernels plus cob with husks removed in ranked order were (n = 13): < 0.01 (9), and 0.02 (4) mg/kg.

The Meeting estimated a maximum residue level of 0.04 mg/kg and an STMR of 0.01 mg/kg and an HR of 0.02 mg/kg for residues of mefentrifluconazole in sweet corn (corn-on-the-cob) (kernels plus cob with husk removed).

Sugar cane

The critical GAP for sugar cane is from the United States; 2×146 g ai/ha, 14-day RTI (days) and a 14-day PHI. The Meeting received supervised residue trials conducted on sugar cane in the United States matching the critical GAP. The Meeting also received trials conducted in Brazil, but none matched the critical GAP.

Mefentrifluconazole residues in sugar cane in ranked order were (n=8): 0.10, 0.25, 0.31, 0.36, 0.38, 0.42, 0.48 and 0.97 mg/kg.

The Meeting estimated a maximum residue level of 1.5 mg/kg and an STMR of 0.37 mg/kg for sugar cane.

Tree Nuts

The critical GAP for tree nuts is from the United States; 3×146 g ai/ha, 7-day RTI (days) (all tree nuts, except pistachio) and 10-day RTI (days) (pistachio) and a 14-day PHI. The Meeting received supervised residue trials conducted on pecans and almonds in the United States matching the critical GAP. For pistachios, the application rate and PHI of the residue trials matched the critical GAP, however, the RTI (days)s were 7-days.

Mefentrifluconazole residues in pecans were in ranked order (5): < 0.01 (5) mg/kg.

Mefentrifluconazole residues in almonds were in ranked order (5): < 0.01 (4) and 0.02 mg/kg.

Mefentrifluconazole residues in pistachios were in ranked order (3): 0.01, 0.01 and 0.04 mg/kg.

The Meeting noted that the United States GAP covers the group of tree nuts. The median residues in pecans, almonds and pistachios are within a 5-fold difference and the Kruskal-Wallis test also determined that the datasets were from the same population. Despite the shorter RTI (days) in the crop field trials for pistachios, the Meeting decided the combined dataset was suitable to estimate the maximum residue level, STMR and HR.

Combined mefentrifluconazole residues in pecans, almonds and pistachios were (n=13): < 0.01 (9), 0.01 (2), 0.02 and 0.04 mg/kg.

The Meeting estimated a maximum residue level of 0.06 mg/kg, an STMR of 0.01 mg/kg, and an HR of 0.06 mg/kg (based on the highest residue of replicate samples) for the Group of tree nuts.

Oilseeds and oilfruits

Small seed oilseeds

The critical GAP for rapeseeds is from the United States; 2×146 g ai/ha, 14-day RTI (days) and a 21-day PHI. The Meeting received supervised residue trials conducted on rapeseed in Canada and the United States matching the critical GAP.

Mefentrifluconazole residues in rapeseed in ranked order were (n=13): < 0.01, 0.01 (2), 0.04 (2), 0.05, 0.06 (2), 0.12, 0.15, 0.25 (2) and 0.74 mg/kg.

Noting that the United States GAP covers the subgroup of rapeseeds and that rapeseeds are the representative crop of the subgroup small seed oilseeds, the Meeting estimated a maximum residue level of 1 mg/kg and an STMR of 0.06 mg/kg for the Subgroup of small seed oilseeds.

Sunflower seeds

The critical GAP for sunflower seeds is from the United States; 2×146 g ai/ha, 7-day RTI (days) and a 21-day PHI. The Meeting received supervised residue trials conducted on sunflower seeds in Canada and the United States matching the critical GAP. The Meeting also received trials conducted in United States, but none matched the critical GAP.

Mefentrifluconazole residues in sunflower seeds in ranked order were (n=10): < 0.01 (4), 0.01 (2), 0.04, 0.05 and 0.06 (2) mg/kg.

Noting that the United States GAP covers the subgroup of sunflower seeds and that sunflower seeds are the representative crop of the subgroup sunflower seeds, the Meeting estimated a maximum residue level of 0.15 mg/kg and an STMR of 0.01 mg/kg for the Subgroup of sunflower seeds.

Cotton seeds

The critical GAP for cotton seeds is from the United States; 3×146 g ai/ha, 7-day RTI (days) and a 30-day PHI. The Meeting received supervised residue trials conducted on cotton seeds in the United States matching the critical GAP.

Mefentrifluconazole residues in cotton seeds in ranked order were (n=10): < 0.01, 0.01 (2), 0.03 (2), 0.04 (2), 0.05 (3), 0.10 and 0.12 mg/kg.

Noting that the United States GAP covers the subgroup of cotton seeds and that cotton seeds are the representative crop of the subgroup cotton seeds, the Meeting estimated a maximum residue level of 0.2 mg/kg and an STMR of 0.04 mg/kg for the Subgroup of cottonseed.

Peanuts

The critical GAP for peanuts is from the United States; 3×202 g ai/ha, 14-day RTI (days) and a 14-day PHI. The Meeting received supervised residue trials conducted on peanuts from the United States matching the critical GAP.

Mefentrifluconazole residues in peanuts were (n = 11): < 0.01 (11) mg/kg.

The Meeting estimated a maximum residue level of 0.01(*) mg/kg and an STMR value of 0.01 mg/kg for peanuts.

Coffee bean

The critical GAP for coffee bean is from Ecuador; 3×160 g ai/ha, 60-day RTI (days) and a 45-day PHI. The Meeting received supervised residue trials conducted on coffee beans from South America matching the critical GAP.

Mefentrifluconazole residues in coffee beans in ranked order were (n = 19): < 0.01 (11), 0.01 (2), 0.02 (3), 0.07, 0.14 and 0.33 mg/kg.

The Meeting estimated a maximum residue level of 0.4 mg/kg and an STMR of 0.01 mg/kg for coffee beans.

Residues in animal feeds

Legume animal feeds

The critical GAP for legume vegetables, except soya bean, is from the United States; 3×146 g ai/ha, 7-day RTI (days) and a 21-day PHI for bean forage, bean hay, pea vines, and pea hay. The Meeting received trials on pea vines and hay from Canada and the United States matching the critical GAP.

Peas - Vines and hay

Mefentrifluconazole residues in pea vines in ranked order were (n=8): 0.8, 1.3, 2.2, 2.8, 4.3, 7.5, 9.5 and 10.2 mg/kg.

The Meeting estimated a median residue of 3.5 mg/kg and a highest residue of 10.3 mg/kg (based on the highest residue of replicate samples) for pea vines.

Mefentrifluconazole residues in pea hay in ranked order were (n=8): 4.4, 5.7, 6.3, 9.2, 10.3, 10.6, 11 and 12 (highest 13) mg/kg (dry weight).

The Meeting estimated a maximum residue level of 30 mg/kg, a median residue of 9.74 mg/kg and a highest residue of 13 mg/kg (based on the highest residue of replicate samples) for pea hay (dry weight).

Soya bean - Forage and hay

The critical GAP for soya beans is from the United States; 2×146 g ai/ha, 7-day RTI (days) and a 14-day PHI for forage and 21-day PHI for hay.

Mefentrifluconazole residues in soya bean forage from trials matching the critical GAP were: 1.2 and 2.9 mg/kg.

The Meeting noted there were an insufficient number of trials approximating the critical GAP to estimate median and highest residues for soya bean forage.

Mefentrifluconazole residues in soya bean hay from trials matching the critical GAP were in ranked order (n=17): 1.1, 1.7, 2.3, 3.0, 3.2, 4.0, 4.1, 4.3, 4.5, 5.7, 6.0, 6.1, 7.1, 8.2, 8.8, 9.0 and 11 (highest 12) mg/kg (dry weight).

The Meeting estimated a maximum residue level of 20 mg/kg, a median residue of 4.5 mg/kg and a highest residue of 12 (based on the highest residue of replicate samples) for soya bean hay (dry weight).

Non-grass forages

The critical GAP for non-grass forages is from the United States; 3×146 g ai/ha, 7-day RTI (days) and a 14-day PHI. The Meeting received trials on alfalfa forage and hay and clover forage and hay from the United States.

While supervised field trials were conducted according to the critical GAP, the RTI (days)s between the second and third applications were significantly longer (14–48 days), without reliable data to estimate half-lives, the Meeting concluded that the overall impact of these parameters on the residue was >25 percent, and maximum residue levels, median residues and highest residues could not be estimated for alfalfa forage and hay or clover forage and hay.

Straw and hay of cereal grains (including pseudocereals)

Wheat

The critical GAP for wheat forage, hay and straw is from the United States; 2×146 g ai/ha, 14-day RTI (days), and a 21-day PHI.

Mefentrifluconazole residues in wheat forage in ranked order were (n=24): < 0.01, 0.12, 0.28, 0.33, 0.56, 0.57, 0.63, 1.1, 1.2, 1.7, 2.5, 2.7, 2.8, 3.3, 3.6, 3.8, 4.0, 4.2 (2), 5.5, 5.9, 6.8, 7.8 and 9.6 mg/kg (dry weight).

Mefentrifluconazole residues in wheat hay in ranked order were (n=24): < 0.01, 0.12, 0.21, 0.23, 0.32, 0.54, 0.72, 1.0, 1.3, 1.5, 2.1 (2), 2.7, 3.5 (2), 3.6, 4.5, 4.7, 4.9, 5.4, 5.6, 5.7, 5.8 and 5.9 mg/kg (dry weight).

Mefentrifluconazole residues in wheat straw in ranked order were (n = 23): < 0.01, 2.8, 3.1, 3.5, 4.5, 5.3, 6.5, 6.8, 7.1, 8.7, 9.5, 10.3, 10.6, 10.8, 11.9, 12.1, 13.4, 14.3, 17.0, 17.1, 18.1, 18.4 and 25.7 mg/kg (dry weight).

Barley

The critical GAP for barley hay and straw is from the United States; 2×146 g ai/ha, 14-day RTI (days), and a 21-day PHI.

Mefentrifluconazole residues in barley hay in ranked order were (n=9): 0.57, 5.3, 5.5, 6.8, 7.2, 8.0, 8.1, 9.1 and 11.1 mg/kg (dry weight).

Mefentrifluconazole residues in barley straw in ranked order were (n=10): < 0.01, 3.0, 3.8, 7.3, 8.1, 11.3, 13.8, 18.1, 20.9 and 22.7 mg/kg (dry weight).

Rice

The critical GAP for rice is from China; 2×12 g ai/ha, 5-day RTI (days), 21-day PHI. The Meeting received supervised residue trials conducted on rice in China matching the critical GAP.

Mefentrifluconazole residues in rice straw in ranked order were (n = 12): 0.12, 0.14, 1.1, 1.6, 2.2, 2.7, 3.4, 4.0, 4.7, 5.0, 7.3 and 10 mg/kg based on a dry matter content of 90 percent derived from the OECD 2018 feed calculator.

Mefentrifluconazole residues in rice husks in ranked order were (n = 12): 0.08, 2.5, 2.6, 3.0, 3.1, 4.4, 4.5, 5.7, 7.4, 9.3 and 9.4 (2) mg/kg.

Sorghum

The critical GAP for sorghum is from the United States; 2×146 g ai/ha, 14-day RTI (days) and a 21-day PHI. The Meeting received supervised residue trials conducted on sorghum forage and fodder (stover) in the United States matching the critical GAP.

Mefentrifluconazole residues in sorghum forage in ranked order were (n = 9): < 0.01, 0.60, 0.76, 1.3, 1.7, 2.1, 3.4, 4.4, and 4.8 mg/kg (dry weight).

Mefentrifluconazole residues in sorghum stover in ranked order were (n=9): < 0.01, 1.2, 1.3, 3.2, 4.1, 4.4, 4.7, 6.3, and 9.1 mg/kg (dry weight).

Maize

The critical GAP for maize is from the United States; 2×146 g ai/ha, 14-day RTI (days) and a 21-day PHI. The Meeting received supervised residue trials conducted on maize forage and fodder (stover) in the United States matching the critical GAP.

Mefentrifluconazole residues in maize forage in ranked order were (n = 17): < 0.01, 1.0, 1.3 (2), 1.6, 1.8, 2.4, 2.5, 3.1, 3.5, 3.7, 4.0, 4.1, 4.4, 4.7, 5.4, and 7.2 mg/kg (dry weight).

Mefentrifluconazole residues in maize stover in ranked order were (n=17): < 0.01, 3.0, 3.2, 3.7, 5.0, 5.2 (2), 6.3, 8.0, 8.1, 8.2, 8.3, 9.7, 9.9, 10, 11, and 12 mg/kg (dry weight).

Sweet corn

The critical GAP for maize is from the United States; 3×146 g ai/ha, 7-day RTI (days) and a 21-day PHI. The Meeting received supervised residue trials conducted on sweet corn forage and fodder (stover) in Canada and the United States matching the critical GAP.

Mefentrifluconazole residues in sweet corn forage in ranked order were (n = 13): < 0.01, 1.6, 2.8, 3.5, 3.7, 4.1, 4.2, 4.3, 4.6, 5.5, 5.8, 6.4 and 6.6 mg/kg, based on a dry matter content of 48 percent derived from the OECD 2018 feed calculator.

Mefentrifluconazole residues in sweet corn stover in ranked order were (n=13): < 0.01 (2), 0.45, 0.84, 1.2, 1.3, 1.9, 2.4, 2.5, 3.1 (2), 3.3 and 4.2 mg/kg (dry weight).

The Meeting estimated residues in cereal forages as follows:

Wheat forage median residue of 2.75 mg/kg and highest residue of 9.6 mg/kg (dry weight),

Sorghum forage median residue of 1.7 mg/kg and highest residue of 4.8 mg/kg (dry weight),

Maize forage median residue of 3.1 mg/kg and highest residue of 7.2 mg/kg (dry weight), and

Sweet corn forage median residue of 4.2 mg/kg and highest residue of 6.6 mg/kg (dry weight).

Based on the similarity of residues and commodities within the group of straw and hay of cereal grains (including pseudocereals), the Meeting agreed to make a recommendation based on the trials giving the highest estimates. The Meeting estimated a maximum residue level of 50 mg/kg (dry weight; from barley straw), a median residue of 10.3 mg/kg (dry weight; from wheat straw) and a highest residue of 25.7 mg/kg (dry weight; from wheat straw) for straw and hay of cereal grains (including pseudocereals).

Grass forages

The critical GAP for grass forages is from the United States; 3×146 g ai/ha, 7-day RTI (days) and a 0-day PHI. The Meeting received trials on forages of Bermuda grass, blue grass, brome grass and fescue from

the United States. While supervised field trials were conducted according to the critical GAP in terms of application rate and harvest time, the RTI (days)s were longer (14 days). Without reliable data to estimate half-lives, the Meeting concluded that the overall impact of these parameters on the residue was >25 percent, and maximum residue levels, median residues and highest residues could not be estimated for Bermuda grass, blue grass, brome grass and fescue forage and hay.

Miscellaneous fodder and forage crop

Sugar beet tops

The critical GAP for sugar beets is from the United States; 2×146 g ai/ha, 14-day RTI (days), 7-day PHI. The Meeting received supervised residue trials conducted on sugar beet tops in Canada and the United States where the RTI (days) was 7 days and the sugar beet roots were harvested at DALAs of 14–21days. Therefore, a maximum residue level could not be estimated for sugar beet tops.

Almond hulls

The critical GAP for tree nuts is from the United States; 3×123 g ai/ha, 7-day RTI (days) (all tree nuts, except pistachio) and a 14-day PHI. The Meeting received supervised residue trials conducted on almonds in the United States matching the critical GAP.

Mefentrifluconazole residues in almond hulls were in ranked order (5): 1.1 (2), 1.2, and 1.7 (2) mg/kg.

The Meeting estimated a maximum residue level of 4 mg/kg and a median residue of 1.2 mg/kg.

Peanut hay

The critical GAP for peanuts is from the United States; 3×202 g ai/ha, 14-day RTI (days) and a 14-day PHI. The Meeting received supervised residue trials conducted on peanuts from the United States matching the critical GAP.

Mefentrifluconazole residues in peanut hay were (n = 11): 3.1, 3.5, 4.4, 7.0, 7.1, 8.9, 9.3, 10.6, 14.2, 14.3 and 28.8 mg/kg (dry weight).

The Meeting estimated a maximum residue level of 40 mg/kg, a median residue of 8.9 and a highest residue of 30 mg/kg (based on the highest residue of replicate samples) for peanut hay (dry weight).

Fate of residues during processing

Effects on the nature of the residue during processing

The Meeting received information on the hydrolysis of mefentrifluconazole under simulated processing conditions and the effects of processing on residues of mefentrifluconazole in several commodities.

High temperature hydrolysis

In studies on the hydrolytic stability of aqueous solutions of radiolabelled mefentrifluconazole, samples were incubated under three sets of conditions, each designed to simulate an appropriate process: 90 °C (pH 4, 20 minutes) to simulate pasteurisation, 100 °C (pH 5, 60 minutes), to simulate boiling, baking and brewing, and 120 °C (pH 6, 20 minutes in the dark) to simulate sterilisation.

Under conditions representative of industrial and household processing procedures such as pasteurisation (pH 4, 90 °C, 20 min), baking, boiling, brewing (pH 5, 100 °C, 60 min) and sterilisation (pH 6,

120 °C, 20 min), no degradation product exceeding 2 percent of total radioactivity was detected, demonstrating that mefentrifluconazole is hydrolytically stable. In addition, no change in the isomer ratio was observed. Therefore, the nature of the residue is not affected by processing operations.

Residues in processed commodities

The Meeting evaluated processing studies for oranges, apples, plums, peaches, grapes, strawberries, cucumbers, tomatoes, soya beans, sugar beets, potatoes, wheat, barley, rice, corn, cotton, and coffee. For field corn grain, no reliable processing factors can be calculated since the residues in the raw agricultural commodities (RAC) were <LOQ. Maximum residue levels (mrl) in processed commodities are only estimated when they are higher than the maximum residue levels for the RAC. Processing factors and residue estimates are summarized in Table 178. As the maximum residue level, STMR and HR in lemon were higher than orange, residues in lemons were used to calculate the residues in citrus processed commodities.

Table 178 Processing factors and residue estimates for mefentrifluconazole

	Residue in RAC, mg/kg				Processing Factors		Residue in processed commodity, mg/kg

Using the estimated maximum residue level of 1.5 mg/kg for the subgroup of lemons and applying the processing factors of 2.6 for citrus dried peel and 41 for citrus oil, the Meeting estimated maximum residue levels of 4 mg/kg and 70 mg/kg for citrus dried peel and citrus oil, respectively.

Using the estimated maximum residue level of 1.5 mg/kg for pome fruits and applying the processing factor of 9.9 for dried pomace, the Meeting estimated a maximum residue level of 15 mg/kg for apple dried pomace.

Using the estimated maximum residue level of 1.5 mg/kg for the subgroup of plums and applying the processing factor of 4.1 for dried prune, the Meeting estimated a maximum residue level of 7 mg/kg for dried prune plum.

Using the estimated maximum residue level of 2 mg/kg for wine grapes and applying the processing factors of 4.26 for dry pomace, the Meeting estimated a maximum residue level of 9 mg/kg for grape dried pomace.

Using the estimated maximum residue level of 0.7 mg/kg for the subgroup of tomatoes applying the processing factor of 9.2 for sundried tomatoes, the Meeting estimated a maximum residue level of 7 mg/kg for dried tomatoes.

Using the estimated maximum residue level of 0.6 mg/kg for sugar beets and applying the processing factor of 4.75 for dried pulp, the Meeting estimated a maximum residue level of 3 mg/kg for sugar beet dried pulp.

Using the estimated maximum residue level of 0.4 mg/kg for wheat grain and applying the processing factors of 2.94 for wheat unprocessed bran, 1.12 for wheat germ, 3.53 for shorts and 38.5 for aspirated grain fractions, the Meeting estimated maximum residue levels of 1.5 mg/kg for wheat

unprocessed bran, 0.5 mg/kg for wheat germ, 1.5 mg/kg for wheat shorts and 16 mg/kg for wheat aspirated grain fractions.

Using the estimated maximum residue level of 3 mg/kg for barley grain and applying the processing factors of 3.67 for barley flour, 5 for unprocessed barley bran and 2.38 for dry brewer's grain, the Meeting estimated maximum residue levels of 15 mg/kg for each barley flour and barley bran and 8 mg/kg for brewer's grain (dry).

Residues in animal commodities

The following adjustment factors were applied to the mefentrifluconazole residues in the livestock feeding studies, to account for both free and conjugated residues of mefentrifluconazole, which are only present in animal offal, for compliance with the MRL.

Ruminant liver: mefentrifluconazole residues × 1.1

Ruminant kidney: mefentrifluconazole residues × 1.6

Poultry liver: mefentrifluconazole residues × 4.5

Similarly, the following adjustment factors were applied to the residues of mefentrifluconazole and M750F022 in the livestock feeding studies, to account for free and conjugated residues, where applicable, for dietary risk assessment:

Milk: mefentrifluconazole residues + M750F022 residues × 7.45 × 1.15 (MW factor)

Ruminant liver: mefentrifluconazole residues × 1.1 + M750F022 residues × 1.15 (MW factor)

Ruminant kidney: mefentrifluconazole residues × 1.6 + M750F022 residues × 5.6 x 1.15 (MW factor)

Poultry commodities: mefentrifluconazole residues × 4.5 + M750F022 residues × 1.15 (MW factor)

Farm animal feed studies

The Meeting received a feeding study in dairy cattle where mefentrifluconazole was administered orally once daily to five groups of three lactating cattle for 28 days.

Based on mean daily feed consumption, the dosing levels were equivalent to 1.5, 7.5, 50 and 150 ppm (2 groups) in the feed. Milk was collected twice daily (am and pm sampling pooled) throughout the 28 days of dosing. On day 21, milk was also separated into cream and skimmed milk. Muscle, liver, kidney and fat samples were collected at sacrifice 22-24 hours after the final dose, except for one of the 150 ppm dose groups which were sacrificed three, seven and fourteen days after the final dose to monitor the decline of residue levels post dosing. Samples were analysed for the parent compound by LC-MS/MS (LOQ of 0.010 mg/kg).

At the lowest feeding level of 1.5 ppm, residues of mefentrifluconazole were below the LOQ in milk and muscle, however, they were measurable in liver, kidney and fat. The Metabolite M750F022 was not analysed in milk or any of the tissues at this lowest feeding level. A summary of the results are shown in Table 179. For the depuration study, measurable residues of mefentrifluconazole and M750F022 were observed in milk and tissues after three days of withdrawal, however, after seven and fourteen days of withdrawal, low or no residues above the limit of quantification of 0.01 mg/kg were detected, demonstrating a rapid excretion of mefentrifluconazole and M750F022.

Table 179 Residues of mefentrifluconazole in milk and tissues from lactating goats dosed at 7.5, 50 and

150 ppm mefentrifluconazole daily for 28 days (n=3 at each dose level)

	Mefentrifluconazole (free + conjugated) residues [a] (mg/kg)					
	Feeding level: 7.5 ppm		Feeding level: 50 ppm		Feeding level: 150 ppm	
	Mean	Max	Mean	Max	Mean	Max
Muscle	< 0.01	< 0.01	0.07	0.11	0.16	0.22
Liver	0.16	0.19	1.05	1.48	3.21	3.79
Kidney	0.08	0.12	0.47	0.82	2.10	3.06
Fat	0.05	0.08	0.65	0.9	1.71	2.29
Milk (Day 28)	< 0.01	< 0.01	0.05	0.06	0.21	0.25
	Mefentrifluconazole (free + conjugated) + M750F022 (free + conjugated) residues [b] (mg/kg)

Notes:

[a] For MRL determination.

[b] For HR and STMR determination for dietary risk assessment.

The Meeting also received a feeding study in laying hens where mefentrifluconazole was administered orally once daily to 4 groups of 12 hens per group by gelatine capsule for 34 days, at dose levels equivalent to 1.5, 4.5 and 15 ppm (2 groups) in the feed. Eggs were collected twice daily (am and pm sampling pooled) throughout the 34 days of dosing. On day 24, egg samples from the 15 ppm level were separated into egg yolk and egg white. Muscle, liver, skin with fat and abdominal fat samples were collected at sacrifice 6 hours after the final dose, except for the hens of one of the 15 ppm group which were sacrificed two, seven and fourteen days after the final dose to monitor the decline of residue levels post dosing.

Samples were analysed for the parent compound by LC-MS/MS and for the metabolite M750F022 by GC-MS, with LOQs of 0.010 mg/kg.

Quantifiable residues of mefentrifluconazole were observed in eggs and muscle at the highest dose tested only. In fat and skin with fat, parent residues were measurable at the 4.5 ppm and 15 ppm feeding levels and in liver, residues were quantifiable at all feeding levels. Similarly, residues of M750F022 were measurable in eggs at 4.5 ppm and 15 ppm dosing levels, in muscle at the highest dose tested and in liver, fat and skin with fat at all feeding levels (except 0.15 ppm for liver and fat, where no residues were quantifiable). A summary of the results are shown in Table 180. For the depuration study, no measurable residues of mefentrifluconazole were observed in tissues after two days of withdrawal. In liver and skin no residues of M750F022 above the LOQ could bedetermined after seven days of withdrawal. In fat residue concentrations decreased steadily to below the LOQ (0.01 mg/kg) after 14 days of withdrawal. The results are shown in Table 175.

Table 175 Residues of mefentrifluconazole (free and conjugated) in eggs and tissues from laying hens dosed at 1.5 ppm, 4.5 ppm and 15 ppm mefentrifluconazole daily for 28 days (n= 12 hens per dosing level)

Farm animal dietary burden

Dietary burdens were calculated for beef cattle, dairy cattle, broilers and laying poultry based on feed items evaluated by the current JMPR Meeting. The dietary burdens, estimated using the most recent version of the OECD livestock dietary burden calculator, are presented in Annex 6 and summarised in Table 176.

Table 176 Estimated maximum and mean dietary burdens of farm animals

	Animal dietary burden: mefentrifluconazole, ppm of dry matter diet							
	United States-Canada		**EU**		**Australia**		**Japan**	
	max	**mean**	**max**	**mean**	**max**	**mean**	**max**	**Mean**
Beef cattle	4.7	2.3	36	18	60	22	15	6.1
Dairy cattle	23	10	36	17	67 ❶	28 ❷	10	4.0
Broilers	0.81	0.81	0.81	0.58	0.92	0.92	0.34	0.34
Layers	0.66	0.66	12 ❸	5 ❹	0.92	0.92	0.54	0.54

Notes:

❶ Highest maximum dairy cattle dietary burden suitable for MRL for milk and mammalian tissues and HR estimates for tissues.

❷ Highest mean dairy cattle dietary burden suitable for STMR estimates for milk and mammalian tissues.

❸ Highest maximum poultry dietary burden suitable for MRL and HR estimates for poultry tissues and eggs.

❹ Highest mean poultry dietary burden suitable for STMR estimates for poultry tissues and eggs.

Animal commodity maximum residue levels

Cattle

The calculations used to estimate maximum residue levels, STMR and HR values for cattle matrices are shown in Table 177.

Table 177 Estimated residues for maximum residue levels, HRs and STMRs for mefentrifluconazole in cattle commodities

Mefentrifluconazole feeding study	Feed level (ppm) for milk residues	Residues (mg/kg) in milk	Feed level (ppm) for tissue residues	Residues (mg/kg)

Notes:

[a] For MRL determination: Residues of mefentrifluconazole (free and conjugated).

[b] For HR and STMR determination: Total residues of mefentrifluconazole (free and conjugated) and M750F022 (free and conjugated), expressed as parent equivalents.

Based on the calculated residues of mefentrifluconazole (free and conjugated) in milk and cattle tissues, the Meeting estimated maximum residue levels of 0.10 mg/kg in milks, 0.15 mg/kg in meat from mammals other than marine mammals, 1.5 mg/kg in mammalian fats and 2.0 mg/kg in mammalian offal (based on liver).

Based on the highest total residues of mefentrifluconazole (free and conjugated) and M750F022 (free and conjugated) in cattle tissues, the Meeting estimated HR values of 0.14 mg/kg in mammals other than marine mammals, 1.26 mg/kg in mammalian fats and 1.91 mg/kg in mammalian offal (based on liver).

Based on the mean total residues of mefentrifluconazole (free and conjugated) and M750F022 (free and conjugated) in milk and cattle tissues, the Meeting estimated STMR values of 0.07 mg/kg in milks, 0.04 mg/kg in mammals other than marine mammals, 0.39 mg/kg in mammalian fats and 0.61 mg/kg in mammalian edible offal (based on liver).

Poultry

The calculations used to estimate maximum residue levels, STMR and HR values for poultry matrices are shown in Table 178.

Table 178 Estimated residues for maximum residue levels, HRs and STMRs for mefentrifluconazole in poultry commodities

Mefentrifluconazole feeding study	Feed level (ppm) for egg residues	Residues (mg/kg) in egg	Feed level (ppm) for tissue residues	Residues (mg/kg)		
				Muscle	Liver	Fat

Dietary burden	5.00	0.032	5.00	0.012	0.124	0.12

Notes:

[a] For MRL determination: Residues of mefentrifluconazole (free and conjugated)

[b] For HR and STMR determination: Total residues of mefentrifluconazole (free and conjugated) and M750F022 (free and conjugated), expressed as parent equivalents

Based on these calculated residues of mefentrifluconazole (free and conjugated) in eggs and poultry tissues, the Meeting estimated maximum residue levels of 0.04 mg/kg in eggs and 0.03 mg/kg in poultry meat, 0.2 mg/kg in poultry fatsand 0.7 mg/kg in poultry edible offal.

Based on the highest total residues of mefentrifluconazole (free and conjugated) and M750F022 (free and conjugated) in eggs and poultry tissues, the Meeting estimated HR values of 0.094 mg/kg in eggs, 0.053 mg/kg in poultry meat, 0.503 mg/kg in poultry fat and 0.844 mg/kg in poultry offal.

Based on the mean total residues of mefentrifluconazole (free and conjugated) and M750F022 (free and conjugated) in eggs and poultry tissues, the Meeting estimated STMR values of 0.032 mg/kg in eggs and 0.012 mg/kg in poultry meat, 0.124 mg/kg in poultry fat and 0.12 mg/kg in poultry edible offal.

RECOMMENDATIONS

On the basis of the data from supervised trials the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessment.

Definition of the residue for compliance with the MRL and dietary risk assessment for plant commodities: *mefentrifluconazole*

Definition of the residue for compliance with the MRL for animal commodities: *mefentrifluconazole (free and conjugated)*

Definition of the residue for dietary risk assessment for animal commodities: sum of *mefentrifluconazole (free and conjugated) +* 2-[4-(4-chlorophenoxy)-2-(trifluoromethyl)phenyl]propane-1,2-diol *(*M750F022*), free and conjugated, expressed as mefentrifluconazole equivalents.* The molecular weight conversion factor to express M750F022 in mefentrifluconazole equivalents = 1.15.

The residue is fat soluble.

a. On the basis of the information provided to the JMPR it was concluded that the estimated acute dietary exposure to residues of mefentrifluconazole for the consumption of commodities from the subgroups of Leafy greens and Leaves of Brassicaceae may present a public health concern.

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The ADI for mefentrifluconazole is 0–0.04 mg/kg bw. The International Estimated Daily Intakes (IEDIs) for mefentrifluconazole were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the JMPR. The results are shown in Annex 3 of the 2022 JMPR Report.

The IEDIs ranged from 6–40 percent of the maximum ADI.

Acute dietary exposure

The ARfD for mefentrifluconazole is 0.3 mg/kg bw. The International Estimate of Short-Term Intakes (IESTIs) for mefentrifluconazole were calculated for the food commodities and their processed commodities for which HRs/HR-Ps or STMRs/STMR-Ps were estimated by the present Meeting and for which consumption data were available. The results are shown in Annex 4 of the 2022 JMPR Report.

The IESTIs were at or less than 100 percent of the ARfD, except for:

Amaranth leaves, chicory leaves and edible leaved chrysanthemums (140 percent each for Belgian toddlers)

Raw endive (130 percent for Dutch children)

Cooked/boiled endive (240 percent for Dutch toddlers)

Cos lettuce (140 percentfor Dutch children)

Head lettuce (140 percent for Dutch children)

Leaf lettuce (120 percent for Dutch children)

Chinese cabbage (240 percent for Chinese children)

Kale (110 percent for German children)

Mustard greens (200 percent for Chinese children)

The meeting concluded that acute dietary exposure to residues of mefentrifluconazole in commodities where the ARfD is exceeded may present a public health concern.

Threshold of toxicological concern (TTC) consideration for metabolites

The Meeting agreed that the fatty acid conjugates of M750F022 (M750F023, M750F024 and M750F025) identified in poultry matrices could be assessed using the TTC approach (Cramer Class III threshold of 1.5 µg/kg bw per day).

The current Meeting estimated dietary exposures for metabolite M750F023 of 0.056 µg/kg bw/day, for M750F024 of 0.034 µg/kg bw/day and for M750F025 of 0.033 µg/kg bw/day.

The Meeting concluded that the estimated dietary exposure to residues of M750F023, M750F024 and M750F025 from uses considered by the JMPR is below the TTC for Cramer Class III compounds and is unlikely to present a public health concern. Should further uses be considered in the future, these conclusions may need to be re-evaluated.

METALAXYL (138)/METALAXYL-M (212)

First draft prepared by Professor E Dutra Caldas, University of Brasilia, Brazil

BACKGROUND

Metalaxyl and metalaxyl-M are fungicides. Metalaxyl is a racemic mixture of R- and S-enantiomers, where the R-enantiomer is the biologically active form, and metalaxyl-M consists of a minimum of 97 percent of the R-enantiomer.

Metalaxyl was evaluated under the periodic review and metalaxyl-M was evaluated for new uses by the JMPR in 2021. At the same Meeting, both were evaluated for toxicology, when a ADI and a ARfD were established, which apply to both metalaxyl and metalaxyl-M

The current Meeting received GAP information, analytical method, and residue trials on metalaxyl in pineapple from the Government of Thailand. Furthermore, data provided to the 2021 on dried ginseng was re-evaluated.

ANALYTICAL METHOD

A summary report of the analytical method to analyse metalaxyl in pineapple was submitted. Pineapple samples were extracted with acetone and dichloromethane, sodium chloride and sodium sulfate were added, and the extract cleaned-up with silica gel column. Metalaxyl was determined by GC-NPD. Recovery at concentrations of 0.01, 0.1 and 1.0 mg/kg (n=10) ranged from 90 to 91 percent, with a RSD of <15 percent. The LOQ was set at 0.01 mg/kg.

The method used to analyse the field trial samples include extraction with acetone and dichloromethane, with no cleanup step. One trial reported recoveries ranging from 89.9 to 95 percent at 0.02, 0.05 and 0.5 mg/kg with RSD <5 percent. The LOQ was set at 0.02 mg/kg.

USE PATTERNS

Table 1 Registered use of metalaxyl in pineapple in Thailand

WP formulation, ai g/kg	Application					PHI, days
	Method	No	Rate, kg ai/ha	Spray concentration, kg ai/hL	Interval, days	
250	Foliar	2	0.25	0.05	60	14

RESIDUES RESULTING FROM SUPERVISED TRIALS

A summary report of the residue trials conducted in pineapple was provided, with information of analytical method used. The results are shown in Table 2

Table 2 Residues of metalaxyl in pineapple treated with metalaxyl in supervised trials conducted in Thailand in 2010 using 2 foliar applications of a WP formulation (60 days interval).

APPRAISAL

Metalaxyl is a racemic mixture of R- and S-enantiomers, where the R-enantiomer is the biologically active form, and metalaxyl-M consists of a minimum of 97 percent of the R-enantiomer.

The 2021 JMPR evaluated metalaxyl under the periodic review and metalaxyl-M for new uses. A single ADI and ARfD were also established by the same Meeting.

The residue definitions for metalaxyl and metalaxyl-M for plant commodities are:

Compliance with MRL: metalaxyl (sum of enantiomers)

Dietary risk assessment: metalaxyl (sum of enantiomers) and N-(2-hydroxymethyl-6-methylphenyl)-N-(methoxyacetyl)alanine methyl ester (M8; free and conjugated; sum of enantiomers), expressed as metalaxyl.

The present Meeting received analytical method, GAP information and residue trials for pineapple from the Government of Thailand. Additionally, data evaluated by the 2021 JMPR for dried ginseng was re-assessed.

Method of analysis

A summary report, provided to the Meeting, describe a GC-NPD method to analyse metalaxyl in pineapple. The method included extraction with acetone and dichloromethane, clean-up with silica gel column and was validated at a LOQ of 0.01 mg/kg. The method used in the analysis of field trial samples, however, does not include a clean-up step and has a reported LOQ of 0.02 mg/kg, with very limited validation data.

Results of supervised residue trials on crops

The estimated values for metalaxyl are intended to cover uses of metalaxyl-M. For dietary risk assessment, a factor of 1.3 is applied to STMR and HR values found in the fruits to account for the presence of metabolite M8 (free and conjugated). No factor is needed for bulb, root, and tuber crops or for crops when no residues are expected to be found.

Pineapple

Five residues trials were conducted with metalaxyl in Thailand in 2010 according to GAP (2×0.25 kg ai/ha, 60 days interval, and 14 days PHI). Residues were < 0.02 (2), 0.02, 0.03 and 0.06 mg/kg.

The Meeting estimates a maximum residue level of 0.1 mg/kg, a STMR of 0.026 mg/kg and a HR of 0.78 mg/kg for metalaxyl in pineapple.

Ginseng

The 2021 JMPR evaluated trials conducted with metalaxyl-M in South Korea (GAP of 0.08 kg ai/ha, 10-day interval, 14-day PHI) and recommended a MRL of 0.03(*) mg/kg for metalaxyl in ginseng.

Fresh ginseng samples were washed, dried in hot air to reach the water content under 14 percent and analysed. Residues were < 0.06 mg/kg (n= 9).

Based on the data evaluated by the 2021 JMPR, the Meeting estimates a maximum residue level of 0.06(*) mg/kg, and a STMR and HR of 0.06 mg/kg for metalaxyl in ginseng, dried including red ginseng.

RECOMENDATIONS

On the basis of the data from supervised trials, the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessment.

Definition of the residue for metalaxyl and metalaxyl-M for compliance with the MRL for plant commodities: *metalaxyl (sum of enantiomers).*

Definition of the residue for metalaxyl and metalaxyl-M for dietary risk assessment in plant commodities: *metalaxyl (sum of enantiomers) and N-(2-hydroxymethyl-6-methylphenyl)-N-(methoxyacetyl)alanine methyl ester (M8; free and conjugated; sum of enantiomers), expressed as metalaxyl.*

Definition of the residue for for metalaxyl and metalaxyl-M for compliance with the MRL in animal commodities: *the sum of metalaxyl (sum of enantiomers) and metabolites (free + conjugated) M3 (N-(2,6-*

dimethylphenyl)-N-(hydroxyacetyl)alanine methyl ester) and M8 (N-(2-hydroxymethyl-6-methylphenyl)-N-(methoxyacetyl)alanine methyl ester (sum of enantiomers), expressed as metalaxyl.

Definition of the residue for metalaxyl and metalaxyl-M for dietary risk assessment in animal commodities: *the sum of metalaxyl (sum of enantiomers) and metabolites (free + conjugated) M1 (N-(2,6-dimethylphenyl)-N-(methoxyacetyl) alanine), M3 (N-(2,6-dimethylphenyl)-N-(hydroxyacetyl)alanine methylester), M6 (N-(2,6-dimethylphenyl)-N-(hydroxyacetyl)alanine), M7 (N-(2,6-dimethyl- 5-hydroxyphenyl)-N-(methoxyacetyl)alanine methyl ester) and M8 (N-(2-hydroxymethyl-6-methylphenyl)-N-(methoxyacetyl)alanine methyl ester (sum of enantiomers), expressed as metalaxyl*.

The residue is not fat-soluble.

CCN	Commodity	Maximum residue levels, mg/kg		STMR or STMR-P, mg/kg	HR or HR-P, mg/kg
		New (basis)[a/]	Previous		
FI 0353	Pineapple	0.1 (M)		0.026	0.078
DV 0604	Ginseng, dried including red ginseng	0.06* (MM)		0.06	0.06

[a/] residue data that was the basis for the estimation: metalaxyl (M), metalaxyl-M (MM)

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The ADI for metalaxyl and metalaxyl-M (alone or in combination) is 0–0.08 mg/kg bw. The International Estimated Daily Intakes (IEDIs) estimated for the 17 GEMS/Food Consumption Cluster Diets estimated by the 2021 JMPR was not impacted by the recommendation made for pineapple by the current Meeting. No consumption data is available for ginseng, dried.

The Meeting concluded that long-term dietary exposure to residues of metalaxyl residues from the uses considered the JMPR is unlikely to present a public health concern.

Acute dietary exposure

The ARfD for metalaxyl is 0.5 mg/kg bw. The International Estimate of Short Term Intakes (IESTIs) for metalaxyl were calculated for pineapple and ginseng, dried. The results are shown in Annex 4 of the 2022 JMPR Report.

The IESTIs varied from 0–1 percent of the ARfD for children and 0–1 percent for the general population. The Meeting concluded that acute dietary exposure to residues of metalaxyl from uses considered by the current Meeting is unlikely to present a public health concern.

METHIDATHION (051)

First draft prepared by Dr H Kobayashi, Ministry of Agriculture, Forestry and Fisheries, Japan

EXPLANATION

Methidathion is an organic thiophosphate insecticide. It has a role as an acetylcholinesterase inhibitor. It is registered in some countries. Methidathion was evaluated by JMPR in 1992 in the periodic review programme and re-examined several MRLs in 1994.

At the Fifty-first Session of CCPR (2019), methidathion was scheduled for consideration by the 2020 JMPR in the periodic review programme. The Meeting received the data for methidathion on plant and animal metabolism, method of analysis, use pattern, and residues resulting from supervised trials in apple, cherry, grape, mandarin, mango and peach. It is noted that the current Meeting did not receive some information that had been provided to 1992 JMPR on plant and animal metabolism, environmental fate and processing study.

IDENTITY

ISO common name	Methidathion
IUPAC name	S-2,3-dihydro-5-methoxy-2-oxo-1,3,4-thiadiazol-3-ylmethyl O,O-dimethyl phosphorodithioate
Chemical Abstract name	S-[(5-methoxy-2-oxo-1,3,4-thiadiazol-3(2*H*)-yl)methyl] O,O-dimethyl phosphorodithioate
CAS No.	950-37-8
CIPAC No.	193
Synonyms	DMTP, GS-13005
Molecular formula	Structural formula	$C_6H_{11}N_2O_4PS_3$
Molecular weight	302.33 g/mol

Specifications

Specifications for Methidathion have not been established by JMPS.

METABOLISM AND ENVIRONMENTAL FATE

The studies for plant metabolism (oranges, tomatoes, common beans and alfalfa) and animal metabolism (lactating cows and goats) were conducted with the test materials with the label position indicated in Figure 1.

	2-carbonyl-^{14}C-methidathion	^{14}C-desmethyl methidathion
	^{14}C-RH-sulfone	^{14}C-oxygen analogue

Plant metabolism

The Meeting received information on plant metabolism of methidathion using some compounds in Figure 1 in oranges, tomatoes, beans and alfalfas. In the following texts, total radioactive residues (TRR) or applied radio activity (AR) is expressed in mg-methidathion equivalents/kg.

Oranges (Burnett 1992, ML-91-704)

The metabolism of methidathion under field condition in a commercial orchard was studied on a navel orange tree (Beck, 4 years old, 1.8 m high). The soil was a sandy loam (73.3 percent sand, 20.0 percent silt, 6.7 percent clay, 0.4 percent organic matter, pH 6.5, CEC 6.7 meq/100 g, bulk density 1.48 kg/L, 17.3 percent moisture hold capacity at 33 kPa). The EC-formulated 2-carbonyl-^{14}C-methidathion (0.06 kg ai/hL, 500 mL) was twice applied to an orange tree at 11 days after bloom and 43 days after the first application at rates of 0.067 kg ai/ha. A control tree was in the same orchard and 235 m away from the treated tree.

Oranges were sampled at maturity 159 days after last application (DALA). Leaves were sampled after the first application, 28 days after the first application and at maturity of fruits (159 DALA). All fruits and leaves harvested were stored at -17 °C.

Oranges were washed with deionized water, scrubbed gently with a soft-bristled brush using a surfactant commonly used during commercial orange processing (Brogdex #567-10, 1.25 mL/L), and then rinsed with deionized water. The washes and rinse were combined. The fruits were peeled. The peeled fruit was processed in a blender, centrifuged and the juice decanted. The pulp was washed once with deionized water and centrifuged again. The pulp rinse and juice were weighed and volumes determined. The pulp was air-dried. The peel was processed by a food processor with dry ice added.

Subsamples of each solid matrix were homogenized to determine the TRR. Other samples were extracted with methanol-water (9:1, v/v) and then partitioned with chloroform. The radioactivity of each fraction was analysed by liquid scintillation counting (LSC). The organic fraction was analysed by TLC and the aqueous fraction by anion ion-exchange column chromatography and TLC.

The total radioactive residues in leaves were 39 mg eq/kg after the first treatment, 36 mg eq/kg at 28 days after the first treatment and 45 mg eq/kg at 159 DALA. The TRR in mature orange fruit harvested 159 DALA was 0.56 mg eq/kg, with 66 percent TRR (1.0 mg eq/kg) in orange peel, 11 percent TRR (0.40 mg eq/kg) in orange pulp and 22 percent TRR (0.25 mg eq/kg) in orange juice. In the wash, 0.5 percent TRR (< 0.01 mg eq/kg) was detected.

Table 4 Distribution of radioactivity in orange tissues (Application rate: 0.067 kg ai/ha)

Sample	% TRR	mg eq/kg
Leaves		
After 1st treatment	na	39
28 days after the first treatment	na	36
159 DALA	na	45
Orange	100	0.56
Peel	66	1.0
Pulp	11	0.40
Juice	22	0.25
Wash	0.5	<0.01

Note:

na= Not analysed.

The extractability of radioactivity in the leaves and fruits is summarized in Table 5 and Table 6, respectively. In orange peel, 65 percent TRR (0.67 mg eq/kg) was extracted with methanol-water (9:1, v/v) and 27 percent TRR (0.28 mg eq/kg) was unextracted. When this extract was partitioned into water-chloroform, 29 percent TRR (0.31 mg eq/kg) was water soluble and 24 percent TRR (0.25 mg eq/kg) was partitioned into chloroform, and 6.4 percent TRR (0.067 mg eq/kg) was unknown volatile components in the rotary evaporation distillate. For pulp, majority was unextracted residue (57 percent TRR,

0.23 mg eq/kg) and only 17 percent TRR was extracted (0.068 mg eq/kg), in which 12 and 2.5 percent TRR (0.048 and 0.010 mg eq/kg) were partitioned in aqueous and chloroform phase, respectively. Almost all residues in juice (94 percent TRR, 0.24 mg eq/kg) was partitioned into the aqueous phase.

Unextracted residues in the orange peel were further treated by sequential acid and base hydrolysis as shown in Table 7. Low percentages were hydrolysed with either acid or base (0.11–3.5 percent TRR, 0.001–0.036 mg eq/kg).

Table 7 Radioactive residues in unextracted fraction from orange peel

Residues in plant extracts were further analysed by TLC and anion ion-exchange chromatography. In all samples, organic soluble fractions consisted of methidathion. From aqueous soluble fractions, three clusters of compounds, designated cluster A, B and C, were separated. Cluster A contained RH-alanine conjugate, cluster B contained RH-acetic acid conjugate, RH-lactic acid conjugate,

RH-hydroxy acetic acid conjugated and cluster C contained desmethyl-methidathion (Table 8). In this study, oxygen analogue of methidathion was not detected.

The Meeting also received a supplementary study (Simoneaux, 1993, ABR-93021).

Mature orange leaves (159 DALA) from study ML-91-704 were extracted with methanol-water (9:1, v/v), concentrated by rotary evaporation to remove methanol, and then partitioned with chloroform. The aqueous fraction was separated into three clusters (cluster A, B and C) by anion exchange column chromatography. These fractions were further cleaned up with chromatography using non-polar adsorbent resin column and analysed by TLC. The radioactivity was analysed by LSC.

Clusters A, B and C of mature leaves prepared by this study, and of orange peel and orange juice prepared by study ML-01-704 were derivatized for identification. Cluster A was incubated with beta-glucosidase, cellulase or N-glycosidase at 37 °C. Clusters A, B and C were butylated by adding 3 mol/L HCl in n-butanol and heating at 115 °C for 15–30 minutes. These were evaporated to remove solvent, dissolved in ethyl acetate and partitioned with water. The organic fraction was separated by preparative TLC for purification.

The butyl esters were further esterized. Purified butyl esters of cluster B and C were dried up under N_2, dissolved in acetic anhydride and heated at 155 °C for 5 minutes for acetylation. Purified butyl esters of cluster A were dissolved in trifluoroacetic anhydride and heated at 155 °C for 5 minutes. Each reaction mixture was dissolved in water, adjusted pH to 7 and partitioned with ethyl acetate. The ethyl acetate fractions were dried over sodium sulphate, filtered and analysed by TLC, HPLC-MS/MS. The distribution of TRR in each cluster was shown in Table 9 (Radioactive residue of aqueous solution = 100 percent).

Table 9 Characterisation of radioactive residues in anion exchange clusters from analysis of aqueous soluble residues of selected mature orange plant parts

	Leaves 159 DALA		Orange peel		Orange juice	
Cluster	[% TRR of aqueous soluble]	[mg eq/kg]	[% TRR of aqueous soluble]	[mg eq/kg]	[% TRR of aqueous soluble]	[mg eq/kg]
A	3.8	1.4	41	0.42	42	0.11
B	19	6.6	18	0.19	26	0.06
C	37	13	11	0.12	20	0.05
Total	59		70		88	

Clusters A, B and C accounted for almost all of the aqueous soluble fractions in orange leaves, peel and juice. For cluster A from juice, attempt to further clean-up with non-polar adsorbent resin column was unsuccessful because of the presence of large amount of sugar. Derivatisation of the sugar co-extractants and/or the proposed alanine conjugate in juice was impossible as no purified sample for TLC was obtained. Therefore, for further identification and characterization, clusters A, B and C isolated from leaves (159 DALA) were used. In clusters A, B and C, TRRs were 2.4, 10 and 23 percent, respectively (Table 10).

Table 10 TRR Characterisation in orange leaves (159 DALA)

	Leaves 159 DALA (% TRR)		
	Organic soluble	Aqueous soluble	Bound residues
	26	38	23
Cluster A	-	1.4	-
Cluster B	-	7.2	-
Cluster C	-	14	-

When clusters A, B and C were subject to non-polar adsorbent resin column clean-up followed by being re-chromatographed on anion ion-exchange column, most of the radioactive residue were retained on the resin and subsequently released by methanol (Table 11).

Table 11 Characterisation of radioactive residues in the water and methanol fraction of non-polar adsorbent resin column of aqueous extracts from orange leaves (159 DALA)

	[%] of total radioactivity in Clusters	
Cluster	aqueous fraction	Methanol fraction
A	27	73
B	6.5	92
C	33	74

In the Cluster A aqueous fraction, there was no evidence of release of the radioactive ring of methidathion that may be associated as an aglycone of a sugar conjugate. An attempt at derivatizing the water fraction from the non-polar adsorbent resin column with the butylating agent went only to approx. 23 percent completion. Butylated cluster A was partitioned with ethyl acetate and then analysed by TLC. Spot was at the origin for water fraction, while an Rf was given for ethyl acetate fraction.

The Cluster A methanol fraction showed a spot with an R_f value consistent with where the alanine conjugate would be expected. The ethyl acetate fraction after esterification shows a much higher R_f spot consistent with a derivatised alanine conjugate. The ethyl acetate fraction further separated with HPLC resulted in 2 compounds (namely A1 and A2). For A1, a structure could not be determined from the

spectra obtained because of the high background. For A2, the observed molecular ion was *m/z* 275 and the daughter spectra showed fragments at *m/z* 259, 220, 202, 185 and 174, consistent with the butyl ester of RH-alanine conjugate.

Cluster B was retained quantitatively on the resin and therefore only the methanol was available for chromatography. The chromatogram of Cluster B showed two main spots and one minor spot. The methanol fraction was butylated and separated by preparatory TLC. Two bands B1 and B2 were isolated, acetylated and cleaned up by preparative TLC.

Band B1 was purified by HPLC and split in two peaks B1A and B1B. These two fractions were collected and analysed by mass spectral analysis. Peak B1A showed only one component with a mass of *m/z* 318 and daughter fragments of *m/z* 277, 259, 245, 217, 203, 185, 175 and 143. These were consistent with lactic acid conjugate of methidathion with the attached butyl and acetyl groups from the derivatisation. Peak B1B showed two components from butylated products. The first component had a mass of *m/z* 276 with daughter fragments of *m/z* 221, 203, 175 and 133, consistent with the butyl ester of the lactic acid conjugate of RH. The second component had a mass of *m/z* 262 with daughter fragments of *m/z* 245, 207, 189, 161, 147 and 133, consistent with the butyl ester of the hydroxyl acetic acid conjugate of RH.

Band B2 was purified by preparative TLC and gave two components which were analysed by mass spectral analysis. The component B2A had a mass of *m/z* 318 with daughter fragments of *m/z* 277, 259, 245, 221, 203, 175, 157 and 146, consistent with the structure for B1A. The second component B2B had a mass of *m/z* 304 with daughter fragments of *m/z* 263, 231, 245, 203 and 161, consistent with the structure of the hydroxyl acetic acid conjugate of RH that is both butylated and acetylated.

For Cluster C, the methanol fraction after the resin chromatography was butylated and separated by preparatory TLC. The butylated product was acetylated and purified by TLC and HPLC resulting in two peaks C1 and C2. The larger peak C1 was purified using another HPLC method and separated in two peaks C1A and C1B, which were analysed by mass spectral analysis. No further work was done on C2.

Peak C1A showed one component that had a mass of *m/z* 318 with daughter fragments of *m/z* 277, 259, 245, 217, 203, 185, 175 and 101, consistent with the double derivative of the lactic acid conjugate of RH, which is the same compound as in peak B1A. Peak C1B gave two components by mass spectral analysis. The first component had a mass of *m/z* 276 with daughter fragments of *m/z* 221, 203, 175, 147 and 133, consistent with the butyl ester of the lactic acid conjugate of RH. The second component had a mass of *m/z* 262 with daughter fragments of *m/z* 245, 207, 189, 161, 147 and 133, consistent with the butyl ester of the hydroxyl acetic acid conjugate of RH.

TLC analysis showed the Cluster B and C methanol fractions contain the same components and Cluster C water and methanol fractions contained the same components with obvious spots off the diagonal consistent with the aforementioned degradation. These data indicate that when Cluster B and C components are identified in a more definitive manner that the same metabolites will be present in each cluster as a result of Cluster C degrading to Cluster B component during the isolation process.

Samples of methanol/water non-extractables from orange peel and pulp were incubated successively with pectinase, cellulase and protease enzymes prior to acid hydrolysis with 0.1N HCl and 1.0N HCl. Anion exchange chromatography of the combined pectinase and cellulase hydrolysate from orange peel and combined pectinase, cellulase and protease hydrolysates from orange pulp contained prominent A and B clusters released by the enzymes. Pectinase released primarily Cluster B components, whereas cellulase released primarily Cluster A components. No Cluster C components were released by enzyme treatment because of degradation of Cluster C to B components. As there were the small

amounts of radioactivity available in relation to the large amounts of co-extractants present, further analysis was impossible (Table 12, Table 13).

Table 12 Characterisation of radioactive residues in hydrolysates from extracted orange peel

Total pulp recovery	100	132	76	0.30

In conclusion, the organic soluble residues of orange plant parts were mostly methidathion. Parent compound was not detected in orange juice. Predominant metabolites were: RH-alanine conjugate; RH-lactic acid conjugate and RH-hydroxy acetic acid conjugate; and RH-keto acid conjugate and RH-glyoxylic acid conjugate, respectively. Enzyme treatment of unextracted residues released the same components.

The proposed metabolic pathway of methidathion was shown in Figure 2.

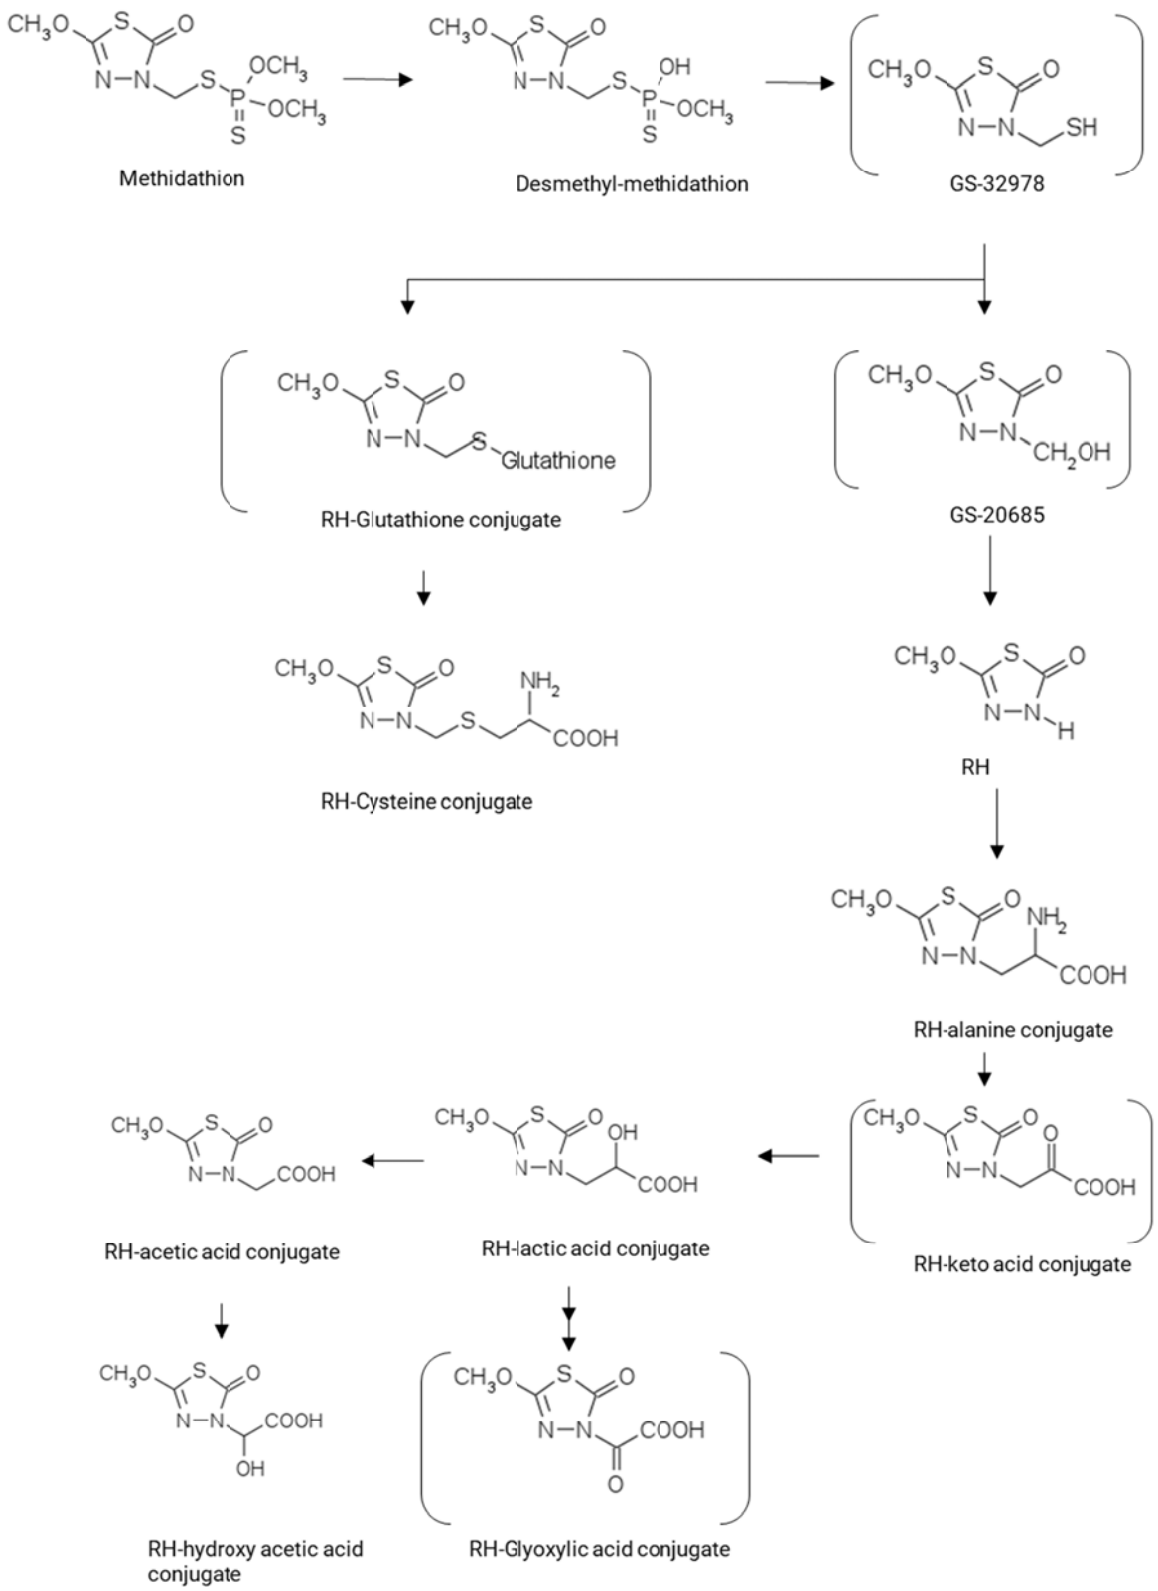

Figure 2 Proposed metabolic pathway of methidathion in orange

Tomatoes (Chopade et al, 1981)

The metabolism of methidathion was studied on tomato fruits (Manapal). To the surface of detached semi-ripe tomato fruits (100–150 g), 2-carbonyl-^{14}C-methidathion (1, 7 and 14 mg/kg) and the following labelled metabolites (7 mg/kg) were applied: ^{14}C-desmethyl methidathion, ^{14}C-RH sulfide, ^{14}C-RH sulfoxide, and ^{14}C-RH sulfone (Figure 1). Treated and control tomatoes were stored at room temperature (22–24 °C) and sampled at 0, 3, 7 and 14 days after treatment (DAT) with 2-carbonyl-^{14}C-methidathion and at 0 and 7 days after the application of labelled metabolites.

Sampled fruits were homogenized, extracted twice with acetone-water (9:1, v/v) and centrifuged. The supernatants were combined, and acetone was removed under vacuum. The extracts were partitioned with chloroform. The chloroform extract was concentrated under N_2 and the aqueous phase extracts were lyophilized. Both were stored at -15 °C until further analysis by TLC.

The chloroform extract was analysed with TLC. The lyophilized aqueous phase was dissolved in water and separated by chromatography using non-polar adsorbent resin column. The fractions that eluted with the potassium bromide gradient that represented an individual peak were pooled and lyophilized. The radioactive compounds were extracted from the residue into methanol and concentrated under N_2. The concentrated methanol extracts were analysed by TLC.

Treatment with 2-carbonyl-^{14}C-methidathion

In the analysis of tomatoes treated with 2-carbonyl-^{14}C-methidathion at 14 DAT, most of radioactivity was recovered (91–97 percent AR), with 82–92 percent TRR in aqueous phase and 3.8–14 percent TRR in chloroform phase.

TLC analyses of the chloroform extracts revealed four compounds: methidathion (2.5–9.8 percent TRR, 0.02–1.1 mg eq/kg) the oxygen analogue of methidathion 0.51–3.2 percent TRR (0.004–0.37 mg eq/kg), RH-sulfoxide and GS-20685 comprised ≤1.3 percent TRR (≤0.08 mg eq/kg).

There were 4 peaks separated by the chromatography from water soluble extract. The largest peaks corresponded to RH-cysteine conjugate (33–47 percent TRR, 0.37–3.8 mg eq/kg), followed by desmethyl-methidathion (24–41 percent TRR, 0.19–4.8 mg eq/kg). The other two (1.8–6.3 percent TRR, 0.37–3.8 mg eq/kg; and 5.4–6.6 percent TRR, 0.19–4.8 mg eq/kg) were not further identified. The summary is shown in Table 14.

According to the time-course experiment using 2-carbonyl-^{14}C-methidathion, the data indicated extensive degradation of methidathion over a 14-day period. At day 14, more than 80 percent TRR was found in the aqueous phase. Non-extracted residues were in the order of 3-4 percent TRR over the entire time course studied, indicating little if any breakdown to [^{14}C]-carbon dioxide and incorporation into the carbon pool. Some loss of radioactivity from the treated tomato fruit occurred during the storage in the chamber, which increased with time and decreased with increasing dose level, varying between 3-9 percent of the initial applied dose of 2-carbonyl-^{14}C-methidathion over a 14-day period. The amount of desmethyl methidathion relative to the RH-cysteine conjugate increased with the increased dose.

Treatment with ^{14}C-desmethyl methidathion

After treatment of tomatoes with ^{14}C-desmethyl methidathion, most of the radioactivity (93–99 percent AR) was recovered, with the distribution of 90–96 percent TRR in aqueous phase and ≤1.6 percent TRR in chloroform phase. The amount of non-extractables increased from 4.2 percent to 8.4 percent TRR (0.29 and 0.52 mg eq/kg, respectively) from 0 to 7 DAT, which indicated some breakdown of the compounds and incorporation in the carbon pool.

In the chloroform extract of samples 7 DAT, two compounds, RH-sulfide (1.1 percent TRR, 0.07 mg eq/kg) and unchanged desmethyl methidathion (0.32 percent AR, 0.02 mg eq/kg), were identified.

In the aqueous phase of samples 7 DAT, the largest amount of unchanged desmethyl methidathion was found (52 percent TRR, 3.2 mg eq/kg), followed by RH-cysteine conjugate (21 percent TRR, 1.3 mg eq/kg) and two unknown compounds (5.3–7.1 percent TRR, 0.33–0.44 mg eq/kg). A similar pattern was observed for 0 DAT (Table 15).

Treatment with ^{14}C-RH-sulfide

Radioactivity in samples 7 DAT with ^{14}C-RH-sulfide was recovered at 96 percent AR and observed in chloroform phase (82 percent TRR, 4.6 mg eq/kg), aqueous phase (18 percent TRR, 0.99 mg eq/kg) and non-extractable (0.36 percent TRR, 0.02 mg eq/kg). In the chloroform extract, two compounds were identified: RH-sulfoxide (60 percent TRR, 3.4 mg eq/kg) and unchanged sulfide (20 percent TRR, 1.1 mg eq/kg). In the aqueous phase, three peaks were separated with the largest being RH-cysteine conjugate (14 percent TRR, 0.78 mg eq/kg) and other two (1.1–1.4 percent TRR, 0.06–0.08 mg eq/kg) being unknown (Table 16).

Treatment with ^{14}C-RH-sulfoxide

The recovery of radioactivity of samples 7 DAT with ^{14}C-RH-sulfoxide was 95 percent of applied radioactivity (AR), with the distribution of 86 percent TRR in chloroform phase (5.8 mg eq/kg), 10 percent TRR in aqueous phase (0.68 mg eq/kg) and 3.9 percent TRR in unextracted (0.26 mg eq/kg). The predominant compound in chloroform phase was unchanged RH-sulfoxide (70 percent TRR, 4.7 mg eq/kg), followed by RH-sulfone (16 percent TRR, 1.1 mg eq/kg). In aqueous phase, RH-cysteine conjugate (7.7 TRR, 0.52 mg eq/kg) and three unknown compounds (0.74 percent AR, 0.05 mg eq/kg) were separated (Table 17).

The proposed metabolic pathway in tomato was shown in Figure 3.

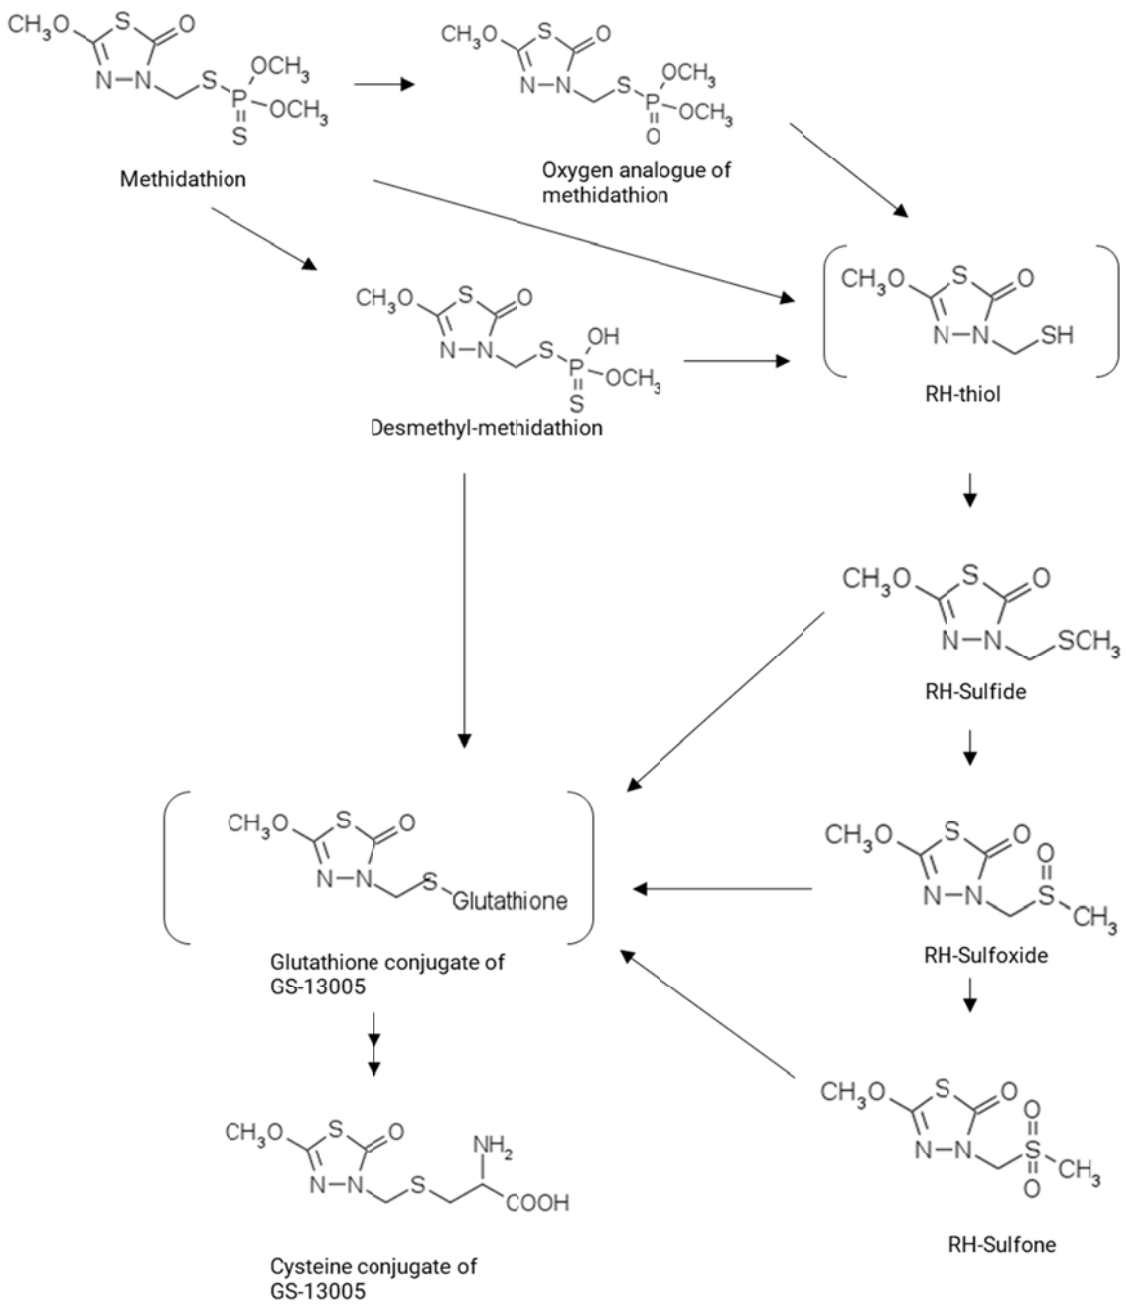

Figure 3 Proposed metabolic pathway of methidathion in tomato

Common beans and alfalfa (Dupuis et al, 1971)

Common bean plants (*Phaseolus vulgaris*) were cultivated in pots and then transferred into the metabolism chamber with conditions of temperature 22 °C, relative humidity 60 percent and 14 hour/day illumination when the second trifoliate leaf appeared. Radioactive materials, 2-carbonyl-^{14}C-methidathion, 3-methylene-^{14}C-methidathion, O-methyl-^{14}C-methidathion, ^{14}C-oxygen analogue, and 2-carbonyl-^{14}C-RH (Figure 1), were dissolved in 100 µL of acetone and topically applied to leaves (1 primary leaf or 8 young leaves, application rates shown in Table 20**)**. No phytotoxic symptom was observed after treatment. Normal air was drawn through the system at a rate of 2 L/min and CO_2 was absorbed in two wash bottles with NaOHaq (2 mol/L).

Alfalfa plants (*Medicago salvia*) were grown in the field and acclimated for 3 weeks in the experimental room. One plant was transferred into the above-mentioned metabolism chamber. Others were cultivated in the experimental room. The height of the plants at the time of treatment was 30-40 cm. A radioactive material, 2-carbonyl-^{14}C-methidathion, was dissolved in 100 µL of acetone and topically applied to leaves (40 leaves, application rates shown in Table 21). No phytotoxic symptom was observed after treatment.

Generally, the radioactivity detected in the untreated parts of the plant was small, and in most experiments present in the form of polar metabolites. Only in the case of stem of alfalfa and bean plants, trace amounts of methidathion were found after 1 and 2 weeks representing approximately 0.2-0.5 percent AR.

The rate of release of $^{14}CO_2$ after topical application of methidathion labelled with ^{14}C at 3 different positions was measured. With regard to common beans, the release was faster for 2-carbonyl-^{14}C-methidathion (22 percent AR was excreted as $^{14}CO_2$ at 8 DAT), followed by 3-methylene-^{14}C-methidathion (20 percent AR excreted at 8 DAT), and O-methyl-^{14}C-methidathion (5 percent AR excreted at 8 DAT). The rate of release of $^{14}CO_2$ in alfalfa was slower (7 percent AR of 2-carbonyl-^{14}C-methidathion excreted at 8 DAT) than that in beans.

Plants were homogenized and extracted with acetone:water (8:2, v/v). After evaporation of the acetone, the aqueous extract was partitioned with chloroform. The chloroform phase was further separated by TLC and methidathion, oxygen analogue and RH were identified by co-chromatography with reference materials.

Both in common bean and alfalfa, high radioactivity was observed in water phase. At least 4 metabolic fractions were found in the aqueous phase, but no satisfactory separation was achieved by TLC with neutral solvent systems. The use of systems containing formic acid or ammonium hydroxide allowed the separation of distinct zones which, however, were partially the result of decomposition of the original constituents. The pattern of products on the TLC was almost the same among the 3 types of labelled methidathion (Table 19). RH was originated not only compounds in Zone 1 (Table 19) but also those in Zone 2, indicating the presence of several metabolites resulting in the same compound after hydrolysis.

The final product of this degradation was a stable compound which also liberated from 1/3 of the water-soluble radioactivity by acid hydrolysis (7 mol/L HCl, 23 °C, 24 h) of the total aqueous phase and was identified as RH. In chloroform phase, parent methidathion was predominant (Tables 20 and 21).

In this study, dosage was described based on the number of leaves or plant, not based on the weight, and it was impossible to calculate the concentration of residues.

Notes:

[a] Plants cultivated in metabolism chamber.

[b] Plants cultivated under open-air conditions.

The proposed metabolic pathway in beans and alfalfa is shown in Figure 4.

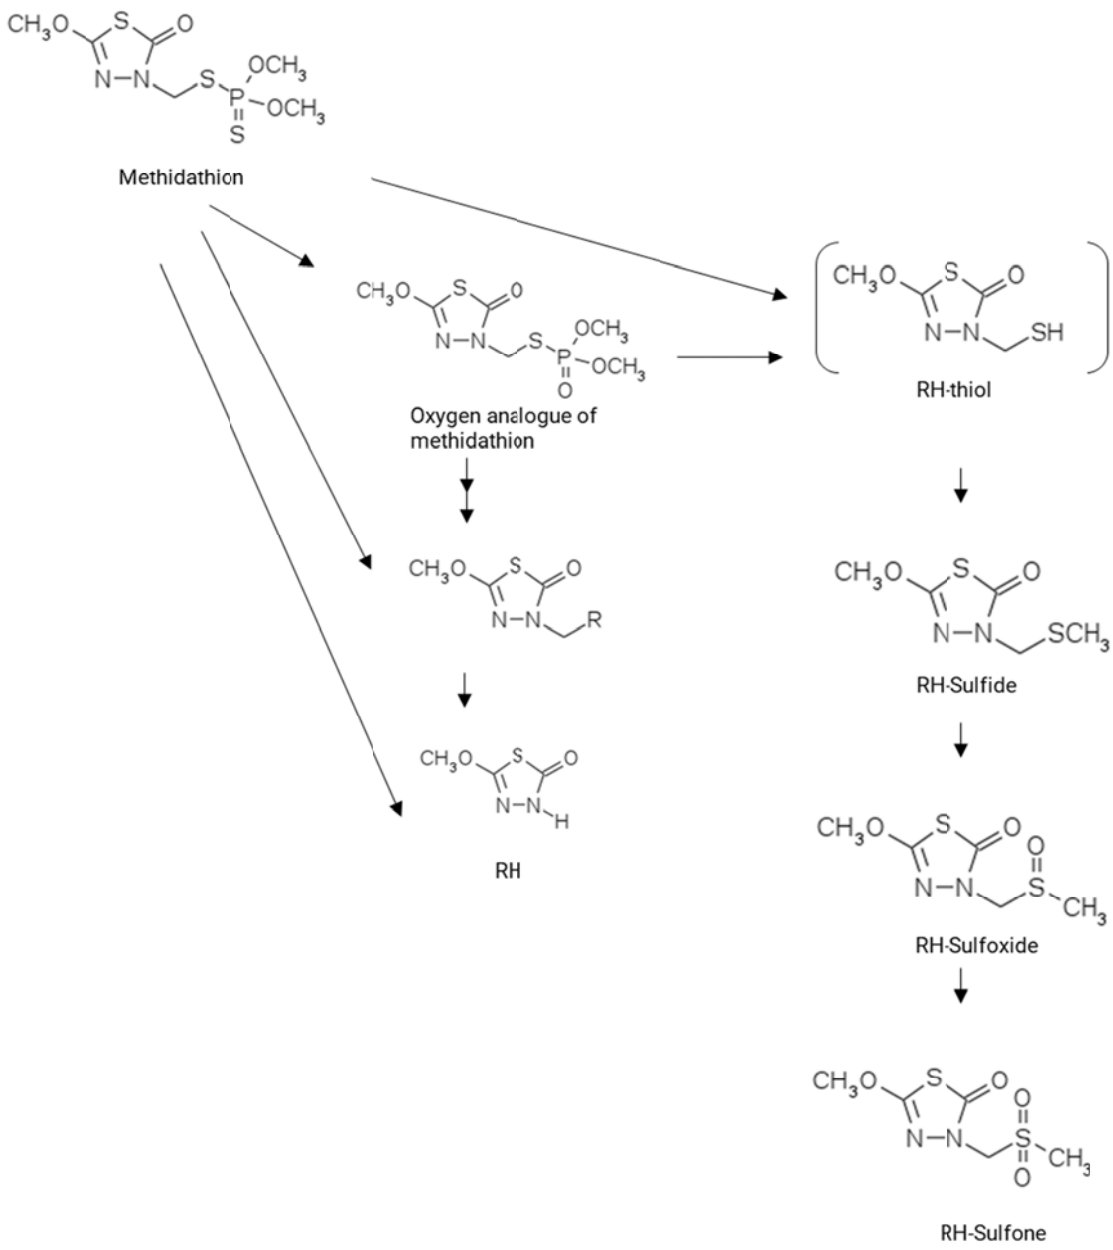

Figure 4 Proposed metabolic pathway of methidathion in bean and alfalfa

Conclusion

Metabolic pathways in orange, tomato, bean and alfalfa were qualitatively similar.

Animal metabolism

Information was available on metabolism of methidathion in lactating cows and lactating goats.

Lactating cows (Cassidy et al., 1969)

The metabolism of methidathion in a lactating cow (Holstein, 500 kg, age unknown) was studied using 2-carbonyl-^{14}C-methidathion administered orally in gelatine capsules (containing 165 mg of 2-carbonyl-^{14}C-methidathion), three times daily for 5 days. The daily administration rate was 1 mg/kg bw/day and

equivalent to 32 ppm (feed intake: 15.5 kg/day). A cow (Holstein, 455 kg, age unknown) was used as a control. Blood samples were taken 1 hour after the animal received the second dose capsule in the day. Milk was collected twice daily using milking machines. Excreta (urine, faeces) were collected daily.

At the end of the 10 days post dosing period, the animals were sacrificed. The following tissues subsampled and frozen: brain, heart, kidney, liver, round muscle, tenderloin muscle, spleen, blood and fat (omental, tail head, perirenal, subcutaneous).

Urine samples were radioassayed without further treatment. Faeces samples were extracted with acetone-methanol (1:1, v/v), concentrated and radioassayed. Insoluble faecal residues and blood samples were combusted and then analysed.

Milk was radioassayed using a wetting reagent and anthracene. Milk samples extracted by acetone were further fractionated in benzene soluble fraction and water-soluble fraction. The oxygen analogue of methidathion was analysed using silica gel TLC developed with chloroform-acetone (9:1, v/v) to be identified by inhibition of fly head cholinesterase.

Total radioactivity in tissues except fat were analysed by combustion using six replicates. Mean (±SD) recoveries for spiked samples at 0.02 and 0.1 mg/kg of seven tissue types were 93±6 percent and 93±2 percent, respectively.

Total radioactivity in fat was determined by pre-treating a homogenized subsample with NCS toluene quaternary ammonium base. The samples were heated in closed vial on the steam bath for several hours, cooled, diluted with toluene and analysed by LSC.

Milk

The total amount of radioactivity throughout the study period in milk was found at 0.6 percent AR (0.5 mg eq/kg), with 70 percent TRR (0.35 mg eq/kg) in aqueous fraction and 20 percent TRR (0.1 mg eq/kg) in the non-extractables.

The radioactivity observed in milk was increased by day 6 (1 DALA, 0.5 mg eq/kg) and no plateau was observed. The radioactivity was decreased to 0.004 mg eq/kg at 10 DALA, with 50 percent TRR in aqueous fraction and the rest in the non-extractables. Oxygen analogue of methidathion was not detected (LOD=0.01 mg eq/kg) in any of the milk samples. No further identification or characterization was conducted.

Tissues

Following daily oral administration of ^{14}C-methidathion to a cow at a dose of 1 mg/kg bw/d for 5 consecutive days and 10 days post-treatment period, residues in tissues were 0.11 mg eq/kg in liver, 0.04 mg eq/kg in kidney and 0.02-0.03 mg eq/kg in other tissues (Table 22). Metabolites were neither characterized nor identified.

Table 22 TRR in tissues from a cow fed ^{14}C-methidathion for 5 consecutive days

Tissue	Total radioactive residues [mg eq/kg]
Liver	0.11
Kidney	0.04
Heart	0.02
Muscle	
round	0.02
tenderloin	0.02
Spleen	0.03

Tissue	Total radioactive residues [mg eq/kg]
Brain	0.02
Fat	
perirenal	0.03
subcutaneous	0.02
omental	0.03
tail head	0.02

Urine, faeces

In the urine, 24 percent AR was recovered. The largest amount was observed in the specimen collected at 3 days after the first treatment. After the last capsule was administered (day 5), the radioactivity decreased. Predominant compound (about 85 percent) in urine was very polar and had different Rf value on paper chromatography with acetonitrile-water-ammonia (40:9:1, v/v/v) from that of methidathion, oxygen analogue of methidathion or RH. No further identification was conducted.

In the faeces, 34 percent AR was recovered, with 18 percent in acetone-methanol extracts and 16 percent in the residues. Radioactivity peaked at 4 days after the first treatment. After the last capsule was administered, the radioactivity decreased rapidly. The metabolite in faeces was polar and different from the reference materials of methidathion, oxygen analogue of methidathion or RH on TLC. No further identification was conducted.

Lactating cows (Polan and Chandler, 1970)

The metabolism of methidathion in lactating cows was studied. Cow 290 (Jersey, 413 kg, 4 years old) was administered 2-carbonyl-^{14}C-methidathion orally in capsules (containing 206 mg of 2-carbonyl- ^{14}C-methidathion) twice daily for 30 days. The daily administration rate was 1 mg/kg bw/day and equivalent to 65 ppm (feed intake: 6.4 kg/day). On the 31st day, the cow received 700 mg of 2-carbonyl-^{14}C-methidathion orally in a capsule (1.7 mg/kg bw, 110 ppm).

Cow 282 (Jersey, 469 kg, 4 years old, producing 11.6 kg milk daily) orally received 768 mg (1.7 mg/kg bw, 120 ppm) of 2-carbonyl-^{14}C-methidathion (single dose). Blood samples were taken 0.5, 1, 2, 3, 4, 6, 8, 10, 16, 24, 36, 48, 72 and 96 hours after the animal received the dose. Milk and excreta (urine, faeces) were totally collected for 96 hours after administration and individual samples were taken at various intervals. Exhaled CO_2 was trapped for four-minute intervals in NaOH (concentration not mentioned) periodically through 24 hours.

Total radioactivity of blood, urine and faeces were aliquoted for direct counting in liquid scintillation systems. For CO2, since expired CO2 was not quantitatively collected during the four-minute collection period, an aliquot of the trapping alkali was counted and the radioactivity corrected for counting efficiency. Another aliquot was reacted completely with BaCl2, the resulting precipitate was dried and $BaCO_3$ determined gravimetrically.

In the case of single dose, almost all radioactivity applied was collected (99.1 percent AR). Radioactivity was mainly found in exhaled CO_2 (50.8 percent AR) and urine (43.2 percent AR). For multi-dose experiment, the majority was found in urine (37.9 percent AR) followed by CO_2 (16.0 percent AR) among the total recovery of 60.6 percent AR (Table 23). In both cases, radioactivity was at low level in milk (0.8–1.2 percent AR).

Table 23 Recovery of labelled carbon from excretory routes in lactating cows for 96 hours after administration of 2-carbonyl- ^{14}C-methidathion

	Radioactive residues (% AR)	
	Cow 290 (administered for 31 days)	Cow 282 (single dose)
Exhaled CO_2	16.0	50.8
Urine	37.9	43.2
Faeces	5.5	4.3
Milk	1.2	0.8 (0.53 mg eq/kg)
Total	60.6	99.1

In addition, Cow 446 (Holstein, 556 kg, 4 years old) was given orally 1.25 mg/kg bw daily of methidathion (non-labelled) for 16 days. On 17th day, the cow was dosed with 945 mg of 2-carbonyl-^{14}C-methidathion (1.7 mg/kg bw, equivalent to 61 ppm). Milk was sampled at the end of 12 and 24 hours after administration.

Milk was extracted with acetone and filtered, and the residue on the filter was washed with benzene. All extracts were combined and left to stand for a few minutes to allow separation.

The benzene phase was evaporated to an oily residue and dissolved in hexane, followed by extraction with acetonitrile. The acetonitrile phase was dried up and dissolved in benzene. It was chromatographed on silica gel TLC with toluene-acetone (45:15) as mobile phase. The aqueous phase was partitioned with dichloromethane. The dichloromethane phase was dehydrated with anhydrous sodium sulphate, evaporated and dissolved in benzene. Final determinations for methidathion, RH-sulfone and RH-sulfoxide were conducted on GC-FID and by TLC (mobile phase (1): toluene-acetone=3:1, (2): acetonitrile-water-NH3 aq=40:9:1).

Radioactivity in the milk for 0–12 and 12–24 hours was 1.2 and 0.7 percent AR, respectively. Methidathion was not detected in either milk samples. RH-sulfone and RH-sulfoxide accounted for 3.4 and 0.9 percent, respectively, of the total radioactivity in milk during the first 12 hr. Distribution of milk extract radioactivity is in Table 24.

Table 24 Methidathion, RH-sulfone and RH-sulfoxide in extracted milk by TLC (Counts per minutes per spot)

	Mobile phase (1)		Mobile phase (2)	
	0-12 hr after dose	12-24 hr after dose	0-12 hr after dose	12-24 hr after dose
RH-sulfoxide	450	0	480	0
RH-sulfone	2050	155	2175	145
Methidathion	0	0	0	0

Lactating goats (Dupuis, et al., 1971)

The metabolism of methidathion in a lactating goat (55 kg, 2-year-old) was studied using 2-carbonyl-^{14}C-methidathion once administered by stomach tube (48.2 mg of 2-carbonyl-^{14}C-methidathion dissolved in 50 mL water-ethanol (1:4, v/v)). The dose was 0.88 mg/kg bw and equivalent to 38 ppm (assuming the feed intake of lactating goat as 1.27 kg). Milk was extracted with methanol-acetone (1:1, v/v), removed acetone, and then partitioned with chloroform.

Radioactivity in the range of 1 percent AR was found in the milk 72 hours after a single dose. Approximately 95 percent of radioactivity in milk was found in aqueous phase. Methidathion or its oxygen

analogue was not found in milk. No further identification or characterization of metabolites was conducted.

Conclusion

In milk, methidathion and its oxygen analogue were not detected. RH-sulfone and RH-sulfoxide, metabolites of methidathion identified, were detected, but they were accounted only for <5 percent TRR, which means other metabolites should exist but not identified. Radioactivity disappeared from milk in 10 DALA. In tissues, radioactivity remained in 10 DALA. As no further information was available, it was not possible to estimate metabolic pathway in livestock.

ENVIRONMENTAL FATE

Degradation under sunlight in soil (Lourdes et al, 2005)

Four types of 10 g of soil samples, namely unamended soil (S), amended with biosolid (4 percent w/w, SB), tetradecyltrimethylammonium (TDTMA, SS) as surfactant and both biosolid and surfactant (SBS), were placed on petri dishes (9.7 cm i.d.), added 10 mL of water and air dried for 48 h to level the surface of solid (0.89±0.09 mm thickness). Three mL of methidathion solution (33 mg/L) in water (S and SB) or in a TDTMA solution (SS and SBS) was dripped uniformly, and then heated under pressure for 1 h/d for three consecutive days to suppress the microbial activity. All petri dishes were covered with a glass disk and sealed with silicon. The experiment was conducted outdoors in Granada between July and August (2000) and air temperatures ranged between 15–38 °C, and irradiation from 0 (night) – 9870 (day) Wm^{-2}. At different time intervals, two Petri dishes of each type of soil (0, 1, 3, 7, 10, 14 and 21 days) and their corresponding dark controls (0, 3, 10, 14 and 21 days) were analysed.

For analysis, soil samples were extracted using Soxhlet with 75 mL of acetone for 6 h. The extract was concentrated using rotary evaporator, added 2 mL of hexane-toluene (1:1, v/v) and extracted. Samples were analysed by GC-FPD for methidathion and GC-MS (column: DB5-MS, 0.25 mm id × 30 m, EI mode) for photoproducts.

Degradation of methidathion was observed in all samples, and it was considered first order kinetic degradation. In all soil types, the degradation of methidathion was faster under sunlight (Table 25). In this study, neither methidathion oxygen analogue nor RH was detected after 3 days of sunlight irradiation of SS.

Table 25 First-order kinetic parameters for methidathion degradation under sunlight and in the dark in unamended soil (S) and soil amended with biosolid (SB), TDTMA (SS) and both amendments (SBS)

Soil	Sunlight			Dark controls		
	$k \times 10$ (d^{-1})	$t_{1/2}$ (days)	R^2	$k \times 10$ (d^{-1})	$t_{1/2}$ (days)	R^2
S	3.9±0.3	1.7	0.8869	1.7±0.1	4.1	0.9244
SS	4.3±0.3	1.6	0.8611	1.2±0.1	5.8	0.9401
SB	3.8±0.3	1.8	0.8960	2.7±0.3	2.6	0.8531
SBS	3.9±0.3	1.8	0.8898	2.3±0.1	3.0	0.9532

RESIDUE ANALYSIS

Analytical methods

The Meeting received seven methods of analysis for supervised residue trials.

Mandarin-1972 (Gotoh (1603[1]), 1979a; Gotoh (1604), 1979b; Suzuki (1607), 1971; and Kato (1608), 1972)

Pulp or peel of mandarin (50 g) was homogenized, extracted by 250 mL of ethyl acetate and cleaned up with florisil. Analysis was conducted by GC-ECD with a 5 percent QF-1 column (3 mm i.d. × 1.5 m). LOD reported was 0.05 mg/kg. Information on linearity of calibration curve was not available. Recovery for methidathion in mandarin was 73–94 percent (pulp) and 79–87 percent (peel), noting that only one sample was analysed for lower concentrations (0.02 and 0.04 mg/kg). Since LOQ was not reported, the Meeting determined LOQ as 0.1 mg/kg, the lowest fortification level with more than three trials (Table 26).

Table 26 Recovery data for Method Mandarin-1972

Matrix	Analyte	Fortification mg/kg	n	Recovery range mg/kg (mean)	RSD percent
Mandarin, flesh	Methidathion	0.02	1	73	-
		0.04	1	79	-
		0.1	4	63-80 (73)	9.9
		1	4	85-100 (94)	7.1
Mandarin, peel		0.02	1	83	-
		0.04	1	79	-
		1	4	75-106 (87)	16

Mandarin-1991 (Odanaka (1601), 2007; Higuchi and Matsuzawa (1602), 2008; Matano and Kobayashi (1605), 1991a; and Kuroda and Higuchi (1606), 1991)

Flesh or peel of mandarin (20 g) was homogenized, extracted with 100 mL of acetone and cleaned up with C18 cartridge column. Analysis was conducted with GC-FPD with DB-5 column (0.55 mm i.d. × 15 m). LOD was reported to be 0.005 mg/kg. Since LOQ was not reported, it was determined by the meeting as the lowest fortification level at 0.1 mg/kg that has acceptable recoveries. The calibration curve was linear (R^2>0.99) between 0.025 and 1 mg/kg. Recovery for methidathion in mandarin was 87–104 percent (pulp) and 92–98 percent (peel) (Table 27).

Table 27 Recovery data for Method Mandarin-1991

Matrix	Analyte	Fortification mg/kg	N	Recovery range mg/kg (mean)	RSD percent
Mandarin, flesh	Methidathion	0.1	2	103-105 (104)	-
		0.2	4	84-90 (87)	3.0
Mandarin, peel		0.2	2	93-94 (94)	-
		0.4	2	90-93 (92)	-
		20	2	97-98 (98)	-

Apple-1976 (Kato (1340), 1977 and Kaneuchi (1341), 1977)

Apples (50 g) were homogenized and extracted with 200 mL of ethyl acetate. It was cleaned up with silica gel column chromatography and dried under N_2. The solution was analysed by GC-flame thermionic detector (FTD) with GE XE-60 column (3 mm i.d. × 1.5 m). LOD was 0.01 mg/kg. Since LOQ was not reported, it was determined by the meeting as the lowest fortification level at 0.2 mg/kg that has acceptable recoveries. Information on linearity of calibration curve was not available. Recovery for methidathion in apples was 94 percent (Table 28). Sufficient information was not available for validation of the method.

[1] Report code number for reference

Table 28 Recovery data for Method Apple-1976

Matrix	Analyte	Fortification mg/kg	N	Recovery range mg/kg (mean)	RSD percent
Apple	Methidathion	0.2	3	91-97 (94)	3.2
		0.3	4	87-100 (94)	6.1

Apple-1988 (Kuroda and Higuchi (1395), 1992; Matano and Kobayashi (1396), 1991b; Kuroda and Higuchi (1397), 1990b; Matano and Kobayashi (1398), 1991c; Kuroda and Higuchi (1400), 1991; Kuroda and Higuchi (1401), 1990a; Kato (1402), 1988; Kuroda and Higuchi (1403), 1988; Kato (1501), 1974; Tsuchiya (1502), 1974; Gotou et al (1503), 1991; Kuroda and Higuchi (1504), 1990e; Tamai (1505), 1999; Kato (1506), 1979 and Tsuchiya (1507), 1979)

Apples or grapes (20 g) was homogenized, extracted with 100 mL of acetone and cleaned up by diatomite. Analysis was conducted with GC-flame photometric detector (FPD) with 5 percent OV-17 column (2.6 mm i.d. × 0.3 m). LOD reported was 0.002 mg/kg. Since LOQ was not reported, it was determined by the meeting as the lowest fortification level at 0.1 mg/kg that has acceptable recoveries.. Information on linearity of calibration curve was not available. Recovery for methidathion was 89–98 percent and 86–100 percent in apples and grapes, respectively (Table 29). Sufficient information was available for validation of the method for the analysis of methidathion in apple, but not in grape.

Table 29 Method recovery data for Method Apple-1988

Matrix	Analyte	Fortification mg/kg	N	Recovery range mg/kg (mean)	RSD percent
Apple	Methidathion	0.1	3	97-100 (98)	1.6
		0.12	6	86-93 (90)	3.2
Grape		0.04	2	87-92 (89)	-
		0.1	2	96-104 (100)	-
		0.2	4	72-98 (90)	13
		1.0	2	82-90 (86)	-

Peach-1981 (Goto (1431), 1981; Kato (1432), 1981; Goto (1455), 1990a; Goto (1456), 1990b; Kuroda and Higuchi (1457), 1990c; Kuroda and Higuchi (1458), 1990d; Ishitsuka (1459), 2014; Kato (1901), 1981; Imano and Shouji (1902), 1981 and Iijima et al (2013), 2013)

Peaches (50 g for pulp or 20 g for peel) or cherries (50 g) was homogenized and extracted with 150 mL of acetone. Analysis was conducted with GC-FID with 1.95 percent OV-2 + 1.5 percent OV-17 column (2 mm i.d. × 0.3 m). LOD was reported to be 0.002 mg/kg for peach pulp and cherries and 0.005 mg/kg for peach peel. Since LOQ was not reported, it was determined by the meeting as the lowest fortification level at 0.1 mg/kg that has acceptable recoveries. The calibration curve was linear (R^2>0.99) between 0.05 and 2 mg/kg. Recovery for methidathion was 88-100 percent, 93-114 percent and 82-94 percent in peach, pulp; peach, peel and cherry, respectively (Table 30).

Table 30 Method recovery data for Method Peach-1981

Matrix	Analyte	Fortification mg/kg	n	Recovery range mg/kg (mean)	RSD percent
Peach, pulp	Methidathion	0.1	4	90-109 (100)	8.6
		0.2	4	86-92 (88)	3.0
Peach, peel	Methidathion	0.1	2	112-118 (114)	-
		0.2	6	87-101 (93)	5.2

Matrix	Analyte	Fortification mg/kg	n	Recovery range mg/kg (mean)	RSD percent
Cherry	Methidathion	0.06	2	85-88 (87)	-
		0.1	4	80-84 (82)	2.0
		0.2	4	90-102 (94)	6.0
		1.0	4	85-90 (88)	2.4

Mango-2003 (Ebisu (2001), 2003 and Hashimoto (2002), 2005)

Mangos (20 g) was homogenized and extracted by 100 mL of acetone. The extract was cleaned up by diatomite followed by florisil. Analysis was conducted with GC-FID with DB-1 column (0.53 mm i.d. × 15 m). LOD and LOQ were 0.002 and 0.005 mg/kg, respectively. The recovery was 73 and 85 percent at 0.1 and 0.005 mg/kg, respectively (Table 31). The calibration curve was linear (R^2>0.99) between 0.04 and 2 mg/kg. Recovery for methidathion in mango was between 73–100 percent (Table 31).

Table 31 Recovery data for Method Mango-2003

Matrix	Analyte	Fortification mg/kg	n	Recovery range mg/kg (mean)	RSD percent
Mango	Methidathion	0.005	3	77-91 (85)	8.3
		0.025	3	90-109 (100)	9.5
		0.1	3	70-77 (73)	5.2
		2.5	3	77-79 (78)	1.1

LC-MS/MS Method (Nakatsuji (1903), 2014; Nakatsuji (1904), 2015; Sugimoto (2003), 2016; Shimamura and Fujita (2019c), 2019; Ogiyama (JP2017C303), 2018; Morita (JP2018C021), 2019a; and Morita (JP2018C023), 2019b)

Samples (20 g) was homogenized and extracted with 100 mL of acetone. After filtration with Celite, acetone was removed under N_2, added saturated sodium chloride aqueous solution and extracted with n-hexane/ethyl acetate (1:1, v/v). The extract was cleaned up with a graphite carbon/ethylenediamine-N-propyl silylation silica gel column. Analysis was conducted by LC-MS/MS with C_{18} column (m/z 303.0 > 145.1). The LOD and LOQ were 0.0025 and 0.005 mg/kg, respectively. The calibration curve was linear (R^2>0.999) between 0.025 and 0.05 mg/kg. Recovery for methidathion was 89–103 percent in peach (fruit), 89–94 percent in peach (pulp), 76–80 percent in cherry, 83–86 percent in grapes and 98–114 percent in mango (Table 30).

Table 32 Method recovery data for LC-MS/MS Method

Matrix	Analyte	Fortification mg/kg	n	Recovery range mg/kg (mean)	RSD percent
Peach (fruit)	Methidathion	0.005	5	100-105 (103)	2.1
		0.1	5	92-98 (94)	4.2
		0.5	5	81-96 (89)	6.8
Peach, pulp		0.005	5	91-97 (94)	2.9
		0.1	5	81-95 (89)	6.6
Cherry		0.005	5	78-83 (80)	2.3
		1	5	75-77 (76)	1.1
Grape		0.005	5	79-86 (83)	3.2
		0.1	5	80-87 (85)	3.4
		0.5	5	81-89 (86)	4.2

		0.5	6	93-107 (98)	5.0

STABILITY OF PESTICIDE RESIDUES IN STORED ANALYTICAL SAMPLES

The Meeting received storage stability studies of methidathion in commodities with high water content, apple, cherry, mango, and peach and high acid content and high-water content, grape and mandarin. In all studies, samples fortified was not analysed at day 0; however, mean procedural recovery was available.

Mandarin (Higuchi and Matsuzawa (1602), 2008; Matano and Kobayashi (1605), 1991a; and Kuroda and Higuchi (1606), 1991)

Mandarin (20 g) was homogenized and fortified with methidathion at 0.2 and 1.0 mg/kg for pulp and 0.2, 1.0 and 5.0 mg/kg for peel. Samples were stored at -20 °C for 21–207 days and analysed with method Mandarin-1972 or Mandarin-1991.

The summary of data is shown in Table 34.

Table 33 Storage stability data for methidathion in mandarin

Matrix	Spike level [mg/kg]	Storage period [days]	Recovery of Methidathion [%]	Mean recovery after storage [%]	Mean procedural recovery [%]	Study
Mandarin, flesh	0.2	136	75, 74	74	104 (@0.1 mg/kg)	Ref. 1605[1]

Apple (Kuroda and Higuchi (1395), 1992; Matano and Kobayashi (1396), 1991b; Kuroda and Higuchi (1397), 1990b; Matano and Kobayashi (1398), 1991c; Kuroda and Higuchi (1400), 1991; Kuroda and Higuchi (1401), 1990a; Kato (1402), 1988; and Kuroda and Higuchi (1403), 1988)

Apples (25 g), after removal of core, were homogenized and fortified with methidathion at 0.2 or 1.0 mg/kg. Samples were stored at -20 °C for 14–120 days and analysed with method Apple-1988.

In one study (Ref 1400), samples of apple, after removal of core, were not homogenized but chopped to about 1 cm^3 and fortified with methidathion at 1.0 mg/kg. Samples were stored at -20 °C for 106-208 days and analysed with method Apple-1988.

The summary of data is shown in Table 34.

<u>Mango</u> (Hashimoto (2002), 2005 and Sugimoto (2003), 2016)

Mango, after removal of seed, was homogenized (20 g) and fortified with methidathion at 0.25 or 0.5 mg/kg. Samples were stored at -20 °C for 34–123 days and analysed by method Mango-2003 (Ref 2002) or LC-MS/MS Method (Ref 2003) (Table 38).

Table 38 Storage stability data for methidathion in mangoes

Matrix	Spike level [mg/kg]	Storage period [days]	Recovery of Methidathion [%]	Mean recovery after storage [%]	Mean procedural recovery [%]	Study
Mango	0.25	34	105, 102	104	100 (@0.025 mg/kg) 78 (@2.5 mg/kg)	Ref. 2002[1]
	0.5	115	95, 88	92	103 (@0.1 mg/kg)	Ref. 2003[2]

USE PATTERN

The Meeting received the cGAP for mandarins, cherries, peaches, apples, grapes and mangoes (Table 39). The label provided covers a broader spectrum of uses. In all Japanese GAPs, interval period is not specified.

It is noted that in Japan, retreatment interval between applications is not specified for crops to which methidathion could be applied more than once on the label, but that an interval of 7 days is common in practice.

Table 39 Registered uses of methidathion on various crops considered by the Meeting

Crop	Country	Formulation	Application						Timing/PHI (days)
			Method	Rate (kg ai/ha)	Dilution rate	Spray conc. (kg ai/hL)	Water volume[3] (L/ha)	Max number of applications	
Mandarins	Japan	EC 400 g ai/L	foliar spray		x 1500	0.027	7000	4	14
		EC 300 g ai/L+ EC 400 g ai/L	Spray at tree trunk (2) + foliar spray(2)		x50 x 1500	0.6 0.027	1800 7000	2 + 2	Egg laying timing of longicorn 14
Apples	Japan	EC 300 g ai/L	Spray at tree trunk		x100	0.3	1800	2	30
	Japan	WP 360 g ai/L	Foliar spray		x1500	0.024	7000	2	30
Cherries	Japan	EC 400 g ai/L	Foliar spray		x1500	0.027	7000	3	7
Peaches	Japan	WP 360 g ai/L+ EC 300 g ai/L	Foliar spray Spray at tree trunk and main branch		x1500 x 200	0.024 0.15	7000 1800	2[1] 2[1]	21 60
Grapes	Japan	WP 360 g ai/L	Foliar spray		x1500	0.024	7000	2[2]	14
		WP 360 g ai/L	Soil irrigation		x500	0.072	100000	2[2]	90
		EC 300 g ai/L	Spray at tree trunk and main branch		x200	0.15	1800	1[2]	Before bud burst
Mangos	Japan	EC 400 g ai/L	Foliar spray		x1500	0.027	7000	2	45

Notes:

[1/] Number of applications can be two for each formulation, and can be up to four applications in total..

[2/] Use of methidathion on grape, regardless of formulation type, can be up to twice in a year. Within the limit, before bud burst, methidathion can be used only once.

[3/] Recommendation.

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received supervised trials on mandarins, cherries, peaches, apples, grapes and mangoes. In many trials, samples from the same supervised trial were analysed in two different laboratories. As many of the analytical results from replicated analyses were significantly different (i.e. differences are larger than the expanded measurement uncertainty estimated by Horwitz equation), the larger value between two analyses was taken for conservative estimation of residues.

Mandarins (Gotoh (1603), 1979a; Gotoh (1604), 1979b; Suzuki (1607), 1971; and Kato (1608), 1972; Odanaka (1601), 2007; Higuchi and Matsuzawa (1602), 2008; Matano and Kobayashi (1605), 1991a; and Kuroda and Higuchi (1606), 1991)

The Meeting received 18 supervised trials conducted between 1971 and 2006 on mandarins in Japan. In eight trials, mandarins received four foliar applications of methidathion diluted with water at 0.040 kg ai/hL; in two trials, three foliar applications at 0.027 kg ai/hL; in six trials, two foliar applications at 0.027–0.040 kg ai/hL; and in two trials, two foliar applications at 0.027 kg ai/hL and two sprays at tree trunk at 0.012 kg ai per tree.

Mandarin was peeled and peel and pulp were separately analysed. The concentration in whole fruit was calculated from the analytical values for peel and pulp. Methidathion formulation was 0.40 kg/L EC (foliar application) or 0.30 kg/L EC (sprays at tree trunk). The first application was made at 35–131 days before harvest (BBCH 60–81). The longest storage interval was 136 days. The results are shown in Table 41.

Notes:

[1/] Recommended water volume to spray is 7000 L/ha.

[2/] Each sample was analysed twice in each of two different laboratories. The higher mean analytical result was shown in the table.

[3/] Analyzed by Method Mandarin-1972.

[4/] Analyzed by Method Mandarin-1991 (LOQ: 0.1 mg/kg for pulp and 0.2 mg/kg for peel).

Apples (Kato (1340), 1977 and Kaneuchi (1341), 1977; Kuroda and Higuchi (1395), 1992; Matano and Kobayashi (1396), 1991b; Kuroda and Higuchi (1397), 1990b; Matano and Kobayashi (1398), 1991c; Kuroda and Higuchi (1400), 1991; Kuroda and Higuchi (1401), 1990a; Kato (1402), 1988; and Kuroda and Higuchi (1403), 1988)

The Meeting received 57 supervised trials conducted between 1976 and 1990 on apples in Japan. In two trials, EC formulation of methidathion diluted with water at 0.024 kg ai/hL applied to apples twice, followed by the injection of WP formulation of methidathion to the trunk once (0.72 kg ai/hL). In other trials, apples received 1–5 foliar application(s) of WP formulation as aqueous solution with the concentrations of 0.018–0.024 kg ai/hL. The longest storage interval was 189 days. The result is shown in Table 42.

Apples were analysed after removal of core and the analytical results were shown as the weight of analysed portion basis. The weight of core is estimated 9.8-14 percent of fruit, using the data of apples (Golden delicious, Granny Smith, Gold Spur, Spartan, Red Gold and Royal Delicious) in *Satish et al. (2017)* and assuming that the shapes of apples are flat sphere and the density of each part of apple is uniform (Table 43).

Table 42 Residues in apples without core resulting from supervised trials in Japan (foliar spray of methidathion 360 WP or 300 EC formulations)

Red Gold	6.31	5.52	5.20	1.77	115	12.8	11
Royal Delicious	6.76	6.04	5.73	2.10	145	14.1	9.8

Notes:

[1/] Assuming that (1) the shape of apples is flat sphere, (2) the shape of core is cylinder, and (3) the density is uniform.

Cherry (Kato (1901), 1981; Imano and Shouji (1902), 1981; Nakatsuji (1903), 2014; Iijima et al. (2013), 2013; and Shimamura and Fujita (2019c), 2019)

The Meeting received 20 supervised trials conducted between 1981 and 2018 on cherries in Japan. Cherries received EC formulation of methidathion (0.40 kg ai/L) diluted with water at 0.018-0.027 kg ai/hL three times. In trials in Refs 1901 and 1902, every sample was analysed in two different laboratories and the higher values were shown in the table. The longest storage interval was 54 days.

Cherries were analysed after removal of seeds and the results were shown as the weight of whole fruit basis, except in trials of 1901 and 1902 in which they were analysed portion basis. For these two trials, the analytical values were converted to whole fruit basis using the information that seed weight is 7.6 percent of whole fruit according to *Kalyoncu et al. (2009)*.

The result is shown in Table 44.

Table 44 Residues in cherries resulting from supervised trials in Japan (foliar spray of methidathion 400 EC formulation)

Notes:

[1/] Each sample was analysed twice in each of two different laboratories. The higher mean analytical result was shown in the table.

[2/] Analysed by Method Peach-1981 (LOQ: 0.1 mg/kg)

[3/] Analysed by LC-MS/MS Method (LOQ: 0.01 mg/kg)

[4/] These trials were conducted in the same city and 10 km away from each other. Therefore, these data are not considered independent.

Peaches (Goto (1431), 1981; Kato (1432), 1981; Goto (1455), 1990a; Goto (1456), 1990b; Kuroda and Higuchi (1457), 1990c; Kuroda and Higuchi (1458), 1990d; Ishitsuka (1459), 2014; Ogiyama (JP2017C303), 2018; and Morita (JP2018C021), 2019a)

The Meeting received 17 supervised trials conducted between 1981 and 2018 on peaches in Japan. Peaches were received foliar application of WP formulation of methidathion diluted with water at 0.024 kg ai/hL. In some trials EC formulation (0.15–0.30 kg ai/hL) was injected to the trunk twice before foliar application. In several trials, samples were analysed in two different laboratories. The longest storage interval was 136 days. Samples were analysed after removal of seeds and analytical results were shown as the weight of analysed portion basis.

In trials with footnote 5, peel and pulp were analysed separately and the analytical values for fruit were calculated from the analytical values of peel and pulp, based on the weight of fruit after removal of seed. In other trials, whole fruit and pulp after removal of seed were analysed. The result is shown in Table 45.

Grapes (Kato (1501), 1974; Tsuchiya (1502), 1974; Gotou et al (1503), 1991; Kuroda and Higuchi (1504), 1990e; Tamai (1505), 1999; Kato (1506), 1979 and Tsuchiya (1507), 1979; and Morita (JP2018C023), 2019b)

The Meeting received 15 supervised trials using foliar application conducted between 1973 and 2018 on grapes in Japan. In four trials, grapes received a foliar application of EC formulation (0.30 kg ai/L) diluted with water at 0.15 kg ai/hL with 127-143 DALA. In 11 trials, WP formulation (0.36 kg ai/L) diluted with water at 0.024 kg ai/hL was applied to grapes twice by foliar application. Samples were analysed after removal of stem and the analytical results were shown as the weight of analysed portion basis. In several trials, samples were analysed in two different laboratories and the higher values were shown. The longest storage interval was 150 days. The result is shown in Table 46.

The Meeting also received four trials in conjunction with drenching or steam fog applications (Table 47).

Notes:

In all trials analytical method was Method Apple-1988. (Validation data not available).

[1/] Recommended water volume to spray is 7000 L/ha.

[2/] Each sample was analysed twice in each of two different laboratories. The higher mean analytical result was shown in the table.

[3/] Trunk application.

[4/] Soil drenching.

[5/] Steam fog application.

[6/] Longer storage interval than stability study.

Mango (Ebisu (2001), 2003 and Hashimoto (2002), 2005; and Sugimoto (2003), 2016)

The Meeting received five supervised trials using foliar application conducted between 2003 and 2015 on mangoes in Japan. Mangoes received a foliar application of EC formulation (0.30 kg ai/L) diluted with water at 0.027 kg ai/hL with 30–60 DALA twice (four trials) or three times (one trial). The longest storage interval was 116 days. The result is shown in Table 48.

Samples were analysed after removal of seeds and concentration was expressed as analysed portion basis. In the study 2003, the weights of seed ranged from 5.1 to 8.3 percent of whole fruit (Table 50).

3	422	24.5	5.8
4	508	32.7	6.4
5	383	24.3	6.3
6	390	32.2	8.3
7	410	26.2	6.4
8	363	22.2	6.1
9	498	25.2	5.1
10	458	25.2	5.5
11	530	36.6	6.9
12	446	28.6	6.4

FATE OF RESIDUES IN STORAGE AND PROCESSING

No processing study was provided by the sponsor. However, some information was available from published literature.

Dried grape (Özbey et al., 2017)

Sultana grape was treated with 45 µL/kg of methidathion through spraying onto surface and stood still for 12 h at room temperature. Grapes were separated from stems and dried under several conditions: under sunlight for 21 days, and in a ventilated oven at various temperatures (at 50 °C for 72 hours, at 60 °C for 60 hours, at 70 °C for 48 hours and at 80 °C for 36 hours).

Methidathion was analysed as follows: grape samples were homogenized, mixed well with acetonitrile, added anhydrous $MgSO_4$ and NaCl and centrifuged. Extracts were analysed by GC/MS. Moisture content was analysed by AOAC 930.15.

In all trials, methidathion reduced significantly, in particular, when grapes were dried under high temperature (**Table** 50). During oven-drying, methidathion followed the first order kinetic model. Half-life time of methidathion was 19.8 hours at 50 °C and 10.8 hours at 60 °C.

Table 50 Processing factors of methidathion while producing dried grapes under various conditions

Condition	Processing factor
80 °C, 36 h	0.02
70 °C, 48 h	0.06
60 °C, 60 h	0.13
50 °C, 72 h	0.35
Sun-drying, 21 days	0.18

Degradation in fruit juices (Kyriakidis et al, 2000)

Methidathion (final concentration of 1.6 mg/kg) was added to orange and peach juices that were obtained at a market. Juices were stored at 0 ±1 °C, 15 °C or 40±1 °C. Samples were taken every 15 days for juices stored at 0 °C (up to 105 days), every 10 days for juices stored at 15 °C (up to 110 days), and every day up to the 4th day and then every 2 days for juices stored at 40 °C (up to 20 days). Samples were analysed by GC-NPD.

Methidathion degradation followed the first order kinetic model. The half-lives of methidathion depended on the temperature, but not on the type of juice (Table 51).

Table 51 Half-life times of methidathion in orange and peach juices

Storage temperature	Half-life of methidathion (days)	
	Orange juice	Peach juice
40 °C	4.1	3.8
15 °C	115	114
0 °C	330	385

Farm animal feeding studies

No feeding study was provided by the sponsor. However, some information was available from the published literature.

Cows (Polan et al., 1969)

Three groups of four dairy cows (4 years old, Holstein) were orally treated methidathion in gelatin capsules twice daily for at least 55 consecutive days (another group of four cows for control). The dose rates were 7.5, 15 and 30 ppm. The cows were fed with 1 kg of a 16 percent crude protein concentrate per 3 kg of milk produced and permitted ad libitum consumption of an alfalfa-orchard grass hay (1.5-1.8 percent of body weight). Milk samples were taken on three consecutive days before initial treatment, twice daily at five-day intervals during and for eight weeks following cessation of pesticide administration. One cow from each treatment group was slaughtered on Day 55 or 56 and samples of heart, brain, spleen, kidney, liver, Longissimus dorsi, Biceps femoris, omental, perirenal and subcutaneous fat were collected for residue analysis. Samples were analysed by GC.

Milk samples were analysed from cows treated at all doses collected between 30 and 54 days and at 15 pm collected at 54 and 60 days. All milk samples contained <0.01 mg/kg of methidathion and <0.025 mg/kg of oxygen analogue. In tissues analysed, all samples contained <0.01 mg/kg of methidathion and <0.025 mg/kg of oxygen analogue.

Laying hens (Wiseman and Young, 1970)

Ten groups of two laying hens (40 weeks old, S.C. White Leghorn) were orally fed *ad libitum* containing methidathion at 0 (control), 10, 50, 100 and 500 ppm. Eggs were collected each third day after administration for residue analysis. For 500 ppm-group, feed consumption (94–111 g/day for other groups and 71–80 g/day for 500 ppm group) and egg production rate (69-81T for other groups and 52–60 percent for 500 ppm group) decreased.

Methidathion was not detected (LOQ 0.002 mg/kg) in egg yolk from 10 ppm-group hens. In 50 ppm and 100 ppm group hens, low concentration (<0.02 mg/kg) of methidathion were detected after 18 or 21 days, respectively, of consecutive administration.

APPRAISAL

Methidathion, whose IUPAC name is S-2,3-dihydro-5-methoxy-2-oxo-1,3,4-thiadiazol-3-ylmethyl O,O-dimethyl phosphorodithioate, is an organophosphate insecticide. Its mode of action is by inhibition of acetylcholinesterase. Methidathion was last evaluated for residues in 1994.

At the Fifty-first Session of CCPR (2019) methidathion was scheduled for periodic re-evaluation by the 2020 JMPR but was postponed to the 2022 JMPR. The Meeting received the data for methidathion on plant and animal metabolism, methods of analysis, GAP information, and residues resulting from supervised trials on apple, cherry, grape, mandarin, mango and peach.

The code names, chemical names and chemical structures of the compounds are as follows.

Table 52 Summary information on compounds referred to in the appraisal

Compound code name and chemical name	Structure
Methidathion S-2,3-dihydro-5-methoxy-2-oxo-1,3,4-thiadiazol-3-ylmethyl O,O-dimethyl phosphorodithioate	Desmethyl methidathion S-2,3-dihydro-5-methoxy-2-oxo-1,3,4-thiadiazol-3-ylmethyl O-methyl phosphorodithioate	Oxygen analogue of methidathion S-2,3-dihydro-5-methoxy-2-oxo-1,3,4-thiadiazol-3-ylmethyl O,O-dimethyl phosphorothioate	GS-20685 2,3-dihydro-3-hydroxymethyl-5-methoxy-1,3,4-thiadiazol-2-one	Glutathione conjugate of GS-13005 RH-Glutathione conjugate 2,3-dihydro-5-methoxy-2-oxo-1,3,4-thiadiazol-3-ylmethyl-thioglutathione	Cysteine conjugate of GS-13005 RH-Cysteine conjugate 2-amino-3-(2,3-dihydro-5-methoxy-2-oxo-1,3,4-thiadiazol- 3-ylmethylthioxy) propionic acid	RH 2,3-dihydro-5-methoxy-1,3,4-thiadiazol-2-one	RH-Alanine conjugate 2-amino-3-(2,3-dihydro-5-methoxy-2-oxo-1,3,4-thiadiazol- 3-ylmethyl) propionic acid	
Compound code name and chemical name	Structure
RH-Keto acid conjugate 2-oxo-3-(2,3-dihydro-5-methoxy-2-oxo-1,3,4-thiadiazol- 3-ylmethyl) propionic acid	RH-Lactic acid conjugate 3-(2,3-dihydro-5-methoxy-2-oxo-1,3,4-thiadiazol-3-ylmethyl)-2-hydroxypropionic acid	RH-glyoxylic acid conjugate 2-(2,3-dihydro-5-methoxy-2-oxo-1,3,4-thiadiazol-3-yl) -2-oxo-acetic acid	RH-Acetic acid conjugate 2-(2,3-dihydro-5-methoxy-2-oxo-1,3,4-thiadiazol-3-yl) acetic acid	RH-Hydroxy acetic acid conjugate 2-(2,3-dihydro-5-methoxy-2-oxo-1,3,4-thiadiazol-3-yl)- 2-hydroxy-acetic acid	RH-thiol 2,3-dihydro-5-methoxy-4-sulfanyl-1,3,4-thiadiazol-2-one	RH-sulfide 2,3-dihydro-5-methoxy-4-methylsulfanyl-1,3,4-thiadiazol-2-one	RH-sulfoxide 2,3-dihydro-5-methoxy-4-methylsulfinyl-1,3,4-thiadiazol-2-one	RH-sulfone 2,3-dihydro-5-methoxy-4-methylsulfonyl-1,3,4-thiadiazol-2-one	
With respect to the physical and chemical properties that may impact on residues in crops, methidathion is not regarded as volatile, it is unlikely to be fat soluble as the log P_{ow} is 2.2, and the hydrolysis half-lives range from 13 days at pH 9 to 48 days at pH 7.

Plant metabolism

The Meeting received information on the fate of methidathion in oranges, tomatoes, common beans and alfalfa. In the metabolism studies, total radioactive residues (TRR) are expressed in mg methidathion equivalents/kg.

In a metabolism study on oranges, 2-carbonyl-^{14}C-methidathion was applied twice to an orange tree under outdoor conditions as foliar spray at rates of 0.067 kg ai/ha. Oranges were harvested at maturity 159 days after last application (DALA), washed by water with surfactant, and peeled. In plant metabolism study, juice was prepared from the peeled fruit. Subsamples of each matrix were homogenized to determine the TRR.

Radioactivity was mainly located in peel (66 percent TRR, 1.0 mg eq/kg), followed by juice (22 percent TRR, 0.25 mg eq/kg) and pulp (11 percent TRR, 0.40 mg eq/kg). Residues in the aqueous surface wash were insignificant (0.5 percent TRR, < 0.01 mg eq/kg). Peel and pulp were extracted with methanol-water (9:1). From orange pulp, 17 percent TRR (0.068 mg eq/kg) was extracted and when partitioned with water-chloroform, 12 and 2.5 percent TRR (0.048 and 0.010 mg eq/kg) were found in water and chloroform phase, respectively. Residues in pulp were not further characterized.

Since only radioactivity in peel and juice was subject to identification, the Meeting could not calculate the metabolite composition for the whole fruit.

In orange peel, 65 percent TRR was extracted by aqueous methanol and the following compounds were identified methidathion (24 percent TRR, 0.25 mg eq/kg), RH-alanine conjugate (14 percent TRR, 0.14 mg eq/kg), conjugates of RH with acetic acid, lactic acid or hydroxy acetic acid (3.5–4.2 percent TRR, 0.04 mg eq/kg), and desmethyl-methidathion (1.7 percent TRR, 0.02 mg eq/kg). Unextracted residues in the orange peel were further treated by sequential acid (0.1 and 1 mol/L HCl) and base (5 mol/L NaOH) hydrolysis. After hydrolysis with 0.1 mol/L HCl, 1 mol/L HCl and base, 0.68 percent TRR (0.007 mg eq/kg), 12 percent TRR (0.12 mg eq/kg) and 3.8 percent TRR (0.039 mg eq/kg), respectively, were extracted.

In orange juice, residues were predominantly aqueous soluble (94 percent TRR, 0.24 mg eq/kg). Parent methidathion was not detected. RH-alanine conjugate was predominant (72 percent TRR, 0.18 mg eq/kg), followed by RH-lactic acid conjugate (10 percent TRR, 0.03 mg eq/kg) and desmethyl-methidathion (3.1 percent TRR, < 0.01 mg/kg). In a metabolism study on tomatoes, the following compounds ^{14}C-labelled at 2-carbonyl in thiadiazol ring were used: methidathion, desmethyl methidathion, RH-sulfide, RH-sulfoxide and RH-sulfone. Labelled compounds, at rates of 1–14 mg/kg for ^{14}C-methidathion or a rate of 7 mg/kg for other compounds, were directly applied on the surface of detached semi-ripe tomato fruits. The fruit was stored at room temperature for 3–14 days (^{14}C-methidathion) or 7 days (other compounds) and then extracted with acetone-water (9:1). When ^{14}C-methidathion at a rate of 14 mg/kg was applied, 97 percent of applied radioactivity (AR, 12 mg eq/kg) was recovered 14 days after treatment (DAT). Desmethyl methidathion was the main residue (41 percent TRR, 4.8 mg eq/kg), followed by RH-cysteine conjugate (33 percent TRR, 3.8 mg eq/kg), methidathion (9.8 percent TRR, 1.1 mg eq/kg), its oxygen analogue (3.2 percent TRR, 0.37 mg eq/kg) and GS-20685 (0.43 percent TRR, 0.05 mg eq/kg).

In tomatoes treated with ^{14}C-desmethyl methidathion (7 DAT), 93 percent AR (6.2 mg eq/kg) was recovered. Identified compounds were: unchanged desmethyl methidathion (52 percent TRR, 3.2 mg eq/kg), RH-cysteine conjugate (21 percent TRR, 1.3 mg eq/kg) and RH-sulfide (1.1 percent TRR, 0.07 mg eq/kg). In tomatoes treated with ^{14}C-RH-sulfide (7 DAT), 96 percent AR (5.6 mg eq/kg) was recovered. Identified compounds were RH-sulfoxide (60 percent TRR, 3.4 mg eq/kg) and RH-cysteine conjugate (14 percent TRR, 0.78 mg eq/kg) and unchanged RH-sulfide (20 percent TRR, 1.1 mg eq/kg). In tomatoes treated with ^{14}C-RH-sulfoxide (7 DAT), 95 percent AR (6.8 mg eq/kg) was recovered. Identified compounds were unchanged RH-sulfoxide (70 percent TRR, 4.7 mg eq/kg), RH-sulfone (16 percent TRR, 1.1 mg eq/kg), and RH-cysteine conjugate (7.7 percent TRR, 0.52 mg eq/kg). When ^{14}C-RH-sulfone was applied, 96 percent AR (6.4 mg eq/kg) was recovered in the fruit, with 89 percent TRR (5.8 mg eq/kg) of unchanged RH-sulfone and 2.8 percent TRR (0.18 mg eq/kg) of RH-cysteine conjugate.

In a metabolism study on common beans, plants were cultivated in pots and methidathion ^{14}C-labelled at 2-carbonyl, 3-methylene, O-methyl or 2-carbonyl-RH was topically applied to leaves. Samples were collected 7–16 days after the treatment. The samples were extracted with acetone-water (8:2) and partitioned with chloroform and radioactivity in the chloroform phase was identified by TLC. Aqueous phase was not further identified. During the experiment, $^{14}CO_2$ was collected in 2 mol/L NaOH traps. Radioactivity was found in chloroform phase (3.6–8.9 percent AR), water phase (20–55 percent AR), non-extracted (1.6–12 percent AR) and $^{14}CO_2$ (2.3–27 percent AR). When methidathion or methidathion oxygen analogue was applied, methidathion, oxygen analogue and RH were recovered in chloroform phase (1.3–6.0 percent AR, 0.15–up to 5.4 percent AR, respectively). When RH was applied, radioactivity was mainly found in water phase (55.3 percent AR) and 5.4 percent AR of RH was recovered. Further information is not available in the study on common beans.

In a metabolism study on alfalfa, plants were cultivated in field and 2-carbonyl-14C-methidathion was topically applied to leaves. Samples were collected 7–16 days after the treatment. The sample was extracted by acetone-water (8:2) and partitioned with chloroform and chloroform phase was identified by TLC. During the experiment, $^{14}CO_2$ was collected in 2 mol/L NaOH traps. Radioactivity was found in chloroform phase (33–56 percent AR), water phase (14–32 percent AR), non-extracted (2.9–6.4 percent AR) and $^{14}CO_2$ (14 percent AR). In chloroform phase, methidathion, its oxygen analogue and RH were 32–53, 0.33–0.86 and 0.43–1.7 percent AR, respectively. In water phase, RH conjugate was found. Further information is not available in the study on alfalfa.

Summary of plant metabolism

When methidathion was applied to oranges, the parent methidathion was found in peel (24 percent TRR, 0.25 mg eq/kg), but not in juice. Major metabolites were RH-alanine conjugate (14 percent TRR, 0.14 mg eq/kg in peel and 72 percent TRR, 0.18 mg eq/kg in juice) and RH-acetic acid, lactic acid or hydroxy acetic acid conjugate (3.7 percent TRR, 0.04 mg eq/kg in peel and 10 percent TRR, 0.03 mg eq/kg in juice). When methidathion was applied to tomato fruits, desmethyl-methidathion (39–42 percent TRR, 2.3–4.8 mg eq/kg), RH-cysteine conjugate (34–35 percent TRR, 2.1–3.8 mg eq/kg), parent methidathion (9.8 percent TRR, 1.1 mg eq/kg), and its oxygen analogue (3.2 percent TRR, 0.37 mg eq/kg). When tomatoes were treated with ^{14}C-desmethyl methidathion, the major residues were unchanged desmethyl methidathion (52 percent TRR, 3.2 mg eq/kg) and RH-cysteine conjugate (21 percent TRR, 1.3 mg eq/kg) were the major metabolites. When methidathion was applied to common beans and alfalfa, parent methidathion (1.3–53 percent AR), its oxygen analogue (0.15–0.86 percent AR) and RH (≤1.7 percent AR) were found.

The Meeting noted that metabolites found in various plants were desmethyl-methidathion, the oxygen analogue of methidathion and RH or its conjugate, although some of them might not be observed

depending on plant species. The Meeting concluded that the metabolic profiles between the species were qualitatively similar.

Animal metabolism

The Meeting received animal metabolism studies on rats, lactating cows and lactating goats.

Rats

The metabolism of methidathion in rats was reviewed in the framework of the toxicological evaluation by the WHO Core Assessment Group of the 2022 JMPR.

Cattle

In a metabolism study on lactating cow, 2-carbonyl-^{14}C-methidathion was administered orally in capsules three times per day for 5 consecutive days at 1 mg/kg bw per day (equivalent to 32 ppm) and the cow was sacrificed 10 days after the last application (DALA). Radioactivity in milk increased to 0.5 mg eq/kg at 1 DALA and then decreased to 0.004 mg eq/kg at 10 DALA, and no clear plateau was observed. Through the study period, accumulated total radioactivity recovered from milk was 0.6 percent AR (0.5 mg eq/kg) and oxygen analogue of methidathion was not found in milk (LOD: 0.01 mg eq/kg). Radioactivity was detected in liver at 0.11 mg eq/kg, kidney at 0.04 mg eq/kg, omental fat at 0.03 mg eq/kg, and muscle, at 0.02 mg eq/kg after 10 days of post-dosing period. No identification or characterization was conducted.

In another study of metabolism on lactating cow, 2-carbonyl-^{14}C-methidathion was administered orally once at 1.7 mg/kg bw (equivalent to 120 ppm). Radioactivity in milk collected after administration for 96 hours was 0.8 percent AR (0.53 mg eq/kg).

In the same study, an additional metabolism study on lactating cow was conducted. A cow was given orally 1.25 mg/kg daily of methidathion (non-labelled) for 16 days, and then 2-carbonyl-^{14}C-methidathion was orally administered once at 1.7 mg/kg bw (equivalent to 61 ppm). Milk was collected at the end of 12 and 24 hours after administration. Radioactivity in the milk for 0–12 and 12–24 hr after the application of labelled methidathion was 1.2 and 0.7 percent AR, respectively. In both milk samples, methidathion was not detected, and RH-sulfone and RH-sulfoxide accounted for 3.4 and 0.9 percent of TRR in milk, respectively, of the total radioactivity in milk collected within 12 hours after application. Further identification for the rest of radioactivity (95.7 percent TRR of milk) was not conducted.

Goat

In a metabolism study on lactating goats, 0.88 mg/kg bw (equivalent to 38 ppm) of 2-carbonyl-^{14}C-methidathion was once administered by stomach tube. At 3 DAT (72 hours after the single dose), 1 percent AR of radioactivity was found in milk. Methidathion or its oxygen analogue was not found in milk. No further identification or characterization was conducted.

Summary of animal metabolism

When single or multi dose of methidathion was orally administered to cattle, radioactivity was detected in the most of tissues and milk. In milk, RH-sulfone and RH-sulfoxide were detected (<5 percent AR total), and methidathion and its oxygen analogue were not detected. Since information on metabolites was insufficient in milk or tissues, it was not possible to estimate metabolic pathway in livestock.

Environmental fate

On soil surface, degradation of methidathion in soil followed first order kinetic degradation with half-lives of 1.7 days under the sunlight and 2.6–5.8 days in the dark, depending on the existence of microorganisms and surfactant. Neither RH nor the methidathion oxygen analogue was produced by light degradation. Further identification was not conducted. The Meeting concluded that degradation of methidathion was rapid in soil.

Methods of analysis

The Meeting received seven methods of analysis used for the determination of methidathion in the supervised field trials. Six of them were similar GC methods with some modifications and one was an LC-MS/MS method. In the validation studies, spiked samples were not analysed at day zero. However, since analysis of at least one sample within 1 month after spiking resulted in satisfactory recovery, the Meeting considered that the analytical values at day zero would be almost 100 percent of spike.

For GC methods, methidathion was extracted with acetone or ethyl acetate, cleaned up, and analysed using GC coupled with FID, ECD or FPD. The Meeting confirmed that the methods were validated for methidathion in mandarin, apple, peach and cherry with an LOQ of 0.1 or 0.2 mg/kg and mango with an LOQ of 0.005 mg/kg.

For the LC-MS/MS method, methidathion was extracted with acetone, cleaned up, and analysed using LC-MS/MS. The Meeting confirmed that the method was validated for methidathion in peach, cherry and grape with an LOQ of 0.005 mg/kg and mango with a LOQ of 0.01 mg/kg.

Stability of pesticide residues in stored analytical samples

Stability studies on methidathion residues in fortified mandarin (up to 7 months), apple (up to 7 months), cherry (up to 2.5 months), peach (up to 9 months), grape (up to 10 months) and mango (up to 4 months) were available. Noting the various storage periods for matrices in the same group, the Meeting concluded that methidathion in high water and high acid content commodities stored at ≤ -20 °C was stable for at least 9 and 7 months, respectively. In supervised trials received at the current Meeting, all samples were kept frozen at ≤ -20 °C and analysed within 7 months from sampling except in two trials, where the data were not used in the assessment.

Definition of the residue

Plant commodities

In the metabolism studies on orange, tomato, common beans and alfalfa, parent methidathion was found in all primary crop commodities analysed (7.2 percent TRR in orange, 8.4–9.4 percent TRR in tomato, 1.3–6.0 percent AR in bean plant and 32–53 percent AR in alfalfa plant). The Meeting noted that suitable analytical methods exist to determine methidathion in plant commodities. The Meeting considered that parent methidathion was suitable marker for MRL-compliance.

Based on the plant metabolism studies, the following compounds could be included in the residue definition for dietary risk assessment: conjugate of RH with alanine, acetic acid, hydroxyacetic acid, lactic acid, methanol (GS-20685), cysteine and sulfoxide; desmethyl-methidathion and the oxygen analogue of methidathion.

For RH and its conjugates of alanine, lactic acid, acetic acid, hydroxyacetic acid, cysteine, methanol (GS-20685) or sulfoxide, the Meeting concluded that the same ADI as methidathion should apply (0-0.002 mg/kg bw) and no ARfD was necessary due to lack of phosphate moiety. The Meeting

noted that the total levels of RH (free and conjugated) in the metabolism studies were significant: 7.2 percent TRR (0.26 mg eq/kg) in peel and 82 percent TRR (0.21 mg eq/kg) in juice in the study on oranges; 36–37 percent TRR (2.2–4.0 mg eq/kg) in the study on tomatoes; 0.55–0.66 percent AR in the study on beans; and 0.33–0.86 percent AR in the study on alfalfa. The Meeting concluded that these RH conjugated compounds should be included in the residue definition.

For desmethyl methidathion, the Meeting concluded that the same ADI and ARfD as methidathion should apply (ADI: 0–0.002 mg/kg bw, ARfD: 0.01 mg/kg bw). The Meeting noted that the level of desmethyl methidathion in the study on tomato was significant (39–42 percent TRR, 2.3–4.8 mg eq/kg). The Meeting concluded that desmethyl methidathion should be included in the residue definition.

For oxygen analogue, it was found in the metabolism study of tomato, bean and alfalfa but not in the study on orange. In the case of tomato, as the ratio of oxygen analogue (0.37 mg eq/kg) to the parent compound (1.14 mg eq/kg) was higher than 10 percent, the Meeting concluded that oxygen analogue should be included in the residue definition.

The Meeting concluded that since the mechanism of toxicity was similar to that of methidathion, oxygen analogue should be considered together with the parent methidathion for dietary risk assessment. As the potency of the oxygen analogue as a AChE inhibitor was considered to be about four times that of methidathion, the Meeting agreed to apply a potency factor of 4 to the residues of the oxygen analogue for long-term and short term risk assessment.

In conclusion, the definition of the residue for compliance with the MRL for plant commodities: *methidathion*.

The definition of the residue for long-term dietary exposure assessment for plant commodities: *sum of methidathion, S-2,3,-dihydro-5-methoxy-2-oxo-1,3,4-thiadiazol-3-ylmethyl O-methyl phosphorodithioate (desmethyl methidathion) and 2,3-dihydro-5-methoxy-1,3,4-thiadiazol-2-one (RH; free and conjugate), and 4x S-2,3-dihydro-5-methoxy-2-oxo-1,3,4-thiadiazol-3-ylmethyl O,O-dimethyl phosphorothioate (oxygen analogue), expressed as methidathion*.

Definition of the residue for acute dietary exposure assessment for plant commodities: *sum of methidathion and 4× S-2,3-dihydro-5-methoxy-2-oxo-1,3,4-thiadiazol-3-ylmethyl O,O-dimethyl phosphorothioate, expressed as methidathion.*

Animal commodities

For cattle, parent methidathion was detected in muscle, kidney and fat but not in liver and milk. In addition, methidathion may be detected in egg yolk (See animal feeding study). The Meeting considered that parent methidathion alone was not a suitable marker for enforcement.

In the metabolism studies, a large portion of radioactivity was not identified. Due to lack of further information on metabolites, the Meeting could not establish residue definitions for animal commodities.

Results of supervised residue trials on crops

Since all the metabolites included in the residue definition for dietary risk assessment were not analysed in the supervised trials, and the information in the metabolism studies was not sufficient to estimate conversion factors, the Meeting could not estimate STMRs and HRs. The Meeting agreed to estimate maximum residue levels but not to recommend them for adoption.

Citrus fruits

Mandarins

The critical GAP for methidathion on mandarin in Japan is four foliar applications of 0.027 kg ai/hL and a PHI of 14 days.

No trials matched the Japanese GAP. The Meeting could not estimate a maximum residue level.

Pome fruits

Apple

The critical GAP for methidathion on apple in Japan is for two foliar applications of 0.024 kg ai/hL with a PHI of 30 days.

In trials matching the GAP in Japan, residues of methidathion in apple were (n=7): < 0.1 (7) mg/kg. In trials with one application at 0.024 kg ai/hL and a PHI of 30 days at the same location as the trials with two applications, residues of methidathion in apple were higher than with two applications in 2 trials: 0.10 and 0.11 mg/kg. Therefore, residues of methidathion in apple were ((n=7): < 0.1 (5), 0.10 and 0.11 mg/kg.

In these supervised trials, the concentration was expressed on the basis of fruit weight after removal of core. The Meeting considered that the contribution of the core to the weight of the whole fruit is 9.8–14 percent and concluded that correcting the residue levels using this weight/weight ratio would lead to the same maximum residue level.

The Meeting estimated a maximum residue level of 0.2 mg/kg.

Since the analytical data for compounds in the residue definition were not sufficient in the supervised trials and metabolism study was not sufficient to estimate conversion factors, the Meeting could not conclude the assessment.

Pear

The Meeting could not estimate maximum residue level for pears since no data were available.

Stone fruits

Cherries

The critical GAP for methidathion on cherries in Japan is three foliar applications at 0.027 kg ai/hL and a PHI of 7 days. In trials matching the GAP conducted in Japan, residues of methidathion in cherries were (n=9): < 0.01 (2), 0.01, 0.02, 0.04, 0.05 and < 0.1(3) mg/kg.

In the supervised trials, the concentration was expressed on the basis of fruit weight after removal of seeds. The Meeting considered that the contribution of the seed to the weight of the whole fruit is less than 10 percent and concluded that correcting the residue levels using this weight/weight ratio would lead to the same maximum residue level.

The Meeting estimated a maximum residue level of 0.3 mg/kg.

Since analytical data for compounds in the residue definition were not sufficient in the supervised trials and metabolism study was not sufficient to estimate conversion factors, the Meeting could not conclude the assessment.

Peaches

In the critical GAP for methidathion on peaches in Japan is for 2 trunk injections (0.15 kg ai/hL) followed by two foliar applications of 0.024 kg ai/hL with a PHI of 21 days.

In trials matching the GAP, residues of methidathion in peaches were (n=4): 0.006, 0.011, 0.020 and < 0.1 mg/kg. The Meeting could not estimate a maximum residue level due to insufficient number of trials.

Berries and other small fruits

Grapes

The critical GAP for methidathion on grapes in Japan is two foliar applications at 0.024 kg ai/hL and a PHI of 14 days.

In trials matching the critical GAP conducted in Japan, residues of methidathion in grapes were (n=5): 0.008, 0.01, 0.02, 0.05 and 0.18 mg/kg. The Meeting could not estimate a maximum residue level due to insufficient number of trials.

Tropical and sub-tropical fruits – inedible peel

Mango

The critical GAP for methidathion on mangoes is in Japan and consists of two foliar applications of 0.027 kg ai/hL and a PHI of 45 days. In trials matching the GAP conducted in Japan, residues of methidathion in mango was (n=4) 0.02, < 0.03, 0.04 and 0.08 mg/kg.

In one supervised trial, mango was treated with three foliar applications at the same concentration and PHI as cGAP. In the trial, the residue of methidathion in mango was 0.007 mg/kg, which was lower than residue data from 3 applications. The Meeting assumed that the trial was considered to approximate GAP since the first application applied 59 days before harvest did not contribute to the residues at harvest.

In the trials on mango conducted in Japan approximating the GAP residue level were (n=5): 0.007, 0.02, < 0.03, 0.04 and 0.08 mg/kg.

The Meeting noted that in the supervised trials, the concentration was expressed as the basis of fruit weight after removal of seeds. The Meeting considered that the contribution of the seed to the weight of the whole fruit is less than 10 percent and concluded that correcting the residue levels using this weight/weight ratio would lead to the same maximum residue level.

The Meeting estimated a maximum residue level of 0.15 mg/kg.

Since the analytical data for compounds in the residue definition were not sufficient in the supervised trials and metabolism study was not sufficient to estimate conversion factors, the Meeting could not conclude the assessment.

Tea, green, black

The Meeting could not estimate a maximum residue level for tea, green, black since no data were available.

Fates of residues during processing

Processing study on grape to dried grape was available. Degradation of methidathion was observed in the process and the processing factors were 0.02–0.35, depending on the temperature of drying. The Meeting assumed the worst case scenario (50 °C, 72 hours) and the processing factor from grape to dried grape was estimated 0.35.

A study on degradation of methidathion in fruit juices (orange and peach) was available. When juices were stored at 40 °C, methidathion was reduced (half-life of 3.8–4.1 days), but degraded more slowly at lower temperatures (half-lives of =114–115 days at 15 °C and 330–385 days at 0 °C). At ambient temperature, the Meeting considered that the degradation of methidathion in juices at the shelf could be negligible.

Residues in animal commodities

Farm animal feeding studies

A dairy cow feeding study was available to the Meeting. Methidathion in gelatine capsule was administered orally twice daily to three groups of dairy cow (four for each) for 66 days at levels equivalent to 7.5, 15 or 30 ppm. The residue levels of methidathion and oxygen analogue of methidathion in milk and any tissues were < 0.01 mg/kg and < 0.025 mg/kg, respectively.

A laying hen feeding study was available in open literature. Feed containing methidathion at levels of 10, 50, 100 or 500 ppm were fed *ad libitum*. The residue was not detected in egg yolk from 10 ppm group hens (LOQ: 0.002 mg/kg). In 50 and 100 ppm group, low level of methidathion residues (< 0.02 mg/kg) were detected in egg yolk. No information on residues was available.

Farm animal dietary burden

From the commodities evaluated, the only processed commodity appearring in the OECD feed table was apple pomace. Since processing factors from apple to apple pomace for methidathion, desmethyl methidathion, oxygen analogue and RH (free+conjugate) were not available, the Meeting could not estimate the concentration of methidathion and its metabolites in animal commodities.

Animal commodity maximum residue levels

Since no conclusion could be reached on a residue definition for animal commodities, the Meeting withdrew all previous recommendations for animal commodity maximum residue levels for methidathion.

RECOMMENDATIONS

Definition of the residue for compliance with the MRL for plant commodities: methidathion

Definition of the residue for long-term dietary exposure assessment for plant commodities: sum of methidathion, S-2,3,-dihydro-5-methoxy-2-oxo-1,3,4-thiadiazol-3-ylmethyl O-methyl phosphorodithioate and 2,3-dihydro-5-methoxy-1,3,4-thiadiazol-2-one (free and conjugate), and 4× S-2,3-dihydro-5-methoxy-2-oxo-1,3,4-thiadiazol-3-ylmethyl O,O-dimethyl phosphorothioate, expressed as methidathion

Definition of the residue for acute dietary exposure assessment for plant commodities: sum of methidathion and 4× S-2,3-dihydro-5-methoxy-2-oxo-1,3,4-thiadiazol-3-ylmethyl O,O-dimethyl phosphorothioate, expressed as methidathion.

Definition of the residue for animal products (for compliance with the MRL and for dietary exposure assessment): **a conclusion could not be reached**.

The residue is not fat soluble.

Table 53 Recommendations for residues of methidathion from the 2022 JMPR

CCN	Commodity	Maximum residue level (mg/kg)		STMR (mg/kg)	HR (mg/kg)
		New	Previous		
FC0226	Apple	W	0.5		
FS0013	Cherries	W	0.2		
FB0269	Grapes	W	1		
FC0206	Mandarins (including mandarin like hybrids)(subgroup)	W	5		
FP0230	Pear	W	1		
DT1114	Tea, green, black (black, fermented and dried)	W	0.5		

DIETARY RISK ASSESSMENT

No recommendations were made at the present meeting as the Meeting could not reach a conclusion on the residue definitions for animal commodities and sufficient residue data for metabolites were not available. No dietary risk assessment was conducted.

PYRIDATE (315)

First draft prepared by Mr C Sieke and Dr J Heidler, Federal Institute for Risk Assessment, Germany

EXPLANATION

Pyridate is an herbicide of the phenylpyridazine class used to control annual broad-leaved weeds. It acts by inhibiting the photosynthetic electron transport at the photosystem II. The IUPAC name of pyridate is *O*-6-chloro-3-phenylpyridazine-4-yl *S*-octyl thiocarbonate

Pyridate was scheduled at the Fiftieth Session of the CCPR for evaluation as a new compound by the 2020 JMPR, reviewed by the 2019 JMPR for toxicology, where an ADI of 0–0.2 mg/kg bw and an ARfD of 2 mg/kg were established. The residue assessment was rescheduled to the current JMPR.

The Meeting received information on identity, physicochemical properties, metabolism (plant, confined rotational crops and animals), environmental fate, methods of residue analysis, freezer storage stability, registered use patterns, supervised residue trials, fate of residues in processing, and livestock feeding studies.

IDENTITY

ISO common name:	Pyridate
IUPAC name:	*O*-6-chloro-3-phenylpyridazine-4-yl *S*-octyl thiocarbonate
CA nomenclature:	*O*-(6-chloro-3-phenylpyridazinyl) *S*-octyl thiocarbonate
CAS No.:	55512-33-9
CIPAC No.:	447
Synonyms:	CL 11344
Structural formula	Molecular formula:	$C_{19}H_{23}ClN_2O_2S$
Molecular mass:	378.91 g/mol

Specifications

Specifications for pyridate were not yet developed by FAO.

PHYSICAL AND CHEMICAL PROPERTIES

Table 1 Physical and chemical properties of pure pyridate

Property	Results	Method (test material)	Reference
Appearance	Colourless solid, slightly aromatic odour	Batch RS-0033: 98.9 percent purity (purified ai)	Kettner, 1995, PYRIDATE_001

Property	Results	Method (test material)	Reference
Melting point	26.5-27.8 °C	OECD 102, EEC A1 Batch RS-0033: 98.9 percent purity (purified ai)	Bates, 1996, PYRIDATE_002

METABOLISM AND ENVIRONMENTAL FATE

Metabolism studies were conducted using [^{14}C]-labelled pyridate at the pyridazine ring. The position of the label for the test substances is presented in the following figure:

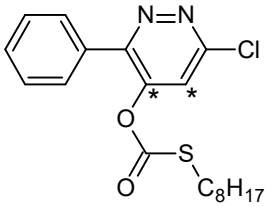

Figure 1 Structure of pyridate and position of radiolabels

Chemical names, structures and code names of metabolites and degradation products of pyridate are shown in Table 2.

Table 2 Known metabolites of pyridate

Code Names	Chemical Names (IUPAC)	Structure	Where found
Pyridate (CL 11344)	6-chloro-3-phenylpyridazine-4-yl-S-octyl-thiocarbonate	 378.9 g/mol	Plants matrices: broccoli (leaves), maize (leaves), peanut (forage, hay, hulls) Soil
Pyridafol (CL 9673)	6-chloro-4-hydroxy-3-phenylpridazine	 206.6 g/mol	Plants matrices: broccoli (leaves), maize (leaves), peanut (forage, hay) Animal matrices: Cow (kidney), goat (kidney, milk) Soil

Code Names	Chemical Names (IUPAC)	Structure	Where found
Pyridafol-O-methyl (Pyridafol-OMe; CL 9869)	6-chloro-4-methoxy-3-phenylpridazine	 220.7 g/mol	Plants matrices: peanut (forage, hay, hulls) Animal matrices: Goat (kidney) Soil

Plant metabolism

The metabolic fate in plants was investigated following foliar application of [4,5-pyridazine-^{14}C]-radiolabelled pyridate to broccoli, maize and peanut.

In all studies, pyridate did undergo rapid hydrolytic cleavage into pyridafol, which is considered the herbicidal active compound. Detoxification of pyridafol occurred mainly by glucosidic conjugation, yielding in the CL9673-N-glucoside and CL9673-O-glucoside. Further degradation led to highly polar metabolites, before the radioactivity was incorporated into the carbon pool of natural plant constituents.

Broccoli

A metabolism study with broccoli (variety: Italica) under combined greenhouse and outdoor conditions was performed with [4,5-pyridazine-^{14}C]-radiolabelled pyridate (Zohner, 1988, PYRIDATE_014). Broccoli plants received one foliar application at the 2–3 leaf stage using a rate of 1.8 kg ai/ha. Plant samples were taken at 0 (immediately after the treatment), 14, 45, 73, 94 and 108 DAT.

The homogenized sample material was extracted once with acetone, followed by four times with acetone/water (8:2). The radioactivity of each extract was determined by liquid scintillation counting (LSC), while for the separation of the metabolites the extracts were combined and analysed by thin layer chromatographs (TLC). Identification was accomplished by co-chromatography with non-radiolabelled standards. Conjugates were hydrolysed with 2 mol/L hydrochloric acid and β-glucosidase. The post extraction solids (PES) were subjected to combustion and determination of the radioactivity by LSC, as well as to hydrolysis with 2 mol/L acetonic hydrochloric acid in order to characterize the PES. The unextracted residue was also characterized by means of a cell wall fractionation using α-amylase, protease, pectinase and dioxane/2 mol/L hydrochloric acid (9:1).

The TRR and the extracted radioactivity are shown in Table 3. The TRR was highest at 20 mg eq/kg in leaves immediately after treatment and declined to 0.011 mg eq/kg in samples taken at 108 DAT (days after treatment). At 0.009 mg eq/kg, similar levels were found in the combined edible samples from 75, 96 and 108 DAT. Extraction with acetone and acetone/water (8:2) liberated at least 75 percent TRR, except for stems and roots where the extractability was lower with 55 percent and 34 percent TRR, respectively.

Table 3 Total radioactive residues and extracted residues after one foliar application of [4,5-pyridazine-^{14}C]-radiolabelled pyridate to broccoli, expressed as pyridafol equivalents

Matrix	DAT	TRR mg eq/kg	Extract mg eq/kg (% TRR)	PES mg eq/kg (% TRR)
Leaves	0	20	20 (100)	0.05 (0.31)
	14	6.1	5.7 (94)	0.35 (6.3)
	45	0.31	0.28 (86)	0.03 (14)
	108	0.011	0.008 (75)	0.003 (25)

Matrix	DAT	TRR mg eq/kg	Extract mg eq/kg (% TRR)	PES mg eq/kg (% TRR)
Edible parts (flowers)	75, 96, 108[1]	0.009	0.008 (84)	0.001 (16)
Stems	108	0.014	0.008 (55)	0.007 (45)
Roots	108	0.093	0.032 (34)	0.061 (66)

Notes:

[1] Edible parts were harvested at three intervals and combined.

The identification/characterization of radioactivity in broccoli leaves (0, 14, 45 DAT) and root is presented in Table 4. Characterization of the broccoli flowers was not performed due to their low radioactivity in the extract. Parent pyridate was a major identified residue in leaf samples from 0 and 14 DAT, accounting for 42–60 percent TRR (2.6–12 mg eq/kg), while in leaves from 45 DAT and in the root parent pyridate was not detected at all. As a major metabolite pyridafol was detected as well in in leaf samples from 0 and 14 DAT, accounting for 7.4–18 percent TRR (0.45–3.5 mg eq/kg). Additionally, the N- and O-glucoside of pyridafol was detected in leaf samples from 14 and 45 DAT accounting for 19–25 percent TRR (0.06–1.5 mg eq/kg). Two unknown components, M6 and M7, were detected at significant levels in leaf samples from 45 DAT and in the roots. Fractionation of the unextracted residue from selected leaf samples (14 or 45 DAT) demonstrated that the remaining radioactivity could be assigned to natural constituents such as starch, proteins, pectin and lignin.

Maize

A metabolism study with maize (variety: not stated) under combined greenhouse and outdoor conditions was performed with [4,5-pyridazine-^{14}C]-radiolabelled pyridate (Zohner, 1988, PYRIDATE_015). Maize plants received one foliar application at BBCH 16–17 using a rate of 1.8 kg ai/ha. Plant samples were taken at 0 (immediately after the treatment), 14, 45, 90 and 118 DAT. Over daytime, plants were exposure to natural environmental conditions and kept in greenhouse overnight.

The homogenized sample material was extracted with acetone (1st and 5th extraction) and with acetone/water (8:2) (2nd to 4th extraction). The radioactivity of each extract was determined by LSC, while for the separation of the metabolites the extracts were combined and analysed by TLC. Identification was accomplished by co-chromatography with non-radiolabelled standards. Conjugates were hydrolysed with 2 mol/L hydrochloric acid and β-glucosidase. The PES was subjected to combustion and determination of

the radioactivity by LSC, as well as to hydrolysis with 2 mol/L acetonic hydrochloric acid in order to characterize the PES. The unextracted residue was also characterized by means of a cell wall fractionation using α-amylase, protease, pectinase and dioxane/2 mol/L hydrochloric acid (9:1).

The TRR and the extracted radioactivity are shown in Table 5. The TRR was highest with 17 mg eq/kg in leaves immediately after treatment and declined to 0.5 mg eq/kg in treated leaf samples taken at 108 DAT. In newly grown plant parts, the radioactivity was significantly lower at maximum 0.04 mg eq/kg, while in maize grain it was even lower at around the LOQ. Extractability of the residue with acetone and acetone/water (8:2) was good, liberating at least 75 percent TRR for the treated leaves from 0, 14 and 45 DAT. It was lower at later sampling time points, newly grown plant parts and grains.

The identification/characterization of radioactivity in treated maize leaves (0, 14, 45, 90 and 108 DAT) is presented in Table 6. Characterization of the residue in all other matrices was not performed due to their low radioactivity in the extracts. Parent pyridate was a major identified residue in leaf samples from 0 and 14 DAT, accounting for 11–82 percent TRR (0.31–17 mg eq/kg), while in samples from later time points parent pyridate was around the LOD or lower. Pyridafol was detected as a major metabolite in treated leaf samples from 0 and 14 DAT, accounting for 15–16 percent TRR (0.44–2.6 mg eq/kg), but was significantly lower in samples from later time points. Additionally, the N- and O-glucoside of pyridafol was detected in treated leaf samples from 14 and 45 DAT accounting for 5.4–7.0 percent TRR (0.07–0.15 mg eq/kg). Two unknown components, M7 and M8, were detected in leaf samples from 14, 45 and 90 DAT at significant levels of 15–38 percent TRR (0.07–0.69 mg eq/kg). Fractionation of the unextracted residue from a 90 DAT leaf sample demonstrated that the remaining radioactivity could be assigned to natural constituents such as starch, proteins, pectin and lignin. The proposed metabolic pathway of pyridate is shown in Figure 2.

Notes:

[1] Sum of an unresolved region.

A second study with maize (variety: LG 9) under outdoor conditions was performed with [4,5-pyridazine-^{14}C]-radiolabelled pyridate (Ellgehausen, 1987, PYRIDATE_016). Plants received one foliar application at BBCH 14–15 using a rate of 1.73 kg ai/ha. Plant samples were taken at 0 (immediately after the treatment), 14, 45, 90 and 148 DAT.

The TRR in the homogenized sample material from all sampling time points was determined by combustion followed by LSC. Thereafter, aliquots of the homogenized treated leaves from 14, 45 and 148 DAT were sequentially extracted with (1) acetone, (2) acetone/water (8:2), (3) acetone in a Soxhlet overnight and (4) with acetone/0.1 mol/L hydrochloric acid (8:2). The radioactivity of each extract was determined by LSC, while for the characterization of the metabolites the extracts from steps 1–3 were combined for the treated leaves from 14 DAT and analysed by TLC and GC-FID. Identification was accomplished by co-chromatography with non-radiolabelled standards. Extracts from the 14 and 45 DAT samples were also hydrolysed with 2 mol/L and 4–6 mol/L hydrochloric acid. The PES was subjected to combustion and determination of the radioactivity by LSC.

The TRR and the extracted radioactivity are shown in Table 7. The TRR was highest with 168 mg eq/kg in leaves immediately after treatment and declined to 0.27 mg eq/kg at 148 DAT. At harvest, the TRR in maize grain was equal to 0.014 mg eq/kg. Extractability of the residue was good for leaves from 14 DAT, liberating at least 72 percent TRR, but was lower at later sampling time points. Maize grain was not extracted due to the low level of radioactivity in the samples.

Husks/Stalks	148	Not extracted		

The identification/characterization of radioactivity was only performed in 14 DAT treated maize leaves and in new plant parts (leaves and stems) (Table 8). For the new plant parts,

identification/characterization was only reported for the water-soluble radioactivity, while the dichloromethane-soluble fraction was not further analysed. This was justified by a low level of radioactivity and a high amount of natural constituents in the dichloromethane-soluble fraction, despite having a similar level of radioactivity as the water-soluble fraction. Hence, a full mass balance could not be calculated. Parent pyridate was a minor residue in treated leaves and in new plant parts, accounting for 1.7–3.0 percent TRR (0.01–0.80 mg eq/kg). Pyridafol was detected as a minor metabolite only in treated leaf samples, accounting for 5.3 percent TRR (1.4 mg eq/kg). With M2 and M3 two major unknown metabolites were detected at 20–41 percent TRR (5.3–11 mg eq/kg). Further characterization of both metabolites by acid hydrolysis demonstrated that only M2 was susceptible and was assumed to be a conjugated derivative of pyridafol with an additional hydroxyl group. Unknown M3, not susceptible to acid hydrolysis, was assumed to be a neutral or weakly acidic metabolite susceptible to alkylating reagents. Additional unknown components were metabolite M1 and M5, ranging between 5.2–9.5 percent TRR (1.4–2.5 mg eq/kg). The proposed metabolic pathway of pyridate is shown in Figure 2.

Table 8 Distribution of radioactivity found in treated leaves of maize plants after one foliar application of [4,5-pyridazine-^{14}C]-radiolabelled pyridate, expressed as pyridate equivalents

Notes:

[1] Sum of M3 found in the water- and dichloromethane phase.

[2] Individual components found in the water phase, only. The dichloromethane phase was not reported. Therefore a full mass balance could not be conducted.

Peanut

A metabolism study with peanut (variety: not stated) under combined greenhouse and outdoor conditions was performed with [4,5-pyridazine-^{14}C]-radiolabelled pyridate (Zohner, 1988, PYRIDATE_017). Peanut plants received one foliar application when the plants reached a height of 12.7 cm, using a rate of 3.6 kg ai/ha. Plant samples were taken at 0 (immediately after the treatment), 14, 45 and 219 DAT.

The homogenized sample material was extracted once with acetone, followed by four times with acetone/water (8:2). The radioactivity of each extract was determined by LSC, while for the separation of the metabolites the extracts were combined and analysed by TLC. Identification was accomplished by co-chromatography with non-radiolabelled standards. Conjugates were hydrolysed with 2 mol/L hydrochloric acid and β-glucosidase. PES were subjected to combustion and determination of the radioactivity by LSC, as well as to hydrolysis with 2 mol/L acetonic hydrochloric acid in order to characterize the PES. The

unextracted residue was also characterized by means of a cell wall fractionation using α-amylase, protease, pectinase and dioxane/2 mol/L hydrochloric acid (9:1).

The TRR and the extracted radioactivity are shown in Table 9. The TRR was highest with 59 mg eq/kg in leaves immediately after treatment and declined to 0.22 mg eq/kg in treated leaf samples taken at 219 DAT. In the nut meat, radioactivity was low at 0.04 mg eq/kg. Extractability of the residue with acetone and acetone/water (8:2) was good, liberating at least 78 percent TRR from the treated leaves at 0 and 14 DAT, but was lower in all other matrices.

Table 9 Total radioactive residues and extracted residues after one foliar application of [4,5-pyridazine-^{14}C]-radiolabelled pyridate to peanut plants, expressed as pyridafol equivalents

Matrix	Sampling interval DAT	TRR mg eq/kg	Extract mg eq/kg (% TRR)	PES mg eq/kg (% TRR)

	14	28	22 (78)	6.2 (22)
	45	10	5.3 (54)	4.9 (48)
	219	0.22	0.09 (44)	0.13 (59)
Hay	45	38	24 (64)	14 (36)
	219	1.5	0.55 (43)	0.92 (63)
Hulls	219	0.36	0.13 (38)	0.23 (64)
Nut meat	219	0.04	0.01 (33)	0.03 (75)

The identification/characterization of radioactivity in peanut forage, hay and hulls (0, 14, 45 and 219 DAT) is presented in Table 10. Characterization of the residue in the nut meat was not performed due to its low radioactivity in the extract. Parent pyridate was a major identified residue only in forage samples from 0 DAT, accounting for 86 percent TRR (51 mg eq/kg), while in all other samples levels were significantly lower. Among major metabolites, only pyridafol in 0 DAT forage samples and the sum of the N- and O-glucoside of pyridafol in 14 DAT forage samples occurred at 10 percent TRR (6.2 mg eq/kg) and 20 percent TRR (5.5 mg eq/kg), respectively. Further, two unknown components, M6 and M7, were detected as major residues in basically all samples, except forage, from 0 DAT. Further characterization of both metabolites by acid hydrolysis as well as treatment with β-glucosidase demonstrated that only M7 was susceptible and was assumed to be a conjugate. A minor metabolite, only identified in the 215 DAT samples was CL 9869, accounting for up to 4.7 percent TRR (0.07 mg eq/kg). The cell wall fractionation of the unextracted residue from a 45 DAT forage sample demonstrated that the remaining radioactivity could be assigned to natural constituents such as starch, proteins, pectin and lignin. The proposed metabolic pathway of pyridate in plants is shown in Figure 2.

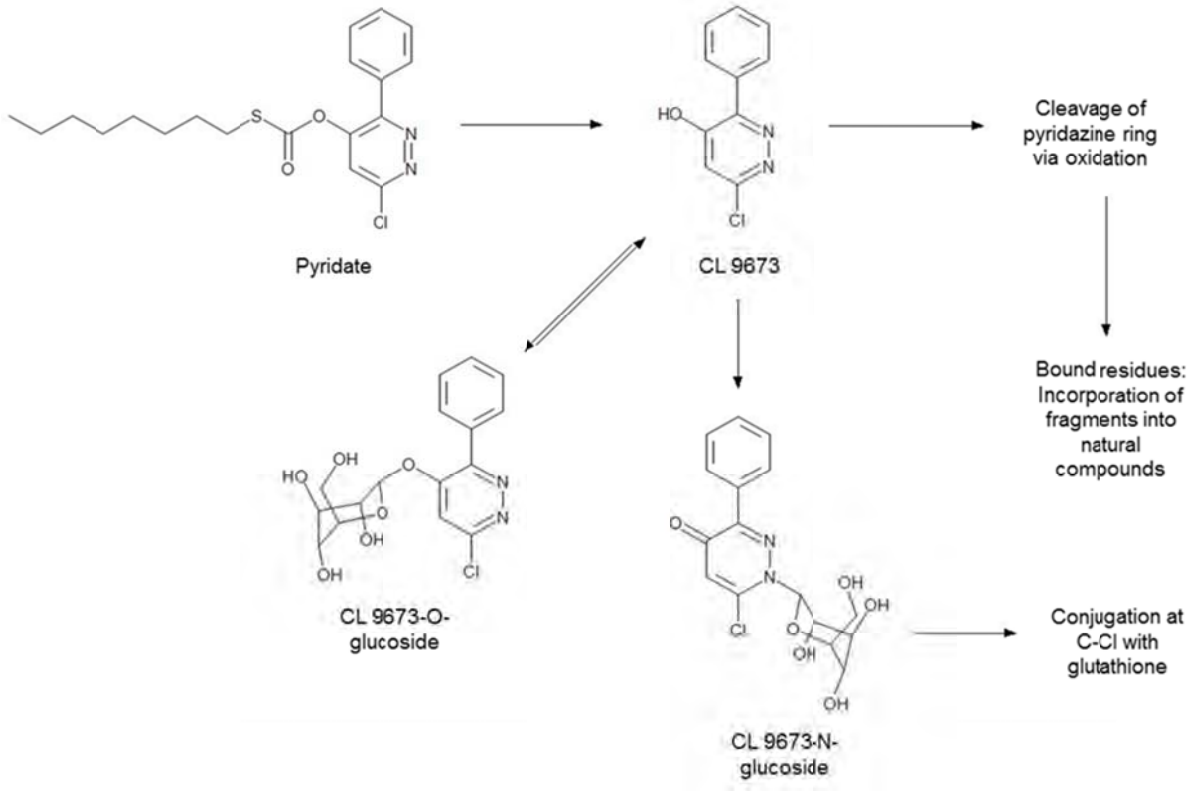

Figure 2 Proposed metabolic pathway of pyridate in broccoli, maize and peanut.

ENVIRONMENTA FATE

The Meeting received studies on aerobic soil degradation, soil photolysis and on the behaviour in confined rotational crops.

Aerobic soil degradation

The rate of degradation of pyridate and its metabolite pyridafol was studied in four aerobic soils using [4,5-pyridazine-^{14}C]-radiolabelled pyridate at a nominal application rate of 3.6 mg/kg oven dry soil, corresponding to 2690 g ai/ha (Morgenroth, 1995, PYRIDATE_022). One soil (Speyer 2.2 SP 211) was treated at a rate of 1.8 mg/kg, equivalent to a field application rate of 1350 g ai/ha. Soil characteristics are shown in Table 11.

Table 11 Characteristics of the soils used in study by Morgenroth (1995)

Soil	Classification (USDA)	Sand (%)	Silt (%)	Clay (%)	pH (KCl)	OC (%)	CEC (mval/kg)	MWHC (g/100 g)	C_{mic} (mg/kg)
Speyer 2.2	Sand	91.3	4.7	4.0	6.0	2.58	100	39.4	318
Speyer 2.2 SP 211	Loamy sand[a]	81.9	13.0	5.1	6.0	2.29	97	44.3	642
Auboden	Silt loam	67.3	26.5	6.2	7.5	1.80	202	47.7	294

Les Evouettes	Silt loam/loam	59.4	29.3	11.3	6.1	1.40	155	55.3	364

Notes:

[a] = DIN classification

The test system was maintained in the dark at a nominal temperature of 20 ± 2 °C for 350 days (Speyer 2.2) or 96 days (all other soils). Volatile organics and CO_2 were trapped with ethanediol and 2 mol/L NaOH, respectively. Samples were taken at increasing intervals after the application.

The soil samples were sequentially extracted with acetonitrile (+0.5 percent acetic acid), acetonitrile/water (+0.5 percent acetic acid) (4:1), methanol (+0.5 percent acetic acid) and a Soxhlet extraction with acetone. Extracts were analysed by LSC for total radioactivity and by TLC and/or HPLC against reference standards to identify metabolites. The PES was further extracted with 0.5 mol/L NaOH to liberate unextracted radioactivity associated with the humin, fulvic acid and humic acid fractions. The soil remaining after the extraction was combusted followed by LSC.

Parent pyridate declined from 92–104 to <0.1–1.3 percent of applied radioactivity (AR) over the study time (Tables 12 and 13). Levels of metabolite pyridafol increased to a maximum of 72–90 percent AR over a course of 2–3 days, before declining to 3.1–13 percent AR at the end of study. Similar, levels of pyridafol-OMe peaked between days 7–64 at 3.5–6.1 percent AR Additionally, some unidentified radioactivity was detected at up to 6 percent AR. Further analysis of the bound residues from Speyer 2.2 soil after 28 and 64 days showed 4.1–7.0, 5.6–8.4, and 13–31 percent of the applied radioactivity was associated with the fulvic acid, humic acid and humin fractions, respectively.

Calculated $DegT_{50/90}$ values for pyridate and its metabolite pyridafol are summarised in Table 14. Pyridate was rapidly degraded in soil under aerobic conditions with normalised $DegT_{50}$ values, ranging from 0.3 to 3.3 days. Normalised $DegT_{50}$ values for the major metabolite pyridafol (pyridafol) ranged from 17 to 43 days.

Table 14 Calculated $DegT_{50/90}$ values for [4,5-pyridazine-^{14}C]-radiolabelled pyridate and its metabolite pyridafol in aerobic soils

In a second study, the degradation of the pyridate metabolite pyridafol was investigated in four soils under aerobic conditions. Soils were treated with [4,5-pyridazine-^{14}C]-radiolabelled pyridafol at a nominal application rate of 2.9 mg/kg dry soil, corresponding to a field application rate of 1800 g ai/ha (Zohner, 1985, PYRIDATE_023). Soil characteristics are shown in Table 15.

Table 15 Characteristics of the soils used in study by Zohner, 1985

Soil	Classification (USDA)	Sand (%)	Silt (%)	Clay (%)	pH	OC (%)[a]	CEC (mval/kg)
Auboden	Silty loam	11.8	79.1	9.1	7.5	1.68	150

Ranker	Sandy loam	67.3	20.9	11.8	5.8	0.99	104

Notes:
[a] OC = OM/1.724.

Test systems were maintained in the dark at a nominal temperature of 18–23 °C for 70 days. Since in a preliminary study no volatile ^{14}C-compounds were detected, only CO_2 was trapped with 2 mol/L KOH. Samples were taken at 0, 8, 16, 23, 30 and 70 days after application.

The soil samples were sequentially extracted with acetone followed by water saturated n-butanol in a Soxhlet apparatus. Liquid samples were analysed by LSC for total radioactivity and by TLC against reference standards to identify metabolites. The soil remaining after extraction was combusted followed by LSC.

Pyridate metabolite pyridafol declined in all soils from 83–94 percent AR to 21–28 percent AR over 70 days while levels of metabolite pyridafol-O-methyl generally increased at up to 16 percent AR

(Table 16). Similar, levels of $^{14}CO_2$ peaked at day 70, accounting for up to 25 percent AR. Unextracted radioactivity was determined at day 70 only and accounted for 31–37 percent AR (Table 16).

Calculated $DegT_{50/90}$ values for pyridafol and pyridafol-OMe are summarised in Table 17. Normalised $DegT_{50}$ values for pyridafol) ranged from 20 to 28 days. Normalised $DegT_{50}$ values for pyridafol-OMe ranged from 14 to 25 days. For one soil (Auboden), no reliable $DegT_{50}$ value could be derived.

In a third study, the degradation of the pyridate metabolite pyridafol-OMe (CL 9869) was investigated in three soils under aerobic conditions. Soils were treated with [4,5-pyridazine-^{14}C]-radiolabelled pyridafol-OMe at a nominal application rate of 0.14 mg/kg dry soil, corresponding to a field application rate of 107 g ai/ha (Mewes, 1996, PYRIDATE_024). Soil characteristics are shown in Table 18.

Table 18 Characteristics of the soils used in study by Mewes, 1996

Soil	Gramastetten	Flaach	Feldkirchen
USDA Classification	Sandy loam	Sandy clay loam	Sandy loam
Clay (< 0.002 mm) (%)	16	25	10

Organic carbon (%)	2.6	1.3	1.1
CEC (mmol/z/kg soil)	135	122	54

Test systems were maintained in the dark at a nominal temperature of 20±1 ˚C for 129 days. Volatile organics and CO_2 were trapped with ethanediol and 0.25 or 2.5 mol/L NaOH, respectively. Samples were taken at 0, 2, 4, 8, 18, 35 and 64 days after application for all soils and additionally at 88 and 129 days for Gramastetten soil.

The soil samples were sequentially extracted with acetone/water (8:2) or methanol/water (8:2) followed by acetone/0.2 mol/L HCl (1:1), acetone/1 mol/L HCl (1:1) and water. Extracts from the first and second extraction were further cleaned up by SPE on a C18 cartridge. Liquid samples were analysed by LSC for total radioactivity and by TLC and HPLC against reference standards to identify metabolites. The soil remaining after extraction was combusted followed by LSC.

Pyridate metabolite pyridafol-OMe declined in all soils from 90–98 percent AR to 4.7–7.2 percent AR over the study time, while levels of metabolite pyridafol generally increased up to 2.7–6.3 percent AR at day 8, before decreasing to 0.2–1.5 percent AR at the end of the study (Table 19). Levels of $^{14}CO_2$ increased over the study time, accounting for up to 12–43 percent AR. Similar, unextracted radioactivity increased as well, accounting for 35–45 percent AR at the end of the study.

The calculated $DegT_{50/90}$ values for pyridafol-OMe (CL 9869) are summarised in Table 20. Pyridafol-OMe degraded rapidly in the test soils under aerobic conditions with SFO $DegT_{50}$ values ranging from 12 to 13 days.

Table 20 Calculated $DegT_{50/90}$ values for [4,5-pyridazine-^{14}C]-radiolabelled pyridafol-OMe in aerobic soils

Flaach	12.6	41.9	SFO
Feldkirchen	12.0	39.9	SFO

Notes:

[a] No reliable fit (not significant).

Soil photolysis

The soil surface photolytic behaviour of pyridate was investigated in a sandy loam soil using [4,5-pyridazine-^{14}C]-radiolabelled pyridate at a nominal application rate of 14 mg/kg, equivalent to 2000 g ai/ha. (Van Dijk & Baranowski, 1992, PYRIDATE_025). Soil characteristics are shown in Table 21.

Table 21 Characteristics of the soil used in study by Van Dijk & Baranowski, 1992

Soil	Classification (USDA)	Sand (%)	Silt (%)	Clay (%)	pH[a]	OC[b] (%)	CEC (mval/kg)	MWHC (g/100 g)
Ripperdan	Sandy loam	72.0	23.0	5.0	5.8	1.8	53	27.1

Soil samples were prepared on glass plates (~1 mm thick) and subjected to intermittent irradiation (12 hours light/dark cycles) for 31 days at 22 ± 2 °C using a xenon irradiation source with filters to eliminate wavelengths of 290 nm. Dark control samples were prepared in parallel. Volatile

organics and CO_2 were trapped with ethanediol and NaOH (molarity not specified), respectively. The irradiated and non-irradiated soil samples were analysed at 0, 2, 4, 8, 17 and 31 days.

The soil samples were extracted twice with acetonitrile/acetic acid (99.5+0.5), once with methanol/acetic acid (99.5+0.5) and once with methanol/0.5 percent acetic acid in water (8:2). Additionally samples were extracted exhaustively with acetonitrile/acetic acid (99.5+0.5) by refluxing for 16 hours. Extracts were analysed by LSC and TLC to determine the radioactivity and metabolite pattern, respectively. The soil remaining after extraction was combusted followed by LSC.

The percentage recovery of the applied radioactivity in irradiated moist and dark soil is presented in Table 22. Parent pyridate declined from 81 percent to 1.8 percent AR over the irradiation time, while metabolite pyridafol increased from 7.8 percent to 51 percent AR at day 4, before declining to 25 percent AR at day 31. At day 31, ultimate degradation via mineralisation to CO_2 accounted for 12 percent AR and unextracted radioactivity for 27 percent AR). In the dark controls, pyridate was hydrolysed to pyridafol as well, peaking at 57 percent AR at day 31. However, from day 4 onwards, no further significant degradation of pyridate was observed and no CO2 or volatiles were detected.

Calculated photolysis $DegT_{50}$ values for pyridate and pyridafol were 1.8 and 19 days, respectively. The results of the kinetic assessment are summarized in Table 23. Kinetic evaluation of the dark samples was not possible due to strong data scattering.

Table 23 Calculated photolysis $DegT_{50/90}$ values for [4,5-pyridazine-^{14}C]-radiolabelled pyridate and its metabolite pyridafol in soil

Substance	Conditions	$DegT_{50}$ (days)	$DegT_{90}$ (days)	Kinetics
Pyridate	Irradiated	1.8	5.9	SFO
	Dark	No reliable fit owing to data scattering		
Pyridafol (pyridafol)	Irradiated	19	65	SFO→SFO
	Dark	No reliable fit owing to data scattering		

Confined rotational crops

A confined rotational crop study under mixed outdoor and indoor conditions was conducted with [4,5-pyridazine-^{14}C]-radiolabelled pyridate applied at a rate of 1.8 kg ai/ha to a silty loam soil (Zohner, 1985, PYRIDATE_026). After plant-back intervals (PBIs) of 28 and 56 days, the nature and level of radioactive residues were investigated in lettuce (variety Kagraner Sommer (1st rotation); Grüner Escariol (2nd rotation)), carrots (variety Nantaise) and spring barley (variety not stated). Crops were harvested from the 28 day PBI, at 97 DAT for lettuce, 133 DAT for carrots and 163 DAT for barley, while crops from the 56 day PBI were harvested at 156 DAT for lettuce, 169 DAT for carrots and 209 DAT.

Ground soil samples were combusted prior to the determination of total radioactivity by LSC, while liquid samples such as extracts were directly measured by LSC. In order to characterize and identify the radioactivity present, soil samples were exhaustively extracted firstly with acetone, followed by water saturated n-butanol in a Soxhlet apparatus, while plant samples were extracted sequentially with methanol, followed by three times with methanol/water (8:2). Conjugates present in the extracts were hydrolysed overnight with 2 mol/L HCl. For the characterization and identification of the radioactivity, TLC against reference standards was applied.

Radioactive residues in soils samples decreased from 1.1 mg eq/kg at 0 DAT to 0.28 mg eq/kg over 97 days and remained fairly constant up to the last sampling time point (Table 24).

Table 24 TRR and extractability of radioactive residues in soil samples (soil layer 0–10 cm)

Soil sample (Event)	Total	Extracted		Unextracted	
	mg eq/kg	mg eq/kg	% TRR	mg eq/kg	% TRR
0 DAT (date of application)	1.1	1.1	99	<0.02	1

209 DAT (harvest barley, 2nd PBI)	0.39	0.068	18	0.32	82

Notes:

[1] Soil layer 0-21 cm.

Radioactivity in plant samples was generally low, peaking in barely straw at 0.1 mg eq/kg. In edible plant matrices, the TRR was highest in barley grain at up to 0.030 mg eq/kg, while in lettuce and carrot root radioactivity remained at <0.01 mg eq/kg (Table 25). Samples from the later PBIs showed similar levels of radioactivity, often slightly higher compared to the earlier PBI. Extractability of samples from the 28 day PBI ranged between 57–83 percent TRR, except for wheat grain where the extractability was significantly lower. Extractability of the 56 day PBI samples was generally lower as well (Table 25). Due to low levels of radioactivity, lettuce, carrot and barley grain samples were not analysed further.

Characterization and identification of the radioactivity was only performed in the extracts of barley straw. While levels of parent pyridate or any other metabolite were constantly <0.01 mg eq/kg, the main portion of the extracted radioactivity was allocated to saccharides. No characterization of the unextracted straw residue was performed. Rather a comparison to primary crop metabolism studies was done, stating that in those studies the large fraction of unextracted radioactivity could be allocated to natural constituents such as cellulose, starch, proteins, lignin etc.

Animal metabolism

Metabolism studies were provided for ruminants (lactating cow and goat) and poultry (laying hens and broiler chicken) using [4,5-pyridazine-^{14}C]-radiolabelled pyridate. Metabolism in laboratory animals was evaluated by the WHO Panel of the current Meeting.

Ruminants

A metabolism study with one lactating cow was performed with [4,5-pyridazine-^{14}C]-radiolabelled pyridate (Cameron, *et al*., 1989, PYRIDATE_018). The compound was administered once at a dose of 0.3 mg/kg bw (equivalent in feed not stated) at day 1 and 14 by intrarumenal injection. After administration of the first dose, urine and faeces were collected once daily for 7 consecutive days (except urine which was collected three times within the first 24 hours). Milk was collected twice daily throughout the study. Blood samples were taken in increasing intervals within 7 days after the first administration. The animal was sacrificed approximately 6 hours after administration of the second dose and organs, tissues and body fluids were collected.

Total radioactivity in liquid samples such as urine, plasma, milk and various extracts were directly measured by LSC. Faecal, whole blood and tissue samples were subjected to combustion prior to the determination of total radioactivity by LSC. Liver and kidney samples were homogenized with methanol. Liver samples were further cleaned up on C18 cartridges. Characterization of the extracts was carried out by TLC against reference standards.

After three days, the elimination of administered radioactivity was complete. The main route occurred via urine (92 percent AR), followed by faeces (8.6 percent AR). In all other organs, tissues and body fluids, radioactivity was significantly lower. A summary of the recovered radioactivity is presented in Table 26 and Table 27.

In milk the total radioactivity was very low, reaching a maximum of 0.03 mg eq/kg after 7 hours. After 31 hours no radioactivity was detected in any milk samples. The results are summarized in Table 28.

Table 28 Recovered radioactive residues in milk after the first intrarumenal injection of [4,5-pyridazine-^{14}C]-radiolabelled pyridate to a lactating cow

Days	Time (hours)	mg eq/kg	% TRR
1 (morning)	0	0.0	0.0
1 (afternoon)	7	0.03	0.1
2 (morning)	23	0.01	0.05
2 (afternoon)	31	0.0	0.01
3 (morning) – 8 (morning)	47-168	0.0	0.0

Characterization of the radioactivity in edible tissues was only done for liver and kidney. While no information was given on the extractability of the residue, co-chromatography of the extracts with reference standards identified pyridafol in kidney (level not given), as well as pyridafol-N- and O-glucoside (0.0–0.1 mg eq/kg) in liver.

A second metabolism study with one lactating goat was performed with [4,5-pyridazine-^{14}C]-radiolabelled pyridate (Ellgehausen, 1987, PYRIDATE_019). The compound was administered orally once

daily to one lactating goat at 2.8 ppm (0.38 mg/kg bw) for 10 consecutive days. Urine and feces were collected once daily (also more frequently during the depuration phase), while milk was collected twice daily. The animal was sacrificed approximately 24 hours after the last dose and samples of organs, tissues and body fluids were collected.

Total radioactivity in liquid samples such as urine, bile, cage wash and various extracts were directly measured by LSC. Faecal, blood, milk and tissue samples were subjected to combustion or digestion prior to the determination of total radioactivity by LSC.

After homogenization, liver and kidney samples were extracted four times with acetone/water (8:2), followed by one acetone Soxhlet extraction. The extracts were evaporated to the aqueous remainder and partitioned against dichloromethane. The radioactivity in unextracted residue was determined by combustion followed y LSC. Milk samples were deproteinated with acetone, followed by liquid-liquid partitioning against n-hexane/dichloromethane (1:1). Only urine samples were subjected to hydrolysis with 1 mol/L hydrochloric acid. Characterization of the extracts was carried out by TLC, as well as by GC-FID and GC-MS.

The total recovery of the administered radioactivity was equal to 103 percent. The majority of the radioactivity was found in urine (95 percent AR) followed by faeces (6.5 percent AR). Radioactive residues in the edible tissues were low at 0.019 mg eg/kg and 0.033 mg eq/kg in liver and kidney, respectively. In milk, residues were low as well at 0.04 mg eq/kg. A summary of the recovered radioactivity is presented in Table 29 and Table 30.

In milk, the detected radioactivity was very low, ranging between 0.015–0.048 mg eq/kg. The results are summarized in the following Table 31. A plateau was reached after 3 days of consecutive administration of the compound Figure 3.

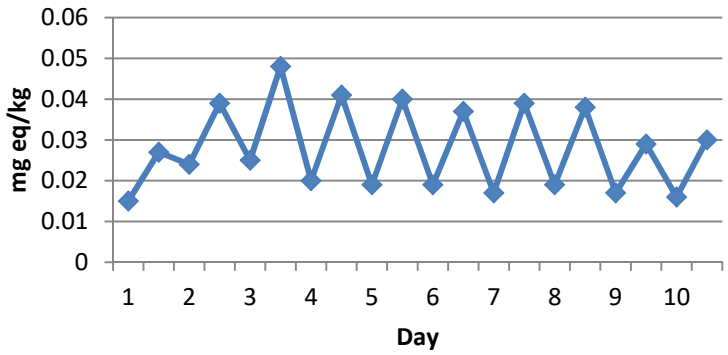

Figure 3 Time course of the concentrations of pyridate in milk

Extraction with acetone/water (8:2) followed by acetone released 63 percent TRR from liver and 87 percent TRR from kidney. Since radioactivity was low, identification was only successful in kidney, where metabolites pyridafol and pyridafol-OMe were assumed to be present at 32 percent TRR (0.010 mg eq/kg) and 48 percent TRR (0.015 mg eq/kg), respectively (Table 32). In milk only CL-9673 was identified at 49–71 percent TRR (0.012–0.015 mg eq/kg) (Table 33).

Poultry

A metabolism study was performed with 6 laying hens and 6 broiler chickens receiving a single oral dose of [4,5-pyridazine-^{14}C]-radiolabelled pyridate at 2.5–4.7 ppm (0.2 mg/kg bw) (Cameron, *et al*., 1989, PYRIDATE_020). Excreta were collected once daily up to 96 hours post dose, while eggs were collected twice daily if possible and separated in to egg yolk and white. All animals were sacrificed at 96 hours post dose, washed, plucked and rewashed prior to analysis for total radioactivity. No individual organs or tissues were collected.

After dilution with water if necessary, the total radioactivity in liquid samples such as egg yolk and white, cage wash and solutions was directly measured by LSC. Excreta samples were subjected to combustion prior to the determination of total radioactivity by LSC.

Within 24 hours post dose, the majority of the radioactivity was found in excreta at 93–96 percent, increasing to 97–99 percent after 96 hours, demonstrating fast elimination of the compound after cessation of the dosing (Table 34).

Table 34 Mean recovered radioactive residues after a single oral administration of [4,5-pyridazine-^{14}C]-radiolabelled pyridate to laying hens and broiler chickens

Sample	Mean recovered, in %AR	
	Laying hens (n=6)	Broiler (n=6)
Excreta (0-96 h)	99	97
Cage wash (0-96 h)	3.2	5.9
Cage debris (0-96 h)	2.3	0.82
1st bird wash	0.05	0.05
2nd bird wash	0.09	0.07
Carcass	0.43	0.20
Total (0-96h)	105	104

Detected radioactivity in egg yolks and egg whites was consistently <LOQ for throughout the sampling time of 0–96 hours post-dose, with the exception of egg whites collected at 24–48 hours post dose with a mean of 0.03 percent AR (0.004 mg eq/kg).

No further identification or characterization of the radioactive residues in organs or tissues was performed. However, in excreta metabolites pyridafol and hydroxylated pyridafol accounted for up to 74 percent TRR and 44 percent TRR, respectively.

A second metabolism study was performed with 9 laying hens receiving [4,5–pyridazine-^{14}C]-radiolabelled pyridate orally once daily for 5 consecutive days at ~3 ppm (0.19 mg/kg bw) (Ellgehausen, 1987, PYRIDATE_021). Excreta and eggs were collected once daily and during the depuration phase additionally at 4, 8, and 24 hours after the last treatment. Eggs were separated in yolk and white. Three hens each were sacrificed at 8 hours, 3 days and 7 day after the final dose and liver, kidney, stomach, heart, muscle, brain, skin, blood, ovaries and spleen were collected.

Samples of blood/plasma, tissues, organs, egg yolk and white were treated with tissue solubiliser followed by determination of the total radioactivity by LSC. Excreta and cage wash were lyophilized and subjected to combustion prior to the determination of total radioactivity by LSC.

The majority of the radioactivity was found in excreta, at 93–96 percent AR, indicating rapid elimination (Table 35). Radioactive residues in the edible matrices were generally low, peaking at 0.04 mg eq/kg in kidney after 8 hours depuration. An even lower radioactivity was observed in egg samples with maximum residues in yolks and whites at 0.007 mg eq/kg and 0.01 mg eq/kg, respectively (Table 36). No further identification or characterization of the radioactive residues in organs or tissues was performed.

Plant materials

Method No. 758 a (Bayzer & Heegemann, 1983, PYRIDATE_027)

The sample material is homogenized with an alkaline solution of ammonium acetate, acetone and morpholine (100+20+0.5) (pH 9 with NH_3), thereby converting pyridate to pyridafol. The extract is evaporated to the aqueous remainder, reconstituted in an alkaline solution of ammonium acetate and washed with dichloromethane. The conjugates in the alkaline phase are hydrolysed by refluxing with 0.05 mol/L sulfuric acid in methanol (pH 4–5). The hydrolysed phase is adjusted to pH 8–9 with ammonia, evaporated to dryness and partitioned between ammonium acetate and dichloromethane, firstly at pH 9, then at pH 4.5 and once re-extracted at pH 9.

Final determination of pyridafol was done by HPLC with column switching technology using a Polygosil-$N(CH_3)_2$ column and a Spherisorb ODS and detection at 280/300 nm (LC-LC-UV). Quantitation was done with external standards in solvent.

Partially recoveries were outside of the acceptable range, especially for pyridate as pyridafol and pyridafol-O-glucoside as pyridafol (Table 38). Also, recoveries were corrected for blank values, which not common practice in pesticide analysis. In conclusion, data generated with this method cannot be considered as reliable.

Table 38 Recovery data for the common moiety method No. 758 a measuring pyridate and its metabolites pyridafol and pyridafol-O/N-glucosides in various plant matrices using LC-LC-UV

Method No. 758 d (Pfarl, 1989, PYRIDATE_028)

The sample material is homogenized with acetone/ammonium acetate (5:1) + 0.5 mL morpholine, thereby converting pyridate to pyridafol. The extract is evaporated to a "syrup-like" remainder, reconstituted in an alkaline ammonium acetate solution (pH 9) and washed with dichloromethane. The conjugates in the alkaline phase are hydrolysed by adding 1 mol/L sulfuric acid (pH 4) and letting the mixture react at 60 °C for 40 minutes. Following the hydrolysis, the mixture is partitioned against dichloromethane, the aqueous phase is discarded and the organic phase is cleaned up on a silica cartridge. CL9673 is eluted with methanol/dichloromethane (5:100), the eluate is evaporated to dryness, and the remainder is reconstituted in ammonium acetate solution (pH 9).

Final determination of pyridafol is done by HPLC with column switching technology using a Nucleosil 10-N$(CH_3)_2$ column and a Ultrasphere ODS and detection at 280/300 nm (LC-LC-UV). Quantitation is done with external standards in solvent.

Although no validation data was included in the study, the method is considered acceptable since sufficient validation data is provided in analytical reports of the respective field trials using method 758 d.

Method No. 758 e (Pfarl, 1992, PYRIDATE_029)

The extraction, clean-up and quantitation of method 758 e is identical to method No. 758 d. Presented recovery data seems to support the suitability of the method for the determination of pyridafol in high water content, high acid content, high oil content and dry matrices with an LOQ of 0.05 mg/kg (Table 39). However, validation data to demonstrate the conversion of pyridate and pyridafol-O-glucoside to pyridafol was insufficient or not available at all. Since hydrolytic conditions were comparable to method S11-01578 (see below), it can be assumed that method 758 e is also suitable for the detection of pyridate and pyridafol-O-glucosides as pyridafol. Although, chromatograms of fortified samples and matrix blanks were not included in the report, the method is considered acceptable since sufficient validation data including chromatograms are provided in the analytical reports of the respective field trials using method 758 e.

Method No. 1005 (Pfarl, 1990, PYRIDATE_030)

The sample material is homogenized with acetone/water (4:1), followed by filtration. The extract is evaporated to a "syrup-like" remainder, reconstituted in water/dichloromethane (1:1) and the pH set to 3–3.5 with acetic acid. After centrifugation, the conjugates of pyridafol in the aqueous phase are hydrolysed by adding 10 mol/L hydrochloric acid and acetone and letting the mixture react at 70 °C for 45 minutes. Residues of pyridate and pyridafol in the dichloromethane phase are treated morpholine (to convert pyridate to pyridafol) und alkaline conditions (pH >8) and partitioned again ammonium acetate buffer (pH 9). The aqueous layers are combined and partitioned against dichloromethane. While the aqueous phase is discarded, the organic phase containing pyridafol is further cleaned up on a silica cartridge. Pyridafol is eluted with methanol/dichloromethane (5:100), the eluate is evaporated to dryness, and the remainder is reconstituted in ammonium acetate solution (pH 9).

Final determination of pyridafol is done by HPLC with column switching technology using a Nucleosil 10-N$(CH_3)_2$ column and a Ultrasphere ODS and detection at 280/300 nm (LC-LC-UV). Quantitation is done with external standards in solvent.

Generally, one fortification per level is considered insufficient and recoveries of pyridafol-O-glucoside as pyridafol are just outside the acceptable range (Table 40). Also, recoveries were corrected for blank values, which not common practice in pesticide analysis. In conclusion, data generated with this method cannot be considered as reliable.

Table 40 Recovery data for the common moiety method No. 1005 measuring pyridate and its metabolites pyridafol, pyridafol-O/N-glucosides in peanut matrices using LC-LC-UV

	Peanut (nutmeat)	0.15	1	67	-	-	

Notes:

Corrected for blank values.

Method REM 191.01 (Gasser, 1998, PYRIDATE_031, Gasser, 1998, PYRIDATE_032)

The homogenized sample material is sequentially shaken with acetone/ammonium acetate (5:1) + 0.5 mL morpholine, followed by acetone/ammonium acetate (5:1) + 0.2 mL ammonia with centrifugation in between extractions. The extracts are combined and are evaporated to the aqueous remainder. The alkaline extract (after addition of sodium hydroxide solution) is washed with ethyl acetate, the pH

adjusted to pH 4–4.5 by acidification with concentrated hydrochloric acid and conjugates hydrolysed at 60 °C for 40 minutes. After cool down to room temperature, the mixture is cleaned up on a C18 SPE cartridge and analytes are eluted with methanol. The eluate is evaporated to near dryness and the remainder acidified with hydrochloric acid, diluted with 1 mol/L aqueous sodium chloride solution, before further cleaned up by solid-supported liquid-liquid partition using against n-hexane/tert-butyl methyl ether (1:1).

Final determination of pyridafol is done by HPLC with column switching technology using a Zorbax SB-CN column and a Multospher 100 RP 18 FBS and detection at 220 nm (LC-LC-UV). Quantitation is done with external standards in solvent.

Mean recovery and precision were within acceptable limits, as well as linearity and selectivity was sufficiently demonstrated. However, the method was only tested with parent pyridate as pyridafol, but not with the O-glucoside. Since hydrolytic conditions were comparable to method S11-01578 (see below), it is assumed that method REM 191.01 is also suitable for the detection of pyridafol-O-glucosides. The method is considered acceptable for the determination of pyridate and its metabolites pyridafol and pyridafol-O-glucosides in high water content and dry matrices with an LOQ of 0.02 mg/kg per analyte (Table 41).

Method S11-03700 (Weber, 2012, PYRIDATE_033); Independent laboratory validation (Mewis, 2012, PYRIDATE_034)

Pyridate, metabolite pyridafol and its O- and N-glucoside conjugates are extracted from plant material by maceration with an alkaline solution of ammonium acetate, acetone and morpholine (pH 9). The extract is evaporated at 60 °C until the aqueous phase remains (at this step pyridate is converted to pyridafol), and thereafter partitioned between an alkaline solution of ammonium acetate and dichloromethane. The aqueous fraction undergoes an acidic hydrolysis using sulphuric acid at pH 4 (60 minutes, 95 °C) for cleavage of pyridafol conjugates and the pyridafol residue is subsequently extracted into dichloromethane. The organic phase is evaporated to dryness, and the pyridafol residue is re-dissolved in a mixture of methanol/0.05 percent acetic acid.

Samples were analysed by LC-MS/MS in positive ionization mode using an Ascentis express C18 column; and monitoring the ion transitions m/z 207→68 and 207→104. Quantitation is done with external standards in solvent.

Mean recovery and precision were within acceptable limits, as well as linearity and selectivity was sufficiently demonstrated. Matrix effects were below 20 percent. The method is considered acceptable for monitoring of pyridate and its metabolites pyridafol and pyridafol-O-glucosides in high water content,

high oil content and dry matrices with an LOQ of 0.05 mg/kg per analyte (Tables 42 and 43). However, in the primary method the pyridafol-N-glucoside does not hydrolyse to pyridafol under acidic conditions. The method was not validated for acidic matrices, but since the extraction was done with an alkaline buffer solution, the matrix group can be considered as covered by high water content matrices. In conclusion, the method is considered to be suitable for monitoring, as well as for risk assessment purposes.

Animal matrices

Method 1211 (Pfarl, 1995, PYRIDATE_035)

The sample material is homogenized with alkaline acetone/ammonium acetate (5:1) + 0.5 mL morpholine, thereby converting pyridate to pyridafol. The extract is evaporated to a “syrup-like” remainder, reconstituted in an alkaline ammonium acetate solution (pH 9) and washed with dichloromethane. The aqueous phase is acidified with sulphuric acid to pH 3–3.5 and partitioned against dichloromethane. For liver only, an additional clean up step is performed on a silica SPE cartridge. The organic extracts of all matrices are evaporated to dryness, and the remainder is reconstituted in ammonium acetate solution (pH 9).

Final determination of pyridafol is done by HPLC with column switching technology using a Nucleosil 10-N$(CH_3)_2$ column and a Ultrasphere ODS and detection at 280/300 nm (LC-LC-UV). Quantitation is done with external standards in solvent.

Mean recovery and precision were within acceptable limits, as well as linearity and selectivity was sufficiently demonstrated (Table 44). The method is considered acceptable for risk assessment purposes for the determination of pyridate and its metabolite pyridafol in animal matrices with an LOQ of 0.03 mg/kg per analyte.

Method S11-01578 (Keller, 2012, PYRIDATE_036); Independent laboratory validation (Wiesner & Breyer, 2012, PYRIDATE_037)

Pyridate and its metabolite pyridafol are extracted from animal matrices by shaking with acetonitrile/water (5:1) in the presence of morpholine. The extract was acidified with 0.1 mol/L sulphuric acid and a salt mixture of magnesium sulphate, sodium chloride, trisodium citrate, disodium hydrogen citrate sesquihydrate (QuEChERS Citrate Mix) was added. After centrifugation, an aliquot of the extract was cleaned by transfer on a C18 SPE cartridge and rinsed dropwise. An aliquot of the eluate was then diluted with methanol/water (1:1 with 0.1 percent acetic acid) and analysed for residues of pyridate and pyridafol as pyridafol.

Samples were analysed by LC-MS/MS in positive ionization mode using a Phenomenex Synergi Hydro RP 80A column and monitoring the ion transitions m/z 207→104 and 207→77. Quantitation is done with external standards in blank matrix.

Mean recovery and precision were within acceptable limits, as well as linearity and selectivity was sufficiently demonstrated (Table 45). The method is considered acceptable for monitoring of pyridate and

its metabolite pyridafol in animal matrices with an LOQ of 0.05 mg/kg as pyridate and 0.03 mg/kg for pyridafol. Compared to the method for food of plant origin, the hydrolysis of conjugates at pH 4 at 95 ˚C is not conducted. In addition, no validation with glucose conjugates was done. The method was independently validated (Table 46).

STABILITY OF PESTICIDES RESIDUES IN STORED ANALYTICAL SAMPLES

Plant matrices

The storage stability of pyridate under frozen conditions was investigated in incurred radiolabelled residues originating from plant metabolism studies with maize, peanuts, broccoli and alfalfa (Zohner, 1988, PYRIDATE_039).

Leaves of maize, peanuts, broccoli and alfalfa were taken at 0 DAT and kept deep frozen for 4.2 months (maize), 4.5 months (peanuts), 9.4 month (broccoli) and 14 month (alfalfa) prior to analysis. Samples were homogenized and extracted sequentially with acetone and acetone/water at various ratios. The combined extracts were analysed by LSC and TLC and the residue expressed as the sum of pyridate, pyridafol and hydrolysable pyridafol conjugates. After periods of 10 to 28 months, re-analysis was conducted and the metabolic profile compared to the first analysis was considered. The recovered amount was based on all compounds analysed by the common moiety methodology for pyridate, CL 6972 and its hydrolysable conjugates (Table 47).

Table 47 Storage stability of pyridate in incurred residues from whole plant samples of maize, rape, field pea and onion (greens only)

Crop	DAT (h)	Storage period (months)	Residues		Subsequent storage (months)	Residues
			Extracted (% TRR)	Sum of pyridate, pyridafol and hydrolysable pyridafol conjugates (% TRR)		Sum of pyridate, pyridafol and hydrolysable pyridafol conjugates (% TRR)
Maize leaves	2.75	4.2	99.7	97.7	26	86.0
Peanuts leaves	3.5	4.5	99.8	95.7	28	69.5
Broccoli leaves	1.5	9.4	99.8	99.8	12	85.7
Alfalfa	1	14	99.8	99.8	10	90.0

The storage stability of pyridate under frozen conditions was investigated in incurred residues from whole plant samples of maize, rape, field pea and onion (greens only) (Pfarl, 1996, PYRIDATE_038).

Samples were stored deep frozen at -20 °C and analysed for the first time after about 3 months (onion) to about one year (maize, rape, field pea) after sampling. The storage time between first and second analyses was about two years (rape, field pea), three years (onion) or five years (maize). Samples were analysed in duplicates according to method 758 d or 758 e as the sum of pyridate, pyridafol and hydrolysable pyridafol conjugates. (Table 48)

Table 48 Storage stability of pyridate in incurred residues from whole plant samples of maize, rape, field pea and onion (greens only)

Commodity	Mean pyridafol (mg/kg)[1]	Storage time (months)	% remaining	Mean procedural recovery (%)
Maize plant	24	14	-	76
	19	59	81	77
Rape plant	7.1	11	-	71
	11	25	155	84
Field pea plant	14	13	-	76
	13	24	93	85
Onion greens	5.2	3	-	80
	4.6	35	89	76

Notes:

[1] Results not corrected for recovery.

Animal matrices

The storage stability of pyridate under frozen conditions in milk, muscle, fat, liver and kidney fortified at 0.5 mg/kg was determined over a period of 7 months (Gasser, 2002, PYRIDATE_040). Samples were stored deep frozen at -18 °C and analysed in duplicate after 0, 3/4, and 7 months according to method 1211, as the sum of pyridate and pyridafol (Table 49).

Table 49 Storage stability of pyridate in animal matrices fortified at 0.5 mg/kg

Storage time (months)	Milk		Muscle		Fat		Liver		Kidney	
	% remaining	Mean concurrent recovery (%)[1]	% remaining	Mean concurrent recovery (%)[1]	% remaining	Mean concurrent recovery (%)[1]	% remaining	Mean concurrent recovery (%)[1]	% remaining	Mean concurrent recovery (%)[1]
0	90	89	79	83	79	84	73	76	78	76
3 (4 liver)	89		80		72		78		81	
7	76	83	67	77	70	80	76	80	74	84

Notes:

[1] Samples from 0 and 3 months were analysed in the same analytical sequence.

USE PATTERN

Pyridate is an herbicide used to control annual broad-leaved weeds. The GAP information taken from the submitted current labels for crops supported with residue data is summarized in Table 50.

Table 50 List of uses of pyridate (450 g/kg WP formulation, foliar spray)

Crop/ Commodity	Country	Application			PHI (days)
		Rate (g ai/ha)	Water volume (L/ha)	No or Seasonal max. (interval)	
Alfalfa	Austria	900	200-400	1	28

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

Residue levels were reported as measured. Application rates were always reported as pyridate equivalents. When residues were not detected they are shown as below the LOQ, e.g., < 0.01 mg/kg. Application rates, spray concentrations and mean residue results have generally been rounded to two significant figures. Values from the trials conducted according to maximum GAP have been used for the estimation of maximum residue levels. These results are underlined.

Laboratory reports included method validation including batch recoveries with spiking at residue levels similar to those occurring in samples from the supervised trials. Dates of analyses or duration of residue sample storage were also provided. Field reports provided data on the sprayers used and their calibration, plot size, residue sample size and sampling date. Although trials included control plots, no control data are recorded in the tables except where residues in control samples exceeded the LOQ. Residue data are recorded unadjusted for percent recovery. Residues were generally determined as pyridafol and the pyridate equivalent calculated by multiplication with 1.834 (Pyridate: 378.9 g/mol and pyridafol: 206.6 g/mol).

A summary of the submitted trials is shown in Table 51.

Bulb vegetables

Onion, bulb

A total of nine field trials were conducted with bulb onion in France and Italy during the 2006 growing season (Partington, 2007, PYRIDATE_041) and in France, Greece, Spain and the UK during the 2009 growing season (Semrau, 2012, PYRIDATE_108). The trials received one applications (at BBCH 15–17 or 41–47) at a rate of 900 g ai/ha. Residues of pyridate and pyridafol, including conjugates were determined

using an Agrisearch in-house method, identical to method S11-03700, with a limit of quantification of 0.01 mg/kg as pyridafol (0.02 mg/kg expressed as pyridate). It was noted that this is in contradiction to the results table of the study where the LOQ as pyridate equivalents was set at 0.01 mg/kg. However, the latter LOQ seems acceptable since also procedural recoveries were performed with pyridate fortified at 0.01 mg/kg.

Another set of nine field trials were conducted with bulb onion in Austria during the 1986–1992 growing seasons (Heegemann, 1986, PYRIDATE_042; Pfarl, 1991, PYRIDATE_043; Pfarl, 1992, PYRIDATE_044; Pfarl, 1993, PYRIDATE_045) and in the UK during the 1990 growing season (Pfarl, 1991, PYRIDATE_097. The trials received one application (at BBCH 13–16) at a rate ranging between 900–1800 g ai/ha. Residues of pyridate and pyridafol, including conjugates were determined using methods 758 c, 758 d or 758 e with a limit of quantification of 0.03 mg/kg as pyridafol (0.05 mg/kg expressed as pyridate). Mean procedural recoveries were generally acceptable, except for pyridafol in report No. 1095 were recoveries were at 61 percent, unacceptably low. The results are shown in Table 52.

Whittlesford, Cambridge, UK, 1990 (Balstora)	1800	200	Semi mature	29	Bulb	<0.03	<0.05	Report No. 1102 Pfarl, 1991, PYRIDATE_097 Storage time: max. 11 months Method 758 d 87 % (n=2) at 0.05 mg/kg pyridafol

Notes:

[1] Results from two replicate field samples are presented and values in parentheses represent mean values.

[2] The bulbs of trial S09-02296-01 were harvested at an immature stage (i.e. BBCH 42) and not at normal commercial harvest (BBCH 49), as was done in the other trials, because the sampling timing was set at a PHI of 35 days. The BBCH-stage 42 corresponds to "20 % of the expected bulb or shaft diameter reached" and is therefore clearly an immature stage that is not representative for normal commercial harvest.

NA: Not analysed.

Leek

A set of 14 field trials were conducted with leek in France (in 1996 & 2006), Italy (in 2006), the Netherlands (in 1987 &1989), Spain (in 2006), Switzerland (in 2001) and in the UK (in 1990). The trials received one application (at BBCH 17 to early harvest) at a rate of 900g ai/ha. Residues of pyridate and pyridafol, including conjugates were determined using methods 758 d and 758 e with a LOQ of 0.03 mg/kg as pyridafol (0.05 mg/kg as pyridate), method REM 191.01 with a LOQ of 0.02 mg/kg as pyridafol (0.04 mg/kg as pyridate) or a method identical to method S11-03700 with a LOQ of 0.01 mg/kg as pyridafol (0.02 mg/kg as pyridate). It was noted that the LOQ for pyridate in the method equivalent to S11-03700 is in contradiction to the results table of the study, where the LOQ as pyridate equivalents was set at 0.01 mg/kg. However, the latter LOQ seems acceptable since also procedural recoveries were performed with pyridate fortified at 0.01 mg/kg. The results are shown in Table 53.

Spring onion

A total of six field trials was conducted with green onion in Spain during the 2006 growing season (Partington, 2007, PYRIDATE_041) and in Germany, Greece, Spain and the UK, during the 2009 growing season (Semrau, 2012, PYRIDATE_051). The trials received one application (at BBCH 13–14 or 41–43) at a rate of 900 g ai/ha. Residues of pyridate and pyridafol, including conjugates were determined using a method identical to method S11-03700, with a limit of quantification of 0.01 mg/kg as pyridafol (0.02 mg/kg as pyridate). The results are shown in Table 54.

Brassica vegetables (except brassica leafy vegetables)

Flowerhead brassicas (broccoli, cauliflower)

A total of four field trials were conducted with broccoli in Austria during the 1986 growing season (Heegemann, 1987, PYRIDATE_052) and in the UK during the 1989-90 growing season (Pfarl, 1991, PYRIDATE_097; Pfarl, 1991, PYRIDATE_097). Additionally, trials were conducted with cauliflower and Brussels sprouts in the UK during the 1990 growing season (Pfarl, 1991, PYRIDATE_097). The trials received one application (at different growth stages) at a rate ranging between 900-2000 g ai/ha. Residues of pyridate and pyridafol, including conjugates were determined using methods 758 c or d with a limit of quantification of 0.03 mg/kg as pyridafol (0.05 mg/kg as pyridate). The results are in Table 55.

Cabbages

A total of 36 field trials were conducted with cabbage in France, Germany, Greece, Spain and the UK during the 2009 growing season (Semrau, 2012, PYRIDATE_053), in the UK during the 1988, 1990, 1995 & 1996/97 growing seasons (Carrier & Pfarl, 1996, PYRIDATE_055; Carrier, 1997, PYRIDATE_056; Pfarl, 1989, PYRIDATE_096; Pfarl, 1991, PYRIDATE_097) and Austria during the 1986 & 1988 growing seasons

(Pfarl, 1989, PYRIDATE_057; Heegemann, 1986, PYRIDATE_091; Heegemann, 1986, PYRIDATE_092; Heegemann, 1986, PYRIDATE_093; Pfarl, 1989, PYRIDATE_094; Pfarl, 1989, PYRIDATE_095). The trials received one application (at BBCH 14-19 or 41-43 or not stated) at a rates ranging between 900-1800 g ai/ha. Residues of pyridate and pyridafol, including conjugates were determined using methods 758 c & 758 e with a LOQ of 0.03 mg/kg as pyridafol (0.05 mg/kg as pyridate), a Novartis method with a LOQ of 0.03 mg/kg as pyridafol (0.05 mg/kg as pyridate) or a method identical to method S11-03700 with a LOQ of 0.01 mg/kg for both, pyridafol and pyridate.

Additionally, three field trials were conducted with fodder cabbage in France during the 1982 growing season (Bosio, 1982, PYRIDATE_054). The trials received one application (at 4F-5F) at a rate of 900 g ai/ha. The method was not stated, but the description is similar to method 758 a, with an LOQ of 0.2 mg/kg as pyridafol. The results are shown in Table 56.

Kohlrabi

Four field trials were conducted with kohlrabi in Austria during the 1986 and 1988 growing seasons (Pfarl, 1989, PYRIDATE_058; Heegemann, 1986, PYRIDATE_098). The trials received one application (at BBCH 14-17) at rates ranging between 900-1800 g ai/ha. Residues of pyridate and pyridafol, including conjugates were determined using method 758 c with a LOQ of 0.03 mg/kg as pyridafol (0.05 mg/kg as pyridate). The results are shown in Table 57.

Leafy vegetables (including brassica leafy vegetables)

Kale

Eight field trials were conducted with kale in France, Switzerland and the UK during the 1998 growing season (Gasser, 1999, PYRIDATE_059, Gasser, 1999, PYRIDATE_060, Gasser, 1999, PYRIDATE_061, Gasser, 1999, PYRIDATE_062, Gasser, 1999, PYRIDATE_063, Gasser, 1999, PYRIDATE_064, Gasser, 1999, PYRIDATE_065, Gasser, 1999, PYRIDATE_066). The trials received one application (at BBCH 13–15) at a rate of 900 g ai/ha. Residues of pyridate and pyridafol, including conjugates were determined using method REM 191.01 with a LOQ of 0.02 mg/kg as pyridafol (0.04 mg/kg as pyridate). The results are shown in Table 58

Notes:

[1] It was noted that trial 3083/98 and 3084/98 were performed at the same location/time and differed only in the cultivated kale variety. Therefore the trials could not be considered as independent.

[2] It was noted that trial 3085/98 and 3086/98 were performed at the same location. However, treatment and harvest time each differed by 7 days. Therefore the trials are considered as independent.

Legume vegetables

Chickpea

Six field trials were conducted with chickpeas in France, Greece, Italy and Spain during the 2015 growing season (Grall, 2016, PYRIDATE_067). The trials received one application (at BBCH 19) at a rate of 900 g ai/ha. Residues of pyridate and pyridafol, including conjugates were determined using method S11-03700 with a LOQ of 0.05 mg/kg as pyridate (Table 59).

Another four field trials were conducted with chick-peas in the United States (growing season not reported) (Anonymous, year not stated, PYRIDATE_068). The trials received two applications (at BBCH 12–16 and 20 ± 2 days later) at a rate of 1000 and 2000 g ai/ha. Residues of pyridate and pyridafol, including conjugates were determined using method 758 e with a LOQ of 0.03 mg/kg as pyridafol (0.05 mg/kg as pyridate). However, no analytical report, including chromatograms, linearity etc. was included. The results are shown in Table 60.

Cereal grains

Maize

Fifteen field trials were conducted with maize in France during the 1992, 1996 and 2000 growing seasons (Gasser, 2002, PYRIDATE_101; Krennhuber, 1997, PYRIDATE_102, Pfarl, 1992, PYRIDATE_104), in Austria in the 1990 & 1991 growing seasons (Pfarl, 1991, PYRIDATE_103; Pfarl, 1994, PYRIDATE_104; Pfarl, 1992, PYRIDATE_105; Pfarl, 1992, PYRIDATE_106) and in Germany during the 1991 growing season (Pfarl, 1992, PYRIDATE_107). The trials received one application (at BBCH 14-17) at rates ranging from 900 to 1800 g ai/ha. Residues of pyridate and pyridafol, including conjugates were determined using method REM 191.01 with a LOQ of 0.02 mg/kg as pyridafol (0.04 mg/kg as pyridate), or method 758 d & e with a limit of quantification of 0.03 mg/kg as pyridafol (0.05 mg/kg expressed as pyridate). It was noted that no storage stability study for dry crops was available. Hence, the storage period of the field samples could not be validated. The results are shown in Table 61.

Sweet corn (Corn-on-the-cob)

Three field trials were conducted with sweet corn in France during the 1998 growing season (Gasser, 1999, PYRIDATE_100; Gasser, 2002). The trials received one application (at BBCH 16–18) at a rate of 900 g ai/ha. Residues of pyridate and pyridafol, including conjugates were determined using method REM 191.01 with a LOQ of 0.02 mg/kg as pyridafol (0.04 mg/kg as pyridate).

Additional nine field trials with maize were considered if at an intermediate stage samples of maize cob (at BBCH 71-85) were taken. These trials were performed in France during the 1996 & 2000 growing seasons (Gasser, 2002, PYRIDATE_101; Krennhuber, 1997, PYRIDATE_102) and in Germany during the 1991 growing season. The trials received one application (at BBCH 16–33) at a rate of 900 g ai/ha. Residues of pyridate and pyridafol, including conjugates were determined using method REM 191.01 with a LOQ of 0.02 mg/kg as pyridafol (0.04 mg/kg as pyridate) or method 758 d & e with a limit of quantification of 0.03 mg/kg as pyridafol (0.05 mg/kg expressed as pyridate). The results are shown in Table 62.

Notes:

[1] It was noted that trial RE98063and RE98064 were performed at the same location and year. However, sowing time differed by 2 weeks. Therefore the trials are considered as independent.

Feeding commodities

Alfalfa

A total of 12 field trials were conducted with alfalfa in Hungary during the 1989 growing season (Anonymous, 1989, PYRIDATE_069), in France during the 1992 & 1998 growing seasons; in Austria during the 1986 & 1987 growing seasons (Heegemann, 1986, PYRIDATE_076, Pfarl, 1990, PYRIDATE_077). The trials received one application (mostly at BBCH 14–16 or not stated) at a rate of 900, 1350 or 1800 g ai/ha. Residues of pyridate and pyridafol, including conjugates were determined using methods REM 191.01 with a LOQ of 0.02 mg/kg as pyridafol (0.04 mg/kg as pyridate); 758 c, 758 d or 758 e with a LOQ of 0.03 mg/kg as pyridafol (0.05 mg/kg as pyridate). The results are in Table 63.

Clover

A total of 11 field trials were conducted with clover in France during the 1998 and 2000 growing seasons, in the United Kingdom during the 1998 growing season (Gasser, 1999, PYRIDATE_081) and in Austria during the 1989 growing season (Pfarl, 1989, PYRIDATE_087). The trials received one application (at various BBCH stages) at a rate of 900 g ai/ha. Residues of pyridate and pyridafol, including conjugates were determined using methods REM 191.01 with a LOQ of 0.02 mg/kg as pyridafol (0.04 mg/kg as pyridate) or 758 d with a LOQ of 0.03 mg/kg as pyridafol (0.05 mg/kg as pyridate). The results are shown in Table 64.

Notes:

[1] It was noted that trial 0021301, 0021302 and 0021303 were performed at the same location and year. However, treatment and harvest time each differed by 2-6 weeks. Therefore the trials are considered as independent.

[2] It was noted that trial 3118/97 and 3120/97 as well as trial 3119/97 and 3121/97 were performed at the same location and time. Therefore the trials could not be considered as independent.

Maize forage

18 field trials were conducted with maize in France during the 1996 & 2000 growing season and in Germany during the 1991 growing season (Pfarl, 1992, PYRIDATE_107). The trials received one application (at BBCH 14-17) at rates ranging between 900 and 1370 g ai/ha. Residues of pyridate and pyridafol, including conjugates were determined using method REM 191.01 with a LOQ of 0.02 mg/kg as pyridafol (0.04 mg/kg as pyridate) or method 758 d & e with a limit of quantification of 0.03 mg/kg as pyridafol (0.05 mg/kg expressed as pyridate). The results are shown in Table 65.

Additionally, three field trials were conducted with sweet corn forage in France during the 1998 growing season (Gasser, 1999, PYRIDATE_100). The trials received one application (at BBCH 16–18) at a rate of 900 g ai/ha. Residues of pyridate and pyridafol, including conjugates were determined using method REM 191.01 with a LOQ of 0.02 mg/kg as pyridafol (0.04 mg/kg as pyridate) (Table 66).

Notes:

[1] It was noted that trial RE98063 and RE98064 were performed at the same location and year. However, sowing dates differed by 2 weeks. Therefore the trials are considered as independent.

Maize straw

Eleven field trials were conducted with maize in France during the 1996 & 2000 growing seasons (Gasser, 2002, PYRIDATE_101; Krennhuber, 1997, PYRIDATE_102) and in Austria during the 1990 & 1991 growing seasons (Pfarl, 1991, PYRIDATE_103; Pfarl, 1994, PYRIDATE_105; Pfarl, 1994, PYRIDATE_106). The trials received one application (at BBCH 16–18) at rates ranging between 900 to 1370 g ai/ha. Residues of pyridate and pyridafol, including conjugates were determined using method REM 191.01 with a LOQ of 0.02 mg/kg as pyridafol (0.04 mg/kg as pyridate) or method 758 d & e with a limit of quantification of 0.03 mg/kg as pyridafol (0.05 mg/kg expressed as pyridate). Results are shown in Table 67.

FATE OF RESIDUES IN STORAGE AND PROCESSING

Nature of residue during processing

No study was provided to simulate pasteurization, boiling, baking and brewing and sterilization

Residues after processing

Peanut and maize

The transfer of the total pyridate residue into maize and peanut oil was investigated with radiolabelled incurred residues from nature of residue studies (Zohner, 1988, PYRIDATE_088). The nature of residue

studies were performed with exaggerated rates of 1×3600 g ai/ha (4×) for peanut and 1×1800 g ai/ha (2×) in maize. Samples of maize grain were harvested at 118 DAT, while peanuts were harvested at 91 and 223 DAT. For processing both commodities were extracted with petroleum ether in a Soxhlet apparatus, followed by evaporation of the solvent. The total radioactivity the RAC was determined by combustion, followed by LSC. The oil samples were analysed by TLC and gel permeation chromatography. Additionally an alkaline hydrolysis was performed to determine distribution of the radioactivity in the glycerol and fatty acid moieties (Table 68).

Table 68 Total radioactivity residues (TRR) found in peanut and corn samples before and after oil processing and oil yields, calculated on a dry weight basis.

Crop	Project No.	Oil Yield* (%)	TRR (mg/kg)	
			Before oil processing	In oil
Maize grain	M8503M	3.6	0.016	0.019
		4.1	0.019	0.018
Peanut Nutmeat	M8503E	30.7	0.054	0.050
		30.7	0.054	0.050
	M8713	34.5	0.127	0.100
		32.8	0.136	0.106

Notes:

*Average of duplicate determinations.

Attempts to separate the radioactivity from the oil by GPC and to identify individual components were not successful. The following alkaline hydrolysis of the oil demonstrated no release of residues >LOD and a uniform distribution of radioactivity between fatty acids and glycerol.

RESIDUES IN ANIMAL COMMODITIES

Farm animal feeding studies

Lactating cows

The transfer of residues of pyridate into animal matrices was investigated in a study with dairy cows (Cameron, *et al*., 1989, PYRIDATE_089). The study was conducted with [4,5-pyridazine-^{14}C]-radiolabelled pyridate at treatment rates of 1 (1×), 3.3 (3×), and 10 (10×) ppm (0.03, 0.1 and 0.3 mg/kg bw) for 28 days.

The cows in the treatment groups (three animals per group) were treated twice daily via an implanted cannula directly into the rumen. Milk samples were collected twice daily. Additionally, selected milk samples (day 2, 9, 16, 23) were separated into fat, curds and whey samples. Whole blood samples were taken immediately before each treatment and after treatment on day 1 and day 27. Plasma was separated from blood samples by centrifugation. All cows were sacrificed within 6 hours of administration of the last dose. Samples of liver, kidney, heart, lung, brain, skeletal muscle (shoulder, rump, dorsal), subcutaneous fat, perirenal fat, whole blood, plasma, milk (collected immediately before sacrifice), bladder urine and bile were collected and taken for analysis.

Total radioactivity in liquid samples such as urine, plasma, milk and various extracts were directly measured by LSC. Whole blood and tissue samples were subjected to combustion prior to the determination of total radioactivity by LSC.

Muscle, liver and kidney samples were homogenized with methanol. Fat samples were ground with acid washed sand and mixed with methanol. Plasma and bile samples were mixed with methanol and ethanol, respectively. Urine was cleaned up after dilution with citrate buffer on a C18 cartridge.

Conjugates in kidney, liver and urine were cleaved with 2 mol/L hydrochloric acid. Characterization of the extracts was carried out by HPLC against reference standards.

Residues in milk plateaued after one day in all dosing groups. In edible tissues residues were highest in kidney ranging from 0.19 mg/kg (1×) to 1.9 mg/kg (10×). The findings in tissues are summarised in Table 86. An individual component was only identified in muscle, kidney, liver and fat of the 10× dosing group with a retention time close to pyridafol. Additionally, in urine and bile pyridafol and its glucuronides were identified (Table 69).

n/d = Not detected.

Laying hens

The transfer of residues of pyridate into animal matrices was investigated in a study with laying hens (Johnston*, et al*., 1989, PYRIDATE_090). The study was conducted with [4,5-pyridazine-^{14}C]-radiolabelled pyridate at treatment rates of 1.3 (1×), 4 (3×), and 13 (10×) ppm (0.1, 0.3 and 1 mg/kg bw) for 28 days.

The hens in the treatment groups (10 animals per group) were treated with pyridate by gavage twice daily. Eggs were collected twice daily throughout the study period and separated into yolks and whites. All hens were sacrificed within 6 hours of administration of the last dose and samples of muscle (leg, breast), fat pad, skin and fat, liver, whole blood, plasma, kidney and heart were collected and taken for analysis.

Total radioactivity in liquid samples such as plasma, egg yolk and white and various extracts were directly measured by LSC. Whole blood and tissue samples were subjected to combustion prior to the determination of total radioactivity by LSC.

Ground kidney samples were suspended in water, followed by precipitation of protein with trichloroacetic acid. Muscle and fat samples were mixed with quartz sand, followed by extraction with methanol. Liver, plasma, excreta, egg white and yolk were extracted with methanol. Conjugates in excreta, kidney, liver and plasma were cleaved with 2 mol/L hydrochloric acid. Characterization of the extracts was carried out by HPLC against reference standards.

Residues in eggs whites plateaued after two days in all dosing groups, while in egg yolks a plateau was reached after 5–7 days. In edible tissues residues were highest in kidney ranging from 0.05 mg/kg (1×) to 0.23 mg/kg (10×). The findings in tissues are summarised in Table 87. An individual component was identified in egg yolk, kidney, liver and muscle of the 10x dosing group only, with a retention time close to pyridafol (Table 70).

Table 70 Average total radioactive residues (TRR) found in various animal samples following twice daily administration of [^{14}C]-pyridate at concentrations of 0 (Group 1), 1.3 (Group 2), 4 (Group 3) and 13 ppm (Group 4)

APPRAISAL

Pyridate is an herbicide of the phenylpyridazine class used to control annual broad-leaved weeds. It acts by inhibiting the photosynthetic electron transport at the photosystem II. The IUPAC name of pyridate is *O*-6-chloro-3-phenylpyridazine-4-yl *S*-octyl thiocarbonate

Pyridate was scheduled at the Fiftieth Session of the CCPR for evaluation as a new compound by the 2020 JMPR, reviewed by the 2019 JMPR for toxicology, where an ADI of 0–0.2 mg/kg bw and an ARfD of 2 mg/kg bw were established. The residue assessment was rescheduled to the current JMPR.

The Meeting received information on identity, physicochemical properties, metabolism (plant, confined rotational crops and animals), environmental fate, methods of residue analysis, freezer storage stability, registered use patterns, supervised residue trials, fate of residues in processing, and livestock feeding studies.

Table 71 Abbreviations used for relevant compounds referred to in the appraisal

Code	Name	Structure
Pyridate (CL 11344)	6-chloro-3-phenylpyridazine-4-yl-S-octyl-thiocarbonate	 378.9 g/mol
Pyridafol (CL 9673)	6-chloro-4-hydroxy-3-phenylpridazine	 206.6 g/mol
Pyridafol-O-methyl (CL 9673-OMe; CL 9869)	6-chloro-4-methoxy-3-phenylpridazine	 220.7 g/mol

Physical and chemical properties

Pyridate and pyridafol (CL 9673) are not volatile. Pyridate is hydrolytically and photolytically unstable, resulting in the cleavage of the ester bond leading to pyridafol. The n-octanol water partition coefficient (log P_{ow}) of pyridate is 4.0.

Plant metabolism

The Meeting received plant metabolism studies in broccoli, maize and peanuts following application of [4,5-pyridazine-^{14}C]-radiolabelled pyridate.

Broccoli

[4,5-pyridazine-^{14}C]-radiolabelled pyridate was foliar applied once at the 2–3 leaf stage using a rate of 1.8 kg ai/ha under combined greenhouse and outdoor conditions. Plant samples were taken at 0 (immediately after the treatment), 14, 45, 73, 94 and 108 DAT.

The TRR was highest at 20 mg eq/kg in leaves immediately after treatment and declined to 0.011 mg eq/kg in samples taken at 108 DAT. In the edible parts (flower heads), TRR was significantly lower at 0.009 mg eq/kg (DAT 75, 96, 108 combined).

Broccoli samples were extracted with acetone and acetone/water (8:2). Conjugates were hydrolyzed with 2 mol/L hydrochloric acid and β-glucosidase in extracts. Extracted radioactivity in the leaves and edible parts (flowers) was high, ranging between 75-100 percent TRR.

Post-extracted solids (PES) in leaf samples (14 or 45 DAT) was further subjected to 2 mol/L acetonic HCl and enzymatic hydrolysis for characterisation of radioactivity in natural products, such as starch, proteins, pectin and lignin.

Characterization of the radioactivity in broccoli flowers was not performed due to their low radioactivity in the extract. Parent pyridate was a major identified residue in leaf samples from 0 and 14 DAT, accounting for 42–60 percent TRR (2.6–12 mg eq/kg), while in leaves from 45 DAT parent pyridate was not detected at all. As a major metabolite, pyridafol was detected in leaf samples from 0 and 14 DAT, accounting for 7.4–18 percent TRR (0.45–3.5 mg eq/kg). In addition, N- and O-glucoside conjugates of pyridafol were found as the predominant residue at 14 and 45 DAT (19–25 percent TRR, 0.06–1.5 mg eq/kg). Two unknown components were detected at significant levels in leaf samples from 14 and 45 DAT, in combination accounting for 7.1 percent (0.43 mg eq/kg) and 23 percent TRR (0.07 mg eq/kg), respectively. One of these was characterized as very polar and resistant to hydrolysis treatment. The other was also characterized as being highly polar and susceptible to hydrolysis with beta-glucosidase (no corresponding aglycon identified).

Maize

The Meeting received two studies with maize (study 1: indoors at nights and outdoors during daytime; study 2: only outdoors), both performed with [4,5-pyridazine-^{14}C]-radiolabelled pyridate. Maize plants at BBCH 14–15 (study 1) or BBCH 16–17 (study 2) were treated once with pyridate at 1.8 (study 1) or 1.73 (study 2) kg ai/ha. Plant samples were taken at 0 (immediately after the treatment), 14, 45, 90 and 118 (study 1) or 148 (study 2) DAT.

Generally, the detected radioactivity was higher in study 2. In both studies the TRR was highest in leaves ranging between 17 mg eq/kg (study 1) and 168 mg eq/kg (study 2) at 0 DAT and declined to 0.5 mg eq/kg (study 1) at 108 DAT and 0.27 mg eq/kg (study 2) at 148 DAT. The radioactivity in newly grown plant parts was at least one order in magnitude lower in both studies at the respective sampling time points compared to the treated leaves, indicating limited translocation in the plant. In maize grain, the TRR was low in both studies ranging between 0.01-0.014 mg eq/kg.

In both studies, samples were solvent extracted with acetone and with acetone/water (8:2), followed by a harsher acidic or enzymatic hydrolysis of the PES. Solvent extracted radioactivity was high in the treated leaves from 0–14 DAT, ranging between 82–100 percent, but was lower in treated leaves from 45–108 DAT and in newly grown leaves, ranging between 24–75 percent TRR.

For maize grain, the radioactivity in the extract was < 0.01 mg eq/kg (study 1, 118 DAT) and no further analysis of the radioactivity was performed. No extraction was performed in grain samples from study 2 (148 DAT).

In the treated leaves from study 1 taken at 0 and 14 DAT, parent pyridate was a major identified residue, accounting for 82 percent TRR (14 mg eq/kg) and 11 percent TRR (0.31 mg eq/kg), respectively. In leaves taken at later DAT, parent pyridate was at or below the LOD.

As a major metabolite, pyridafol was detected in leaf samples taken at 0 and 14 DAT, accounting for 15–16 percent TRR (0.44–2.6 mg eq/kg), decreasing to levels of around or below the LOD in leaf samples taken at later DAT, its N- and O-glucosides accounting for 5.4–7.0 percent TRR (0.07–0.15 mg eq/kg).

Two unknown components were detected at significant levels in leaf samples taken at 14–90 DAT, accounting for a total of 15–38 percent TRR (0.07-0.69 mg eq/kg). One compound was characterized as being highly polar and was susceptible to hydrolysis with beta-glucosidase (no corresponding aglycon identified). The other decomposed into many unknown compounds following acid hydrolysis, however none could be attributed to pyridafol.

In the treated leaves of study 2 (14 DAT only), neither parent pyridate (3.0 percent TRR; 0.80 mg eq/kg), nor pyridafol (5.3 percent TRR; 1.4 mg eq/kg) were identified as major residues. Instead, three unknown components accounted for 9.5 percent TRR (2.5 mg eq/kg), 20 percent TRR (5.3 mg eq/kg) and 41 percent TRR (11 mg eq/kg).

Peanut

[4,5-pyridazine-^{14}C]-radiolabelled pyridate was foliar applied once to peanut plants (12.7 cm high) using a rate of 3.6 kg ai/ha under combined greenhouse and outdoor conditions. Plant samples were taken at 0 (immediately after the treatment), 14, 45 and 219 DAT.

The TRR was highest at in peanut forage taken immediately after treatment at 59 mg eq/kg and in hay from 45 DAT at 38 mg eq/kg. However, levels in both matrices declined to 0.22 mg eq/kg in forage and 1.5 mg eq/kg in hay taken at 219 DAT. In peanut hulls and nutmeat from 219 DAT, TRR levels were 0.36 mg eq/kg and 0.04 mg eq/kg, respectively.

The samples were extracted with acetone and acetone/water (8:2). Conjugates were hydrolyzed with 2 mol/L hydrochloric acid and β-glucosidase. Extracted radioactivity was high from peanut forage taken at 0 and 14 DAT, ranging between 78–100 percent TRR, but lower for forage samples taken at later DAT, as well as for peanut hay and hulls ranging between 38–64 percent TRR. For nutmeat, the extracted radioactivity was even lower at 33 percent TRR.

The PES was further subjected to harsher treatments using acid and enzymatic hydrolysis as well as characterisation of radioactivity into natural products for forage samples (45 DAT), demonstrating assignment to natural constituents such as starch, proteins, pectin and lignin.

Characterization of the residue in the nutmeat was not performed due to its low radioactivity in the extract.

Parent pyridate and pyridafol were major identified residues in forage samples from 0 DAT only, accounting for 86 percent TRR (51 mg eq/kg) and 10 percent TRR (6.2 mg eq/kg), respectively. In forage from later DAT, as well as in hay or hulls levels of pyridate and pyridafol were much lower (up to 4.6 percent TRR, 0.83 mg eq/kg) or non-detectable and also pyridafol-N or O-glucoside was found at low levels not exceeding 5.6 percent of the TRR (max. 1.1 mg eq/kg in hay). Two unknown components were detected at significant levels in forage (14-45 DAT), hay and hulls accounting for 14–19 percent TRR (1.4–5.4 mg eq/kg), 10–18 percent TRR (0.15–6.9 mg eq/kg) and 11 percent (0.04 mg eq/kg), respectively. One minor identified metabolite was pyridafol-OMe at up to 4.7 percent TRR (0.07 mg eq/kg) in hay (215 DAT).

Alfalfa

Reference to an additional plant metabolism study for the use of pyridate on alfalfa was made in the storage stability study on incurred radioactive residues. The study was not provided to the Meeting.

In summary, the metabolic pathway of pyridate in broccoli, maize and peanut was similar. In all studies, pyridate did undergo rapid hydrolytic cleavage into pyridafol. Biotransformation of pyridafol occurred mainly by glucosidic conjugation, yielding in the pyridafol-N-glucoside and pyridafol-O-glucoside. Further degradation led to highly polar metabolites, before the radioactivity was incorporated into the carbon pool of natural plant constituents. Only limited translocation in the plant was observed.

Environmental fate

For the investigation of the environmental fate of pyridate, the Meeting received studies on hydrolysis, aerobic soil degradation, soil photolysis and on the behaviour in confined rotational crops.

Hydrolysis

Pyridate was shown to be susceptible to hydrolysis, by cleavage of the ester bond leading to pyridafol. DT_{50} values at 25 °C ranged between 117 hours at pH 4 to 6.2 hours at pH 9. The Meeting concluded that hydrolysis of pyridate will be a significant route of degradation in the aquatic environment.

Aerobic soil metabolism

The rate of degradation of pyridate and its metabolite pyridafol was studied in various aerobic soils using [4,5-pyridazine-^{14}C]-radiolabelled pyridate, pyridafol and pyridafol-OMe. Rapid degradation of pyridate was observed at 20°C with estimated half-lives ranging from 0.3 to 3.3 days. Metabolite pyridafol peaked at day 1 or 2 at a maximum of 72–91 percent AR and showed moderate degradation with half-lives ranging from 17–43 days. Additionally, metabolite, pyridafol-OMe was detected at up to 3.5–16 percent AR on day 7–70 and showed moderate degradation with half-lives ranging from 12–25 days. The Meeting concluded that pyridate and its metabolites are not persistent in soil.

Soil photolysis

The soil surface photolytic behaviour of pyridate and its metabolite pyridafol was studied in an aerobic soil using [4,5-pyridazine-^{14}C]-radiolabelled pyridate. Under the assumption of average daylight of 12 hours, half-lives were estimated for pyridate and pyridafol at 1.8 days and 19 days respectively. Further degradation products were not identified. The Meeting concluded that photolysis is a significant degradation pathway for pyridate and moderately affects its metabolite pyridafol.

Rotational crop metabolism

Confined rotational crop studies

The Meeting received one confined rotational crop study under mixed outdoor and indoor conditions with lettuce, carrots and spring barley grown in rotation.

The study was conducted with [4,5-pyridazine-^{14}C]-radiolabelled pyridate applied at a rate equivalent to 1.8 kg ai/ha to a silty loam soil and plant back intervals (PBIs) of 28 and 56 days. The nature and level of radioactive residues from the 28 day PBI were investigated in lettuce at 97 DAT, in carrots at 133 DAT and in barley at 163 DAT. In crops from the 56 day PBI residues were investigated in lettuce at 156 DAT, in carrots at 169 DAT and in barley at 209 DAT.

Radioactivity in plant samples was generally low (< 0.01 mg eq/kg), except for barely straw (up to 0.1 mg eq/kg) and barley grain (up to 0.030 mg eq/kg).

Samples were extracted with methanol and methanol/water (8:2). Conjugates present in the extracts were hydrolysed overnight with 2 mol/L HCl. Extractability for all samples was between 19–83 percent TRR. No characterization of the unextracted residue was performed.

Characterization and identification of the radioactivity was only performed in the extracts of barley straw. While no pyridate or metabolites could be identified, the main portion of the extracted radioactivity was allocated to saccharides.

The Meeting concluded that uptake from soil is low and pyridate in metabolized into highly polar metabolites, before the radioactivity was incorporated into the carbon pool.

Animal metabolism

The Meeting received animal metabolism studies on rats, lactating cows and goats and laying hens where animals were dosed with [4,5-pyridazine-^{14}C]-radiolabelled pyridate.

Rats

The metabolism of pyridate in rats was reviewed in the framework of the toxicological evaluation by the WHO Core Assessment Group of the 2019 JMPR.

Cattle

[4,5-pyridazine-14C]-radiolabelled pyridate was administered once as a single dose of 0.3 mg/kg bw (equivalent in feed not stated) at day 1 and 14 by intra-ruminal injection to one cow. After administration of the first dose, urine and faeces were collected once daily for 7 consecutive days (except urine which was collected three times within the first 24 h). Milk was collected twice daily throughout the study. The animal was sacrificed approximately 6 hours after administration of the second dose and tissues were collected.

After three days, the elimination of administered radioactivity was complete. The main route occurred via urine (92 percent AR), followed by faeces (8.6 percent AR).

In organs and tissues, radioactivity was significantly lower with 1.957 mg eq/kg in the kidney, 0.138 mg eq/kg in the liver and < 0.0034 mg eq/kg in the muscle. In milk the total radioactivity was low too, reaching a maximum of 0.03 mg eq/kg after 7 hours. After 31 hours, no radioactivity was detected in any milk samples.

Characterization of the radioactivity in edible tissues was only done for liver and kidney. While no information was given on the extractability of the residue, co-chromatography of the extracts with reference standards identified pyridafol in kidney (level not given), as well as pyridafol-N- and O-glucoside (up to 0.1 mg eq/kg) in liver.

Goats

[4,5-pyridazine-^{14}C]-radiolabelled pyridate was administered orally once daily to one lactating goat at 2.8 ppm (0.38 mg/kg bw and d) for 10 consecutive days. Urine and faeces were collected once daily, while milk was collected twice daily. The animal was sacrificed approximately 24 hours after the last dose and samples of organs, tissues and body fluids were collected.

The majority of the radioactivity was found in urine (95 percent AR) followed by faeces (6.5 percent AR). Radioactive residues in the edible tissues were low at 0.019 mg eg/kg and 0.033 mg eq/kg in

liver and kidney, respectively. Similar levels were found in milk, ranging between 0.015–0.048 mg eq/kg. A plateau was reached in milk after 3 days of consecutive administration. Residues in muscle and fat were 0.003 mg eq/kg and 0.009 mg eq/kg, respectively.

Extraction with acetone/water (8:2) followed by acetone released 63 percent TRR (0.01 mg eq/kg) from liver and 87 percent TRR (0.027 mg eq/kg) from kidney. Since radioactivity was low, identification was only successful in kidney, where metabolites pyridafol and pyridafol-OMe were tentatively identified, present at 32 percent TRR (0.010 mg eq/kg) and 48 percent TRR (0.015 mg eq/kg), respectively. In milk only pyridafol was identified at 49–71 percent TRR (0.012–0.015 mg eq/kg).

Poultry

A metabolism study was performed with 6 laying hens and 6 broiler chickens receiving a single oral dose of [4,5-pyridazine-^{14}C]-radiolabelled pyridate at 2.5–4.7 ppm (0.2 mg/kg bw and d). Excreta were collected once daily up to 96 h post dose, while eggs were collected twice daily if possible and separated in to egg yolk and white. All animals were sacrificed at 96 hours post dose. No individual organs or tissues were collected.

Within 24 hours post-dose, the majority of the radioactivity was found in excreta at 93-96 percent, increasing to 97–99 percent after 96 hours, demonstrating fast elimination.

Detected radioactivity in egg yolks and egg whites was consistently <LOQ for throughout the sampling time of 0–96 h post dose, with the exception of egg whites collected at 24–48 h post dose with a mean of 0.004 mg eq/kg.

Since no organs or tissue were collected, no further identification or characterization of the radioactive residues was performed. However, in excreta, metabolites pyridafol and hydroxylated pyridafol accounted for up to 74 percent TRR and 44 percent TRR, respectively.

A second metabolism study was performed with 9 laying hens receiving [4,5-pyridazine-^{14}C]-radiolabelled pyridate orally once daily for 5 consecutive days at ~3 ppm (0.19 mg/kg bw and d). Excreta and eggs were collected once daily and during the depuration phase additionally at 4, 8, and 24 hours after the last treatment. Eggs were separated in yolk and white. Three hens each were sacrificed at 8 hours, 3 days and 7 days after the final dose and organs, tissues and body fluids were collected.

Within 8–168 hours post-dose, the majority of the radioactivity was found in excreta at 93-96 percent AR, indicating rapid elimination. Radioactive residues in the edible matrices after 8 hours depuration were generally low, at 0.04 mg eq/kg in kidney, 0.02 mg eq/kg in liver and < 0.01 mg eq/kg in all other edible tissues. Similar levels were found in egg samples with maximum residues in yolks and whites at 0.007 mg eq/kg and 0.01 mg eq/kg, respectively.

No further identification or characterization of the radioactive residues in organs or tissues was performed.

In summary, the Meeting concluded that in all species investigated (cows, goats, hens and rats), the total administered radioactivity was predominantly eliminated in excreta. Information on the metabolic pathway was scarce, mostly due to the low levels of radioactivity in various organs and tissues, but seems comparable between species. The only metabolites identified in edible matrices were pyridafol, found in goat kidney and milk, and pyridafol-OMe in goat kidney.

Methods of analysis

The Meeting received information on analytical methods for pyridate in plant and animal matrices.

For matrices of plant origin, the basic principle of most methods employed extraction with alkaline solution of acetone/ammonium acetate (5:1) + morpholine, thereby converting pyridate to pyridafol. Conjugates were hydrolysed with sulfuric or hydrochloric acid. Clean up involved one or a combination of the following: partitioning between ammonium acetate and dichloromethane, clean up on a silica or C18 cartridge, solid-supported liquid-liquid partition with n-hexane/tert-butyl methyl ether (1:1). Pyridafol was determined by either HPLC with column switching technology and UV detection (LC-LC-UV) with an LOQ of 0.02 or 0.05 mg/kg (as pyridafol), or by LC-MS/MS in positive ESI mode with an LOQ of 0.05 mg/kg (as pyridate).

For matrices of animal origin, two methods were provided. The first method employed extraction with alkaline solution of acetone/ammonium acetate (5:1) + morpholine, hydrolysation of conjugates with sulfuric acid, followed by clean up employing partitioning with dichloromethane and SPE on a silica cartridge. Quantitation was done by LC-LC-UV with an LOQ of 0.03 mg/kg (as pyridafol). The second method involved extraction with acetonitrile/water (5:1) in the presence of morpholine and clean up by SPE on a C18 cartridge. Quantitation of pyridafol was done by LC-MS/MS in positive ESI mode with an LOQ of 0.03 mg/kg (spiked and expressed as pyridafol) or 0.05 mg/kg (spiked and expressed as pyridate).

The Meeting concluded that the presented methods were sufficiently validated and are suitable to measure the total residue of pyridate as pyridafol in plant and animal matrices commodities.

Stability of pesticide residues in stored analytical samples

The Meeting received information on storage stability of pyridate (expressed as the sum of pyridate, pyridafol and hydrolysable pyridafol conjugates) in incurred residues (radiolabelled and non-radiolabelled) from various raw plant commodities.

In a study with radiolabelled residues performed in high water commodities (maize leaves, peanut leaves, broccoli leaves and alfalfa), samples were analysed for total pyridate initially after 4–14 months and re-analysed after an additional 10–28 months. After the first sampling, total pyridate residues covered >99 percent of the TRR analysed by the total residue method. In the second analysis, 86–90 percent TRR were recovered, suggesting that total pyridate was stable for at least 30 month under deep freezer conditions for maize, broccoli and alfalfa leaves. In peanut forage, 69.5 percent of the residue were recovered after 32 months in the second analysis, which is also the maximum storage period tested in this study.

A second study was performed with non-radiolabelled incurred residues in high water commodities (maize plant, rape plant, field pea plant and onion greens). Within the study the samples were analysed for the first time after about 3 to 14 months after sampling, followed by a second analysis after 24 to 59 months. No significant degradation of residues was observed in the respective time interval (> 81 percent of the first analysis).

The Meeting noted that the first analysis did not occur within a short period after harvest to quantify the time zero residue levels. However, since stability of high water commodities was demonstrated in the radiolabelled study, the Meeting concluded that storage up to 14 months is covered by the radiolabelled storage stability study and subsequent months by the non-radiolabelled study.

The Meeting agreed that the demonstrated storage stability on high water plant commodities was at least 59 months and covered the residue sample storage intervals used in the field trials considered by the current Meeting. However, no storage stability data was provided for other plant commodities or animal commodities.

Definition of the residue

Plant commodities

In the plant metabolism studies conducted on broccoli, maize and peanut, no identification of the total radioactivity in broccoli flowers, maize grain or peanut nutmeat was performed.

In other matrices, parent pyridate was a major residue only in samples taken at 0/14 DAT (broccoli leaves 60/42 percent TRR; maize leaves 82/11 percent TRR; peanut forage 86 percent TRR). Significant levels of pyridafol were mainly found in samples taken at 0 DAT (peanut forage 10 percent TRR) and declined rapidly at later DATs. At higher sampling intervals, the N- and O-glucoside of pyridafol were quantified in all matrices, but in major amounts only in broccoli leaves at 19–25 percent TRR.

The Meeting noted that no suitable single maker compound is present at harvest to measure pyridate residues in plant commodities. However, analytical methodology is available capable to quantify the total residue of parent pyridate, its metabolite pyridafol and conjugates thereof.

The Meeting decided to set the residue definition for compliance with the MRL as the sum of pyridate, its hydrolysis product pyridafol and hydrolysable conjugates of pyridafol, expressed as pyridate.

In all matrices investigated, unknown components (two in broccoli leaves, two in maize leaves and three in peanut forage, hay and hull) were found in major amounts, representing up to 41 percent TRR (up to 11 mg eq/kg). Characterisation of these unknown components indicated that they are not structurally related to pyridafol and are not analysed by the total residue method. The application of pyridate as a herbicide happens early in the growing season. Since the peak occurrence of these unknown components was observed primarily at 14 to 90 DAT, which corresponds to PHIs in the use patterns provided, the Meeting concluded that they are likely to be present in harvested commodities and therefore demand identification and consideration in the dietary risk assessment, depending on their toxicological properties. Although identification in metabolism studies was only performed in inedible matrices, major levels of unknown components were found in all crop matrices, suggesting general occurrence in plants. In addition, the Meeting noted that a metabolism study on alfalfa exists, which was not made available to the current Meeting.

Without identification of these unknown components found at significant levels and information on the metabolism of pyridate in alfalfa, the Meeting decided not to establish a residue definition for dietary exposure purposes for pyridate in plant matrices.

Animal commodities

In ruminant metabolism studies, performed in a lactating cow and a goat, parent pyridate was not detected. The hydrolysis product pyridafol was tentatively identified in the goat at 32 percent TRR in kidney and 49-71 percent TRR in milk as well as pyridafol-OMe in kidney at 48 percent TRR. In the cow, the presence of pyridafol in the kidney and the N- and O-glucosides of pyridafol in the liver were postulated.

In poultry metabolism studies, no identification or characterization of the radioactive residues in organs or tissues was performed. However, in excreta metabolites pyridafol and hydroxylated pyridafol accounted for up to 74 percent TRR and 44 percent TRR, respectively.

In radiolabelled farm animal feeding studies performed with lactating cows and laying hens, one individual component was potentially identified in edible tissues of the 10x dosing group with a retention time close to pyridafol. Additionally, pyridafol and its glucuronides were identified in urine and bile from the cow feeding study.

The Meeting noted that the rate of identification in animal metabolism studies was generally low and no suitable single maker compound is present to measure pyridate residues in animal commodities. However, analytical methodology is available capable to quantify the total residue of parent pyridate, its metabolite pyridafol and conjugates thereof, which is suitable for enforcement purposes.

Parent pyridate has a octanol-water partition coefficient of 4.0, suggesting potential accumulation in fat. However, in farm animal feeding studies, total residues in liver, kidney and muscle were generally higher than in fat. Also, no accumulation of residues in egg yolk compared to egg white was observed. Consequently, the Meeting decided that residues of total pyridate in animal commodities are not fat-soluble.

Pending information on the nature of unknown components in plant matrices, exposure of livestock animals via feed cannot be characterized. The Meeting decided not to establish a residue definition for dietary exposure purposes for pyridate in animal matrices.

The Meeting recommended the following residue definitions for pyridate:

Definition of the residue for compliance with the MRL for plant and animal commodities: *Sum of pyridate and 6-chloro-4-hydroxy-3-phenylpridazine (*pyridafol*) (incl. conjugates), expressed as pyridate*.

Definition of the residue for dietary exposure purposes for plant and animal commodities: *Not established.*

The Meeting considers the residue not to be fat soluble.

Results of supervised residue trials on crops

Supervised trials were available for the use of pyridate on onion, bulb, leek, spring onion, broccoli, cabbage, kohlrabi, kale, chickpea, maize and sweet corn (corn-on–the-cob), as well as on alfalfa and clover.

Product labels were available from Germany, Austria, Italy and the Netherlands

In some field trials, the residue was expressed as equivalents of metabolite pyridafol. In order to convert these residues into pyridate equivalents, a molar weight factor of 1.8 was applied ($M_{Pyridate}/M_{pyridafol}$ = 378.9 g/mol^{-1}/206.6 g/mol^{-1} = 1.8).

The Meeting decided not to establish a residue definition for dietary exposure purposes for plants. Consequently, only maximum residue levels according to the residue definition for enforcement purposes are estimated, but no STMR or HR value.

Bulb vegetables

Onion, bulb

The critical GAP for bulb onions in Italy allows one foliar application of pyridate at 900 g ai/ha with a PHI of 21 days.

Field trials with bulb onion following GAP treatment (±25 percent) were conducted in France and Italy. The ranked order of residues for estimating maximum residue levels and dietary risk assessment was (n=3): < 0.01(2), 0.02 mg/kg.

Based on the lack of data matching the GAP, the Meeting concluded that no maximum residue level could be estimated for pyridate in onion based on the Italian GAP.

A GAP for onions in Austria was provided allowing a maximum of one foliar application of pyridate at 900 g ai/hL and a PHI of 56 days. One field trial, with bulb onion following GAP treatment (±25 percent), was conducted in Austria. The ranked order of residues for estimating maximum residue levels was (n=1): < 0.05 mg/kg.

Due to an insufficient number of supervised field trials matching the GAP, the Meeting concluded that no maximum residue level could be estimated for pyridate in bulb onion.

Leek

The critical GAP for leeks in Austria allows one foliar application of pyridate at 900 g ai/ha with a PHI of 28 days.

Field trials with leek following GAP treatment (±25 percent) were conducted in the Netherlands, France, Switzerland, Italy and Spain. The ranked order of residues for estimating maximum residue levels was (n=12): 0.04, 0.05, 0.051, 0.057, 0.06, 0.08, 0.11, 0.14, 0.20, 0.22, 0.63, 0.81 mg/kg.

The Meeting estimated a maximum residue level of 1.5 mg/kg for pyridate in leek.

Spring onion

The critical GAP for spring onion in the Netherlands allows one foliar application of pyridate at 900 g ai/ha with and a PHI of 28 days.

Field trials with spring onion following GAP treatment (±25 percent) were conducted in France, Germany, the UK, Greece and Spain. The ranked order of residues for estimating maximum residue levels was (n=6): < 0.01, 0.02, 0.04, 0.05, 0.07, 0.09 mg/kg.

The Meeting estimated a maximum residue level of 0.2 mg/kg for pyridate in spring onion.

Brassica vegetables (except brassica leafy vegetables)

The critical GAP for brassica vegetables (cabbage, Brussels sprouts, broccoli, cauliflower, kohlrabi) in Austria allows one foliar application of pyridate at 900 g ai/ha with and a PHI of 42 days.

Broccoli

Field trials with broccoli following GAP treatment (±25 percent) were conducted in Austria. The ranked order of residues for estimating maximum residue levels was (n=1): < 0.05 mg/kg.

Due to an insufficient number of supervised field trials matching the GAP, the Meeting concluded that no maximum residue level could be estimated for pyridate in broccoli.

Brussel spouts

No field trials with Brussel sprouts approximated GAP treatment (±25 percent) and residues were only determined as pyridafol *per se*.

Due to an insufficient number of supervised field trials matching the GAP, the Meeting concluded that no maximum residue level could be estimated for pyridate in Brussel sprouts.

Cabbage, head

Field trials with cabbages following GAP treatment (±25 percent) were conducted in France, Germany, Greece, Spain and the United Kingdom. The ranked order of residues for estimating maximum residue levels was (n=16): < 0.01(4), 0.01, 0.02, < 0.05(4), 0.12, 0.38, 0.50, 0.57, 0.85, 0.95 mg/kg.

The Meeting estimated a maximum residue level of 1.5 mg/kg for pyridate in cabbage, head.

Cauliflower

No field trials with cauliflower approximated GAP treatment (±25 percent) and residues were only determined as pyridafol per se.

Due to an insufficient number of supervised field trials matching the GAP, the Meeting concluded that no maximum residue level could be estimated for pyridate in cauliflower.

Kohlrabi

Field trials conducted with kohlrabi following GAP treatment (±25 percent) were conducted in Austria. The ranked order of residues for estimating maximum residue levels was (n=1): < 0.05 mg/kg.

Based on the lack of data matching the GAP, the Meeting concluded that no maximum residue level could be estimated for pyridate in kohlrabi.

Kale

The critical GAP for kale in Austria allows one foliar application of pyridate at 900 g ai/ha with and a PHI of 42 days.

Field trials with kale following GAP treatment (±25 percent) were conducted in Switzerland, the UK and France. The ranked order of residues for estimating maximum residue levels was (n=7): < 0.05(4), 0.081, 0.092, 0.17 mg/kg.

The Meeting estimated a maximum residue level of 0.3 mg/kg for pyridate in kale.

Chick-pea (succulent seeds)

The critical GAP for chick-peas in Italy allows one foliar application of pyridate at 900 g ai/ha up to BBCH 19 with and a PHI of 45 days.

Field trials with chick-peas were conducted in France, Greece, Italy and Spain. The ranked order of residues in legume chick-pea seeds for estimating maximum residue levels was (n=6): < 0.05(6) mg/kg.

The Meeting estimated a maximum residue level of 0.05* mg/kg for pyridate in chickpeas (succulent seeds).

Pulses

Chick-pea (dry)

The critical GAP for chick-peas in Italy allows one foliar application of pyridate at 900 g ai/ha up to BBCH 19 with and a PHI of 45 days.

Field trials with chick-peas were conducted in France, Greece, Italy and Spain. The Meeting noted that storage intervals in all trials were longer than one months. No information on storage stability in high protein matrices was provided and therefore the Meeting could not assess the validity of the measured results.

Due to an insufficient number of supervised field trials matching the GAP, the Meeting concluded that no maximum residue level could be estimated for pyridate in chickpeas (dry).

Cereal grains

Maize

The critical GAP for maize in the Netherlands allows one foliar application of pyridate at 900 g ai/ha at BBCH 16 and with the PHI covered by the conditions of use.

Field trials with maize following GAP treatment (±25 percent) were conducted in France and Germany. The ranked order of residues for estimating maximum residue levels was (n=7): < 0.04, < 0.05(6) mg/kg.

The Meeting noted that no data on storage stability in high starch content matrices was available although field trial samples were stored for 3–16 months (4×3 months, 2×6 months and 1×16 months). Based on the provided metabolism studies on maize dosed at 2× GAP rate, the total radioactive residue in maize grain was low at 0.01–0.014 mg eq/kg. No further identification was undertaken in the samples and therefore the fraction of the TRR covered by the common moiety method remains unknown. However, given the rapid metabolism of pyridate, including the incorporation of the radioactivity into natural constitutes, the Meeting concluded that the levels of the components covered by the residue definition are expected to be even lower. Also, field trial samples treated at 150 percent GAP rate also showed no residues in maize grain for pyridafol after 2 months of storage.

In view of the low radioactivity found in maize metabolism study and the analysis of trial samples according to the common moiety method, the Meeting decided to accept the trials without demonstration of storage stability and estimated a maximum residue level of 0.05(*) mg/kg for pyridate in maize grain.

Sweet corn (Corn-on-the-cob)

The critical GAP for sweet corn in Austria allows one foliar application of pyridate at 900 g ai/ha with and a PHI of 42 days.

Field trials with sweet corn following GAP treatment (±25 percent) were conducted in France. The ranked order of residues in sweet corn (corn-on-the-cob) for estimating maximum residue levels was (n=1): < 0.05(1) mg/kg. The ranked order of residues in sweet corn (kernels) for estimating maximum residue levels was (n=2): < 0.05(2) mg/kg.

Alternatively, a GAP for sweet corn in the Netherlands was provided, allowing one foliar application of pyridate at 900 g ai /ha at BBCH 16 and with the PHI covered by the conditions of use.

Field trials with sweet corn following GAP treatment (±25 percent) were conducted in France. The ranked order of residues for estimating maximum residue levels was (n=10): < 0.04, < 0.05(9) mg/kg. The ranked order of residues in sweet corn (kernels) for estimating maximum residue levels was (n=2): < 0.05(2) mg/kg.

The Meeting noted that only the dataset for sweet corn (corn-on-the-cob) according to the GAP from the Netherlands was sufficiently large and estimated a maximum residue level of 0.05(*) mg/kg for pyridate in sweet corn (corn-on-the-cob)

Residues in animal feeds

Alfalfa forage

The critical GAP for alfalfa in Austria allows one foliar application of pyridate at 900 g ai/ha with and a PHI of 28 days.

Field trials with alfalfa following GAP treatment (±25 percent) were conducted in Austria and France. The ranked order of residues was (n=5): < 0.05(2), 0.05, 0.23, 0.26 mg/kg.

Since alfalfa forage is utilised only as a feed items and insufficient data on the nature of residues relevant for calculating the livestock animal dietary burden are available, the Meeting did not estimate median or highest residues for pyridate.

Clover forage

The critical GAP for clover in Austria allows one foliar application of pyridate at 900 g ai /ha with and a PHI of 28 days.

Field trials with clover following GAP treatment (±25 percent) were conducted in France and the United Kingdom. The ranked order of residues was (n=6): < 0.04, 0.12, 0.26, 1.0, 1.5(2) mg/kg.

Since clover forage is utilised only as a feed items and insufficient data on the nature of residues relevant for calculating the livestock animal dietary burden are available, the Meeting did not estimate median or highest residues for pyridate.

Maize forage

The critical GAP for maize in the Netherlands allows one foliar application of pyridate at 900 g ai/ha at BBCH 16 and with the PHI covered by the conditions of use.

Field trials with maize following GAP treatment (±25 percent) were conducted in France and Germany. The ranked order of residues in maize forage collected at growth stages typical for commercial harvest was (n=12): < 0.04(4), < 0.05(7), 0.068 mg/kg.

Since maize forage is utilised only as a feed items and insufficient data on the nature of residues relevant for calculating the livestock animal dietary burden are available, the Meeting did not estimate median or highest residues for pyridate.

Maize stover

The critical GAP for maize in the Netherlands allows one foliar application of pyridate at 900 g ai/ha at BBCH 16 and with the PHI covered by the conditions of use.

Field trials with maize following GAP treatment (±25 percent) were conducted in France. The ranked order of residues in maize straw for estimating maximum residue levels was (n=5): < 0.04, < 0.05(4) mg/kg.

The Meeting estimated a maximum residue level of 0.05* mg/kg (DM) for pyridate in maize stover.

Fate of residues during processing

The Meeting received no information on the hydrolysis of pyridate, simulating typical processing conditions.

The fate of pyridate residues has been examined simulating commercial processing of maize and peanuts using radiolabelled pyridate. The TRRs in the RAC and in processed commodities (maize and peanut oil) were comparable. However, no components according to the residue definition were identified in the processed commodities and the nature of radioactivity remained unknown. Therefore, the Meeting decided that no processing factors addressing the residue definition for pyridate could be derived.

Residues in animal commodities

Farm animal feeding studies

The Meeting received feeding studies involving pyridate on lactating cows and laying hens using radiolabelled pyridate.

The study with lactating cows was conducted at treatment rates of 1, 3.3 and 10 ppm. Total radioactive residues in milk plateaued after one day in all dosing groups (0.003, 0.015 and 0.033 mg eq/kg, respectively). In edible tissues residues were highest in kidney ranging from 0.19 mg eq/kg (1×) to 1.9 mg eq/kg (10×). An individual component was only identified in muscle, kidney, liver and fat of the 10x dosing group with a retention time close to pyridafol. Additionally, pyridafol and its glucuronides were identified in urine and bile.

The study with laying hens was conducted at treatment rates of 1.3, 4 and 13 ppm. Total radioactive residues in eggs whites plateaued after two days in all dosing groups (0.005, 0.01 and 0.032 mg eq/kg respectively), while in egg yolks a plateau was reached after 5–7 days (0.003, 0.008 and 0.023 mg eq/kg, respectively). In edible tissues residues were highest in kidney ranging from 0.05 mg eq/kg (1×) to 0.23 mg eq kg (10×). An individual component was identified in egg yolk, kidney, liver and muscle of the 10x dosing group only, with a retention time close to pyridafol.

Farm animal dietary burden

Due to insufficient data on the nature of residues relevant for the livestock animal dietary burden, the Meeting decided that no calculation was possible.

Animal commodity maximum residue levels

The Meeting noted that the provided farm animal feeding studies lacked detailed residue data on components covered by the residue definition. Generally, only TRR levels were provided for milk, egg and various tissues, while the presence of metabolite pyridafol was only qualitatively described.

Therefore, the Meeting decided that no recommendations for animal commodities could be given based on the available information from farm animal feeding studies.

RECOMMENDATIONS

Definition of the residue for compliance with the MRL for plant and animal commodities: *Sum of pyridate and 6-chloro-4-hydroxy-3-phenylpridazine (pyridafol) (incl. conjugates), expressed as pyridate*.

Definition of the residue for dietary exposure purposes for plant and animal commodities: *Not established.*

The residue is not fat-soluble.

DIETARY RISK ASSESSMENT

As the Meeting was unable to recommend residue definitions for dietary risk assessment for plants and animal commodities, chronic and acute dietary risk assessments could not be conducted.

FURTHER WORK OR INFORMATION

Desirable information

- Submission of existing metabolism data for pyridate in alfalfa.

- Identification of major unknown components in all plant matrices from broccoli, maize and peanut metabolism studies.
- Data on the transfer of pyridate residues to farm animals (ruminants and poultry) are required, as the information provided was not sufficient to give recommendation for maximum residue levels in animal matrices.
- Storage stability information on commodities of high protein and starch content are required.

  Information on pyridate analytical methods targeting single compounds.
- Information on processed commodities.

QUINCLORAC (287)

First draft prepared by Dr J Cudmore, Chemicals Regulation Division of the Health and Safety Executive, United Kingdom

Presentation at the 2022 JMPR was by Mr C Sieke, Federal Institute for Risk Assessment, DE

EXPLANATION

Quinclorac is a systemic herbicide used with uptake through roots and foliage and used to control annual grass and broadleaf weeds. It was evaluated by the 2015 JMPR for the first time for toxicology and for residues and re-evaluated in 2017 (R) for additional uses. The 2015 JMPR established an ADI of 0–0.4 mg/kg bw, and an ARfD of 2 mg/kg bw.

For plant commodities, the residue definition for compliance with MRLs is quinclorac plus quinclorac conjugates and the residue definition for the estimation of dietary intakes is quinclorac plus quinclorac conjugates plus quinclorac methyl ester expressed as quinclorac. The 2015 JMPR noted that quinclorac methyl ester has a toxicological potency up to 10 times that of quinclorac and agreed to multiply the quinclorac methyl ester residues with a factor of 10 to express it as quinclorac equivalents.

For animal commodities the residue definition for compliance with MRLs and for estimation of dietary intakes is quinclorac plus quinclorac conjugates. The residue is fat-soluble.

Quinclorac was scheduled at the Fifty-first Session of the CCPR for the re-assessment of residue trials for oil seed rape after re-analysis using different analytical methods and the consideration of commercial demonstration trials for rapeseed.

The current Meeting received information on a use pattern, the re-analysis of residue trial samples and commercial demonstration trials for rapeseed. A use pattern, new residue trials and additional validation data for cranberries were also received by the current Meeting.

RESIDUE ANALYSIS

Cranberries and rape seed

Residues of quinclorac and quinclorac methyl ester were determined using method D1607/0. The total residues of quinclorac were determined in three consecutive extraction procedures. For the 1st extraction, samples were extracted with acetonitrile/water (1/1). Parent quinclorac and quinclorac methyl ester were determined using LC-MS/MS. For the 2nd extraction, the seed and forage marc with aqueous phase from the 1st extraction were extracted with acetone/10 mM phosphate buffer at pH 7 (1/1) and with acetone, respectively. Parent quinclorac and quinclorac methyl ester were determined using LC-MS/MS. For the 3rd extraction, the marc from the 2nd extraction was treated with 1N NaOH at 100 °C for 1 hour. This harsh hydrolysis to release quinclorac conjugates was used in the plant metabolism study for rape seed.

Quinclorac and quinclorac conjugates were determined as quinclorac using LC-MS/MS. After each sample extraction and clean-up, residues are determined by LC-MS/MS, monitoring ion transitions at m/z 242→224 (quantitation) and m/z 242→161 (confirmation) for quinclorac, and m/z 256→224 (quantitation) and m/z 256→161 (confirmation) for quinclorac methyl ester. Total residues of quinclorac were reported as the sum from each extraction procedure. Similarly, the total residues of quinclorac methyl ester were determined in two consecutive extraction procedures and reported as the sum from each extraction procedure.

The 2017 JMPR concluded that this method was suitable for the separate determination of quinclorac, including its conjugates, and quinclorac methyl ester residues in rapeseed and forage. The current Meeting received procedural recovery data for cranberries. The procedural recovery data are summarised in table 1.

Table 1 Summary of method procedural recovery data for the determination of quinclorac and quinclorac methyl ester residues in cranberries

Analyte	Fortification level (mg/kg)	Number of samples	Recoveries (%)	Repeatability (% RSD)
Quinclorac	0.02	3	95, 100, 105	5
	0.2	2	101, 104	-
	2	3	91, 94, 95	2.2
Quinclorac methyl ester	0.02	3	82, 93, 95	7.8
	0.2	3	89, 93, 102	7
	2	3	87, 89, 91	2.3

Rapeseed

Multi-residue analytical method (Based on QuEChERS method for acidic herbicides)

The method is similar to the multi-residue analytical method D1502/1 considered by the 2017 JMPR. However, the initial extraction employed is different.

Samples were prepared by homogenizing with liquid nitrogen/dry ice. A subsample was hydrated with water and the pH was adjusted to >9 with NaOH. After shaking the sample for 30 minutes and centrifuging, an aliquot was removed and shaken with dichloromethane (DCM). The DCM was then discarded, the pH adjusted to ≤2 with sulfuric acid.

Samples were then shaken with acetonitrile and cleaned-up by a mixture of "QuEChERS" salts ($MgSO_4$, NaCl, trisodium citrate dihydrate and disodium hydrogen citrate sesquihydrate). The residues in the organic phase were diluted with acetonitrile/water (10/90, v/v) for quinclorac analyses. Final determination was achieved using LC-MS/MS. The ion transitions monitored were m/z 242 → m/z 224 and m/z 242 → m/z 161.

Recovery data were generated during the analysis of the samples from the monitoring trials. A summary of the recovery data are outlined in Table 2.

Table 2 Summary of procedural recovery data for LC-MS/MS method

Analyte	Trial Year	Fortification level (mg/kg)	Number of samples	Recoveries (%)
Quinclorac	2016	0.01	2	84, 110
		1	2	120, 117
	2017	0.01	3	136, 120, 107
		1	3	113, 99, 112

Methods employed in the re-analysis of rape seed samples

The methods employed in the re-analysis of samples were methods D9708/1 and D9806, considered by the 2015 JMPR, and method D1607/01, considered by the 2017 JMPR.

Method D9708/1

Residues of quinclorac were extracted from rape seeds using hexane/0.1 NaOH solution followed be partitioning with acetonitrile. Final determination was by HPLC-MS/MS using the ion transition m/z 240-196 for quantification. The LOQ validated for quinclorac in/on oil seed rape was 0.05 mg/kg.

As the method does not contain a hydrolysis step, then any conjugates of quinclorac present will not be sufficiently released. However, as the metabolism data showed that parent conjugates are not expected for rape seed this is of no concern. A radio-validation study considered by the 2015 JMPR showed that extraction with acetone/0.1 M NaOH converts the quinclorac methyl ester (if present) partly back into the parent compound. This means the parent levels in rapeseed may be overestimated and hence the JMPR in 2015 concluded that this method was not suitable for the estimation of MRLs.

Method D9806

Quinclorac methyl is extracted from rape seed using acetonitrile/hexane and then partitioned with acetonitrile/water and methanol. Final determination is by HPLC-MS/MS using the ion transition m/z 255 – 224 for quantification. The LOQ validated was 0.05 mg/kg. This method is suitable for the determination of quinclorac methyl ester residues in rape seed.

STABILITY OF PESTICIDE RESIDUES IN STORED ANALYTICAL SAMPLES

No additional information was received by the current Meeting on the stability of quinclorac and quinclorac methyl ester residues in stored samples.

USE PATTERN

The use patterns for cranberries and rape seed are outlined in table 3. The GAP for cranberries was considered by the 2015 JMPR and the GAP for rapeseed was considered by the 2017 JMPR. The current Meeting received labels for these GAPs as they remain valid.

Table 3 Use pattern for cranberries and rapeseed

Crop	Country	Indoor/ outdoor	Type	Timing of application	Rate (g ai/ha)	No. of appl (interval)	PHI (days)
Cranberries	United States	Outdoor	Ground spray	See PHI	280	2 (30 days)	60
Rape seed	Canada	Outdoor	Foliar spray	See PHI	100	1	60

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

Cranberries

Four residue trials conducted in the United States in 2008 were considered by the 2015 JMPR to support the GAP. These trials were conducted at an application rate of 2 × 280 g ai/ha with a RTI of 30 days. These trials are summarized in Table 4.

Table 4 Residue trials data, generated by foliar treatment, for cranberries conducted in the United States (evaluated by the 2015 JMPR)

Notes:

[a:] Not considered in 2015 Report, but considered by current JMPR.

[b:] Considered in 2015 Report, but not considered by current JMPR.

Five new residue trials conducted in the United States in 2019 were provided to the current Meeting. At each trial site two applications of quinclorac at a rate of 280 g ai/ha were made with a RTI of 30 days.

Cranberries were harvested between 49–66 days after the last application. Cranberries were stored frozen at ≤ -18 °C. All samples were analysed within 30 days.

Samples of cranberries were analysed separately for quinclorac including conjugates and quinclorac methyl ester using method D 1607/01. Procedural recoveries were conducted at 0.02 mg/kg

and 0.2 mg/kg. The recoveries ranged from 97–134 percent for quinclorac and 86–100 percent for quinclorac methyl.

The residue trials are summarized in Table 5.

Table 5 Residue trials data, generated by foliar treatment, for cranberries conducted in the United States

Location, Country Year, Crop/Variety	Rate (g ai/ha)	RTI (days)	Growth stage at last treatment	DALA	Quinclorac residues (mg/kg)	Methyl ester residues (mg/kg)

Note:

Values in parentheses = mean of two independent representative treated samples taken at the trial site.

Rape seed

No new residue trials were received by this Meeting. Information has been provided to re-consider the residue trials evaluated by the JMPR in 2015; data have been provided to compare the different analytical methods used with the potential to establish analytical correction factors.

In 2015, the JMPR considered sixteen residue trials conducted in Canada and one trial conducted in the United States. These trials are summarized in Table 6.

The trials were conducted at an application rate of 1 × 100 g ai/ha applied at various growth stages with samples taken for analysis 60 days after the application.

Samples were collected and frozen prior to analysis. Samples were stored for up to 6 months prior to quinclorac analysis and for up to 12 months prior to quinclorac methyl ester analysis.

Samples were analysed using method D9708/1 for quinclorac (including quinclorac conjugates using acetone/0.1 M NaOH and LC-MS/MS) and method D9806 for quinclorac methyl ester (using acetone and LC-MS/MS). Procedural recoveries were generated at fortification levels of 0.05–0.5 mg/kg with recoveries ranging from 61–88 percent for quinclorac and 77–120 percent for quinclorac methyl ester.

The 2015 JMPR concluded that the method used in the trials overestimated the residues of quinclorac. A radio-validation study considered by the 2015 JMPR showed that extraction with acetone/0.1 M NaOH converts the quinclorac methyl ester (if present) partly back into the parent compound. This means the parent levels in rapeseed may be overestimated and hence the method is not suitable for the estimation of MRLs.

Re-analysis of previously submitted supervised field trials with other analytical methods

To support the use of the above trials in a reconsideration of the maximum residue level for rape seed oil, information has been provided to demonstrate the extent of the overestimation of the residue levels of quinclorac.

The extent of overestimation has been determined by re-analysing the rape seed samples from the trials considered by the 2017 JMPR using several different analytical methods.

In 2017, the JMPR considered a total of nine residue trials conducted in Canada and the United States. The trials were conducted in 2016 with an application rate of 0.1–0.105 kg ai/ha applied at the 2–6 leaf stage 60 days prior to harvest. The samples were stored frozen for up to 145 days prior to analysis.

Residues of quinclorac, quinclorac conjugates and quinclorac methyl ester were determined using method D 1607/01 (three extractions: a) acetonitrile/water, b) acetone/phosphate buffer pH 7, c) 0.1 M NaOH at 100 ˚C; separate analysis of each extract for parent and methyl-ester using LC-MS/MS). Procedural recoveries of quinclorac and quinclorac methyl ester fortified in control canola seed samples were 74 ± 11 percent (quinclorac) and 96 ± 11 percent (quinclorac methyl ester) at 0.01 mg/kg, and 79 ± 20 percent (quinclorac) and 107 percent (quinclorac methyl ester) at 1.0 mg/kg. The LOQ for both analytes was 0.01 mg/kg.

The current Meeting received information on the re-analysis of the samples from the 2016 trials. The samples were re-analysed using the following methods:

Method D1607/01 determines total quinclorac (quinclorac plus quinclorac conjugates) and quinclorac methyl ester separately Samples are extracted in sequence with a) acetonitrile/water, b) acetone/phosphate buffer pH 7, c) 1 M NaOH at 100 ˚C for 1 hour. Each extract is analysed separately for parent and the methyl-ester using LC-MS/MS.

Method D9708/01 determines total quinclorac (quinclorac plus quinclorac conjugates). It overestimates quinclorac by converting some of the quinclorac methyl ester (if present) to quinclorac; it underestimates quinclorac as release of quinclorac conjugates (if present) is incomplete. Rape seed is not expected to contain conjugates (according to the metabolism studies).

Method D9806 is suitable for the determination of quinclorac methyl ester. The samples were stored frozen prior to the re-analysis for up to 670 days. A summary of the residue trials along with the results of the original analysis and the re-analysis are summarised in Tables 7 and 8 for quinclorac and quinclorac methyl ester respectively.

Monitoring trials (also referred to as demonstration trials)

The current Meeting also received commercial demonstration trials. These trials were conducted to verify the residue levels of quinclorac in rape seed oil when treated at the Canadian GAP under commercial conditions. The trials were not generated following standard criteria and the report did not contain the standard field and analytical phases.

A total of 7 demonstration trials were conducted in 2016 and 2017 in Canada. At each trial site two use patterns were investigated. One plot was treated at a rate of 1 × 125 g ai/ha applied pre-sowing. A second plot was treated at a rate of 1 × 75 g ai/ha with the application applied at the 2–6 leaf stage.

It is stated that samples were collected at normal commercial harvest and followed the approved label conditions, although the dates of harvest are not given and hence the time between the application and harvest is not known.

The samples from the trials conducted in 2016 were stored at ambient temperature for up to 4 months prior to shipment to the laboratory. The storage conditions prior to analysis following shipment are not reported. The samples from the trials conducted in 2017 were stored frozen prior to analysis; the dates of analysis and therefore the length of storage are not reported.

Residues of quinclorac were determined using the LC-MS/MS method based on the QuEChERS method for acidic herbicides. This included extraction using NaOH which is therefore likely to result in a portion of the quinclorac methyl ester (if present) being converted back into quinclorac. Procedural recoveries were conducted at 0.01 mg/kg and 1 mg/kg with recoveries in the range of 84–136 percent.

As the demonstration trials were focused on the residue definition for compliance with MRLs, quinclorac methyl ester residues were not determined. A summary of the trials is outlined in Table 10.

FATE OF RESIDUES DURING PROCESSING

No additional information was received by the current Meeting.

RESIDUES IN ANIMAL COMMODITIES

No additional information was received by the current Meeting.

APPRAISAL

Quinclorac is a systemic herbicide used with uptake through roots and foliage and used to control annual grass and broadleaf weeds. It was evaluated by the 2015 JMPR for the first time for toxicology and for residues and re-evaluated in 2017 (R) for additional uses. The 2015 JMPR allocated an ADI of 0–0.4 mg/kg bw, and an ARfD of 2 mg/kg bw.

For plant commodities, the residue definition for compliance with MRLs is quinclorac plus quinclorac conjugates and the residue definition for the estimation of dietary intakes is quinclorac plus quinclorac conjugates plus quinclorac methyl ester expressed as quinclorac. The 2015 JMPR noted that quinclorac methyl ester has a toxicological potency up to 10 times that of quinclorac and agreed to multiply the quinclorac methyl ester residues with a factor of 10 to express it as quinclorac equivalents.

For animal commodities the residue definition for compliance with MRLs and for estimation of dietary intakes is quinclorac plus quinclorac conjugates. The residue is fat-soluble.

Quinclorac was scheduled at the Fifty-first Session of the CCPR for the re-assessment of residue trials for oil seed rape previously considered by the JMPR, which had used an unsuitable analytical method and could not be used for estimating a maximum residue level.

The current Meeting received information on a use pattern, the re-analysis of residue trial samples and commercial demonstration trials for rapeseed at the request of the CCPR51. A use pattern, new residue trials and additional validation data for cranberries were also received by the current Meeting.

Methods of analysis

The current Meeting considered additional procedural recovery data to support the analytical methods previously considered by the JMPR in 2015 and 2017.

Method D1607/01

Residues in cranberries and in oil seed rape were determined using method D1607/01 which was considered by the 2017 JMPR. This method employs three consecutive extraction procedures that allows the separate determination of quinclorac, quinclorac conjugates and quinclorac methyl ester. Final determination was by LC-MS/MS.

The 2017 JMPR concluded that this method was suitable for the analysis of quinclorac and quinclorac methyl ester residues in rape seed and forage. The LOQ for the sum of quinclorac and quinclorac conjugates residues was 0.01 mg/kg, and the LOQ for residues of quinclorac methyl ester was 0.01 mg/kg.

The current Meeting considered procedural recovery data for cranberries. The meeting concluded that method D1607/01 was suitable for the determination of quinclorac and quinclorac methyl ester residues in cranberries. The LOQ for residues for the sum of quinclorac and quinclorac conjugates is 0.02 mg/kg, and the LOQ for residues of quinclorac methyl ester is 0.01 mg/kg.

Multi-residue analytical method (Based on QuEChERS method for acidic herbicides)

The method was employed in the analysis of the rape seed samples from the commercial demonstration trials (=monitoring trials) provided to the current Meeting. The method is similar to the multi-residue analytical method D1502/1 considered by the 2017 JMPR, although the initial extraction employed is different.

Samples were prepared by homogenizing with liquid nitrogen/dry ice. A subsample was hydrated with water and the pH was adjusted to >9 with NaOH. After shaking the sample for 30 minutes and centrifuging, an aliquot was removed and shaken with dichloromethane (DCM). The DCM was then discarded, the pH adjusted to ≤2 with sulfuric acid and extraction was achieved using acetonitrile and 'QuEChERS' salts. Final determination was by LC-MS/MS.

A radio-validation study considered by the 2015 JMPR showed that extraction with acetone/0.1 M NaOH converts the quinclorac methyl ester (if present) partly back into the parent compound. As this may result in an over estimation of parent levels in rapeseed the Meeting considered the method used in the monitoring trials as unsuitable for the estimation of maximum residue levels.

Stability of pesticide residues in stored analytical samples

The JMPR 2015 concluded that for quinclorac residues were stable in cranberries for at least 14 months of storage, covering storage intervals in the newly provided supervised field trials.

For rape seed samples, the 2015 JMPR concluded that quinclorac residues in oil seed rape are stable for at least 22 months. In the re-analysis of the rape seed samples from trials provided in 2017, maximum storage intervals after sampling were 670 days (=22 months).

Results of supervised residue trials on crops

Cranberries

The critical GAP is for the United States, which consists of two applications at 280 g ai/ha, a re-treatment interval (RTI) of 30 days and pre-harvest interval (PHI) of 60 days.

In 2015, four independent trials matching the GAP were assessed by the JMPR. The residues of quinclorac (including conjugates) were reported as (n=4): 0.16, 0.17, 0.18 and 0.67 mg/kg. The highest individual residue measured in cranberries was 0.68 mg/kg. Residues of quinclorac methyl ester were not determined.

The current Meeting noted that the selection of trial data in the 2015 Report does not correspond to the field trial results underlined correctly in the evaluation and instead of a value of 0.55 mg/kg a lower concentration of 0.16 mg/kg from a replicate trial was considered. Consequently, the corrected ranking of residues of quinclorac (including conjugates) was (n=4): 0.17, 0.18, 0.55 and 0.67 mg/kg. The highest individual residue measured in cranberries remains at 0.68 mg/kg.

The current Meeting received five additional new independent residue trials conducted in the United States in 2019 matching the cGAP. Residues of quinclorac (including conjugates) were (n= 5): 0.08, 0.09, 0.11, 0.26 and 0.56 mg/kg. Residues of quinclorac methyl ester were < 0.02(5) mg/kg.

Based on all trials, residues of quinclorac and its conjugates in cranberry for MRL estimation were (n=9): 0.08, 0.09, 0.11, 0.17, 0.18, 0.26, 0.55, 0.56 and 0.67 mg/kg.

The highest individual residue measured in cranberries was 0.68 mg/kg.

The Meeting estimated a maximum residue level of 1.5 mg/kg in cranberries confirming the previous recommendation.

Residues of quinclorac methyl ester were < 0.02 mg/kg in all five of the new trials considered by the current Meeting. In the supporting plant metabolism study on strawberries reviewed by the 2015 Meeting, quinclorac methyl ester residues were below the limit of detection at DAT 60, corresponding to the pre-harvest interval of the critical GAP. Therefore, the Meeting decided that to estimate residues for dietary exposure, a residue of 0.02 mg/kg for quinclorac methyl ester represents a conservative estimate and should be taken into account for the calculation for the total quinclorac residue in all supervised field trials without measurement of the analyte.

The total residue was calculated based on the formula: (quinclorac + quinclorac conjugate) + 10 × quinclorac methyl ester, all expressed as quinclorac.

Residues for dietary intake estimation in cranberries were (n=9): 0.28, 0.29, 0.31, *0.37*, *0.38*, 0.46, *0.75*, 0.76 and *0.87* mg/kg (values in italics involve no measurement of quinclorac methyl ester). The highest individual residue in cranberries is 0.88 mg/kg.

Based on this data set the Meeting estimated an STMR and HR value of 0.375 mg/kg and 0.88 mg/kg respectively.

Rape seed

The critical GAP is from Canada which allows one application of 100 g ai/ha with a PHI of 60 days.

No new supervised field trials were provided to the current Meeting.

The 2015 JMPR considered 17 residue trials conducted in 1997. As residues were determined using method D9708/1, which may overestimate the quinclorac level due to partial hydrolysis of the quinclorac methyl ester, the trials were not suitable for the estimation of a maximum residue level.

The 2017 JMPR considered nine additional residue trials conducted in 2016, that matched the cGAP for Canada, involving analysis with method D1607/01, measuring quinclorac methyl ester and quinclorac (incl. conjugates) separately, and estimated a maximum residue level of 0.15 mg/kg and an STMR of 0.64 mg/kg.

The current Meeting received information on the re-analysis of the samples from the 2016 trials with the intention to derive correction factors, allowing consideration of trials conducted in 1997. The samples were re-analysed using the following methods:

- Method D1607/01 involves three extractions 1) acetonitrile/water, 2) acetone/phosphate buffer pH 7, 3) 1 M NaOH at 100 °C for 1 hr, each extract analysed separately for parent (including parent released from conjugates) and the methyl-ester (considered by the 2017 JMPR);
- Method D9708/1 involves extraction with acetone/0.1 M NaOH for quinclorac and may convert the methyl ester partly to parent. Hence, it may overestimate the quinclorac residue level (considered by the 2015 JMPR);
- Method D9806 involves extraction with acetone for quinclorac methyl ester (considered by the 2015 JMPR).

The Meeting noted that re-analysis of quinclorac residues using method D9708/1 gave less than the validated LOQ of 0.05 mg/kg in seven of the nine trials. In the other two trials, method D9708/1 recovered 151–216percent of the residue initially measured with method D 1607/01.

The Meeting noted a high variability in the results from both methods in combination with a validated LOQ for method D9708/1, too high for quantification of residues in most samples. Therefore, the Meeting decided not to derive analytical correction factors, which would introduce significant uncertainty to the estimations and does not follow its common assessment practice. The Meeting confirmed its previous conclusion that the residue trials from 1997 are not suitable for estimating a maximum residue level.

In addition, the Meeting considered seven commercial demonstration trials (=targeted monitoring data) provided by the request of the CCPR51, conducted according to the Canadian GAP. Each trial consisted of two sub-plots at rates of 75 or 125 g ai/ha and involved analysis of four field samples for each sub-plot.

Residues of quinclorac were determined using the QuEChERS method for acidic herbicides. This included extraction using NaOH which is therefore likely to result in a portion of the quinclorac methyl ester (if present) being converted back into quinclorac.

Noting the potential overestimation of residues according to the residue definition for enforcement purposes, only five individual results (from two sub-plots) out of 56 total measurements exceeded the maximum residue level of 0.15 mg/kg recommended by the 2017 JMPR. In addition, lack of information on important trial parameters such as the dates of harvest and storage periods prior to analysis were noted. The Meeting decided the provided information was unsuitable for maximum residue level estimation.

The Meeting confirmed its previous recommendations of an MRL of 0.15 mg/kg, a median residues value for livestock feed of 0.017 mg/kg for rapeseed and an STMR of 0.64 mg/kg for the estimation of dietary intake, as well as for rape seed oil edible of 0.70 mg/kg

RECOMMENDATIONS

On the basis of the data from supervised trials, the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessment.

Table 11 Recommendations for residues of quinclorac from the 2022 JMPR

Commodity		MRL, mg/kg		STMR or STMR-P, mg/kg	HR or HR-P, mg/kg
CCN	Name	New	Previous		
FB 0265	Cranberries	1.5	1.5	0.375	0.88
SO 0495	Rape seeds	0.15	0.15	0.64 (median: 0.017 for feed calc.)	-
OR 0495	Rape seed oil, edible			0.70	

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The ADI for quinclorac is 0–0.4 mg/kg bw. The International Estimated Daily Intakes (IEDIs) for quinclorac were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the JMPR. The results are shown in Annex 3 of the 2022 JMPR Report.

The IEDIs ranged from 0–1 percent of the maximum ADI. The Meeting concluded that long-term dietary exposure to residues of quinclorac from uses considered by the JMPR is unlikely to present a public health concern

Acute dietary exposure

The ARfD for quinclorac is 2 mg/kg bw. The International Estimate of Short Term Intakes (IESTIs) for quinclorac were calculated for the food commodities and their processed commodities for which HRs/HR-Ps or STMRs/STMR-Ps were estimated by the present Meeting and for which consumption data were available. The results are shown in Annex 4 of the 2022 JMPR report.

The IESTIs were 0percent of the ARfD for children and 0percent of the ARfD for the general population. The Meeting concluded that acute dietary exposure to residues of quinclorac from uses considered by the present Meeting is unlikely to present a public health concern.

QUINTOZENE (064)

First draft prepared by Dr Yukiko Yamada, International Food Safety Consultant, National Institute on Health Sciences, Ministry of Health, Labour & Welfare, Japan

EXPLANATION

Quintozene, pentachloronitrobenzene (IUPAC name), is an aromatic fungicide, used as soil fungicide or for seed treatment of various vegetables, cereal grains, and oil seeds. It is also used as a slime inhibitor in industrial waters and soil treatment of lawns and ornamentals.

Quintozene was first evaluated by the JMPR in 1969 as a new compound for toxicology and residues. It was reviewed under the CCPR periodic re-evaluation by the 1995 JMPR for toxicology and residues.

The 1998 JMPR received data on environmental fate, residues in rotational crops, additional supervised trials and processing on certain commodities. The 1998 JMPR confirmed the residue definitions and estimated maximum residue levels and STMRs for a number of commodities. The 2004 JMPR estimated maximum residue levels for spices on a basis of monitoring data.

The Forty-third Codex Alimentarius Commission (2020) approved the new work proposals including the priority list of pesticides for evaluation by the 2021 Meeting, including periodic re-evaluation of quintozene. As a result of postponement of the evaluation, quintozene is evaluated by the current Meeting.

No specification has been established for quintozene by the Joint FAO/WHO Meeting on Pesticide Specifications.

The Meeting received information on identity, chemical and physical properties, plant and animal metabolism, rotational crop studies, environmental fate, residue analysis and storage stability, use pattern, supervised trials on various crop, and processing studies.

IDENTITY

ISO common name:	Quintozene
Chemical name	
IUPAC:	Pentachloronitrobenzene (IUPAC PIN, 1,2,3,4,5-pentachloro-6-nitrobenzene)
CAS:	1,2,3,4,5-pentachloro-6-nitrobenzene
CAS Registry No.:	82-68-8
CIPAC No.:	78
Synonym	quintozene (pentachloronitrobenzene)
Structural formula:	Molecular formula:	$C_6Cl_5NO_2$
Molecular mass:	295.33 g/mol

PHYSICAL AND CHEMICAL PROPERTIES

Property	Results	Reference
Appearance	Off white to dark tan coloured crystalline solid with slight musty odour (TGAI)	Suppl. MRID 406686602
Density (specific gravity)	1.72 g/mL (TGAI)	Suppl. MRID 406686602
Dissociation constant	No dissociation	Suppl. MRID 406686602
Melting point	141–146 °C (TGAI)	Suppl. MRID 406686602
Boiling point	Not required (solid at room temperature)	Suppl. MRID 406686602
Vapour pressure	1.27×10^{-2} Pa at 25 °C (Purity, 99 percent)	Thomson, 1989, 900-PCH-305
Solubility in water	1×10^{-4} g/L at 25 °C (purity, 99.2 percent)	Batorewicz & Bakker, 1988, 900-PCH-252
Solubility in organic solvents at 20°C	Acetone 134 g/L Acetonitrile, 46 g/kg Dichloromethane 345 g/kg Ethyl acetate 161 g/L Hexane 33 g/kg Methanol 12 g/kg n-Octanol 8.6 g/L Toluene 618 g/kg (purity, 99.9 percent)	Donnelly, 1998, 900-PCH-175
Octanol/water partition coefficient (Log K_{ow})	5–6 (pH 7, 27 °C) (purity, 99.2 percent)	Polakoff B.M., 1987, 900-PCH-244
Hydrolysis in sterile buffer in the dark	Hydrolytically stable (after 30 days at 25 °C, at pH 5, 7 or 9, no significant degradation was observed) (purity, 99.2 percent)	Bowman B.R., 1988a, 900-PHO-008
Photolysis in sterile water under artificial light	Half-life of quintozene (0.075 mg/L) in sterilized acetate buffer at pH 5 at 25±1 °C under 32 h continuous irradiation with Xenon arc lamp (650 W/m^2): 13.4 h (r^2 =.0.99). Photodegradation products after 32 h: isomeric mixture of chlorinated hydroxybenzenes and/or chloronitrophenols (comprising 49.8 percent of the applied radioactivity).	Horree, D.J., 1992, 900-PHO-018

Formulations

Quintozene is available in the following formulations:

- Flowable (FL) formulation containing quintozene at 480 g/L (40 percent, w/w);
- Wettable powder (WP) formulation containing quintozene at 750 g/kg;
- Emulsifiable concentrate (EC) formulation containing quintozene at 240 g/L;
- Granule (GR) formulation containing quintozene at 100 g/kg.

According to the manufacturer, hexachlorobenzene is allowed up to 0.03–0.05 percent as an impurity in TGAI in the countries where quintozene or PCNB (see Table 1) is registered (the 1995 JMPR reported the maximum to be 0.1 percent at the time of evaluation.).

METABOLISM AND ENVIRONMENTAL FATE

Table 1 below shows the code numbers, IUPAC names and structures of the compounds appearing in the various metabolism and environmental fate studies.

Table 1 Structure of compounds appearing in metabolism and environmental fate studies

Compound Name/Code (MW, g/mol)	IUPAC name	Structure	Found in (food and feed commodities):
5 chlorine atoms on the phenyl ring			
Quintozene Synonym: PCNB (295.32)	Pentachloronitrobenzene		Potato (whole, peel), peanut root, cabbage, Rotational crops (lettuce, wheat foliage), Chicken fat
PCA (265.34)	Pentachloroaniline		Potato (whole, peel), peanut, Rotational crops (turnip top & root, lettuce, wheat foliage), Goat liver, kidney, fat, milk, Chicken fat, egg
PCTA (296.41)	Methyl pentachlorophenyl sulfide (pentachlorothioanisole)		Potato (whole, peel), cabbage, Rotational crops (turnip root, lettuce, wheat foliage), Chicken muscle, egg
PB (250.32)	Pentachlorobenzene		Potato, Rotational crops (lettuce, wheat foliage), Chicken egg
PCA-Gluc (455.49)	*N*-(pentachloroaniline) glucuronide		Goat liver, kidney
PCAN (280.35)	Pentachloroanisole		Potato
PCP (266.32)	Pentachlorophenol		Rotational crops (turnip top & root)
PCP Cys (369.46)	*S*-(pentachlorophenyl) cysteine		Potato (whole, peel), Chicken kidney

Compound Name/Code (MW, g/mol)	IUPAC name	Structure	Found in (food and feed commodities):
PCP-GluCys (498.58)	S-(Pentachlorophenyl)-γ-glutamylcysteine		Potato (whole, peel)
PCP Gly (428.46)	Pentachlorophenol glycoside		Potato peel
PCP-GSH (555.63)	S-(Pentachlorophenyl) glutathione		Potato, Rotational crops (wheat foliage)
PCP-MalCys (455.51)	*S*-(Pentachlorophenyl) malonylcysteine or Pentachlorothiophenyl malonylcysteine (PCTP-MalCys)		Potato, peanut, Rotational crops (lettuce)
PCP-MalCys ester (469.54)	S-(Pentachlorophenyl) malonylcysteine monomethyl ester		Potato (whole, peel), peanut root Chicken excreta
PCP thioacetate (340.42)	*S*-(pentachlorophenyl) thioacetate		Chicken liver, kidney, muscle, excreta
PCP thiopyruvate (368.43)	*S*-(pentachlorophenyl) thiopyruvate		Chicken excreta
PCTASO (PCPMS) (C5MX) (312.41)	Pentachlorophenyl methyl sulfoxide (Pentachlorothioanisole sulfoxide)		Cabbage, Rotational crops (turnip top & root, wheat foliage), Soil (rotational crop study) Chicken liver

Compound Name/Code (MW, g/mol)	IUPAC name	Structure	Found in (food and feed commodities):
PCTASOO (C5MS) (328.41)	Pentachlorothioanisole sulfone		Soil
PCTP (282.38)	Pentachlorothiophenol		Goat liver, kidney Chicken liver, egg, excreta
PCTP dimer (562.75)	Pentachlorothiophenol dimer		Goat liver
PCTP-Gly (444.53)	Pentachlorothiophenyl glycoside		Potato peel
PCTP-X (-)	Pentachlorothiophenyl conjugate		Potato peel, Goat urine
Pentachloroaniline sulfamate (345.40)	Pentachloroaniline sulfamate		Goat urine
NOHPCA (281.34)	*N*-Hydroxypentachloroaniline		Potato (whole, peel), peanut root, cabbage, Goat liver, Chicken kidney
NOHPCA-Gluc [a] (455.49)	Glucuronide of NOHPCA	--	Goat liver

Compound Name/Code (MW, g/mol)	IUPAC name	Structure	Found in (food and feed commodities):
C5SA (330.38)	Pentachlorobenzene-sulfonic acid		Rotational crops (turnip top & root, lettuce, wheat foliage)
C5SAHx (492.52)	Pentachlorobenzene-sulfonic acid hexose ester		Rotational crops (wheat foliage)
C5MX	See PCTASO		
C5MS	See PCTASOO.		
4 chlorine atoms on the phenyl ring			
TCA (230.90)	Tetrachloroaniline		Peanut root
TCA sulfoxide isomers (292.98)	Tetrachloroaniline methyl sulfoxide		Potato, Goat kidney, Chicken fat
TC-MES-P-GSH (583.27)	S-(Tetrachloro-methyl sulfoxy-phenyl)glutathione		Potato
TC-MES-P-MalCys (483.15)	S-(Tetrachloro-methyl sulfoxy-phenyl) malonylcysteine		Potato
TC-MET-A sulfamate (357.04)	Tetrachloro-methylthio-aniline sulfamate		Potato
TCNB isomers (260.88)	Tetrachloronitrobenzene		Potato (whole, peel)

Compound Name/Code (MW, g/mol)	IUPAC name	Structure	Found in (food and feed commodities):
TCNB sulfonic acid isomers (340.94)	Tetrachloronitrobenzene sulfonic acid		Potato
TCNP (276.88)	Tetrachloronitrophenol		Potato (peel)
TCNP-GSH (566.18)	S-(Tetrachloronitrophenyl) glutathione		Potato, peanut
TCNP-MalCys (466.06)	S-(Tetrachloronitrophenyl) malonylcysteine		Potato, peanut
TCNTA isomers (290.91)	Tetrachloronitrothioanisole		Potato
TCP (231.88)	Tetrachlorophenol		Potato (peel)
TCP-diGSH (826.49)	S,S'-(Tetrachlorophenyl) diglutathione		Potato
TCP-dithioacetate (396.07)	S,S'-(Tetrachlorophenyl) dithioacetate		Potato
TCP-GluCys-Cys (583.27)	S,S'-(Tetrachlorophenyl)-γ-glutamyl cysteine-cysteine		Potato

Compound Name/Code (MW, g/mol)	IUPAC name	Structure	Found in (food and feed commodities):
TCP sulfoxide (293.97)	Tetrachlorohydroxyphenyl methyl sulfoxide		Potato
TCPM sulfoxide (C4MX) (277.97)	Tetrachlorophenyl methyl sulfoxide		Cabbage, Rotational crops (wheat foliage)
TCTA (261.97)	Tetrachlorothioanisole		Goat kidney, Chicken fat
TCTP S-Met (294.03)	Tetrachloro (methylthio) thiophenol		Goat liver, kidney, urine
TCTASOO (C4MS) (TCP methyl sulfone) (293.97)	Tetrachlorophenyl methyl sulfone		Cabbage, Rotational crops (turnip top & root, lettuce) Chicken kidney, muscle
TCTP sulfoxide (310.03)	Tetrachlorothiophenol methyl sulfoxide		Potato
TCTP sulfonic acid (328.00)	Tetrachlorothiophenol sulfonic acid		Potato
AM TCA isomers (245.91)	Aminotetrachloroaniline		Potato
AM TCA sulfamate (325.97)	Aminotetrachloroaniline sulfamate		Potato

Compound Name/Code (MW, g/mol)	IUPAC name	Structure	Found in (food and feed commodities):
AM TCB sulfonic acid (310.95)	Aminotetrachlorobenzene sulfonic acid or (C4SANH) (tetrachlorosulfanilic acid)		Potato, peanut, Rotational crops (wheat foliage)
AC TCP-Cys-CysHOG (626.29)	Acetyl S,S'-(tetrachlorophenyl) cysteine-cysteinyl α-hydroxyglutarate		Potato
MTCP-TAA (352.07)	*S*-[(methylthio)tetrachloro-phenyl]-2-thioacetic acid		Peanut root
N-malonyl-S-(tetrachloroaminophenyl)-cysteine (436.08)	N-malonyl-S-(tetrachloroaminophenyl)-cysteine		Peanut
NOHAM TCA (246.90)	N-Hydroxyamino-tetrachloroaniline		Potato
NOHAM TCP (262.90)	N-Hydroxyamino-tetrachlorophenol		Potato
NOHAM TCTA isomers (292.98)	N-Hydroxyamino-tetrachlorophenol		Potato
OH TCA (246.90)	Hydroxytetrachloroaniline		Potato
C4CyCy (454.16)	*S,S'*-tetrachlorophenyl dicysteine		Rotational crops (wheat foliage)

Compound Name/Code (MW, g/mol)	IUPAC name	Structure	Found in (food and feed commodities):
C4CyFCy (482.17)	*S*-(tetrachlorophenyl)-cysteine-*S'*-formylcysteine		Rotational crops (lettuce)
C4MaCyFCy (582.24)	*S*-(tetrachlorophenyl)-*N*-malonylcysteine-*S'*-formylcysteine		Rotational crops (lettuce, wheat foliage)
C4MeAcCy (347.08)	*N*-{1-methyl-2[(tetrachlorophenyl)-thio] ethyl}acetamide (tetrachlorophenyl methyl cysteine)		Rotational crops (lettuce, wheat foliage)
C4MSSA (374.02)	Tetrachlorosulfophenyl methyl sulfone (tetrachlorothioanisole sulfone, sulfonic acid)		Rotational crops (wheat foliage)
C4MXSA (358.03)	Tetrachlorosulfophenyl methylsulfoxide (tetrachlorothioanisole sulfoxide, sulfonic acid)		Rotational crops (wheat foliage)
C4SA (295.94)	Tetrachlorobenzene-sulfonic acid		Rotational crops (turnip top & root, lettuce, wheat foliage)
C4MX	See TCPM sulfoxide		
C4MS	See TCTASOO		
3 chlorine atoms on the phenyl ring			
RCA GluCys-Cys (563.85)	S,S'-(trichloroanilino)-γ-glutamylcysteine-cysteine		Potato
RCHM sulfone (275.52)	Trichlorophenol methyl sulfone		Cabbage

Compound Name/Code (MW, g/mol)	IUPAC name	Structure	Found in (food and feed commodities):
RCNA sulfoxide (303.54)	Trichloronitroaniline methyl sulfoxide		Potato
RCNP-MalCys thioacetate (521.72)	S,S'-(trichloronitrophenyl) malonyl cysteine-thioacetate		Potato
RCTA-GluCys-Cys (594.92)	S,S'-(trichlorothioanisole)-γ-glutamylcysteine-cysteine		Potato
diAC RCAN GSH-Cys (719.98)	Diacetyl *S,S'*-(trichloro-anisole) glutathione-cysteine		Potato
diAC RCTA-diGluCys (808.11)	Diacetyl *S,S'*-(trichloro-thioanisole) diglutathione		Potato
NOHAM RC-OME-A (242.48)	N-hydroxyamino-trichloro-methoxy aniline		Potato
NOH RC-diMET-A (304.63)	N-hydroxy-trichloro-dimethylthioaniline		Potato
C3MS (259.53)	Trichlorophenyl methyl sulfone		Cabbage, Rotational crops (turnip top & root, lettuce, wheat foliage)

Compound Name/Code (MW, g/mol)	IUPAC name	Structure	Found in (food and feed commodities):
C3MSMaCy (464.71)	*N*-malonyl-S-trichloro-(methylsulfonophenyl)-L-cysteine *S*-(trichlorophenyl methyl sulfone)-malonyl cysteine		Rotational crops (turnip root, lettuce)
C3MSSA (339.58)	Trichlorosulfophenyl methyl sulfone (trichlorothioanisole sulfone, sulfonic acid)		Rotational crops (turnip top & root, wheat foliage)
C3MX (243.53)	Trichlorophenyl methyl sulfoxide		Cabbage
C3MXSA (323.58)	Trichlorosulfophenyl methyl sulfoxide (trichlorothioanisole sulfoxide, sulfonic acid)		Rotational crops (wheat foliage)
C3SA (261.50)	Trichlorobenzenesulfonic acid		Rotational crops (turnip top & root, wheat foliage)
C3SANH (276.51)	Trichlorosulfanilic acid		Rotational crops (wheat foliage)
C3SAOH (277.50)	Hydroxy-trichlorobenzene sulfonic acid (trichloro-hydroxybenzene sulfonic acid)		Rotational crops (wheat foliage)
2 chlorine atoms on the phenyl ring			
C2MSMaCy (430.27)	*N*-malonyl-S-dichloro-(methylsulfonophenyl)-L-cysteine-*S*-(dichlorophenyl methyl sulfone)-malonyl cysteine		Rotational crops (turnip top & root)

Compound Name/Code (MW, g/mol)	IUPAC name	Structure	Found in (food and feed commodities):
C2MSSA (305.14)	Dichlorosulfophenyl methyl sulfone (dichlorothioanisole, sulfonic acid)		Rotational crops (wheat foliage)
C2SA (227.06)	Dichlorobenzenesulfonic acid		Rotational crops (turnip top & root, wheat foliage)
Impurity			
HCB (284.77)	Hexachlorobenzene		Impurity

Notes:

[a] Assumed to be equal to PCA-gluc from the proposed structure in the goat metabolism study.

Some code keys (not comprehensive).

First two letters of the code: PC, pentachloro-; TC, tetrachloro-; and RC, trichloro-.Cn, phenyl ring with n chlorine atoms attached to the ring.

SA, sulfonic acid; SO, sulfoxide; SOO, sulfone; MX, methyl sulfoxide; MS, methyl sulfone; Ma or Mal, malonyl; Cys or Cy, cysteinyl; F, formyl, Me, methyl.

The fate and behaviour of quintozene in plants, animal, and soils were investigated using the quintozene uniformly labelled with ^{14}C in the phenyl ring of the molecule. The positions of ^{14}C are shown in Figure 1.

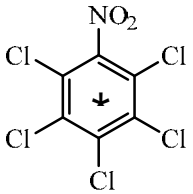

Figure 1 [U-^{14}C]-phenyl labelled quintozene used in the metabolism and environmental fate studies

Plant metabolism

The Meeting received information on the fate of [U-^{14}C]-phenyl labelled quintozene (hereafter abbreviated as ^{14}C-quintozene) in cabbage, potato and peanut after soil treatments. Residues in harvested seeds of maize, peas, sugar beet, wheat and soya bean were also investigated after seed treatment. In the following texts, TRR is expressed in mg-quintozene equivalents/kg.

Cabbage

***Study 1** (McManus & Maisonet, 1990, 900-RES-082)*

The metabolism of quintozene was studied on cabbage plants (variety Stonehead) grown in a greenhouse (temperature controlled) in galvanized steel containers (61 cm × 61 cm × 183 cm = 2 ft × 2 ft × 6 ft) containing soil treated with a single application of ^{14}C-quintozene at 53.8 kg ai/ha before transplanting of 28-day old cabbage plants. Whole plants of cabbage were harvested at one-quarter to one-third (49 DAT), one-half (70 DAT) and full (154 DAT) maturity. At the final harvest, each cabbage head was cut with a knife at the base. The remaining leaves from each of the cabbage plants were also collected. Samples from 49 DAT and 70 DAT were stored frozen immediately after harvest and kept frozen before and after analysis. At the final harvest, two samples of cabbage heads and surrounding leaves were stored in a refrigerator. All remaining samples from the final harvest were stored in a freezer at approximately -20 °C before and after analysis.

Samples were homogenized to a fine consistency with an aid of liquid nitrogen. Homogenized samples were analysed for total radioactive residues (TRR) by combustion / liquid scintillation counting (LSC).

For characterization/identification of residues, a sample aliquot (30 g) was extracted three times with methanol/water (80:20; v/v; 180 mL), followed by acetone (180 ml), then air dried. Liquid fractions were radio-assayed by LSC and unextracted residue in the solids determined by combustion/LSC. The unextracted radioactivity was hydrolysed with methanolic HCl (the ratio of methanol and HCl was not described) at 60 °C for 30 minutes.

The methanol/water extract of the leaf sample was evaporated under vacuum to a small amount and the remaining liquid was passed through a C-18 reverse phase cartridge. Metabolites were eluted with methanol. Radioactive residues were separated by reverse-phase HPLC using a gradient from 100 percent water to 100 percent methanol (both of them contained 1 percent formic acid) and analysed by mass spectrometry in the chemical ionization mode. The radioactive metabolites detected in the radio-chromatogram were collected by preparative HPLC. Collected metabolites were concentrated under nitrogen prior to mass spectral analysis.

The two samples of whole plants taken at the immature stages showed the TRR ranging from 4.1 to 7.9 mg eq/kg. At the maturity, the highest levels of radioactivity were found in the outer leaves (11–18 mg/kg), with lower levels in the heads of 0.70–2.5 mg/kg. (Table 2)

Table 2 Radioactive residues in immature cabbage plants and mature cabbage heads and outer leaves following soil treatment with quintozene at 53.8 kg ai/ha before planting

Sample	DAT	Maturity	TRR (mg eq/kg)	
			Individual values	Mean
Immature whole plant	48	1/4–1/3	7.72; 7.88	7.80
	70	1/2	4.09; 6.39	5.24
Mature head	154	Full	0.874, 0.704, 0.776, 0.757; 1.38, 2.49, 0.914, 1.22	1.14
Mature outer leaves	154	Full	13.0, 11.9, 14.9, 14.6; 16.1, 17.9, 11.7, 11.0	13.89

Table 3 shows that methanol/water extracted 57.5 percent of the total radioactivity in cabbage leaves and acetone 14.7 percent TRR. The post extraction solid (PES) contained 27.8 percent TRR. After refluxing the PES in methanolic HCL for 30 minutes at 60 °C, the radioactivity was soluble in methanol.

Table 3 Extraction of radioactive residues in mature cabbage outer leaves by the solvents and by reflux

Extraction Procedure	% TRR (in outer leaves)
3x MeOH/H_2O (80:20; v/v)	57.5
1x Acetone	14.7
PES	27.8
Heating PES in MeOH/HCl (30 min)	Solubilized

Seven metabolites were identified in MeOH/water extracts of leaf, all of which were more polar than quintozene. From the peak areas of HPLC radio-chromatograms, percent TRR were calculated. These metabolites were isolated and collected by preparative HPLC and analysed by mass spectrometry or by comparison with standard reagents if they were available.

The two main compounds were TCPM sulfoxide (36.1 percent TRR) and TCPM sulfone (41.9 percent TRR). Five minor components (all <10 percent TRR) were identified as a ring-hydroxylated C3MS, C3MS, NOHPCA, PCTASO and PCTA (Table 4).

Attempts were made to identify and quantify metabolites in the solubilized fraction. It was found that the HPLC of solubilized fraction showed similar metabolite profile as the methanol/water extract but the quantification was unsuccessful due to low level radioactivity of each peak and interference from the endogenous plant materials.

Table 4 Metabolites in the methanol/water extracts of cabbage outer leaves following soil application of quintozene at 53.8 kg ai/ha (in the order of high to low polarity)

Component	% TRR
Ring-hydroxylated C3MS	3.7
C3MS [a]	8.9
TCPM sulfoxide (C4MX) [a]	36.1
NOHPCA	4.0
TCPM sulfone [a]	41.9
PCTASO	4.9
PCTA	0.5
Total	100

Notes:

[a] Previously reported as a metabolite of quintozene in parsnip (Cairns *et al.,* 1987).

***Study 2** (Premkumar & Brown, 1992, 900-RES-003)*

Cabbage plants (variety, Copenhagen) were grown in outdoor test plots in California, United States, with sandy loamy soil treated with a single application of ^{14}C-quintozene at 33.7 kg ai/ha. Cabbage seeds were sown after the treatment. Cabbage was harvested at an immature stage (120 DAT) as whole plants, and at maturity (209 DAT) and separated into heads with wrapper leaves, heads without wrapper leaves, and wrapper leaves. Samples were stored frozen immediately after sampling and shipped on dry ice to the analytical laboratory.

Samples were homogenized together with dry ice to a powder-like consistency and stored at -20 °C until analysis. Homogenized samples were analysed for TRR by combustion/LSC.

Table 5 shows the TRR values of all the samples. The highest TRR was observed in immature cabbage plants. The mature cabbage contained significantly less radioactivity and most of the radioactivity was located in wrapper leaves. The combustion was repeated for wrapper leaves and whole cabbage after a long period of freezer storage. The second combustion resulted in higher TRR values,

possibly due to desiccation and repeated thawing and freezing. The TRR values in soil ranged from 2.33 to 5.45 mg eq/kg on a wet weight basis, which indicates that the distribution of quintozene was heterogenous.

Table 5 Radioactive residues in immature cabbage, mature cabbage and soil after soil treatment by quintozene at 33.7 kg ai/ha before planting

Sample	DAT	Mean TRR (mg eq/kg) [a]
Immature cabbage	120	3.37
Mature whole cabbage	209	0.28
Mature cabbage head	209	0.11
Mature wrapper leaves	209	2.03
Soil (0–15 cm)	2 h	5.06 (wet weight basis)

Notes:

[a] Corrected for matrix and oxidizer recovery.

The cabbage samples (whole plant, heads with and without wrapper leaves, and wrapper leaves) were first extracted with hexane followed by methanol. Portions of the mature whole cabbage and mature cabbage wrapper leaf samples were stored frozen. After a long period of storage, they were subjected to the same extraction procedures as above. In these later extractions, the methanol extracts were partitioned with iso-octane, and the iso-octane layers and aqueous layers were separately concentrated under nitrogen gas flow.

The soil samples were extracted with acetone, which extracted 100 percent of TRR.

Sequential extraction with hexane and then methanol extracted a total of about 40–70 percent TRR with about 30–60 percent TRR remaining in the PES. The extractability into hexane and methanol were comparable for each matrix (much higher extractability in methanol than in hexane) as shown in Table 6.

Table 6 Extraction of radioactive residues in immature and mature cabbage samples, after about 5 months and 20–32 months of frozen storage after harvest

Sample	Extraction timing, months after harvest	Hexane extract		Methanol extract		Total		PES

	32 [b]	0.173	6.1	1.40	49.2	1.57	55.3	1.21	42.7
Mature whole cabbage	20 [c]	0.008	2.3	0.161	45.0	0.169	47.3	0.189	52.6
	31 [d]	0.022	7.7	0.17	59.7	0.192	67.4	0.093	32.6

Notes:

[a] TRR, 2.38 mg eq/kg.

[b] TRR, 2.84 mg eq/kg.

[c] TRR, 0.359 mg eq/kg.

[d] TRR, 0.285 mg eq/kg.

The hexane and methanol extracts were profiled by TLC and reversed phase HPLC-UV (gradient with 1 percent acetic acid and acetonitrile). Extractions and HPLC analyses were conducted sometimes more than two years after the harvest due to a problem in developing the HPLC method. Due to the long duration between the harvest and extraction and between extraction and analysis, storage stability was tested for metabolites in the hexane extracts and those in the methanol extracts of wrapper leaves and whole cabbage by comparing the chromatograms before and after the storage. It was found that the metabolites in the hexane extracts were stable during the storage while those in methanol extracts were not. Initial analysis showed more complex profile than the later analysis. Polar metabolites in peaks E, F, G and H seemed to degrade to those in peak D while M1 and M2 in peak C were stable. Only the analytical results of non-polar metabolites and M1/M2 can be used.

In the immature cabbage sample, the level of identification was low at 18.1 percent and total recovery was also low at 65.5 percent TRR. Seven compounds were identified: parent and five metabolites, PCA, PCTA, 6-TCNB and the malonylcysteine conjugates of PCP and TCNP (contained in a single peak of C of HPLC), and impurity HCB. None of them exceeded 10 percent TRR. Metabolites in four polar peak regions (A, D, E and F) were not identified due to their low-level presence.

Table 7 Metabolites in the hexane and methanol extracts of immature cabbage following soil application with quintozene at 33.7 kg ai/ha before planting

Component/region	Hexane extract		Methanol extract		Total	
	mg/kg	% TRR	mg/kg	% TRR	mg/kg	% TRR

Notes:

[a] M1 = TCNP-MalCys; M2 = PCP-MalCys.

In the mature wrapper leaves, the level of identification was low (4.8 or 15.6 percent TRR). Six compounds were identified: parent, the metabolites PCA, PCTA, PB and the malonylcysteine conjugates of PCP and TCNP. None of them exceeded 10 percent TRR. Metabolites in six peak regions (B, D, E, F, G) could not be identified. The TRR of region D was 33 percent TRR (0.93 mg eq/kg) but D region contained a series of peaks suggesting the presence of several components. After freezer storage for about 2 years, metabolites in regions B, E–G seem to be converted to those in region D (less polar region).

The HPLC chromatogram of the last extraction conducted 35 months after harvest showed no peak in the hexane extract and only peaks D and H in the methanol extract, 36.9 and 6.0 percent TRR respectively corresponding to 0.709 and 0.115 mg eq/kg. The PES from methanol extraction contained 43.6 percent TRR (0.839 mg eq/kg).

Notes:

[a] M1 = TCNP-MalCys; M2 = PCP-MalCys.

The methanol extract and PES of the mature cabbage wrapper leaf sample was hydrolysed with 6 mol/L HCl and partitions with dichloromethane. However, only 12.7 percent TRR of methanol extract and 1.9 percent TRR of PES were solubilized.

In the mature whole cabbage, only PCTA and the malonylcysteine conjugates of PCP and TCNP could be identified at small levels up to 5.5 percent TRR (0.016 mg/kg) whereas six regions (up to 43 percent TRR (0.12 mg/kg)) could not be identified. Parent quintozene was not detected.

Potato

Study 1 *(Parkins, 1990, 900-RES-005)*

Potato seed pieces (variety unknown) were planted outdoor into the soil treated with ^{14}C-quintozene by pre-plant incorporation at a rate of 21.1 kg ai/ha.

Potato tubers were harvested at early maturity (11 weeks after planting) and brushed to remove adhering soil. Samples were immediately frozen for shipment and storage until analysis. Frozen samples were thawed to room temperature just prior to analysis. Subsamples were rinsed with warm tap water, dried with paper towels, and cut into quarters. Most of the quarters were separated into peel and flesh fractions while the remaining part was used as the whole potato fraction. The samples were blended with an equal weight of dry ice. The dry ice was allowed to sublime, and aliquots of blended sample were taken for combustion.

Samples were extracted with 80 percent methanol. The methanol was evaporated, and the remainder was adjusted to pH 5.5, and partitioned with chloroform. The spent aqueous phase was then adjusted to pH 2.0 and partitioned with ethyl ether.

Unextracted radioactivity in potato peels was released by heating in anhydrous methanolic HCl for methanolysis at 60 °C for up to two hours according to the method of Tang and Crone (Analytical Biochemistry, Vol. 182 (2), pages 289–294, 1989). The peel hydrolysates were dried by rotary evaporation at 30 °C. The residues were resolubilized in water, partially cleaned up by C18 solid phase extraction and eluted with acetonitrile and methanol. These eluates were analysed by HPLC by co-chromatography with reference standards.

The identification of metabolites focused on the peel, since the highest level of radioactivity was detected in the peel. The aqueous methanol, chloroform and ethyl ether fractions were cleaned up by TLC and HPLC (C18 reverse phase column) followed by mass spectrometric identification. The aqueous phase received additional clean-up on an XAD2 column. Samples were introduced into the mass spectrometer by direct exposure probe utilizing positive and negative chemical ionization with ammonia, methane and isobutane as reagent gases, by thermos-spray utilizing ammonium acetate ionization, or by GC.

TRR obtained by combustion were 2.39 mg/kg in whole potatoes, 11.26 mg/kg in potato peel, and 0.76 mg/kg in potato flesh. Analysis of the chloroform, ethyl ether and water fractions revealed that in potato peel, 38 percent of the total radioactivity (sum of TRRs in fractions and PES) was soluble in chloroform, 11 percent in ethyl ether and 10 percent in water with 40 percent remained in the PES. (Table 10). There is a marked difference in the TRR obtained by combustion versus that obtained by summing up the TRR values in the extracts and PES. This may be because of quenching during LSC. For further calculation of percent TRR, the values obtained as the sum of fractions and PES are used.

Table 10 Radioactive residues in combusted potato and in extracts of potato after soil treatment by quintozene at 21.1 kg ai/ha before planting

Sample	TRR [a] by combustion mg eq/kg	TRR in fractions and PES (mg eq/kg)				
		Chloroform	Ethyl ether	Water	PES	Total
Peel	11.26	6.39	1.83	1.80	6.79	16.81
Flesh	0.76	0.09	0.07	0.16	0.09	0.41
Whole potato	2.39	0.12	0.15	0.23	0.13	0.63

Notes:

[a] Before extraction.

TLC of the chloroform fraction from the peel sample separated into three radioactive bands, each of which was recovered from the plates and further fractionated by reversed phase HPLC. Chloroform soluble metabolites were identified by reconstructed ion chromatography (RIC) and mass spectrometry as PCTA, TCP, unchanged parent, PCA, TCNP and NOHPCA. The first five compounds were found only or mostly in the chloroform fractions while NOHPCA was found in chloroform, ethyl ether and water fractions at almost equal amounts.

TLC of the ethyl ether fraction from the peel sample separated five radioactive bands. The three bands comprising 91 percent of the radioactivity present on the TLC plate were further resolved by HPLC into eight distinct peaks. Potato callus tissue was treated with ^{14}C-quintozene to generate-sufficient material for identification. Ethyl ether soluble material from the callus tissue yielded metabolite peaks with retention times similar to those from the peel fractions. Based on mass spectrometric fragmentation patterns, the following compounds were tentatively identified: PCP-Cys, PCTP-X, PCTP-Gly, PCP-glycoside (PCP-Gly), PCTP-MalCys, a gamma-glutamylcysteine and a glycoside conjugate. The exogenous moieties were identified as PCTP and PCP but which exogenous and endogenous moieties were connected was not identified. However, the likely products are PCTP gamma-glutamylcysteine (PCTP-GluCys) and PCP-Gly (found in a different fraction from traction of the PCP-Gly mentioned above).

TLC of the water extract isolated three radioactive bands which were further separated by HPLC. Identification of radioactive material in the peaks was not confirmed by mass spectrometry, but identities were assumed to be the same as similar elution peaks from chloroform and ethyl ether soluble fractions.

The radioactivity in whole potato was extracted and fractionated as described for peel; the chloroform, ethyl ether, and aqueous extracts were examined by HPLC. The chloroform and ethyl ether soluble fractions each contained four peaks. Tentative identification, based on identifications in the peel, are: NOHPCA, PCA, PCTA, PCTP-MalCys, PCTP-Cys, an artefact and an unknown. The water-soluble fraction yielded two HPLC peaks: PCT-Cys (possibly misidentified) and NOHPCA.

Table 11 Metabolites in the chloroform, ethyl ether and water extracts of potato peel and whole potato following soil application with quintozene at 21.1 kg ai/ha before planting

Component/region	Potato peel		Whole potato	
	mg/kg [a]	% TRR [b]	mg/kg [c]	% TRR [d]

Unexplained [c,d]	-2.83	-16.8	0.08	12.8
Total	16.81	100	0.63	100

Notes:

n.d.: Not detected (LOD calculated to be 0.0062 mg eq/kg).

[a] Sum of the concentrations in chloroform, ethyl ether and water extracts.

[b] Based on the sum of TRR of extracts and PES as quintozene.

[c] Expressed as quintozene.

[d] Calculated by subtracting (radioactivity in PES) and (total identified radioactivity) from the total radioactivity.

Hydrolysis of the PES from potato peel (6.79 mg eq/kg) was reported to release 71 percent of the radioactivity and the released metabolites were purified by passing them through a reverse phase solid phase extraction cartridge and eluting them with acetonitrile and methanol. The eluates were analysed by HPLC with co-chromatography with known reference standards. The peaks matched those of PCA, PCP, and TCP (trace amount).

***Study 2**. (Premkumar and Brown, 1992, 900-RES-004)*

Potatoes (variety Centennial) were grown in outdoor plot in California, United States, in sandy loam soil treated pre-plant with a single application of ^{14}C-quintozene at 30.4 kg ai/ha and incorporated into a depth of 3 inches (7.6 cm). Duplicate samples were harvested from the treated plot. The aerial parts of potato (foliage) were harvested at a 92 DAT (early stage). Aerial parts and tubers were harvested separately at 122 DAT (early stage) and 154 DAT (mature stage). Samples were frozen immediately after sampling and shipped frozen to the analytical laboratory.

Samples were homogenized to a powder-like consistency with dry ice and stored at -20 °C until analysis. Homogenized samples were analysed for TRR by combustion/LSC. The TRR obtained by combustion/LSC of homogenized sample aliquots are shown in Table 10. The immature tuber sample (122 DAT) contained the highest TRR (11.3 mg eq/kg) while the TRR decreased drastically to 1.37 mg eq/kg at the maturity (154 DAT) as the tubers grew.

Table 12 Radioactive residues in potato foliage and tubers after soil treatment by quintozene at 30.4 kg ai/ha before planting

Sample	DAT	TRR (mg eq/kg) [a]	
		1st combustion	2nd combustion
Potato foliage (immature)	92	1.13	--
	122	5.74	7.07
Potato foliage (mature)	154	4.27	4.90
Potato tuber (immature)	122	11.25	--
Potato tuber (mature)	154	1.37	--
Soil (0–15 cm) [b]	2 h	3.74 (dw)	--
Soil (0–15 cm)	3	(dw)	--

Notes:

[a] Corrected for matrix and oxidizer recovery.

[b] Soil core was damaged during shipping, which was the reason for obtaining another soil sample at 3 DAT.

The potato matrices (foliage and tubers) were first extracted with hexane followed by methanol. The methanol extract and the PES from potato foliage and immature tubers were individually treated for 18 hours with 6 mol/L HCl at 120 °C in a closed tube in the presence of nitrogen. However, this attempt to release radioactivity was unsuccessful with only 21.7 percent of TRR in methanol extract and 5.4 percent of TRR in the PES were partitioned in dichloromethane with significant loss of radioactivity.

The extractabilities into the hexane and methanol extracts were comparable for each matrix. Extractability of the radioactivity in potato foliage and tubers with hexane and methanol was 53–77 percent TRR. The ratio of non-polar metabolites (radioactivity in hexane extracts) was low between 10–29 percent TRR. PES contained 23–48 percent TRR.

Table 13 Extraction of radioactive residues in immature and mature potato samples, after harvest and after about 2-years frozen storage

Notes:

[a] M1 = TCNP-MalCys; M2 = PCP-MalCys.

[b] TRR, 4.90 mg eq/kg.

As the 122 DAT potato tubers contained higher TRR than the 155 tubers, the hexane extract was used to validate the GC analytical method. Portions of the tuber samples were extracted 2.9 months after the harvest with ethyl acetate and the extract was cleaned up using Florisil column. The eluate from the Florisil column was concentrated and reconstituted with iso-octane for GC and HPLC. The results of analysis of iso-octane were shown for the earlier extraction in the following table.

In the 122 DAT potato tuber sample, nine compounds were identified: parent and the metabolites PCA, PCTA, PCTP, PB, 4-TCNB, 6-TCNB and the malonylcysteine conjugates of PCP and TCNP and the impurity HCB. Seven polar peak regions were not identified although region D accounted for up to 25.3 percent TRR and up to 2.44 mg eq/kg. Iso-Octane fraction showed similar metabolite pattern of polar metabolites as the hexane extract, but the Florisil clean-up apparently removed M1+M2 (region C) and region D. The levels of total identified were 23 percent and 38 percent of TRR in the two extractions.

In the 154 DAT potato tuber sample, level of identification was low (21 percent TRR). Five compounds were identified: the metabolites PCA, PCTA, PB and the malonylcysteine conjugates of PCP and TCNP. Parent compound was not detected. Three peak regions with TRR up to 26.3 percent were not identified.

Study 3 *(Fang & Mertz, 1999, 900-RES-043)*

To better identify the metabolites of quintozene in potato, a new study was conducted. Potato plants (variety Superior) were grown outdoors in sandy loam soil. The soil was treated with ^{14}C-quintozene applied by pre-plant incorporation at a rate of 22.4 kg ai/ha or 67.3 kg ai/ha, and, on the same day, seed potatoes were planted in the treated soil in half wine barrels at a depth of 10 cm and covered by treated soil. As per agricultural practice, when the plants reached a height of 10–13 cm, they were "hilled" with treated soil, which was repeated when the plants had grown another 10–13 cm. The potato tuber, stem and foliage were harvested 95 days after treatment/planting when the plants had undergone renascence. The samples were stored frozen until analysis.

The frozen potatoes were washed with water to remove adhering soil. The samples were blended with an equal amount of dry ice and aliquots were taken for combustion. Potato tubers were extracted first with methanol followed by 80 percent aqueous methanol. The combined extracts were partitioned with hexane to obtain the hexane fraction. The residual solids from methanol and 80 percent methanol extraction were further extracted (exhaustive extraction) with 80 percent methanol, 50 percent aqueous methanol and then water. These extracts were combined with the aqueous layer from hexane partition. From the combined layer/extracts, methanol was removed and partitioned with ethyl ether to get ether-I fraction. The aqueous layer was adjusted to pH 3 and partitioned with ethyl ether to obtain ether-II fraction and final aqueous fraction. The solids remaining after the second set of extraction with aqueous methanol and water were regarded as PES.

The PES was subjected to enzymatic treatment with α-amylase, cellulase, iso-maltase, maltase, pectinase, and protease, each at their optimum pH. Then, the PES from the enzymatic treatment was subjected to acid treatment (1 mol/L acetyl chloride in methanol) or base hydrolysis (6 mol/L NaOH or KOH) for 2 hours at elevated temperature.

TRR in whole potatoes obtained by combustion were 1.12 mg eq/kg (22.4 kg ai/ha) and 3.54 mg eq/kg (67.3 kg ai/ha).

The majority of the radioactive residue (87–90 percent TRR) was extracted with methanol and methanol/water followed by exhaustive extraction with methanol/water mixtures and water. In the PES, low levels of radioactivity remained unextracted: 6.74 percent TRR (22.4 kg ai/ha) and 9.92 percent TRR (67.3 kg ai/ha).

The TRR present in whole potatoes and the fractions (hexane, ether-I, ether-II aqueous fractions and PES) obtained by extraction and partition are shown in Table 17.

Table 17 TRR and radioactivity in the hexane, ether-I, ether-II and aqueous fractions and PES of 95 DAT whole potato following soil application with quintozene before planting

Fraction	22.4 kg ai/ha		67.3 kg ai/ha	
	mg eq/kg	% TRR	mg eq/kg	% TRR
Whole potato tubers	1.12	100	3.54	100
Solvent extracted	1.05	93.5	3.27	92.3
Hexane fraction	0.18	16.4	0.40	11.4
Ether-I fraction	0.09	8.07	0.27	7.60
Ether-II fraction	0.29	25.5	1.03	29.1
Aqueous fraction	0.45	39.9	1.37	38.6
Total of fractions	1.01	89.8	3.07	86.7
PES	0.08	6.74	0.35	9.92

The metabolites in the fractions in the table above were identified by HPLC-MS, HPLC-MS/MS, GC-MS and GC-MS/MS. Parent and 48 metabolites were identified as shown in Table 18.

The metabolite profile was similar for both application rates, and the identified components together accounted for 60.1–64.1 percent of the TRR. Although no single component accounted for >10 percent of the TRR, except for PCP-MalCys from 67.3 kg ai/ha application, approximately half of the identified radioactivity (27–30 percent TRR) was comprised of five components. The two most abundant residues were parent (7.5–8.0 percent TRR) and PCP-MalCys (9.8–10 percent TRR). Another three metabolites were: PCA (2.4–4.3 percent TRR), PCTA (2.7–3.5 percent TRR), and AM TCB sulfonic acid (3.9–4.8 percent TRR). The rest 44 metabolites each accounted for ≤ 2.8 percent of the TRR. PB was detected at 1.0–1.9 percent of the TRR (≤0.014 mg/kg).

In the hexane fractions, the major component was parent quintozene. Eleven non-polar metabolites were identified with 12 other metabolites at levels too low to quantify. Impurity HCB was below the LOD of 0.001 mg/kg.

The ether-I fraction contained 11 non-polar metabolites. The ether-II fraction contained PCP-MalCys accounting for 10 percent TRR and eight structurally related compounds.

The aqueous fraction contained 32 metabolites. The most abundant metabolite was AMTCB Sulfonic acid accounting for about 9 percent and 6 percent TRR in this fraction.

The PES were treated with variety of enzymes. Protease released about 40 percent of the TRR in the PES, and the molecular sieves indicated that much of the radioactivity was associated with substances with molecular weight higher than 3000. The enzymes used to hydrolyse carbohydrate released minimal amount of radioactivity.

Notes:

[a] 12 minor metabolites in the hexane fraction were identified by GC-MS accounting for 5.81 percent TRR (22.4 kg ai/ha) and 3.77 percent TRR (67.3 kg ai/ha) of the radioactivity in the hexane fraction.

Peanuts

***Study 1** (McManus, 1990, 900-RES-125)*

Peanut plants (variety unknown) were grown in soil that had been treated with ^{14}C-quintozene at a rate equivalent to 420 kg ai/ha for incorporation to a depth of 15 cm. Whether plants were grown outdoor or indoor was not described in the study report.

Peanut whole plants were harvested 21 weeks after planting/treatment and separated into vines, shells, nuts and roots. The vines were air dried. The roots and peanuts were washed with dilute detergent and rinsed with deionized water. The peanut shell and nutmeat were separated and blotted dry, along with the roots, with a paper towel and allowed to air-dry overnight. The samples were then homogenized in a blender with crushed dry ice and stored in plastic bags in the freezer. Subsamples were combusted for determination of TRR.

Sample aliquots of the ground roots, vines, shells and nutmeat were extracted by high-speed homogenization with methanol/water (80:20; v/v) followed by acetone. The extracts were concentrated under reduced pressure prior to clean-up by C-18 solid phase extraction. Radioactive residues in the cleaned-up extracts were analysed by reverse phase HPLC. The extracted plant materials were combusted for TRR analysis. The methanol/water extracts were applied to preparative TLC. The radioactive bands scraped from the plates were extracted with methanol and radioactive metabolites were isolated by preparative HPLC. Metabolites collected multiple times were combined and concentrated under nitrogen prior to mass spectrometry.

The PES were subjected to combustion/LSC. The PES was incubated at 37 °C for 48 hours in 0.5 mL methanolic-HCl (1 mol/L acetyl chloride in methanol).

The highest TRR levels were found in the roots at 1521 mg eq/kg. The vines, shells and nutmeat had lower residues ranging from 42 mg eq/kg in the vines to 5.2 mg eq/kg in the nutmeat. Extraction with methanol/water removed 64–88 percent of the radioactive residue. The PES retained radioactivity from 454 mg eq/kg in the roots to 0.94 mg eq/kg in the nutmeat. An average of more than 90 percent of these residues in the shells, vines and nutmeat was liberated by hydrolysis with methanolic HCl.

Table 19 Radioactive residues in peanut root, vine, shell and nutmeat samples following soil treatment with quintozene at 420 kg ai/ha before planting

Peanut sample	Total radioactivity		Extracted by solvents		PES	
	mg eq/kg	% TRR [a]	mg eq/kg	% TRR [b]	mg eq/kg	% TRR [b]
Roots	1521	28.0	1020	67.1	454	29.9
Vines	42.3	46.1	47.4	>100	14.8	35.0
Shells	128	23.9	121	94.1	4.46	3.5
Nutmeat	5.16	1.93	6.1	>100	0.94	18.3
	Total	99.9				

Notes:

[a] percent of TRR in whole plant.

[b] percent of TRR in respective sample.

The methanol/water extracts were analysed for characterization/identification of residues. The extracts contained seven metabolites. Two major metabolites were identified as PCP-MalCys and TCA, which were found in the roots (33 percent and 25 percent TRR, respectively), vines (20 percent and 14 percent TRR, respectively) and shells (42 percent and 22 percent TRR, respectively). PCP-MalCys was also found in nutmeat at 6.7 percent TRR (0.26 mg eq/kg). Of the five other metabolites, one was identified as MTCP-TAA (*S*-[(methylthio)tetrachlorophenyl]-2-thioacetic acid) which accounted for 14 percent TRR in vines but 8.7 percent TRR in roots and 7.4 percent TRR in shells. The other four minor metabolites (Ia, Ib, II and Vb) were also found in roots, vines, shells and nutmeat, but levels were too low for identification.

Study 2 *(Premkumar & Brown, 1992; 900-RES-002)*

Peanuts (variety Jumbo Virginia) were grown in outdoor plots in California, United States. A single application of ^{14}C-quintozene at 37.9 kg ai/ha was made to sandy loam soil for incorporation into top 7.6 cm of soil. Peanut was planted into the treated soil on the same day of application.

The aerial parts of peanuts (foliage) were harvested at 92 DAT at an early stage. The mature sample was harvested at 185 DAT and separated into vines (foliage), hulls and nut meat. Samples were stored frozen immediately after sampling and shipped on dry ice to the analytical laboratory and stored frozen until analysis in two different freezers.

Samples were homogenized to a powder-like consistency, when possible, under assistance of dry ice and stored at -20 °C until analysis. Homogenized samples were analysed for TRR by combustion/LSC and the results are presented in Table 21.

Table 21 Radioactive residues in peanut foliage, hulls and nutmeat following soil treatment by quintozene at 37.9 kg ai/ha before planting

Peanut sample	DAT	TRR (mg eq/kg) [a]
Foliage	92	3.50
	154	3.97
Hulls	185	26.3
Nutmeat	185	2.00
Soil (0–15 cm)	3	5.94 (dw) [b]

Notes:

[a] Corrected for matrix and oxidizer recovery.

[b] Mean normalized value.

The peanut vines, hulls and nutmeat were first extracted with hexane followed by methanol. The extractions of vines, hulls and nutmeat were carried out more than once using the same extraction solvents at different timing. For peanut vine sample, the hexane extract was concentrated under nitrogen and the resulting hexane fraction was used for GC and HPLC analysis while the resulting aqueous fraction was combined with the methanol extract. The combined fraction was concentrated under nitrogen to obtain the methanol fraction. The remaining solids after methanol extraction were regarded as PES.

The extractabilities into hexane and then into methanol were comparable for each matrix. Extractability of the radioactivity in peanut foliage, hulls and nutmeat with hexane and methanol was 50–87 percent TRR and 13–50 percent TRR remained unextracted in the PES.

The soil was extracted with acetone which solubilized 96.7 percent TRR in soil.

Table 22 Extraction of radioactive residues in mature peanut vine, hulls and nutmeat following soil treatment by quintozene at 37.9 kg ai/ha before planting

Peanut sample	TRR	Hexane extract		Methanol ext.		Total		PES	
		mg eq /kg	% TRR	mg eq /kg	% TRR	mg eq /kg	% TRR	mg eq /kg	% TRR

Hulls	24.3	1.61	6.6	10.6	43.7	12.2	50.3	12.1	49.7
Nutmeat	2.10	1.19	56.6	0.643	30.6	1.83	87.2	0.269	12.8

The hexane and methanol extracts are profiled by TLC, HPLC-UV and GC-ECD.

In the 154 DAT vines, seven compounds were identified: parent and the metabolites PCA, PCTA, PB, 4-TCNB and the malonylcysteine conjugates of PCP and TCNP. Three peak regions (B, D and H), each of which accounted for less than 10 percent TRR, could not be identified.

Notes:

[a] M1 = TCNP-MalCys and M2 = PCP-MalCys.

The identification of 185 DAT nutmeat was not straightforward because it was based on three different extractions: third extraction was conducted to determine the distribution of radioactivity into hexane, methanol and PES (quantitative values in the hexane extract were based on the GC analysis from this extraction; fourth extraction and fifth extraction were conducted as the methanol extract from the third extraction did not provide satisfactory HPLC profiles due to low level radioactivity relative to natural products in this extract. The methanol extract from the fourth extraction was concentrated. Water was added to the concentrate which was then acidified and partitioned between diethyl ether and water. As in the process of concentration of the fourth extract 12 percent of the TRR was lost, in the fifth extraction, the methanol extract was partitioned into iso-octane without concentration. The loss of 12 percent was accounted for by the iso-octane fraction. Table 25 includes the values obtained from three different extractions.

In the 185 DAT nutmeat, eight compounds were identified: parent and the metabolites PCA, PCTA, PB, 4-TCNB, 6-TCNB and the malonylcysteine conjugates of PCP and TCNP. Three peak regions with TRR <10 percent were not identified.

The methanol extracts and the PES from peanuts foliage and nutmeat were hydrolysed by treatment for 18 hours (foliage) or 3 hours (nutmeat) with 6 mol/L HCl at 110 °C in a closed tube in the presence of nitrogen. The majority of radioactivity in the PES remained unextracted after HCl hydrolysis. It was not possible to solubilize significant amount of radioactivity contained in the PES. From methanol extract of nutmeat, after partitioning into iso-octane or methanol extract of vines, HCl hydrolysis released 60 percent or 42 percent, respectively, of the radioactivity in these extracts but it was not possible to identify the released radioactivity.

Study 3 *(McManus & DeMatteo, 1999; 900-RES-042)*

Peanut plants (variety Florunner) were grown in plastic buckets in a greenhouse, with artificial fluorescent lighting for a 14-h photo period, in Connecticut, United States, under simulated normal agronomic conditions. Two groups of treated plants were employed. One group (T1) was treated by pre-plant soil incorporation with ^{14}C-quintozene at a rate of 16.8 kg ai/ha and, after the treatment, peanut seeds were sown. The second group (T2) was treated with ^{14}C-quintozene in two band applications, each at 5.6 kg ai/ha, during and after pegging time, 68 days and 117 days after planting. Peanut seeds were sown on the same day in the first and second group.

Mature plants (193 DAT for pre-plant soil incorporation, and 76 DALA for band applications) were harvested by cutting the plants just above the soil line and vines, roots and peanuts (nutmeat and shells) were separated. The vines were air dried overnight at room temperature to obtain hay. The roots and peanuts were washed with deionized water. The peanut shells and nutmeat were air dried, along with the roots, overnight in a hood. The samples of hay, root, shell, and nutmeat were homogenized to a fine powder with dry ice. Levels of radioactivity in plant samples were determined by combustion/LSC.

The highest levels of radioactivity were found in the shells (166–211 mg eq/kg). The roots, hay and nutmeats had lower residues ranging from 49–122 mg eq/kg in the roots to 1.7–2.1 mg eq/kg in the nutmeat.

Table 26 Radioactive residues in mature peanut samples after soil treatment by quintozene

Peanut sample	TRR (mg eq/kg)	
	Pre-plant soil incorporation at 16.8 kg ai/ha (T1)	Two banded applications, each at 5.6 kg ai/ha (T2)
Hay (dried vines)	13.0	16.3
Nutmeat	2.14	1.72
Shells	166	211
Roots	122	49.0

Subsamples of homogenized hay, nutmeat, shell, and root were extracted by sonication with methanol/water (20:80; v/v) followed by acetone. After centrifugation, the supernatants were separated. The pellets were exhaustively extracted with each solvent system. All extracts were combined and concentrated by rotary evaporation prior to quantification by LSC. Additionally, hay extracts were partitioned with chloroform and two phases (organic and aqueous) were separately radio-assayed by LSC.

Alternatively, Soxhlet extraction was attempted. Aliquots of homogenized hay were extracted for 6 hours with methanol and the methanol extract was radio-assayed by LSC. Aliquots of homogenized

nutmeat were extracted for 4 hours with hexane to remove oils and then extracted with methanol. The hexane and methanol extracts were radio-assayed by LSC.

The remaining solids of nutmeat and hay were incubated at 60 °C for 24 hours in 5 mL methanolic HCl (1 mol/L acetyl chloride in methanol). Following centrifugation, the supernatant was analysed by LSC.

For extraction of radioactivity in nutmeat, Soxhlet extraction was more efficient than sonication. Soxhlet extraction removed 62–66 percent TRR in the nutmeat. For peanut hay, sonication was more efficient than Soxhlet extraction. Sonication removed 62–63 percent TRR in the hay.

Acid hydrolysis additionally removed 30–43 percent of respective TRR. The radioactivity remaining in the PES after acid hydrolysis ranged from 0.06 mg/kg in the nutmeat to 0.95 mg/kg in the hay.

Notes:

[a] After acid hydrolysis

Quantitative HPLC analyses of nutmeats and hay extracts from the two band applications (post-emergence) identified 96.6 percent of the TRR in nutmeats and 91.7 percent of the TRR in hay. Metabolite identities were confirmed using GC/ECD, GC/MS and/or LC/MS.

In nutmeats, the major radioactive residue was quintozene, accounting for 96.6 percent of the TRR (1.7 mg/kg), along with trace levels of PCA.

Table 28 Metabolites in the hexane and methanol extracts and after methanolic HCl hydrolysis of mature peanut meat following 2 band applications with quintozene each at 5.6 kg ai/ha

Compound	Hexane ext. + Methanol Ext.		MeOH/HCl hydrolysate		Total	
	mg/kg	% TRR	mg/kg	% TRR	mg/kg	% TRR
Quintozene	1.1	62.4	0.59	34.2	1.69	96.6
PCA	Trace		--	--	--	--
Total identified					1.69	96.6
PES					0.06	3.40
TRR					1.72	100

In hay, the main residues included: quintozene (18.8 percent TRR, 3.1 mg/kg), PCTP-MalCys (53.1 percent TRR, 8.65 mg eq/kg), and *N*-malonyl-*S*-(tetrachloroaminophenyl)-cysteine (19.8 percent TRR, 3.23 mg eq/kg). Trace amounts of TCNP-MalCys and TCNP-GSH were also identified.

Table 29 Metabolites in the hexane and methanol extracts and after methanolic HCl hydrolysis of mature peanut hay following 2 band applications with quintozene each at 5.6 kg ai/ha

Compound	MeOH/water ext. (Partitioned with chloroform/water)		MeOH/HCl hydrolysate		Total	
	mg/kg	% TRR	mg/kg	% TRR	mg/kg	% TRR
Quintozene	3.06	18.8	--	--	3.06	18.8
PCTP-MalCys	3.83	23.5	4.82	29.6	8.20	53.1
TCNP-MalCys	Trace		--	--		
N-malonyl-S-(tetrachloroaminophenyl)-cysteine	3.23	19.8	--	--	3.23	19.8
TCNP-GSH	Trace		--	--		
Total identified					14.5	91.7
Acetone extract (none identified)					0.47	2.86
PES					0.95	5.84
TRR					16.3	100

While no quantitative information was reported in the study report on metabolites in shell extracts, qualitative information was available. In the peanut shells following soil incorporation treatment, four radioactive metabolites were detected, two principal metabolites and two others in small amounts. Two principal metabolites were quintozene and PCTP-MalCys, and two at smaller amounts were TCNP-MalCys and tetrachloroaminophenyl sulfonic acid.

Treated Seeds (Selman, 1988; 900-RES-058)

Seeds of maize, peas, soya bean, sugar beet and wheat were treated with ^{14}C-quintozene at: 1.7 g ai/kg for sugar beet seeds, 0.72 g ai/kg for soya beans, and about 0.4 g ai/kg for maize, peas and wheat.

The treated seeds were sown and grown in an open-sided greenhouse which allowed exposure to natural sun and weather conditions while eliminating the potential for flooding from rain. Crop matrices were sampled at different growing stages to cover commercially available food and feed commodities. These samples were frozen on the same day of sampling and stored frozen until analysis. Each sample was analysed for radioactivity by combustion/LSC.

There was uptake of radioactivity by all the crops. The highest levels were found in the dry pea vines and soya bean stems at 1.8 and 1.5 mg eq/kg respectively at harvest. The levels in fresh pea vines, sugar beet roots, soya bean hay and wheat forage were 0.57, 0.46, 0.74 and 0.54 mg eq/kg, respectively, and in maize stover and wheat straw 0.02 and 0.06 mg eq/kg, respectively. None of the harvested seeds/grains from maize, wheat, soya bean or peas or other commodities than those mentioned above contained residues above the minimum quantifiable limits.

Table 30 Radioactive residues in commercial commodities following seed treatment of various crop seeds by quintozene

Summary of Plant Metabolism

Metabolism of quintozene in plants after pre-plant soil incorporation application was studied on cabbage, potato and peanut using quintozene uniformly labelled on phenyl ring. In the case of peanut, metabolism following two banded applications to soil at the pegging stage was also investigated. The studies were conducted either outdoor or in greenhouse (one of which allowed sunlight).

In the studies on these crops conducted in 1990 and 1992, intervals between the sample collection and extraction were long, some of them longer than 2 years, pending the development of appropriate analytical method. The storage stability tests conducted during these studies indicated that compounds extracted in non-polar fractions were relatively stable but those extracted in polar fractions might be degraded showing different profiles after long storage. In addition, the identified metabolites and their quantities of the same crop were not consistent between the 1990 study and 1992 study, and none of the compounds in the polar fractions was identified. Therefore, new studies were conducted in 1999 on potato and peanut.

In the newer studies on potato, close to 50 components were identified and quantified including those in the polar fractions showing similar profiles between 22.4 and 67.3 kg ai/ha application rates. About 60–64 percent TRR were identified and approximately about one half of the identified radioactivity (27–30 percent TRR) was comprised of five compounds. PCP-MalCys and its esters together accounted for 10–13 percent TRR. This compound was also found in the old studies on cabbage, potato and peanut. Parent quintozene accounted for 7.5–8.0 percent TRR. PCA and PCTA accounted for 2.4–4.3 percent and 2.7–3.5 percent TRR respectively. AM TCB sulfonic acid accounted for 3.9–4.8 percent TRR. No other metabolites accounted for more than 2.8 percent TRR while the concentrations of many metabolites were higher than 0.01 mg/kg. PB was detected up to 1.9 percent TRR (up to 0.014 mg/kg).

Newly identified metabolites have the common structure of phenyl ring with 2 to 5 chlorine atoms through dichlorination. The nitro group of quintozene was either reduced to NHOH, eliminated or displaced with sulfhydryl group of glutathione conjugate, which is metabolized or oxidized to become sulfoxide,

sulfone and sulfonic acid. They may be further metabolized to produce conjugates with glutathione, cysteine, malonylcysteine, glucose and others or incorporated into biomolecule.

In older studies on cabbage, potato and peanut, the most significant identified metabolites were the sum of TCNP-MalCys and PCP-MalCys (not separated) accounting for about 30 percent TRR. Quintozene, PCA and PCTA were also identified, sometimes more than 10 percent TRR. Therefore, in general, there may be common metabolism among crops.

The proposed metabolic pathway of quintozene in plants after soil treatment based on the new potato metabolism study is presented in Figure 2.

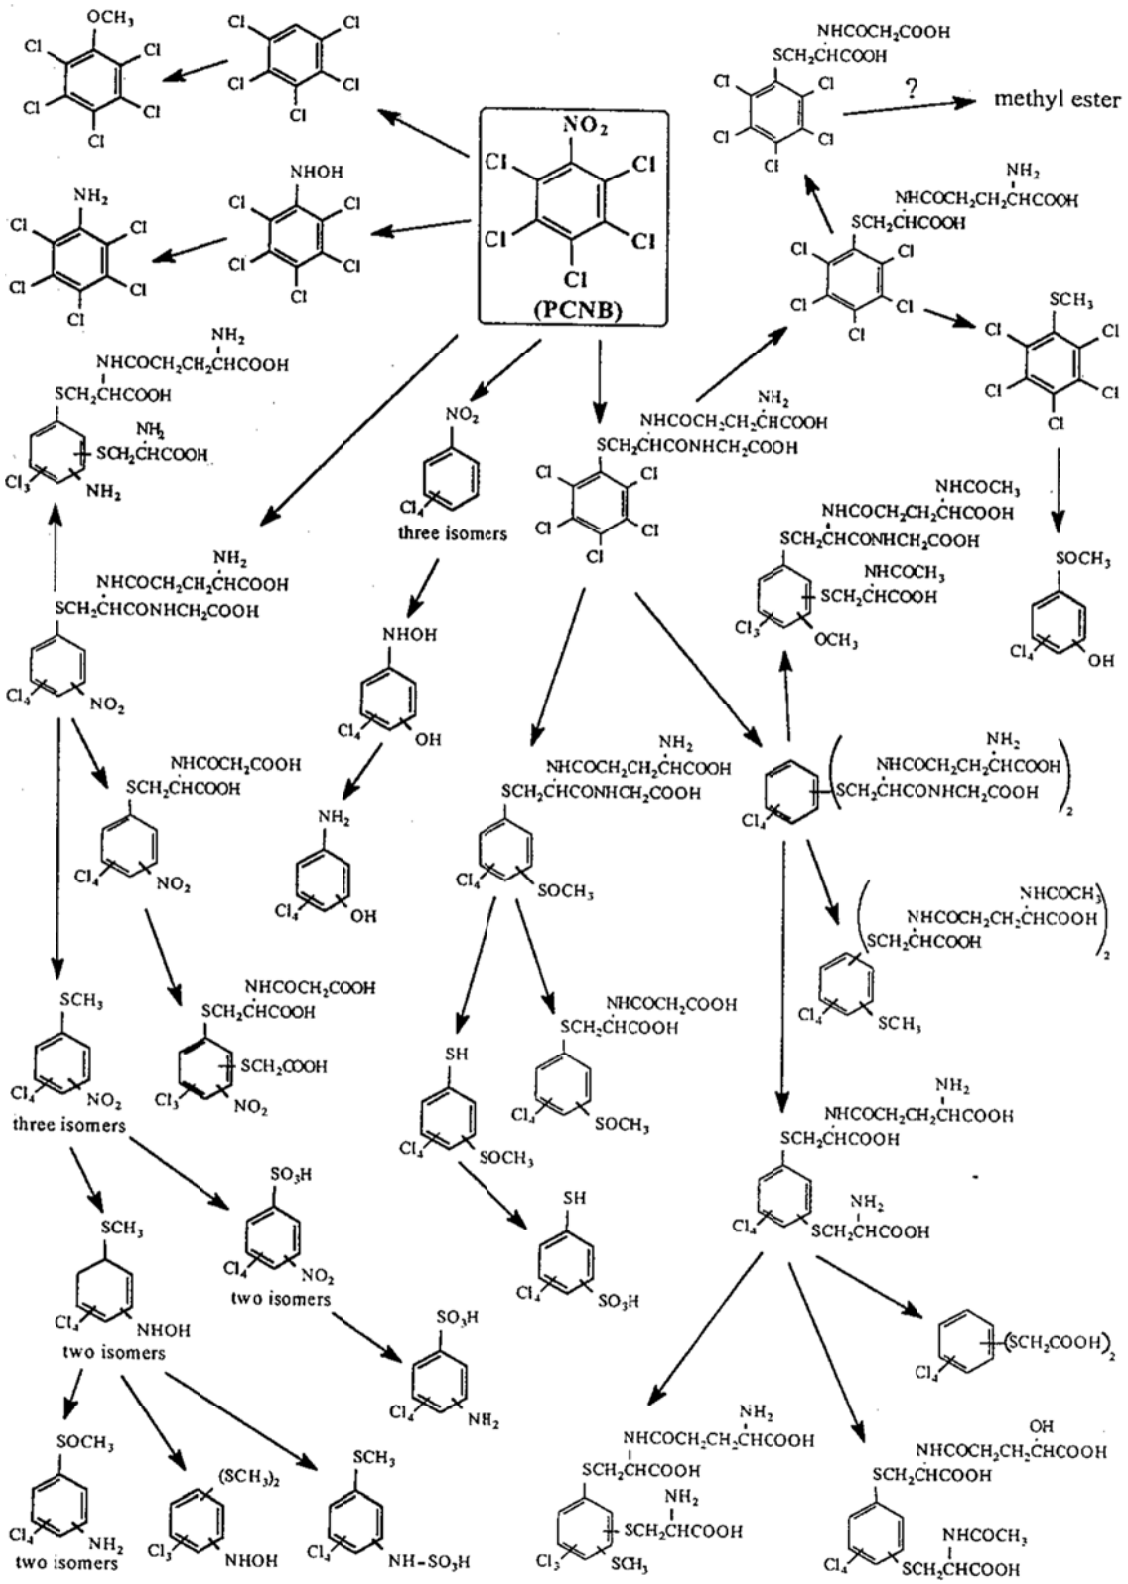

Figure 2 Proposed metabolic pathway of quintozene in plants after soil treatment (based on the studies on potato)

ENVIRONMENTAL FATE

The Meeting received information on environmental fate of quintozene: aerobic soil degradation, anaerobic soil degradation, soil photolysis, field dissipation in soil, adsorption and desorption in soil, and confined and field rotational crop studies. As quintozene has been registered for soil applications, and the use pattern included uses on potato and peanut, the results of studies on degradation in aerobic soil, soil photolysis, hydrolysis, rotational crop studies are relevant to this evaluation. According to the FAO Manual, field dissipation study is a conditional requirement depending on the results of confined rotational crop study. The relevant studies were evaluated and described below.

Aerobic degradation in soils

Study 1. *(Misra, 1993, 900-MET-012)*

Aerobic soil metabolism of ^{14}C-quintozene was studied for 365 days at quintozene concentration of 10 mg/kg on a microbially viable sandy loam soil (pH 6.3, organic matter 4.8 percent; cation exchange capacity 13.4 m eq/100 g, and soil moisture content 22 percent at 33 kPa). The soil temperature in dark was maintained at 25±1 °C and at or around 75 percent field moisture capacity (FMC) at 33 kPa. At the end of the incubation period, soil from the test vessel was transferred into a centrifuge bottle. The rinse of the test vessel with 10 percent 1/3 mol/L phosphoric acid in acetonitrile was added to the soil and the soil was extracted by shaking for about a minute followed by sonication for 10 minutes. Then the soil was centrifuged. The supernatant was collected and this procedure was repeated two more times and the combined soil extract was analysed by LSC and HPLC. GS-MS method was also used for samples from selected sampling periods to confirm the identity of metabolites.

Combustion analysis of the PES indicated that the extraction efficiency of the phosphoric acid decreased with increased incubation time. The soil samples from 30 to 365 days were additionally extracted with 20 percent 1/3 mol/L phosphoric acid in acetone and/or 20 percent 1/3 mol/L phosphoric acid in acetonitrile. The soil extracts were directly analysed by LSC and were concentrated under reduced pressure for HPLC analysis.

The major metabolites identified during the study were: PCA, PCTA, PB, PCTASO and PCTASOO with the maximum concentrations of 9 percent, 8 percent, 1 percent, 4 percent and 6 percent of applied quintozene, respectively. PCA and PCTA were the primary metabolites of quintozene during the study period. PCTASO and PCTASOO, the oxidized form of PCTA, were detected only in soil extracts.

The half-life of quintozene was estimated using a first order kinetics to be 189 days (coefficient of determination (R^2) = 0.79). However, the concentration of quintozene in soil reached less than half of the initially applied concentration in 60 days. The estimated half-life in first order approximation was higher because of the non-linearity of quintozene degradation. Independent first order regression analysis of the first five and last eight points of the data set improved correlation coefficients to 0.95 and 0.92, which gave estimated half-life values of 20 and 278 days, respectively.

Study 2. *(DeFelice, et al., 1977, 900-MOB-006)*

Laboratory leaching studies were conducted with ^{14}C-quintozene on four soil types: sandy loam (pH 4.8, organic matter 1.5 percent, moisture 13 percent at 33 kPa), silt loam (pH 5.0, organic matter 2.0 percent, moisture 30 percent at 33 kPa), sandy soil (pH 5.7, organic matter 0.9 percent, moisture 12 percent at 33kPa), and silt loam (pH 4.7, organic matter 2.5 percent, moisture not reported). ^{14}C-Quintozene was added uniformly to the top 5 cm of a column of 20 cm of untreated soil. Three column volumes of aqueous 0.01 mol/L $CaSO_4$ was then passed through the column. The profile of ^{14}C-quintozene was obtained in the $CaSO_4$ effluents and in 5 cm soil sections.

Quintozene was found to leach in small amounts (2 to 17 percent in four soil types) and only into the adjacent untreated soil zone. Less than 0.1 percent of the added radioactivity was found in the $CaSO_4$ effluent of all the soils tested. Leaching data on two soils aged for 30 days were similar to tests run immediately after treatment with ^{14}C-quintozene.

The recovery of radioactivity in each leaching experiment was in good agreement with the amount added to each column. Cold analyses of quintozene in the hexane phase after partitioning also agreed well with the radioactive count.

Photodegradation in soil

Study 1. *(Bowman B., 1988; 900-PHO-015)*

To samples of sandy loam soil (pH 6.2, organic matter 1.6 percent, moisture 15 percent at 33 kPa) in borosilicate vials, ^{14}C-quintozene in acetonitrile was added at 10.5 µg/g. The vials were then flame sealed to avoid volatilization and the soil samples were exposed to a xenon arc lamp (approximately ½ of the intensity of the sun; filtered to eliminate radiation wavelengths below 290 nm) for 30 days at 25±1 °C. Samples were removed at day 1, 1.02, 3.13, 7.10, 14.0 and 30.1, and extracted with acetone. The extracts were analysed by TLC for degradates by comparing with the standards (quintozene, 2,3,4,5-TCNB, PCA, PCTA, 2,3,5,6-TCNB, HCB and PB). The day 30 soil was extracted by acetone and analysed using GC-MS.

Quintozene was volatile on the surface of soil when irradiated without sealing the vessel. The mean overall total radioactivity recovered was 97.5 percent of the applied radioactivity when the sealed vessels were used. TLC analysis indicated that quintozene was photodegraded on the surface of soil: after 30 days of irradiation, PCA was the major photodegradation product (34.7 percent of the extracted radioactivity). There were no other major photodegradation products in 30 days. In the dark controls, the extracted radioactivity was essentially all quintozene. No degradation products were detected in these samples.

Based on the level of ^{14}C-quintozene in the extracts, a rate constant of 0.0313/day and a half-life of 22.2 days were calculated for the exposed soils. Quintozene was increasingly unextracted from the soil with time. A rate constant based on the loss of quintozene to soil binding was calculated to be 0.00696/day (half-life = 99.6 days). A corrected photolysis rate constant ($k_{exposed} - k_{dark}$) was calculated to be 0.0243/day (half-life = 28.5 days).

Study 2. *(Misra, 1993; 900-PHO-022)*

A thirty-day photolysis study of quintozene in a sandy loam soil (pH 6.3, organic matter 4.8 percent, moisture 22 percent at 33 kPa) was conducted by maintaining soils at around 75 percent FMC at 33 kPa and 25±1 °C, using a specially designed photolysis apparatus (jacketed stainless-steel box and a series of volatile traps with 1 mol/L NaOH and 1 mol/L H_2SO_4). To the soil, ^{14}C-quintozene was added at 9.6 µg/g and the soil was irradiated by a xenon arc light. A dark control study under similar conditions was carried out to compare the rates of degradation under artificial sunlight (12 hours light/12 hours dark cycle per day) with that of the dark control. At the end of irradiation period, the soil was extracted with 10 percent 1/3 mol/L phosphoric acid by shaking, sonication and centrifugation. Radioactivity in samples was measured using LSC. For analysing ^{14}C-quintozene and its degradates in the extracts, HPLC was primarily used. GC-MSD was used for confirmation purposes for the identification of quintozene and its degradates at selected sampling periods.

The major degradates of quintozene identified in sandy loam soil extracts after photo-irradiation were PCA and PCTA. These identities were confirmed by GC-MS. PCA and PCTA were formed in both dark control and under irradiation. PCTA formed faster in the dark control than under irradiation and PCA at

similar amount as under irradiation, which may indicate that photo irradiation does not play significant role in the formation of PCA and PCTA from quintozene. Most of the radioactive volatiles recovered in the traps were identified as quintozene.

Table 31 Distribution of quintozene and its photodegradation products in soil extracts, expressed in mg/kg-soil

Irradiated				Dark Control			
Days	Quintozene	PCA	PCTA	Days	Quintozene	PCA	PCTA
0	9.6	ND	ND	0	9.4	NA	NA
13	8.1	0.38	ND	1	9.2	ND	ND

186	3.4	0.83	0.32	15	7.7	0.37	0.22
261	2.6	0.88	0.31	22	6.9	0.44	0.36
359	1..6	0.70	0.21	30	6.4	0.42	0.30

Notes:

NA, Not analysed.

ND, Below LOD.

The radioactivity not extracted from soil increased nearly two-fold under irradiation compared to the dark control. The half-life values estimated based on quintozene concentrations in soil under irradiation and dark control are 159 hours (13.2 days) and 62.1 days, respectively.

A significant amount of radioactive quintozene was found in the gasket holding the quartz glass plate on the open end of the test vessel for making the vessel air tight.

Field dissipation *(Rice et al., 1989, 900-DIS-015; 1989, 900-DIS-016; 1990, 900-DIS-001; Harned & Creeger, 1993, 900-DIS-012; Harned, 1997, 900-HUM-005; Lengen, 1989, 900-HUM-006)*

Field dissipation studies were conducted with a single pre-plant broadcast application of quintozene at various rates made to bare loamy sand or sandy loam soils in the United States. Immediately after the application, quintozene was incorporated to a depth of 10–15 cm. In some trials, immediately or one day after the application, broccoli or potato was planted. Additionally, a study was conducted on Bermuda grass turf to which quintozene was applied twice at 36.6 kg ai/ha four weeks apart.

Soil core samples to various depths (maximum 1.5 m) were taken on selected days after application. Each soil core sample was separated into increments of 15 cm long. Each increment was finely ground and extracted for analysis of quintozene, PCA, PCTA and PB and the impurity HCB.

The following table indicates the trial sites, types of the soil in 0–15 cm layers, conditions, application rates, maximum sampling periods, DT_{50} values of quintozene and total residues calculated using the first order model.

In general, quintozene and other 4 compounds were found at all sampling intervals in 0–15 cm layer till the end of the studies. It was not possible to calculate half-lives of these 4 compounds as they accumulated at rates greater than their dissipation. PCA was the most significant degradate of quintozene.

These data indicate that quintozene, its associated degradates and the impurity do not leach.

Table 32 Summary of field dissipation studies

Location in United States	Type of soil (0–15 cm)	Conditions	Application rate (kg ai/ha)	Sampling period (max. days)	DT_{50} (days) in 0-15 cm layer	
					Quintozene	Total [a]
Hawkinsville, GA	Loamy sand	Bare soil	11.2	535	12.9	-
Pattison, TX	Sandy loam	Bare soil	2.5	546	135	-
MN	Sandy loam	Bare soil + Potato [b]	28.0	546	193	444
Santa Cruz, CA	Sandy loam	Bare soil + Broccoli [b]	33.6	546	305	401
Madera, CA	Loamy sand	Bare soil + Broccoli [b]	33.6	546	128	263
Fresno, CA	Sandy loam	Bermuda grass turf	36.6 × 2	360	35.4	-

Notes:

[a] Sum of quintozene, PCA, PCTA, PB and HCB.

[b] Planted after the application of quintozene.

The geometric mean of DT_{50} of quintozene calculated from the above studies was 88 days (without the study on turfed soil, 106 days) and that of DT_{50} of total residues was 360 days, indicating that quintozene itself would be moderately persistent but the total residues were persistent.

Residues in rotational crops–Confined rotational crop study

Study 1. *(Halls, 1990, 900-RES-087; Putterman, 1993, 900-RES-104 Volume I Study Overview; Anonymous, 1993, 900-RES-103 Volume II In-Life Portion; Ford & Murty, 1993, 900-RES-105 Volume III Wheat; Ford & Murty, 1993, 900-RES-101 Volume IV Lettuce; Ford & Murty, 1993, 900-RES-102 Volume V Turnip)*

Six tanks (240 cm × 90 cm × 60 cm) were filled to 50 cm with sandy loam soil and located indoor in a greenhouse. Three tanks were used as control plots and the other three tanks as treated plots. Each treated plot was separated into three circular subplots, one for each crop type, which were then treated with ^{14}C-quintozene at 33.7 kg ai/ha.

Lettuce (var. Oakleaf and Black Seeded Simpson), turnip (var. Purple Top White Globe) and wheat (var. Marshall and Wheaton) were planted into the plots at plant back intervals (PBI) of 30, 120 and 365 days. A target cabbage plants (var. Copenhagen Market) was planted in the 120- and 365-day plots to represent cultivation of a target crop during the aging of the soil.

Crops were harvested at immature (33–55 days after planting) and mature (61–107 days after planting) growth stages. The aerial parts of the crops were taken as the immature samples of all crops and as the mature samples of lettuce and wheat. The whole turnip plant was taken at final harvest and separated into tops and roots. Mature wheat was separated into grain, hulls and straw.

Table 33 Harvest timing of immature and mature rotational crops at each plant back interval

PBI	Crop	Immature		Mature	
		Days after planting	Days after treatment	Days after planting	Days after treatment
30-Day	Lettuce	45	75	61	91
	Turnip	33	63	74	104
	Wheat	45	74	77	107
120-Day	Lettuce	34	154	67	187
	Turnip	34	154	67	187
	Wheat	34	154	92	212
365-Day	Lettuce	39	404	61	426
	Turnip	39	404	61	236

PBI	Crop	Immature		Mature	
		Days after planting	Days after treatment	Days after planting	Days after treatment
	Wheat	55	420	107	472

Combustion/LSC analysis were used for determination of radioactivity in each sample. Moisture content of each soil sample was determined and the radioactive residue levels in soil were expressed on a dry weight basis.

The TRR in 0–15 cm layer soil 2 hours after treatment with ^{14}C-quintozene were in the range of 6.56–14.3 mg eq/kg showing some tendency of decrease with aging of the soil. The TRR in 15–31 cm layer soil was significantly lower compared to 0–15 cm layer, but increased gradually from below the LOQ to the maximum 1.05 mg eq/kg.

Comparing with the treatment rate of 33.7 kg ai/ha, the TRR found in lettuce and turnip were not so high (1.40–5.67 mg eq/kg in immature samples). They showed the highest level at 30-day PBI. Significantly high levels of radioactivity were found in wheat straw regardless of PBI days, at 22.2–25.9 mg eq/kg, which were 3–5 times higher than the levels in the corresponding soil samples. The TRR in grain were low at 0.33–0.71 mg eq/kg but did not decrease at longer PBI.

Table 34 Total radioactive residue in soil (0–15 cm) and rotational crops at each plant back interval following a single application of quintozene at 33.7 kg ai/ha

PBI days	crop	Portion	TRR in 0–15 cm soil (mg eq/kg dw)				TRR in plant (mg eq/kg)

Notes:

[a] Two hours after application.

[b] Same as the PBI.

[c] On the same day as immature samples and mature samples were obtained.

[d] The aerial parts of crops were obtained as samples.

For metabolite characterization, the crops were shipped frozen to the analytical laboratory. From homogenized lettuce and turnip top and root samples, endogenous water was removed by centrifugation

as “aqueous extract” and the remaining moist tissues were extracted with methanol. Water was added to the methanol fractions to make a methanol/water ratio to 60:40 (v/v) and the solutions were refrigerated to remove most of chlorophyll. The resulting solutions were partitioned with chloroform to extract the non-polar metabolites in the chloroform fraction. The “aqueous extract” and the aqueous methanol from the chloroform partition were pooled and processed for characterization of the polar metabolites. The solids remaining after methanol extraction was regarded as PES which were hydrolysed with 1 mol/L methanolic hydrochloric acid at 60 °C for 30 minutes. The solids were also treated with cellulase (see below). Fractions were analysed using LSC, HPLC and GC-MS. Mass spectra were obtained with a mass spectrometer using negative ion chemical ionization (NICI) with methane as the reagent gas.

Samples of wheat straw and hulls were extracted with methanol by soaking at 4 °C for 6 days and thereafter centrifuged. The pellets were re-extracted with methanol for one day and centrifuged. The resulting pellets were extracted twice with water. Methanol extracts were diluted with water to a methanol/water ratio of 60:40 (v/v) and partitioned with chloroform to obtain non-polar compounds. The combined aqueous and aqueous methanol portions were concentrated, freeze-dried, and reconstituted in water. The chloroform fractions were concentrated under nitrogen. The solids remaining after extraction with water was regarded as PES, which was acid-hydrolysed in the same way as for lettuce and turnip samples, and alkaline hydrolysed with 1 mol/L NaOH at 60 °C for 17 days. The PES from 30-day PBI wheat straw and post-hydrolysed residue were suspended in pH 4.5 acetate buffer with cellulase and incubated at 37 °C for 24 hours with shaking. Analyses were conducted in the same way as for lettuce and turnip samples.

The 120-day PBI wheat straw was subjected to a Bligh-Dyer extraction. The chloroform and aqueous methanol portions were separated from the solids. The chloroform portion was cleaned-up with a silica SPE cartridge, and the eluants were analysed by GC/NICI-MS. The aqueous methanol portion and the solids were separately subjected to alkaline hydrolysis (see above) and subsequently methylated with iodomethane in the presence of catalyst and toluene, resulted in extraction of radioactivity into toluene. The toluene fractions were cleaned-up with silica SPE cartridges, and the eluents were subjected to GC/NICI-MS.

The extractability by organic solvents were in the range of 36–67 percent TRR. Acid hydrolysis released additional 9.4–619 percent of TRR. In one example of wheat straw, it was demonstrated that the alkaline hydrolysis was slightly more efficient with 21–31 percent TRR released from the PES, compared to 14–16 percent released by the acid hydrolysis.

Notes:

[a] As the US label requires "not to plant root crops in treated fields within 12 months of the last application unless quintozene is registered for use on those crops" (NB, potato), analysis was conducted only on the samples from the 365-day PBI.

Metabolite identification and quantification was performed by HPLC of the aqueous methanol extracts. Parent quintozene was not detected from any of the rotational crops with all PBIs, as in the methanol/water extracts of other studies. Identified metabolites were conjugated forms with either cysteine or glutathione. N,N'-Diacetyl-S,S'-(tetrachloro-p-phenylene)-L,L'-dicysteine / C4CyCy accounted for 12.2 percent TRR (0.093 mg/kg) in turnip tops, and N-acetyl-S-(pentachlorophenyl)-L-cysteine accounted for 12.9 percent TRR in wheat hulls. Other components accounted for <10 percent TRR but they were >0.05 mg/kg in wheat straw and hulls.

The chloroform fractions of rotational crops were analysed by GC-MS. In addition to parent quintozene, PCA/pentachlorohydroxyaniline, PCTA, pentachlorophenylmethyl sulfoxide, and PB were identified with some others. However, no quantitative information was available for lettuce, turnip and wheat samples. Further examination revealed that while the levels of radioactivity remained similar for the wheat straw samples and hull samples, the character of the metabolites changed. With time, the metabolites became more polar and the extent of replacement of chlorine atoms on the aromatic ring increased (also seen in the plant metabolism studies).

Study 2. *(Heath, 1992, 900-RES-015)*

The trial location and setup of this study were the same as study 1 with the exception that the application was done 7 days after that in Study 1. Six plots (240 cm × 90 cm; 3 control and 3 treated) were filled to 45 cm with sandy loam soil and put in a greenhouse. Each "treated" plot was separated into three circular subplots (56 cm diameter), one for each crop type, which were then treated with ^{14}C-quintozene at 34.6 kg ai/ha.

The rotational crops, lettuce (Oakleaf for 31- and 121-day PBI and Black Seeded Simpson for 365-day PBI)), turnip (Purple Top White Globe for three PBIs) and wheat (Marshal spring wheat for 31- and 365-day PBI and Wheaton winter wheat for 121-day PBI) were planted into the plots. Cabbage plants (Copenhagen Market) was planted in the 121- and 365-day PBI plots to represent cultivation of a target crop during the aging of the soil between treatment of the soil and planting of the rotational crops, but the cabbage samples were not analysed. Crops were harvested at immature and mature (60–284 days after planting) growth stages.

Table 37 Harvest timing of rotational crops at each plant back interval

PBI	Crop	Days after planting
31-Day	Lettuce	60
	Turnip	75
	Wheat	75
121-Day	Lettuce	76

PBI	Crop	Days after planting
	Turnip	76
	Wheat	284
365-Day	Lettuce	61
	Turnip	61
	Wheat	90

Notes:

NB, Harvest dates of immature samples were not reported.

The harvested crop was divided into two and three subsamples of each half and were analysed by combustion/LSC.

Samples were extracted by macerating with a solvent (3× hexane followed by 3× methanol). Soil cores were extracted by shaking with acetone. Extracts were centrifuged to separate the supernatant from the residual PES. Extracts and PES were analysed for radioactivity using LSC or combustion/LSC.

The TRR in soil immediately after treatment with ^{14}C-quintozene at 34.6 kg ai/ha were within the range of 2.6–12.7 mg eq/kg and did not decrease with time. The acetone extracts of soil cores (0–15 cm) were analysed by HPLC. The chromatograms indicated the gradual degradation of quintozene during the study producing PCA and PCTASO.

The TRR in lettuce and turnip were not high compared to the rate of application, like in Study 1, and decreased over time as soil aged. Residues in wheat straw were high with 27.7 mg/kg at the 31-day PBI declining to 6.3 mg/kg for the 365-day PBI.

Table 38 Total radioactive residue in rotational crops at each plant back interval following a single application of quintozene at 34.6 kg ai/ha

PBI days	crop	Portion	TRR in plant (mg eq/kg)	
			Immature [a]	Mature

		Roots		1.91
	Wheat	Straw	1.89	6.28
		Grain		1.18
		Hulls		19.33

Notes:

[a] Immature crops were harvested as foliage only.

Metabolite identification and quantification was performed by HPLC of the hexane and methanol extracts.

Lettuce. Most of radioactivity in 121- and 365-day PBI lettuce was extracted in hexane and methanol (total of 77–80 percent TRR; (on average 28 percent in hexane and 50 percent in methanol). These extracts, however, were not analysed by HPLC. The methanol extract of the lettuce from the 365-day PBI was analysed by TLC, which showed radioactivity to be present over the length of the chromatogram, but no individual bands could be resolved, thus indicating a complex mixture of compounds. No further work was carried out on the PES of any samples.

Table 39 Distribution of radioactivity in the organic solvent extracts of mature lettuce

Extract	31-day PBI		121-day PBI		365-day PBI	
	mg eq/kg	% TRR	mg eq/kg	% TRR	mg eq/kg	% TRR
TRR	13.41	100	0.15	100	0.43	100
Hexane extract	0.724	5.4	0.040	26.7	0.130	30.2
Methanol extract	0.724	5.4	0.080	53.3	0.200	46.5
Total extracted	1.45	10.8	0.120	80.0	0.330	76.7

Turnip roots. Analysis of the hexane extracts of 31-day PBI turnip roots (13 percent TRR) by HPLC showed the hexane soluble radioactivity consisted of quintozene, PCA, PCTA and PB. The hexane extracts of 121- and 365-day PBI were not analysed by HPLC. The radioactive profile in the methanol extract from the 31-day PBI sample was much more complex with the malonylcysteine conjugates of TCTP and PCTP (PCP) being the only compounds identified. The HPLC analysis of the methanol extract from the 121- and 365-day PBI could not identify radioactive compounds and therefore the methanol extract was hydrolysed with 6 mol/L HCl at 110 °C for 19 hours resulting in 63–66 percent of the radioactivity being associated with a fine black solid formed during hydrolysis.

The PES of roots retaining 28–50 percent TRR were hydrolysed with 6 mol/L HCL at 110 °C for 19 hours. However, acid hydrolysis at the severe conditions only solubilized small fractions of the radioactivity in PES (1.8–4.6 percent TRR).

Turnip tops. The hexane extracts contained 9.2–14 percent TRR, but, due to the low amount of radioactivity, they were not analysed. The methanol extracts contained 38–55 percent TRR and analysed by HPLC but it was not possible to identify the contained radioactivity. Hydrolysis of the methanol extract of 121-day PBI with 6 mol/L HCl as in a similar method as above resulted in 30 percent of the radioactivity being associated with a fine black solid formed during hydrolysis. No further characterization was attempted.

The PES containing 33–53 percent TRR were also hydrolysed with 6 mol/L HCl in the same way as above but only 5.6–7.9 percent TRR were solubilized. No further characterization was attempted.

As a conclusion, the hexane extracts contained identified compounds whereas methanol extracts showed a complex radioactive profile with the malonyl cysteine conjugates being the only compounds identified.

Acid hydrolysis	0.593	3.5	0.083	1.8	0.134	4.6

Notes:

[a] Not appropriately quantified.

Wheat. Hexane did not extract a significant proportion of the radioactivity (<7 percent, except for 121-day PBI grain with 25 percent TRR extracted) so the hexane extract was not analysed. Methanol extracted 35–49 percent, 40–50 percent and 27–32 percent TRR respectively from grain, hull and straw. HPLC analysis of methanol extracts of hull and straw samples from all PBIs and grain sample from 365-day PBI showed a mixture of polar compounds, none of which corresponded to reference compounds. PES of straw from all PBIs and hull from 121- and 365-day PBI and grain from 365-day PBI contained, if reported, more than half of the TRR, except for the 121-day PBI grain. Hydrolysis of these PES samples with 6 mol/L HCl at 100–120 °C for 18–19h solubilized <1–30 percent TRR, which were not sufficient for identification.

Table 41 Identification and characterization of radioactive metabolites in the hexane and methanol extracts of succeeding wheat at 31-, 121- and 365-day PBI

The chloroform fractions of rotational crops were analysed by GC-MS. Parent quintozene and a couple of metabolites were identified as PCA/pentachlorohydroxyaniline, PCTA, PCTASO, and PB and many more. A quantification was not presented.

However, further examination revealed that while the levels of radioactivity remained similar for the different wheat crops, the character of the metabolites changed, and evidence was presented that with time the metabolites became more polar and the extent of replacement of chlorine atoms on the aromatic ring increased.

Study 3. *(Harned et al., 1998, 900-RES-121)*

Study 3 was conducted to better isolate and identify low-level metabolites in rotational crops using more modern and complex analytical techniques. ^{14}C-Quintozene was applied broadcast to a sandy loam soil at 2.2, 11.2, or 33.6 kg ai/ha and manually incorporated into the top 10 cm of soil. The trials were performed outdoors under typical growing conditions in Madera, CA. United States. After 35, 120 or 365 days of the application, lettuce was planted and after 30, 120 and 365 days, wheat was planted and grown in the treated soil. In the second re-trial, only lettuce was planted at the 30-day PBI. Turnips were planted 365 days after application at 2.2 and 11.2 kg ai/ha. Re-trials were conducted due to the heavy rain fall and weather conditions during the original trial.

Immature and mature lettuce leaves, wheat forage, grain and straw and turnip roots and tops were harvested for analysis as shown in the following table.

Table 42 Harvest timing of rotational crops at each plant back interval

Crop	Harvest (days after planting)					
	30-day PBI		120-day PBI		365-day PBI	
	Immature	Mature	Immature	Mature	Immature	Mature
Lettuce original trial [a]	161	184	71	122	114	140
Lettuce first retrial [a]	--	--	45	68	46	65
Lettuce second retrial	47	63	--	--	--	--
Turnip original trial	--	--	--	--	--	140
Turnip first retrial	--	--	--	--	65	73
Wheat original trial	119	204	57	125	114	188

Notes:

[a] The shortest PBI was 35 days.

TRR in the rotational crops and soil were determined by combustion/LSC. The TRR in soil immediately after treatment with quintozene at 33.6 kg ai/ha were within the range of 2.6–12.7 mg eq/kg.

TRR in rotational crops were >0.05 mg eq/kg in all samples except wheat grain planted 365 days after application at 2.2 kg ai/ha. The TRR in these crops were low considering the application rates, as in Study 1 and 2. Also the highest TRR were found in wheat straw while the wheat grain showed much lower TRR. Lettuce samples from 2.2 or 33.6 kg ai/ha were not analysed.

Notes:

[a] 2nd re-trial.

[b] 1st re-trial.

Samples were finely ground with dry ice. Aliquots of homogenized samples were analysed by combustion/LSC. All remaining samples were extracted with solvents:

- Lettuce samples were extracted with methanol and a mixture of methanol/water (1:1) and the combined extracts were partitioned with chloroform;

- Turnip top samples (only mature samples) were extracted with methanol/water and the extract was partitioned with hexane followed by chloroform;
- Turnip root samples were extracted with methanol/water and the extract was partitioned with chloroform;
- Wheat forage and grain samples were extracted with methanol and methanol/water and the extract was partitioned with chloroform; and
- Wheat straw samples were extracted with methanol/water followed by methanol and the filtrate was partitioned with dichloromethane.

The PES after extraction of lettuce were treated with sequential digestions with three groups of enzymes, followed by hydrolysis with 0.5 mol/L KOH.:

- Cellulase, hemicellulase, sulfatase, β-glucosidase and pectinase (pH 5 compatible enzymes);
- α-amylase, β-glucuronidase and esterase (pH 7 compatible enzymes); and
- Trypsin, chymotrypsin and pronase-E (proteases).

The PES after extraction of turnip tops and roots were hydrolysed with Novozyme 249. The hydrolysate of turnip root PES was then hydrolysed by reflux with 1 mol/L HCl and then separated into hexane/ethyl acetate and aqueous fraction, which was partitioned with dichloromethane.

The PES of the wheat forage samples were composited by PBI and hydrolysed by several sequential techniques: enzymatic hydrolysis with pectinase, cellulase and hemicellulose at pH 5 at 37 °C; phosphate buffer at pH 6, followed by the enzymes pullulanase and α-amylase; then protease, α-chymotrypsin and trypsin at pH 7. The PES from the enzymatic hydrolyses was subsampled for combustion analysis and the remaining solids were subjected to acidic hydrolysis with 2 mol/L HCl/dioxane (1:9). Solids remaining after acidic hydrolysis were subjected to basic hydrolysis with 25 percent KOH at 25 °C.

The PES of the wheat straw samples were hydrolysed by several sequential techniques: incubation in phosphate buffer at pH 7 at 45 °C followed by α-amylase at 37°C; pronase at pH 7.2; pectinase at pH 4.0; acidic hydrolysis with 2 mol/L HCl/dioxane (1:9) at 70 °C. Solids remaining after acidic hydrolysis were subjected to basic hydrolysis with 25 percent KOH at 25 °C. The solids were further treated with 73 percent sulfuric acid at room temperature. Unhydrolysed solids from wheat forage and straw samples were analysed by combustion analysis.

The PES of the wheat grain samples were treated in the manner described for forage samples, except that the solids were treated for 66 hours at 37 °C at pH 5 with cell lysing enzymes, cellulase and hemicellulose prior to the pectinase, cellulase and hemicellulose treatment.

Lettuce: Methanol and methanol/water extracted a total of 56–77 percent of TRR: 27–44 percent in chloroform fraction (non-polar fraction), and 22–38 percent in aqueous fraction (polar fraction). There was no clear tendency according to the length of PBI. The nonpolar fraction contained 34 and 29 percent, 44 and 30 percent, and 29 percent, and 27 percent of the TRR in the immature and mature lettuce at 30-day, 120-day and 365-day PBI. The polar fraction contained 22 and 30 percent, 33 and 38 percent, and 38 and 36 percent of the TRR in the immature and mature lettuce at 30-day, 120-day and 365-day PBI.

The pH 5 and pH 7 compatible enzymes released an average of 2.3 percent and 3.3 percent of TRR, respectively, as a complex mixture of metabolites, none of which were of quantitative significance. The proteases released 9.1 and 9.9 percent, 8.4 and 10.1 percent, and 5.8 and 7.4 percent of the TRR in

the immature and mature lettuce at 30-day, 120-day and 365-day PBI. The KOH released 10.6 and 16.8 percent, 8.2 and 11.3 percent, and 8.5 and 7.9 percent of the TRR in the immature and mature lettuce at 30-day, 120-day and 365-day PBI.

Notes:

[a] Compared with the radioactivity in the initial methanol and methanol/water extracts.

Wheat: From wheat forage (all PBI and application rates), methanol and methanol/water extracted a total of 52–76 percent of TRR: only 5.0–6.8 percent TRR in chloroform fraction (non-polar fraction), and much higher 45–70 percent TRR in aqueous fraction (polar fraction). In forage, quintozene was extensively metabolized to polar compounds.

Similar tendency was observed for wheat straw samples. From the wheat straw samples (from all PBI and application rates), methanol/water and methanol extracted a total of 56–70 percent TRR: dichloromethane fraction (nonpolar fraction) contained only 0.87–7.6 percent TRR while aqueous fraction (polar fraction) contained much higher 51–68 percent TRR.

Only 9.8–33 percent TRR in wheat grain were extracted with methanol and methanol/water showing higher extractability with longer PBI. The chloroform fraction contained 0.89–1.5 percent TRR while aqueous fraction contained 8.8–32 percent TRR (higher at longer PBI) with >57 percent TRR

unextracted. This indicated that the majority of non-polar and polar metabolites were either trapped, bound or incorporated into the grain matrix but at longer PBI they became more extractable.

The PES from wheat samples before hydrolysis were subjected to sequential hydrolysis. Only 4–8 percent of the TRR was released from forage by pH 5 compatible enzymes, indicating that most of the residues in the forage PES were bound, rather than trapped. The forage PES were also digested with pH 6 compatible enzymes and proteases, which did not release more than 4 percent of the TRR each. The three enzyme hydrolysates from each forage sample were composited and profiled by HPLC showing that the residues released were comprised of a complex mixture of metabolites.

The grain PES before hydrolysis were each digested with cell lysing enzymes (pH 5 compatible enzymes) to release residues trapped within the grain matrix. This treatment released 22–55 percent TRR, showing that a substantial amount of the residues in grain PES were physically trapped within the matrix. The grain PES were then digested with a variety of specific enzymes (pH 6 compatible enzymes and proteases). The pH 6 compatible enzymes (α-amylase and pullulanase) released an additional 11–16 percent of the TRR, indicating that the certain amounts of residues in grain were associated with polysaccharides. The proteases released less than 3 percent of the TRR from grain. The pH 5 and pH 6 compatible enzyme hydrolysates of grain (30-day and 120-say PBI) were composited and profiled by HPLC. The resultant reconstructed chromatograms showed a large non-retained peak which may be indicative of residues bound to large biomolecules which would not be retained by conventional HPLC. A complex mixture of retained metabolites were also observed.

Following enzymatic treatments, forage and grain PES samples were subjected to acid hydrolysis which released up to 16 percent of the TRR from forage PES, indicating that a significant amount of quintozene-related unextracted residues were incorporated into lignin in forage. Only a small amount (<5 percent) of the residues in grain were incorporated into ligninacious materials.

Residues still unreleased from forage and grain solids by the acid hydrolysis were subjected to alkaline hydrolysis. Less than 7 percent of TRR was released from forage PES, leaving 2 percent or less in the final PES. Up to 24 percent of the TRR was released from the grain PES by alkaline hydrolysis, leaving 3 percent or less of grain TRR remaining in the final PES.

Metabolites were characterized by RP-HPLC and/or normal-phase TLC. Metabolites of significance were isolated from the appropriate fractions by repetitive RP-HPLC and normal phase TLC. Isolated polar metabolites were further characterized and/or identified by chromatographic comparisons with authentic reference standards using LC- MS/MS or GC-MS.

Analyses of lettuce, turnip tops and roots, and wheat forage and straw identified up to 30 metabolites, the majority of which accounted for only low portions (<10 percent) of the radioactive residues at low concentrations.

Lettuce: Analysis of lettuce extracts was performed by GC-MS, HPLC-LSC and LC-MS/MS. Parent quintozene and twelve metabolites were isolated, identified and quantified in extracts of rotational lettuce. On average, 49 percent TRR was identified and quantified; the remainder was either unextracted (about 31 percent TRR) and hydrolysed with enzymes and KOH, or was present in polar extracts. Quintozene was a major metabolite in 30-day PBI immature and mature lettuce but in 120- and 365-day PBI samples, it was found <10 percent TRR and <0.01 mg/kg.

An average of 96 percent of the non-polar metabolites in lettuce extracts were identified and quantified. These metabolites represented 43–57 percent TRR (0.051–0.28 mg/kg). Quintozene accounted for more than 10 percent TRR (21 percent TRR) at 30-day PBI but both the percentage of TRR and concentrations decreased with longer PBI. PCA was detected at 11.5 percent TRR (0.011 mg/kg) in mature lettuce at 120-day PBI and C3MS at 10.9 percent TRR (0.063 mg.kg) in immature lettuce at 365-day PBI. Except for one unknown fraction, there was no other metabolite accounting for more than 10 percent TRR.

Notes:

[a] Conjugate 330, cysteinyl conjugate but exact structure not confirmed.

[b] Two methyl tetrachlorophenyl sulfone isomers were found. Substitution positions not known because of insufficient material for NMR.

[c] One region with 0.0327 mg/kg consists of multiple compounds.

[d] One region with 0.0180 mg/kg consists of multiple compounds.

Turnip: Analysis of turnip extracts was performed by HPLC-LSC, GC-MS and LC-MS. Fourteen metabolites were isolated and identified. These metabolites represented 65–76 percent (0.039–0.094 mg/kg) and 78–81 percent (0.045 0.19 mg/kg) of the TRR in turnip top and root samples, respectively. Parent quintozene was not detected in any of the samples.

Wheat

Analyses of factions were performed using LC-MS (ESI) or GC-MS (NICI). Quintozene and metabolites were determined by the presence of chlorine isotope clusters, identified by comparison of spectra against authentic standards when available, and quantified by HPLC with fraction collection.

Twelve metabolites were isolated and identified.

- Quintozene at 0.023 mg/kg in straw (2.2 kg ai/ha, 120-day PBI);
- PCA at 0.013 mg/kg in straw (2.2 kg ai/ha, 120-day PBI);
- PCTA at 0.19 mg/kg in straw (2.2 kg ai/ha, 120-day PBI);
- C5SA at 0.14 mg/kg in straw (2.2 kg ai/ha, 120-day PBI);
- three isomers of C4SA at 0.08, 0.33 and 0.06 mg/kg in straw (2.2 kg ai/ha, 120-day PBI) and 0.22 mg/kg in forage (2.2 kg ai/ha, 120-day PBI);
- an isomer of C3SA at 0.17 mg/kg in straw ((2.2 kg ai/ha, 120-day PBI);
- C3MSSA at 0.11 mg/kg in straw (2.2 kg ai/ha, 120-day PBI);
- C3MSOH at 0.009 mg/kg in grain (2.2 kg ai/ha, 120-day PBI);
- C4SANH at 0.15 mg/kg in forage (11.2 kg ai/ha, 30-day PBI); and
- C3MS at 0.18 mg/kg in straw (33.6 kg ai/ha, 30-day PBI).

Identification of terminal metabolites indicated that reduction and conjugation as well as dichlorination are the main metabolic pathways of quintozene in wheat. The reduction product PCA was detected in forage and straw. Oxidation of PCTA, possibly derived from glutathione conjugates produced by plant metabolism or taken up by the roots from soil, yielded other major metabolites such as sulfonic acids and sulfones.

For wheat straw, nineteen metabolites were identified from the extracts of the 2.2 and 11.2 kg ai/ha samples, eight of which were found in the non-polar fraction.

For the 120-day PBI wheat straw samples (2.2 and 11.2 kg ai/ha). The polar extracts were separated into eight fractions which were further separated by different HPLC systems and clean-up procedures to identify individual components. Eleven metabolites were found in the polar fraction. Moreover, in the polar fraction, a number of positional isomers exist for the trichlorobenzenesulfonic acid and tetrachlorobenzenesulfonic acid.

Field Rotational Crop Studies (Gaydosh, 1996, 900-RES-116; Gounaris, 1994, 900-RES-163; Gaydosh, 1996, 900-RES-146; Gounaris, 1994, 900-RES-162)

Two field trials were conducted in 1992–1993 in the typical peanut growing regions of the United States: one in Meigs, GA, and the other in Brookshire, TX. Unlabelled quintozene formulated as GR formulation was applied two times to bare soil as two split applications, 31 (Meigs) or 41 (Brookshire) days apart, each at a rate of 5.6 kg ai/ha (total 11 kg ai/ha) which simulated the then critical US GAP for peanut, which was not on the current label. Applications were made in 30 cm bands using common granular application equipment at a simulated pegging time for peanuts.

At plant-back intervals (PBI) of 30, 120, and 367 or 366 days after the second application, wheat and lettuce were planted. Turnips were planted at a PBI of approximately one year only, in accordance with the United States label restrictions on crop rotation of root vegetables. As a worst case, rotational crops were planted within the treated bands. At each location, from one control plot and two treated plots, duplicate crop samples were taken at each PBI with the exception of a 120-day PBI plot in Brookshire that was inadvertently treated at a higher rate and could not be used. Samples of wheat grain, wheat straw and lettuce were harvested at maturity while wheat forage was sampled immature (Table 51). Excessive soil

was typically shaken off the plant samples. All samples were frozen within 2 hours of harvest and kept frozen until analysis.

Table 51 Harvest timing of immature and mature rotational crops at each plant back interval

PBI	Crop	Immature	Mature
		Days after planting	Days after planting
Meigs, GA			
30-Day	Wheat	54	268
	Lettuce	--	90
120-Day	Wheat	70	178
	Lettuce	--	105
367-Day	Wheat	56	284
	Lettuce	--	106
	Turnip	--	56
Brookshire, TX			
30-Day	Wheat	54	231
	Lettuce	--	202
120-Day	Wheat	42	219
	Lettuce	--	104
366-Day	Wheat	78	255
	Lettuce	--	145
	Turnip	--	102

Samples were homogenized with dry ice. Samples after extraction and clean-up with Florisil column were analysed by GC-ECD for quintozene, PCA, PCTA, PB, HCB, TCA, TCTASOO, and PCTASO using the CAM-24-73 method with an LOQ of 0.005 mg/kg for each analyte. Samples were stored for up to 147 days from sampling until analysis.

The analytical results indicate that, after the application of quintozene two times at a rate of 5.6 kg ai/ha, in most samples of succeeding wheat forage, grain and straw and turnip tops, no residues were expected to occur above the LOQ of 0.005 mg/kg. In lettuce (30-day PBI and 120-day PBI) from the GA site showed quintozene above the LOQ but at the maximum within 3 times of the LOQ value while lettuce samples from the TX site did not contain quintozene above the LOQ. PCA was detected higher than the LOQ in 30-day PBI lettuce, 365-day PBI wheat forage and turnip roots (only planted at 365-day PBI) at the maximum of 0.016 mg/kg which was significantly lower than the residues in potato as a result of the approved use of quintozene to potato.

Summary of rotational crop studies

The uptake of quintozene by rotational crops was investigated through confined rotational crop studies and field rotational study using lettuce, turnip and wheat.

In the confined rotational crop studies using the high application rates (up to 34.6 kg ai/ha pre-plant), similar metabolites as plant metabolism studies were identified showing complex metabolite profile, except that parent quintozene was either not found or found at low levels in rotational crops.

In the field study with unlabelled quintozene (2 × 5.6 kg ai/ha), quintozene, PB, HCB, PCTA or PCTASO were not found above the LOQ of 0.005 mg/kg in lettuce, turnips or wheat planted 365 days PBI. PCA and TCA were found in the turnip root and top samples above the LOQ but at the maximum 0.014 mg/kg; and PCA in wheat forage at the maximum 0.016 mg/kg. At higher application rate to the soil (such as 25 kg ai/ha on the United States label for cabbage and broccoli), residues in the rotational crops may be higher. The metabolism of quintozene in rotational crops seems to follow similar pathway as in the plant metabolism.

Animal metabolism

The Meeting received information on animal metabolism in lactating goat and laying hens, in addition to metabolism in rats.

Rat

Metabolism studies on laboratory animals including rats were reviewed in the framework of toxicological evaluation by the current JMPR and the relevant information is summarized below.

In the rat metabolism studies, the main metabolite found was PCA. The studies also mention some additional metabolites, found in low levels. These included: PCTA, methyl pentachlorophenyl sulfone. An additional metabolism study identified PCA and pentachlorophenyl-N-acetylcysteine (PCC) as the major metabolites in rat. There was insufficient information on the quantity. The metabolism study reports do also mention other structures found in the analyses, but these were not further identified.

Lactating goats

Study 1 *(Cheng, 1989, 900-RES-008 and Cheng, 1991, 900-RES-009(supplement to 900-RES-008))*

In a goat metabolism study, two goats (varieties not described) were dosed orally with ^{14}C-quintozene in capsules for five consecutive days at levels 25 or 50 mg/kg bw, equivalent to 714 or 947 ppm in diet. The goats were milked by hand twice daily. Urinary and faecal samples were collected twice daily. The animals were sacrificed approximately 6 hours after the final dose. Liver, kidney, fats, muscle, blood, bile and gastrointestinal tract were collected, and they were analysed for radioactivity. All samples except blood were stored below 0 °C before and after analysis. Radioactivity in each sample was analysed by LSC or combustion/LSC.

The administered radioactivity was eliminated in feces (36 and 41 percent of total dose), followed by urine (20–30 percent of total dose). A small amount was excreted in milk (0.2 and 0.3 percent of total dose). Within 48 hours after the first dose, only 10 percent of the total administered radioactivity was eliminated in excreta. TRR in milk reached a plateau on Day 3 pm (a maximum of 5.98 mg eq/kg for the low dose goat, and 3.55 mg eq/kg for the high dose goat) and declined on Day 5 (2.37 mg eq/kg for the low dose goat and 1.13 mg eq/kg at the time of sacrifice).

TRR in tissues were: 10.3 and 11.2 mg eq/kg in kidney, 13.4 mg eq/kg in liver, 0.48 and 0.54 mg eq/kg in muscle, and 9.4 and 15.6 mg eq/kg in the fat. The TRR in bile was high (30.8 and 56.9 mg eq/kg), indicating importance of biliary excretion although 0.02 and 0.03 percent of total administered dose was recovered in bile.

The nature of radioactive residue was examined in milk and edible tissues of a lactating goat receiving daily oral dose of 25 mg/kg bw for 5 consecutive days, as the TRR values from this goat were higher than those from the goat receiving an oral daily dose of 50 mg/kg bw. The liver (hereafter, liver-1) and milk were homogenized separately using chloroform/methanol (1:1, v/v) in the presence of a small amount of zinc sulfate. The mixture was centrifuged and separated. The liver chloroform extract was cleaned up through a preparative gel permeation column. The liver (liver-2), kidney fat and muscle were homogenized with a mixture of chloroform, methanol and water. The mixture was centrifuged and separated. The chloroform fraction was evaporated to dryness and the residue was partitioned between acetonitrile and hexane. TRR was examined for each extract and PES. A PES from liver-1 was refluxed in 5 mol/L KOH/methanol overnight. The mixture was neutralized using concentrated HCl. The inorganic salt was removed by filtration, and the filtrate was concentrated and

reconstituted in methanol for chromatography. For each tissue, the chloroform extract was subjected to HPLC and TLC. Quantitation of radioactive metabolites in each tissue was accomplished by comparing the retention times of peaks with those of analytical standards. For milk sample, quantitation was done with TLC. The chloroform extracts of liver, kidney, muscle and fat were composited, concentrated and run through a preparative HPLC column. Fractions were collected and pooled and concentrated and analysed by TLC or GC. The radioactive components were collected from the preparative HPLC eluates. The isolated components were analysed by MS or GC.

From milk, kidney, muscle and fat, the majority of the radioactivity (70.8 and 84.0 percent TRR) was extracted by chloroform. A lessor amount of radioactivity (4.27 and 18.0 percent TRR) was found in the methanol/water fraction. The PES contained 0 (fat)–29.9 percent TRR. For liver, liver 2 showed higher extraction efficiency. The chloroform fractions of liver-1 and liver 2 contained 24.2 percent and 31.4 percent TRR respectively, methanol/water fractions 5.8 percent and 29.5 percent TRR, and PES 69.4 percent and 42.8 percent TRR. The accountability of radioactivity in these tissues and milk ranged from 99.7 to 109 percent.

PCA was identified as the main metabolite in milk (50.2 percent TRR, 3.00 mg eq/kg), kidney (31.2 percent TRR, 3.21 mg eq/kg), muscle (59.2 percent TRR, 0.32 mg eq/kg), and fat (49.4 percent TRR, 7.71 mg eq/kg). PCTA was also identified but at lessor amounts: in milk (4.68 percent TRR, 0.280 mg eq/kg), kidney (2.78 percent TRR, 0.286 mg eq/kg), muscle (6.43 percent TRR, 0.035 mg eq/kg) and fat (1.48 percent TRR, 0.231 mg eq/kg). Five unknown polar metabolites, each accounting for <5 percent TRR, were also isolated from kidney, fat and/or muscle.

As for liver, only liver-1 extracts were subjected to identification/characterization. PCA and PCTA accounted for 9.6 percent (1.34 mg eq/kg) and 1.3 percent TRR (0.180 mg eq/kg), respectively. However, the majority (40 percent TRR) of the radioactivity in liver was associated with an unknown polar metabolite released by base hydrolysis.

In these tissues and milk, parent quintozene was not detected. The radioactivity in the methanol/water fractions and PES was not identified.

Study 2*. (Daun, 1990, 900-RES-075; Daun, 1991, 900-RES-153)*

Two lactating goats (variety not described) were dosed with ^{14}C-quintozene in gelatin capsule once daily for five consecutive days, one at 20 and the other at 50 mg/kg bw/day. Urinary and fecal samples were collected twice daily. The goats were milked by hand twice daily. Animals were sacrificed approximately 6 hours after the final dose. Tissues (kidney, liver, muscle, fat, blood, bile and gastrointestinal tract and its contents) were obtained. All samples, except blood were stored below 0 °C before and after analysis. Radioactivity in each sample was analysed by LSC or combustion/LSC.

The administered radioactivity was eliminated in urine (33 and 38 percent of total dose), feces (19 and 25 percent of total dose) and in milk (0.35 and 0.41 percent of the total dose). TRR in milk reached a plateau on Day 3 pm (a maximum of 5.98 mg eq/kg for the low dose goat, and 3.55 mg eq/kg for the high dose goat) and declined on Day 5 (2.4 mg eq/kg for the low dose goat and 1.1 mg eq/kg at the time of sacrifice). TRR in milk reached the highest level of 3.9 mg eq/kg on Day 2 in the low dose goat, and of 8.4 mg eq/kg on Day 2 in the high dose goat. Toward the end of the study, the TRR in milk slightly decreased. Only about 1 percent of total dose remained in tissues, bile and urine in bladder.

Among the tissues, the highest TRR was found in kidneys (32 and 49 mg eq/kg for the low dose and high dose goat, respectively) followed by liver (26 and 46 mg eq/kg). Fat contained 17–18 and 27–

33 mg eq/kg with renal fat contained slightly higher radioactivity than omental fat. Muscle contained much lower radioactivity at 1.1 and 2.3 mg eq/kg.

Samples of fat, kidney, liver and milk were extracted, and the extracts were analysed by TLC and HPLC for identification/characterization. Fat sample was initially extracted with chloroform by homogenization. The chloroform extract was concentrated to dryness under a stream of nitrogen and dissolved in hexane saturated with acetonitrile. The acetonitrile fraction was partitioned with acetonitrile saturated with hexane. The acetonitrile layer obtained after repeated partition was concentrated for HPLC.

Kidney sample from the low-dose goat was immersed in water, methanol and chloroform (1:2:1, v/v) by homogenization. The chloroform phase was partitioned with water. After removing the chloroform layer, to the remaining aqueous layer chloroform was added. The chloroform layer thus obtained was combined with the previously mentioned chloroform phase. The aqueous layer was also combined with the aqueous layer from the first extraction. The combined aqueous fraction was partitioned with methanol and chloroform to obtain the chloroform fraction and water fraction. The PES was subjected to Type 1 protease by immersing the PES in the protease solution at 37 °C for 20 hours, and then filtrate and solid were separated by filtration. The chloroform and aqueous fractions were analysed by HPLC. These extracts and the protease filtrate were analysed by TLC. Liver sample from the low-dose goat was extracted in a similar way as the kidney sample.

Subsamples of milk from the low dose goat were each extracted with hexane. The combined hexane fractions were partitioned with methanol/water (7:3). The aqueous fractions were applied to Amberlite XAD-2 column for elution by gradient using water and methanol (from 100 percent water to 100 methanol). Fractions were collected by polarity. The fraction eluted by 100 percent water was taken up in sufficient methanol to make a solution of methanol/water (7:3). The solution was partitioned with hexane. Methanol/water was added to facilitate separation. The hexane and aqueous layers were separately concentrated. The hexane fraction was combined with the initial hexane extract. The pooled methanol/water fractions from XAD-2 column were partitioned with hexane and the hexane fraction was also combined with other hexane fractions and then concentrated *in vacuo*. The concentrated hexane fractions were subjected to alumina column clean-up with elution with hexane and then benzene. The hexane eluate was concentrated and re-applied to the same column. The benzene fraction was combined with the benzene fraction from the first attempt. The combined benzene fraction was subjected to TLC.

Majority of radioactivity in kidney and liver from the goat that received the lower dose was extracted in chloroform and water: totaling 68 percent TRR for kidney and 60 percent TRR for liver with 16 percent and 46 percent TRR remaining in the respective PES. Protease hydrolysis released about one half of radioactivity in the kidney PES but only about 5 percent in liver PES. Majority of radioactivity in milk was extracted in hexane and methanol/water (55 percent of TRR) with 31 percent TRR remaining in the PES.

Table 53 Extraction of radioactive residues in the kidney, liver, milk and fat of goat ora2lly administered ^{14}C-quintozene for 5 days at 20 mg/kg bw

Fraction	% TRR		Fraction	% TRR
	Kidney	Liver		Milk
Chloroform	28.8	34.1	Hexane (initial)	32.4
Aqueous	38.8	26.1	Methanol/water 1	3.3
PES	16.4	46.4	Aqueous (initial)	51.1
Filtrate after Protease hydrolysis	10.0	4.8	Methanol/water 2	9.9
Solid after protease hydrolysis	12.8	27.3	Methanol/water 3	8.2
Total [a]	90.3	92.3	Hexane (final)	34.0

Fraction	% TRR	
	Kidney	Liver
Fraction	% TRR	
	Renal fat	Omental fat
Hexane	24.0	22.7
Acetonitrile	68.9	48.2
PES	1.6	1.7
Total	94.5	72.6

Fraction	% TRR
	Milk
PES	30.7
Total	86.1

Notes:

[a] Sum of chloroform fraction, aqueous fraction and filtrate and solid after protease hydrolysis.

In the kidney, analysis of the chloroform extracts identified parent quintozene (9.1 percent TRR, 2.92 mg /kg) as a major component, followed by 2,3,4,5-TCNB (0.5 percent TRR, 0.161 mg eq/kg). There were three unknown peaks each at <3 percent TRR. In the aqueous extracts, a small amount of parent quintozene was identified (0.5 percent TRR, 0.16 mg/kg). One unknown peak accounted for 14 percent TRR and 4.63 mg eq/kg.

In the liver, the chloroform extracts contained parent quintozene and PCA (together 8.3 percent TRR, 2.15 mg eq/kg), PCTA (5.42 percent TRR, 1.40 mg eq/kg), and 2,3,4,5-TCNB (1.0 percent TRR, 0.26 mg eq/kg). In the aqueous extracts, a small amount of parent quintozene (1.4 percent TRR, 0.36 mg/kg) and 2,3,4,5-TCNB (0.7 percent TRR, 0.18 mg eq/kg) were identified. One unknown component was observed at the same retention time as the unknown in the aqueous extracts of kidney at 15.9 percent TRR (4.12 mg eq/kg).

The radioactive residues in milk were not characterized.

***Study 3**. (McManus, 1989, 900-RES-070; McManus, 1990, 900-RES-092)*

One lactating goat was orally dosed with ^{14}C-quintozene for five consecutive days at a level 50 mg/kg bw.

TRR in milk was 58.5 mg eq/kg. The TRR in tissues were 49.1 mg eq/kg in kidney, 45.5 mg eq/kg in liver, 21.8 mg eq/kg in fat, and 2.22 mg eq/kg in muscle.

The liver, kidneys, fat and muscle (investigated separately in 900-RES-092) showed radioactive levels above background and extracted for analysis of nature of residues. Six metabolites were identified in the kidneys, of which two together accounted for more than 80 percent TRR. They were identified as PCA and PCA glucuronide. The four minor metabolites were PCTP, tetrachloro(methylthio)benzenethiol, TCTA and tetrachloromethylsulfinylaniline (TCA sulfoxide). Six metabolites were detected in the liver, mainly PCA and a PCA glucuronide conjugate. Trace amounts of four other products were found: PCPT dimer, *N*-pentachlorophenylhydroxylamine, PCTP and tetrachloro(methylthio) benzenethiol.

Milk, omental fat and renal fat each contained only one metabolite which was identified as PCA. Quintozene was not detected in the tissues, milk or urine. Pentachloroaniline sulfamate (85 percent of the extracted radioactivity (ER)) and pentachloroaniline mercapturic acid (4 percent of ER) were found only in urine along with small amount of *N*-pentachlorophenylhydroxylamine (5 percent of ER) and Tetrachloro(methylthio)benzenethiol (6 percent of ER).

Table 54 Metabolites in the tissues and milk of goat orally administered quintozene at 50 mg/kg bw for 5 consecutive days

Compound	percent of the extracted radioactivity					
	Kidney	Liver	Fat (omental)	Fat (renal)	Milk	Muscle
PCA	26	17	100	100	96	46
PCA-Gluc	55	73				
PCTA						11
PCTP	3.3	2.9				
PCPT dimer		2.7				
TCTA	2.1					
TCTA / Tetrachlorophenyl methyl sulfoxide						42
N-Pentachlorophenylhydroxylamine		4.7				
Tetrachloro(methylthio)benzenethiol	4.5	1				
Pentachloroaniline mercapturic acid						
Tetrachloromethylsulfinylaniline	2.3					

Laying hen

Study 1. *(Cheng, 1989, 900-RES-006; Cheng, 1991, 900-RES-007)*

Two groups of laying hens were dosed orally with ^{14}C-quintozene in capsules for five consecutive days at 25 or 50 mg/kg bw equivalent to 309 or 554 ppm in the diet. Eggs were collected twice daily. Birds were sacrificed approximately 6 hours after the final dose and blood, liver, kidneys, thigh muscle, breast muscle, fat, skin with fat, and GI tract with contents were collected.

The majority of the total administered dose was recovered in excreta (65 and 71 percent for low and high dose hens), followed by in GI tract and contents (6.5 and 9.2 percent), liver (0.03 and 0.04 percent) and kidneys (0.02 percent). Only small amount of administered radioactivity was found in eggs, a total of 0.01–0.02 percent in all eggs, most of which was in the yolk. The elimination rate of radioactivity in excreta was relatively fast and constant, with approximately 70 percent of the dose eliminated within 24 hours after the first dose.

The highest levels of radioactivity in egg yolks were found at sacrifice (1.22 and 2.66 mg eq/kg). On the contrary, the corresponding egg white contained radioactivity at 0.038 and 0.071 mg eq/kg while before sacrifice radioactivity was not detected.

The highest TRR was found in kidneys at 4.52 mg eq/kg (low dose) and 5.45 mg eq/kg (high dose) followed by fat (2.11 and 4.25 mg eq/kg), liver (1.97 and 2.42 mg eq/kg) and skin with fat (1.12 and 2.18 mg eq/kg). In muscle, the TRR was low at 0.13–0.16 mg eq/kg and 0.15–0.31 mg eq/kg. A significant amount of radioactivity was found in GI tract and its contents.

Table 55 Radioactive residues in tissues and blood of hens orally administered ^{14}C-quintozene for 5 days

Tissue	Dose at 25 mg/kg bw		Dose at 50 mg/kg bw	
	mg eq/kg	percent TAR	mg eq/kg	percent TAR
Kidneys	4.52	0.02	5.45	0.02
Liver	1.97	0.04	2.42	0.03
Muscle (thigh)	0.127	<0.01	0.145	<0.01
Muscle (breast)	0.155	0.01	0.305	0.01
Fat (abdominal)	2.11	0.02	4.25	0.04

Tissue	Dose at 25 mg/kg bw		Dose at 50 mg/kg bw	
	mg eq/kg	percent TAR	mg eq/kg	percent TAR
Skin with fat	1.12	0.03	2.18	0.04
GI tract/contents	114.000	6.45	298.000	9.22
Blood	1.47	<0.01	1.85	>0.01

Egg yolk, liver, kidney, fat and muscle were extracted by homogenizing the sample with mixture of chloroform, methanol and water. The mixture was centrifuged and separated. The chloroform fraction was evaporated to dryness, and then partitioned between acetonitrile and hexane. The methanol/aqueous fraction (except for fat sample) was cleaned up using C-18 column with elution with water, methanol, acetonitrile and hexane. The distribution of radioactivity in various fractions was determined in each sample. Egg white was not extracted due to its low radioactivity.

Kidney homogenate (no indication about whether they were from the lower dose or higher dose) was refluxed in 5 mol/L KOH/methanol solution overnight. The mixture was neutralized using 6 mol/L HCl. The inorganic salts were removed by filtration and the filtrate was concentrated and reconstituted in methanol for chromatographic analysis. A liver sample was also hydrolysed using 6 mol/L HCl at 100 °C for 16 hours. The mixture was cooled, dried and reconstituted in acetonitrile for HPLC analysis.

The majority of radioactivity in liver, kidney, fat and muscle was extracted (72–103 percent TRR), with a minor proportion (2.7–37 percent TRR) remaining in the PES. Among the extracts, the highest level of radioactivity was recovered in either methanol layer of methanol/water fraction of liver and kidney (60–65 percent TRR, 1.16–2.92 mg eq/kg), or acetonitrile layer of the chloroform fraction of muscle and fat (70–71 percent TRR, 0.11–1.50 mg eq/kg) and hydrolysates of liver and kidney (48–59 percent TRR). Acid hydrolysis of liver and base hydrolysis of kidney releases soluble radioactivity quantitatively.

Table 56 Extraction of radioactive residues in tissues and egg yolk of hens orally administered ^{14}C-quintozene for 5 days at 25 mg/kg bw

Tissue	% TRR					
	Dose at 25 mg/kg bw			Dose at 50 mg/kg bw		
	Extracted	PES	Total	Extracted	PES	Total
Liver	86.3	25.2	111.5	84.1	16.1	100.2
Liver after acid hydrolysis	97.1	NA	97.1	--	--	--
Kidney	72.3	37.1	110.3	--	--	--
Kidney after 2nd base hydrolysis	91.4	NA	91.4	--	--	--
Fat	103.5	2.74	106.2	--	--	--
Muscle (breast)	97.0	22.4	119.4			
Egg yolk (at sacrifice)	33.5	79.3	112.7	25.9	89.3	115.0

Notes:

NB: there was no description about whether the acid hydrolysed sample was from the high dose or low dose.

Selected fractions were subjected to HPLC and TLC. In muscle and fat, parent quintozene was the major radioactive residue, accounting for 55.8 percent TRR (0.086 mg/kg) in muscle and 59.8 percent TRR (1.26 mg/kg) in fat. The metabolites PCA and PCTA were also detected in muscle at 4.7 percent (0.007 mg eq/kg) and 2.1 percent TRR (0.003 mg eq/kg), respectively, and in fat at 6.4 percent (0.14 mg eq/kg) and 10.3 percent TRR (0.22 mg eq/kg), respectively.

In liver fractions, quintozene, PCA and PCTA each accounted for 3.2 percent, 0.45 percent and 1.5 percent TRR, respectively, and after acid hydrolysis, only quintozene (3.8 percent TRR) and PCA (6.5 percent TRR) were detected. In kidney fractions, also quintozene, PCA and PCTA were detected, each accounting for 0.80 percent (0.063 mg/kg), 2.7 percent (0.12 mg eq/kg) and 0.23 percent (0.01 mg eq/kg) of TRR, respectively. After base hydrolysis, quintozene, PCA and PCTA were detected with slightly different ratio (quintozene at 2.4 percent TRR, PCA at 4.3 percent and PCTA at 1.9 percent TRR). The majority of the radioactivity in liver and kidney was not adequately identified/characterized.

Study 2. *(Parkins, 1990, 900-RES-090; Parkins, 1991, 900-RES-098)*

Three groups (five hens/group) of laying hens were dosed orally with ^{14}C-quintozene in capsule for six consecutive days at 15.8, 39.4 and 78.9 mg/hen/d, equivalent to 105 (low dose), 273 (medium dose) or 512 ppm (high dose) in the diet. Egg and excreta samples were collected daily and pooled. The birds were sacrificed approximately 6 hours after the final dose. Samples of blood, abdominal fat, skin with fat, muscle (thigh and breast), liver and kidney were taken and pooled by group.

The majority of the radioactivity was eliminated in the excreta (87–94 percent of the administered dose). The distribution of radioactivity was similar for all three treatment groups while as the administered dose was higher, TRRs were also higher. The highest TRR was found in fat in these three groups, followed by kidneys, skin with fat and egg yolk. The TRRs in muscles and egg white were much lower (Table 57)

Table 57 Radioactive residues in tissues and eggs of hens orally administered ^{14}C-quintozene for 5 days

Tissue	TRR (mg eq/kg)		
	Low dose	Medium dose	High dose
Liver	0.87	2.72	3.81
Kidneys	1.84	5.05	7.29
Muscle (Thigh)	0.13	0.36	0.71
Muscle (Breast)	0.07	0.17	0.30
Fat	2.64	6.17	10.1
Skin with fat	1.68	3.75	5.92
Egg yolk (Day 5)	1.74	3.52	5.75
Egg white (Day 5)	0.06	0.24	0.29

The tissues and egg yolks were extracted by blending with the proper amounts of chloroform, methanol and water. The chloroform layers were separated from the methanol/water layers. For cleaning up prior to HPLC, solid phase extractions were used. Fat extracts were cleaned up using SPE with Florisil and elution with hexane, and then 25, 50 and 75 percent dichloromethane in hexane, and finally with dichloromethane. Over 90 percent of the radioactivity was recovered in the first hexane eluate. C-18 SPE were used for methanol/water fractions of liver, and elution with water, and methanol. Approximately 75 percent of the radioactivity was in the methanol eluate.

Chromatographic separations were conducted using an HPLC system with reverse phase column and UV and radiological detectors. Mass spectra of isolated samples were obtained using mass spectrometer through the ionization (both positive and negative) source with a direct exposure probe, by thermospray, or by GC.

In fat, quintozene was identified as the major residue, accounting for 48 percent of the extracted radioactivity (ER). Other major metabolites identified in fat included PCA (16 percent ER) and tetrachloromethylsulfinylaniline (31 percent ER). In liver, PCTP (71 percent ER) and PCTASO (21 percent

ER) were identified as the major solvent-soluble residues. The major radioactive residues in base hydrolysates (37 percent TRR) of liver PES were identified as PCA and PCTA. In egg yolks, the majority of radioactivity (75 percent TRR) remained unextracted. Base hydrolysis of the egg yolk PES released 29 percent of the TRR, which was composed primarily of PCTA, along with trace amounts of PB, HCB, quintozene and PCA. In total, from the egg yolk, PCA (70 percent ER), PCTA (9 percent ER), and PCTP (18 percent ER) were identified. In muscle, the major radioactive residue was either PCP thioacetate or TCTA sulfone (88 percent ER), along with minor amount of PCTA (8 percent ER).

PCP-thiopyruvate and PCP-MalCys were only found in excreta at 26 and 19 percent ER respectively.

Table 58 Radioactive metabolites in tissues and eggs of hens orally administered ^{14}C-quintozene for 5 days

Compound	percent of extracted radioactivity					
	Fat	Liver	Kidney	Muscle	Egg yolk	Excreta [b]
Quintozene	48					
N-pentachlorophenylhydroxylamine			50			
PCA	16				70	
Tetrachloromethylsulfinylaniline	31					
PB					4	
PCTA				8	9	
PCTASO		21				
PCTP		71			18	30
PCP-Cys			8			
PCP thioacetate		7	35	88 [a]		17
TCTA	1					
TCTA sulfone			7	[a]		

Notes:

[a] Either PCP thioacetate or TCTA sulfone.

[b] Excluding those metabolites found only in the excreta.

Summary of animal metabolism

The metabolism of quintozene was investigated in lactating goats and laying hens. In general, the metabolic pathways in these species were similar to that in rats.

In goats, quintozene was metabolized mainly to PCA and its glucuronide conjugates (100 percent TRR in fat, 96 percent TRR in milk, 17 percent TRR in liver, and 26 percent TRR in kidney). Other metabolites were formed in much smaller amounts. They were TCTA, PCTA, C4MX. Parent quintozene was not detected in any of the tissues.

In hens, PCA, PCTA, PCTP, PCTP conjugated with cysteine, malonylcysteine, pyruvate and acetate were identified. Other metabolites identified included TCTA, TCTASOO, PCTASO and tetrachloromethylsulfinylaniline. Parent quintozene was detected only in fat at 48 percent ER.

The major metabolic pathway in animals involves (1) displacement of the nitro group by the sulfhydryl group of glutathione or SH-containing amino acids/peptides, followed by catabolic cleavage of the peptide, or by hydroxyl group; (2) reduction of the nitro group to produce N-hydroxypentachloroaniline and conjugated PCA; (3) dichlorination to yield tetrachloro- and trichloro-phenyl compounds. The pathway has some commonality with the metabolism in plants.

The proposed metabolic pathway for animals is shown in Figure 3, below.

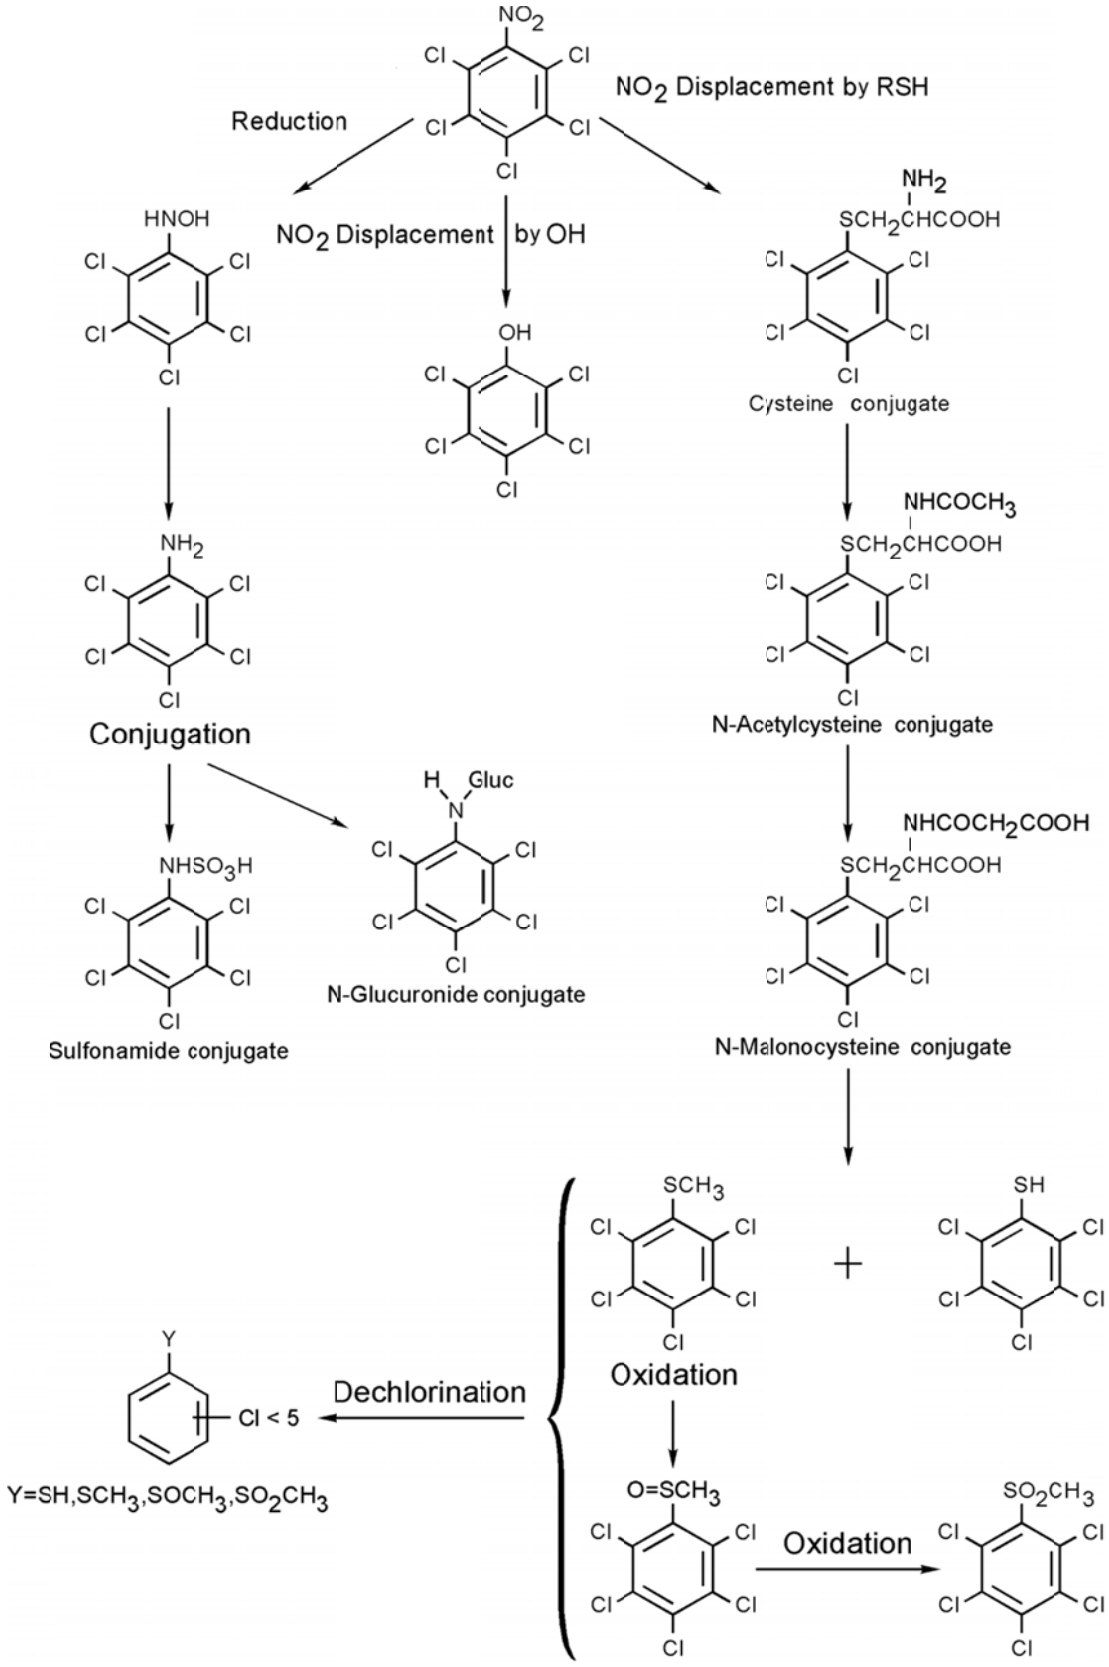

Figure 3 Proposed metabolic pathway of quintozene in lactating goat and laying hens after oral administration for 5 or 6 consecutive days

RESIDUE ANALYTICAL METHODS

The Meeting received information on: analytical methods developed and validated for the determination of quintozene and its metabolites in plant and animal matrices; and frozen storage stability of quintozene and its metabolites in high water content, high oil content, high protein content and high starch content category matrices.

Analytical Methods for Determination of Quintozene Residues–plant commodities

For data generation

CAM-24-73 Method (GC-ECD Method)(Griffith, 1973, 900-ANM-062, Vol.1)

Analyte: Quintozene, PCA, PCTA, PB, 2,3,4,5-TCNB, 2,3,5,6-TCNB
Matrix: Cabbage, pepper, tomato, peanut (nutmeat and hulls)(applicable to various plant commodities)
LOQ: 0.01 mg/kg
Description: Cabbage, pepper, tomato
Ground samples (50 g) were extracted with 2-propanol/hexane (50:50; v/v) by homogenization. After filtration, the extract was washed 3-times with 5 percent sodium chloride solution. A 2.5-mL aliquot of the hexane phase was cleaned-up on a deactivated silica gel column. The hexane eluate was evaporated to 2.5 mL and residues of quintozene and its metabolites were determined by GC-ECD.
Peanut nutmeat and hulls
Ground samples (10 g) were extracted with hexane (3x 75 mL for nutmeat, 1x 100 mL for hulls) by homogenization. After centrifugation, the combined extracts were evaporated to approximately 5-mL. The extract of nutmeat was partitioned three times into acetonitrile and combined acetonitrile extracts were diluted with water and partitioned two times into petroleum ether. Extracts of nutmeat and also hulls were cleaned-up by gel permeation chromatography prior to determination of residues of quintozene and its metabolites by GC-ECD.

CAM-24-73 Method (modified 1) (GC-ECD Method)(no author name, 1988, 900-ANM-080; Yu, 1992, 900-RES-194)
Analyte: Quintozene, PCA, PCTA, PB, HCB
Matrix: Cabbage
LOQ: 0.001 mg/kg
Description: Ground samples (100 g) were extracted with 2-propanol/hexane (50:50; v/v; 200 mL) by blending for 4 minutes. After filtration, the extract was washed three times with 5 percent sodium chloride in water (1 L). The hexane layer was dried over sodium sulfate. An aliquot of the extract was cleaned-up on a Florisil column by elution with hexane. The cleaned-up extract was evaporated and adjusted to 5 mL. Residues of quintozene and its metabolites were determined by GC-ECD.

CAM-24-73 Method (modified 2) (GC-ECD Method)(Gaydosh, 1993, 900-RES-107; 1994, 900-RES-108; and 1992, 900-ANM-107)
Analyte: Quintozene, PCA, PCTA, PB, HCB
Matrix: Green bean, dry bean, cotton
LOQ: 0.0005 mg/kg

Description: Ground samples (e.g., 10 g) were extracted with acetone/hexane (50:50; v/v; 200 mL) by shaking for 20 minutes. After filtration, the extract was washed two times with water (adjusted to pH 12 with sodium hydroxide), which was extracted with hexane. The combined hexane layers were evaporated to 10 mL which was cleaned-up on a Florisil column by elution with ether/hexane (5:95; v/v). The cleaned-up extract was evaporated to 5 mL and the solvent was exchanged against toluene. Residues of quintozene and its metabolites were determined by GC-ECD.

CAM-24-73 Method (modified 3) (GC-ECD Method) (Gaydosh, 1994, 900-RES-149)

Analyte: Quintozene, PCA, PCTA, PB, HCB

Matrix: Lettuce, turnip roots and tops, wheat (whole plant, grain and straw)

LOQ: 0.005 mg/kg

Description: Ground samples (10 g; 5g for turnip tops) were extracted with acetone/hexane (50:50; v/v; 200 mL) by shaking for 20 minutes. After filtration, the extract was washed two times with water (adjusted to pH 12 with sodium hydroxide), which was extracted with hexane. The combined hexane layers were evaporated to 10 mL, which was cleaned-up on a Florisil column by elution with acetone/hexane (12:88; v/v). The cleaned-up extract was evaporated to 5 mL and the solvent was exchanged against toluene (10 mL). Residues of quintozene and its metabolites were determined by GC-ECD.

CAM-24-73 Method (modified 4) (GC-MS and GC-ECD Method)(Maselli, 1997, 900-RES-147)

Analyte: Quintozene, PCA, PCTA, PB, HCB

Matrix: Cotton (RAC and its processed commodities)

LOQ: 0.005 mg/kg

Description: Ground samples (10 g) were extracted three times by blending with hexane and anhydrous sodium sulfate. After filtration, the combined extract was reduced to the added keeper volume (iso-octane, 2 mL) and adjusted to volume with cyclohexane/dichloromethane (50:50; v/v). An aliquot of this solution is cleaned-up by gel-permeation chromatography. The solvent of the cleaned extract was exchanged against hexane, and the extract was cleaned-up on a Florisil column by elution with 3 percent ethyl ether in petroleum ether. The cleaned-up extract was evaporated to a volume of 2 mL for cotton seed or 4 mL for gin trash. Residues of quintozene and its metabolites were determined by GC-MS (cotton seed) or GC-ECD (gin trash).

MP-PCNC-MA1 method (GC-ECD Method)(LeRoy, 1989, 900-ANM-007)

Analyte: Quintozene, PCA, PCTA, PB, 2,3,4.5-TCNB, 2,3,5,6-TCNB, HCB

Matrix: Tomato, snap bean, potato, peanut (whole nut, shell, nutmeat)

LOQ: 0.005 mg/kg

Description: Samples were dried with anhydrous sodium sulfate and were extracted with ethyl acetate. The ethyl acetate extract was concentrated (not to dry up). To the concentrate, isooctane was added, and the mixture was concentrated. The concentrated extract was diluted with isooctane or petroleum ether and then cleaned up using Florisil column chromatography. Samples with high liquid content were cleaned up using gel permeation chromatography before Florisil column chromatography. The eluate (elution with 3 percent ethyl ether in petroleum ether solution) was concentrated, to which isooctane was added. The final solution was subjected to analysis for quintozene and its metabolites by GC-ECD.

MP-PCNC-MA2 Method (GC-ECD Method)(LeRoy, 1991, 900-RES-019, 900-RES-020, 900-RES-024, and 900-RES-026; and LeRoy and Cassidy, 1991, 9000-RES-032)

Analyte: Quintozene, PCA, PCTA, PB, 2,3,4,5-TCNB, 2,3,5,6-TCNB
Matrix: Cabbage, broccoli, pepper, tomato, cotton processed fractions
LOQ: 0.01 mg/kg
Description: Pre-homogenized samples were extracted with acetonitrile/water (approximately 2:1, v/v), followed by a petroleum ether/water partitioning step. The combined petroleum ether layers were concentrated and cleaned-up on a Florisil column. The cleaned-up extract was concentrated. The solvent was exchanged with isooctane, and residues of quintozene and its metabolites were determined by GC-ECD.

Zweig Method (published)(GC-MS Method)(Thornton M., Feiler B.; 900-RES-030; "Analytical Methods for Pesticides and Plant Growth Regulators", ed by Sherma and Zweig, Volume VI, pp 578–580, 1972, Academic Press)

Analyte: Quintozene
Matrix: Potato tuber
LOQ: 0.01 mg/kg
Description: Samples were extracted with a mixture of isopropanol and hexane, the extracts were filtered and then washed with 5 percent NaCl, dried with Na_2SO_4 and passed through a silica gel column for clean-up. Eluate was collected and evaporated to approximately 1 ml and transferred for analysis. Residues of quintozene were determined by GC-MS by monitoring the ions *m/z* = 293, 295 and 249.

For monitoring

Battelle 100117568 Method (QuEChERS extraction + GC-MS method)(Thorn J., 2019, 900-RES-223)

Analyte: Quintozene, PCA, PCTA
Matrix: Broccoli, potato tuber
LOQ: 0.01 mg/kg
Description: A sample of 10 g is transferred into a 50 ml centrifuge tube to which acetonitrile (10 mL) was added for extraction by high-speed homogenization. After homogenization, the content of a QuEChERS Q-Sep Q110 package (4g $MgSO_4$, 1g NaCl, 1g TSCD, 0.5g DHS) was added. The sample was capped, shaken and high-speed homogenization was repeated. After centrifugation, 1 ml of the acetonitrile layer was transferred into the dispersive SPE tube and shaken for 2 minutes followed by centrifugation. An aliquot of the extract was transferred for analysis by GC-MS utilizing electronic ionization in Selected Ion Monitoring mode, monitoring the following three ions for detection of each analyte.

Quintozene: m/z = 295, 297, 293
PCA: m/z = 265, 267, 26
PCTA: m/z = 296, 294, 246

<u>*Analytical methods for animal commodities*</u>

For data generation

CAM-1-69 Method (GC-ECD Method)(Griffith, 1973, 900-ANM-062, Vol. 3)

Analyte: Quintozene, PCA, PB, HCB
Matrix: Milk
LOQ: 0.001 mg/kg for quintozene

Description: An aliquot of the milk sample was diluted with acetone and filtered into a separating funnel. Hexane, water and sulfuric acid were added and residues partitioned into the hexane phase. The hexane layer was dried over sodium sulfate, reduced to 25 mL using a stream of nitrogen and passed through a Florisil column for clean-up. An aliquot of the hexane extract was taken for determination of residues by GC-ECD.

Method for cow tissues (not numbered) (GC-ECD Method)(Griffith et al., 1969, 900-ANM-055)

Analyte: Quintozene, PCA, PB, PCTA, HCB

Matrix: Cow fat, kidney, liver, muscle(meat)

LOQ: 0.003–0.05 mg/kg

Description: Cow fat, kidney and liver

Samples were homogenized with acetonitrile containing sodium sulfate. An aliquot of the extract was diluted 1:1 with water and partitioned into hexane. After centrifugation, the hexane phase was dried over sodium sulfate in a separator funnel. The hexane phase was then used for determination of quintozene, its metabolites and HCB by GC-ECD.

Cow muscle

Samples were extracted by homogenization with hexane containing sodium sulfate. After separation of the solids, an aliquot of the hexane extract was taken for determination of quintozene, its metabolites and HCB by GC-ECD.

CAM-39-75 Method (GC-ECD Method)(Griffith, 1973, 900-ANM-062, Vol.2)

Analyte: Quintozene, PCA, PCTA, PB, HCB

Matrix: Poultry fat, liver, meat and egg

LOQ: 0.002–0.01 mg/kg

Description: Poultry fat, liver, egg white and egg yolk

Samples were extracted by homogenization with acetonitrile. After separation of the solids, an aliquot of the extract was transferred into a separating funnel. Egg white only was additionally diluted with water. Residues were partitioned into hexane. The hexane phase was dried over sodium sulfate. An aliquot of the hexane extract was taken for determination of residues by GC-ECD.

Poultry meat

Samples were extracted by homogenization with hexane containing sodium sulfate. After separation of the solids, an aliquot of the extract was taken for determination of residues by GC-ECD.

Method validation

Recovery data for the above methods are summarized in the following tables.

Table 59 Summary of recovery data of the above-mentioned methods for determination of quintozene and its metabolites in plant commodities

Procedural recovery data obtained in relation to the supervised residue trials and processing studies were presented in Table 60. While no validation data were available for animal commodities, procedural recovery data were provided for animal commodities and are presented in Table 61.

Table 60 Summary of procedural recovery data for determination of quintozene and its metabolites in plant commodities in relation to the supervised residue residue trials and processing studies

Summary of analytical method validation

Information was available for analytical methods for quintozene and its metabolites including PCA, PCTA PB, 2,3,4,5-TCNB and 2,3,5,6-TCNB, and an impurity HCB in the crops for which supervised residue trials were provided to this Meeting. The methods employ extraction of samples with acetone, acetone/hexane, acetonitrile, ethyl acetate, hexane, or isopropanol/hexane, with or without partition, clean-up using Florisil, silica gel, gel permeation or SPE column, and separation and quantification with GC-ECD or GC-MS. The LOQ varied from 0.0005 to 0.01 mg/kg for each analyte.

The results of recovery tests for analytical methods for plant commodities mostly showed acceptable recoveries and RSD, except that for CAM-24-73 (modified 4) method for cotton and its processed commodities, the recoveries at 0.0005 mg/kg in various commodities did not result in acceptable recoveries.

An analytical method using the QuEChERS extraction, clean-up with SPE column, and separation/quantification by GC-MSD was tested for broccoli and potato resulting in recoveries and RSD in the acceptable range.

Procedural recovery result data were also provided for those crops as well as for animal commodities. For analytical methods for animal commodities, there have been no sufficient data to indicate validity of these methods for animal commodities. Also there were not sufficient number of recovery data for each concentration/commodity.

Storage Stability under Frozen Conditions

Plant commodities

The storage stability of quintozene and its metabolites under frozen conditions was investigated in high water content, high oil content, high protein content and high starch content plant commodities.

Study 1 (Ball J.O., 1990, 900-RES-050; and Ball J.O., 1990, 900-RES-112)

The stability of quintozene and its metabolites PCA, PCTA and PB, and the impurity HCB was investigated in fortified control samples of kidney bean, pepper, tomato, tomato ketchup, dried tomato pomace, wheat grain, corn and soya bean during freezer storage (-20 °C or below) for 0–14 months and wheat grain, corn and soya bean during freezer storage (-20 °C or below) for 0–8 months. Control samples of kidney bean, pepper, tomato and its processed commodities, wheat grain, corn and soya bean were individually fortified in duplicate with quintozene and its metabolites at levels of 0.2 mg/kg (kidney bean, pepper, tomato including the processed commodities) or 0.025 mg/kg (wheat grain, corn and soya bean) and stored frozen for 2–14 or 2–8 months, respectively. Day zero samples were extracted immediately after fortification. All samples were analysed by CAM-24-73 (modified) method with an LOQ of 0.005 mg/kg for each analyte. The results of the storage stability study on quintozene and its metabolites and impurities in these commodities are presented in the following table.

Table 62 Storage stability of quintozene, PCA, PCTA, PB and HCB in kidney beans, pepper, and tomato and its processed commodities at -20 °C or below

When frozen storage stability was tested at the fortification level of 0.2 mg/kg at -20 °C or below in kidney beans, quintozene, PCA, PCTA and HCB were stable for at least 14 months (longest period tested). PB declined to below 70 percent after 6 months of frozen storage.

In pepper, when stored frozen at -20 °C or below, quintozene, PCA, PCTA and HCB were stable for up to 4 months. PB was found to be stable for less than 2 months.

In tomato, when stored frozen at -20 °C or below, quintozene, PCA, PCTA and HCB were stable for up to 6 months. PB was stable for up to 2 months. In tomato ketchup, quintozene and HCB were stable for up to 2 months, and PCA and PCTA for up to 4 months. PB was stable for less than 2 months. In tomato dry pomace, quintozene, PCTA, PB and HCB were stable for up to 2 months. For PCA, percent remaining values were all below 70 percent at any time points, even at day zero, and therefore, the results cannot be used.

When frozen storage stability was tested at the fortification level of 0.025 mg/kg at -20 °C or below, in wheat grain, all analytes, quintozene, PCA, PCTA, PB and HCB were stable for at least 8 months (longest period tested).

In corn, quintozene, PCA, PCTA, PB and HCB were stable for less than 2 months, except that PCA remained at 70 percent after storage for 3 months and 8 months. In this study, at day zero, procedural recoveries were in a range of 80–84 percent and if this was taken into consideration, the lowest percent remaining were close to 70 percent.

In soya bean, all analytes, quintozene, PCA, PCTA, PB and HCB were stable for less than 2 months, except that quintozene remained at 72 percent after 6 months of storage and PCA remained at 70 percent after 4 and 6 months of storage.

Study 2. (LeRoy R.L., 1991, 900-RES-016)

The stability of quintozene PCA, PCTA, PB, 2,3,4,5-TCNB and 2,3,5,6-TCNB, and the impurity HCB was investigated in fortified control samples of potato, tomato, snap beans, peanut and broccoli during freezer storage (below 0 °C) for 0–14 months (up to 23 months for snap beans). Homogenized control samples (25 g) of potato, tomato, snap beans, peanut and broccoli were fortified in duplicate with quintozene and separately with a mixture of the metabolites PCA, PCTA, PB, 2,3,4,5-TCNB, 2,3,5,6-TCNB and the impurity HCB at a level of 0.2 mg/kg and stored frozen (below 0 °C) over the given time frame of 2–14 months (2–23 months for snap beans). Day zero samples were extracted immediately after fortification. All samples were analysed by MP-PCNC-MA1 method with an LOQ of 0.005 mg/kg for each analyte. The result of the storage stability of quintozene and its metabolites and impurities in these commodities is resented in the table below.

Table 64 Frozen storage stability of quintozene, PCA, PCTA, PB, 2,3,4,5-TCNB, 2,35,6-TCNB and HCB in potato, tomato, snap beans, peanut and broccoli.

When frozen storage stability was tested at the fortification level of 0.2 mg/kg, quintozene, PCA, PCTA, 2,3,4,5-TCNB and HCB were stable for at least 14 months (longest period tested) in samples of potato, tomato, peanut and broccoli. 2,3,5,6-TCNB was stable for at least 14 months in tomato, peanut and broccoli samples but for less than 1 month in potato sample.

In snap beans, quintozene, PCTA, PB, 2,3,4,5-TCNB, HCB declined to below 70 percent of the fortified level when stored for longer than 3 months, and 2,3,5,6-TCNB for at least 1 month whereas PCA remained stable for at least 23 months (longest period tested for snap beans).

Study 3. (Gaydosh K.A., 1999, 900-RES-149)

The stability of quintozene and its metabolites PCA, PCTA and PB, and the impurity HCB was investigated in fortified control samples of lettuce, turnip roots and tops, and wheat whole plant, grain and straw during freezer storage at -20±5 °C for 0–24 months. Ground control samples (10 g) of lettuce, turnip roots and tops, and wheat whole plant, grain and straw were fortified in duplicate with quintozene and the metabolites PCA, PCTA and PB, and the impurity HCB at a level of 1.0 mg/kg and stored frozen over the given time frame of 1–24 months. Day zero samples were extracted immediately after fortification. All samples were analysed by CAM-24-73 (modified) method with an LOQ of 0.005 mg/kg for each analyte. The results of the storage stability test on quintozene and its metabolites and impurities in these commodities are presented in the table below.

Table 65 Storage stability of quintozene, PCA, PCTA, PB and HCB in lettuce, turnip roots and tops, and wheat whole plant, grain and straw at -20±5 °C

When frozen storage stability was tested at the fortification level of 1.0 mg/kg at -20±5 °C, quintozene, PCA, PCTA, PB and HCB were found to be stable in lettuce, turnip roots and tops and wheat whole plant, grain and straw for at least 24 months (longest period tested).

Study 4. (Gaydosh, 1991, 900-RES-097; Ruhland, 1991, 900-RES-167a; and Keller, 1991, 900-RES-167b)

The stability of quintozene and its metabolites PCA, PCTA and PB, and the impurity HCB was investigated in fortified control samples of cotton seed during freezer storage at below 0 °C for 0–18 months. Ground control samples of cotton seed (10 g) were fortified in duplicate with quintozene and the metabolites PCA, PCTA and PB, and the impurity HCB at a level of 0.2 mg/kg and stored frozen over the given time frame of 1–18 months. Day zero samples were extracted immediately after fortification. All samples were analysed

by MP-Quintozene-MA method with an LOQ of 0.005 mg/kg for each analyte. The results of the storage stability test on quintozene and its metabolites and impurities in cotton seed are presented in the table below.

Table 66 Storage stability of quintozene, PCA, PCTA, PB and HCB in cotton seed at below 0 °C

When frozen storage stability was tested at the fortification level of 0.2 mg/kg at below 0 °C, in cotton seeds, quintozene, PCA, PCTA, PB and HCB were found to be stable for at least 18 months (longest time tested).

Study 5. (Ball, 1990, 900-RES-144)

The stability of quintozene and its metabolites PCA, PCTA and PB, and the impurity HCB was investigated in fortified potato control samples during freezer storage at -20 °C±2 °C for 0–12 months. Ground control potato samples were fortified in duplicate with quintozene and the metabolites PCA, PCTA and PB, and the impurity HCB (fortification level not reported) and stored frozen over the given time frame of 1–12

months. Day zero samples were extracted immediately after fortification. All samples were analysed by CAM-24-73 (modified) method with an LOQ of 0.0005 mg/kg for each analyte. The results of the storage stability test on quintozene and its metabolites and impurities in potato tubers are presented in the table below.

Table 67 Storage stability of quintozene, PCA, PCTA, PB and HCB in potato at -20±2 °C

In potato tubers, quintozene, PCA, PCTA, PB and HCB were found to be stable for at least 12 months when stored frozen at -20±2 °C. However, since the fortification level was unknown, whether the stability in this study applies to the residues arising in the supervised residue trials.

Study 6. (Gaydosh, 1991, 900-RES-096)

The stability of quintozene and its metabolites PCA, PCTA and PB, and the impurity HCB was investigated in fortified control samples of peanut seed during freezer storage at below 0 °C for 0–12 months. Ground control samples (10 g) of peanuts were fortified in duplicate with quintozene, the metabolites and the

impurity HCB at a level of 0.2 mg/kg and stored frozen over the given time frame of 1–12 months. Day zero samples were extracted immediately after fortification. All samples were analysed by a slightly modified MP-PCNC-MA1 method using hexane as the extraction solvent with an LOQ of 0.005 mg/kg for each analyte. The results of the storage stability test on quintozene and its metabolites and impurities in peanut seed are presented in the table below.

Table 68 Storage stability of quintozene, PCA, PCTA, PB and HCB in peanut at below 0 °C

When frozen storage stability was tested at the fortification level of 0.2 mg/kg at below 0 °C, in peanut seed, quintozene, PCA, PCTA, PB and HCB were stable for at least 12 months (longest period tested).

Study 7. *(Stenner et al, 1992, 900-RES-023)*

The stability of quintozene and its metabolites PCA, PCTA, PB, 2,3,4,5-TCNB and 2,3,5,6-TCNB, and the impurity HCB was investigated in fortified control samples of peanut whole nut, shells and nutmeat during

freezer storage (temperature not reported) for 0–6 months. Homogenized control samples (25 g) of peanut whole nut, shells and nutmeat were fortified in duplicate with quintozene and separately with a mixture of PCA, PCTA, PB, 2,3,4,5-TCNB, 2,3,5,6-TCNB and the impurity HCB at a level of 0.2 mg/kg and stored frozen for a maximum of 6 months (176 days). Day zero samples were extracted immediately after fortification. All samples were analysed by MP-PCNC-MA1 method with an LOQ of 0.005 mg/kg for each analyte. The results of the storage stability test on quintozene and its metabolites and impurity in peanut whole nut, shells and nutmeat are presented in the table below.

Table 69 Storage stability of quintozene, PCA, PCTA, PB, 2,3,4,5-TCNB, 2,3,5,6-TCNB and HCB in peanut when frozen

				Individual	Mean	
			176/6	84, 86	85	84

When frozen storage stability was tested at the fortification level of 0.2 mg/kg, quintozene, PCA, PCTA, PB and HCB were stable for at least 6 months (longest period tested) in frozen samples of peanut whole nut, shells and nutmeat. 2,3,4,5-TCNB and 2,3,5,6-TCNB were stable for at least 6 months in whole nut and nutmeat but in shells, degraded to less than 70 percent of the fortified levels after storage for 6 months. However, the residue levels at time zero were as low as 86 percent and 82 percent of fortified level, respectively.

Study 8. (Gaydosh, 1991, 900-RES-097; Ruhland , 1991, 900-RES-167a; Keller J.F., 1991, 900-RES-167b)

The stability of quintozene and its metabolites PCA and PCTA was investigated in fortified control samples of broccoli and potato tubers during freezer storage at below -20 °C for 0–12 months. Ground control samples (10 g) of broccoli or potato tubers were fortified in duplicate with quintozene and the metabolites PCA and PCTA at a level of 0.1 mg/kg and stored frozen over 1–12 months. Day zero samples were extracted immediately after fortification. All samples were analysed by the QuEChERS method as reported in Battelle Study Number: 100117568 with an LOQ of 0.01 mg/kg for each analyte. The results of the storage stability test on quintozene and its metabolites in broccoli and potato tubers are presented in table below.

Table 70 Storage stability of quintozene, PCA and PCTA in broccoli and potato at below -20 °C

When frozen storage stability was tested at the fortification level of 0.1 mg/kg at -20 °C or below, quintozene, PCA and PCTA were stable in broccoli and potato tubers for at least 12 months (longest period tested).

Summary of frozen storage stability of quintozene, PCA, PCTA, PB and HCB is shown below

Category	Commodity	Duration of study (month)	Stable period (months) [a] Quintozene	PCA	PCTA	PB	HCB
High water content	Broccoli	14	14	14	14	14	14
	Peppers	14	Up to 4	Up to 4	Up to 4	<2	Up to 4
	Tomato	14	14	14	14	14	14
	Lettuce	24	24	24	Up to 18	24	24
	Snap bean	23	Up to 3	23	Up to 3	Up to 3	Up 3
	Turnip tops	24	24	24	Up to 18	24	24

High protein content	Kidney bean	14	14	14	14	Up to 6	14
	Soya bean	8	<2	<2	<2	<2	<2
High starch content	Potato	14	14	14	14	14	14
	Turnip root	14	24	24	24	24	24
	Corn	8	<2	<2	<2	<2	<2
	Wheat grain	24	24	24	24	24	24
High oil content	Cotton seed	18	18	18	18	18	18
	Peanut	14	14	14	14	14	14
Dry sample	Wheat straw	24	24	24	24	24	24

Notes:

[a] Where the value of stable period is the same as the duration of study, this indicates that the fortified compound was stable at least for the months in this table. Where the term "up to" precedes the months of stable period, the fortified compound would not be stable after the months specified. The month value with the "<" symbol indicate that significant degradation occurred by the months described.

USE PATTERN

Quintozene is registered in many countries. For the purposes of estimating maximum residue levels, only the registered uses on those crops for which supervised trials were conducted and provided to the Meeting are recorded in the following table. Quintozene is allowed for pre-plant treatment as a broadcast application to bare soil followed by soil incorporation; treatment at planting as an in-furrow application directed to the seed; a post-emergence banded application directed to the soil; or as a transplant solution after transplanting of the crop.

Table 71 Registered uses of Quintozene for the crops for which supervised trials were provided

Crop	country	Form g ai/L or kg	Application Method	Rate kg ai/ha	Max rate/season kg ai/ha	Conc kg ai/ hL	No	PHI days	Note
Broccoli and Cabbage [b]	US	FL 480 [a]	Transplant solution.	1.68	25.2	0.18	-	--	Thoroughly incorporate solution into the soil. Up to 0.35 L of solution per plant.
			Banded soil application, pre-planting	25.2	25.2	10.8	1	--	Spray as a 12-inch band centred on row and incorporate to a depth of 4 to 6 inches immediately prior to planting. May be used on direct seeded cole crops. Thoroughly incorporate solution into the

		750	treatment						dose.
Cotton	PE	WP 750	Seed treatment	0.652 kg ai/100 kg seed			1	--	
Cotton	TH	EC 240	Seed treatment	Mix 5 ml (1.2 g ai) with 1 kg of seeds			1	--	
Cotton	ZA	WP 750	Soil treatment (into furrow)	3.75–5.25		3.75–5.25			All the soil surrounding and covering the seed must be treated.
Peanut	MX	FL 480 [c]	Total application	0.96–1.92			1	--	Use sufficient water for uniform distribution. Apply in band at sowing.
Peanut	MX	WP 750	Mix with seeds Hopper box	0.75–1.50			-	--	Indirect treatment to the soil using higher doses than those uses in a simple seed treatment. In hopper box application, the seed is also used as a vehicle.
Peanut	BR	WP 750	Seed treatment	0.225 kg ai/100 kg seed			1	--	

Notes:

[a] 480 kg ai/L, 40 percent (w/w). Do not graze or feed clippings to livestock. Do not plant root crops in treated fields within 12 months of the last application unless quintozene is registered for use on those crops. Apply by ground boom application only except for greenhouse use.

[b] Listed vegetables together with broccoli and cabbage: Brussels sprouts, Chinese broccoli, cauliflower, Chinese cabbage (tight-headed varieties only), collards, kale, mustard greens.

[c] 370 kg ai/kg (W/W) according to the label.

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

Supervised trials from the United States using either banded application at planting, in-furrow application at planting, post-emergence banded application, banded application at pegging or chemigation of quintozene were conducted on the following crops and their results are summarized in the tables:

Codex Group/Sub-group	Crop tested	Table No.
Brassica vegetables (except Brassica leafy vegetables)		
Subgroup of Flowerhead Brassicas	Broccoli	Table 72
Subgroup of head Brassicas	Cabbages, head	Table 73
Fruiting vegetables, other than Cucurbits		
Subgroup of tomatoes	Tomato	Table 74
Subgroup of pepper and pepper-like commodities	Peppers	Table 75
Legume vegetables		
Subgroup of beans with pods	Beans with pods	Table 76, Table 77
Subgroup of succulent beans without pods	Beans without pods	Table 78
Pulses		
Subgroup of dry beans	Beans (dry)	Table 79, Table 80
Root and tuber vegetables		

Codex Group/Sub-group		Crop tested	Table No.
	Subgroup of tuberous and corm vegetables	Potato	Table 81
Oilseed			
	Subgroup of cotton seed	Cotton seed	Table 82
	Subgroup of other oilseeds	Peanut	Table 83, Table 84

In addition to the descriptions and details of the field trials, each study report includes a summary of the analytical methods, together with the corresponding procedural recoveries (see Table 60), LOQ, LOD, and information on storage of samples. Duration of freezer storage between sampling and analysis were reported for all trials. If the duration is longer than the duration of proven frozen storage stability, this fact is stated before the related table below.

All appropriate trials are summarized and used. In many United States trials, where duplicate (replicate) replicate samples were taken from replicate plots at each sampling interval and were analysed separately, the mean values are presented in the residue tables and used for estimation of maximum residue levels and STMR. Where results from the same location with similar application timing and variety are reported, only the higher/highest results were used.

When residues were not quantifiable, they were shown as below the LOQ of the relevant analytical method (e.g., < 0.01 mg/kg). Application rates were generally rounded to three significant figures. For calculation of the mean residue values, available analytical results without rounding were used. For rounding the mean values from two values, the rule in ISO 80000-1 (round to the nearest even number) was used.

Although control plots were included in the trials, control data are not reported in the following tables unless residues in control samples exceeded the respective LOQ. Results were not corrected for concurrent method recoveries.

Residue values from the trials conducted according to the critical GAP were used for the estimation of maximum residue levels and STMR values. Those results included in the tables are underlined.

For the calculation of the "total" residues as expressed as quintozene equivalents in the following tables, the ratios of the molecular weights are used as follows:

	Molecular weight (g/mol)	MW Ratio Compared to MW of quintozene
Quintozene	295.32	1.00
PCA	265.34	1.11
PCTA	296.41	1.00

Where residue concentrations are below the LOQ, there are regarded to be at the LOQ values for summing up.

Brassica Vegetables

Broccoli

Twelve supervised trials were conducted on broccoli in the United States during the growing seasons 1987, 1988/89 and 2018/19.

In the four trials performed in 1987, the broadcast and banded applications were conducted with ground equipment in two parallel plots, each with a WP formulation or a GR formulation. The broadcast applications were done at a rate of 33.6 kg ai/ha whereas the banded applications were done at a rate of 25.2 kg ai/ha for the WP formulation and at 22.4 kg ai/ha for the GR formulation. Each trial comprised one plot where the WP formulation was applied as a soil drench application at a rate of 67.3 kg ai/ha after transplanting. In the two trials performed in 1987 in Oregon, a directed seed broadcast application was also performed.

In the 1987 trials, mature broccoli samples were obtained at 64–83 DAT and analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 with an LOQ of 0.002 mg/kg for each analyte. PB and HCB were below the LOQ in all the trials.

In the 1988/89 trials, three different application techniques were compared in side-by-side plots, where one application to the soil was performed either as a broadcast spray application with soil incorporation pre-planting of the crop, a banded application at the time of planting, or as a soil drench application after transplanting of the crop.

Mature broccoli was sampled at 58–122 DAT and analysed for quintozene, PCA, PCTA, PB, 2,3,4,5-TCNB, 2,3,5,6-TCNB and HCB using the method MP-PCNC-MA2 with an LOQ of 0.01 mg/kg for each analyte. PB and HCB were below the LOQ in all the trials.

In the trials performed in 2018/19 three trial locations received either a soil drench application, a banded application, or a broadcast spray application, each with a 480 g ai/L FL-formulation at a nominal rate of 25.2 kg ai/ha. Two trials, LR18357-01 and LR18357-05 were performed at the same location with treatment only 10 days apart. LR18357-01 was performed as a soil dench application whereas LR18357-05 was performed as a broadcast spray application to soil. Since the application techniques are not significantly different, the trials were not considered independent.

Mature broccoli was sampled at 89–132 DAT and analysed for quintozene, PCA and PCTA using the Battelle 100117568 method with an LOQ of 0.01 mg/kg for each analyte.

All the samples were stored frozen for periods shorter than the proven storage stability duration.

Applications by direct seed treatment are presented below for completeness but the use is not included in the permitted uses on the label and therefore the results are not used for estimation of maximum residue level or STMR.

Table 72 Magnitude of residues of quintozene in/on broccoli after broadcast application or banded application to soil, soil application after transplanting, or direct seed treatment in the supervised trials conducted in the United States in 1987, 1988/89, and 2018/19 (The portions analysed were head and stalk in all trials.)

Notes:

[a] Mean of the analytical results of two samples. Residues scaled to the critical GAP-rate are presented in brackets.

[b] Same location as LR18357-01 with the application date 10 days earlier prior to planting (LR18357-01 after planting).

Cabbage

Sixteen supervised residue trials were carried out on cabbage in the United States during the growing seasons 1987/88, 1988/89 and 1990/91.

In all trials, three different application techniques were compared in side-by-side plots, where one application to the soil was performed either as a broadcast spray application with soil incorporation pre-planting of the crop, a banded application at the time of planting, or as a soil drench application after transplanting of the crop.

In the seven trials performed in 1987/88, the broadcast and banded applications were conducted with ground equipment in two parallel plots each with a 750 g ai/kg WP formulation and a 100 g ai/kg GR formulation. The broadcast applications were done at a rate of 33.6 kg ai/ha. The banded applications were done at a rate of 25.2 kg ai/ha for the WP formulation and at 22.4 kg ai/ha for the GR formulation. Each trial also comprised one plot where the WP formulation was applied as a soil drench application at a rate of 67.3 kg ai/ha after transplanting. In the 1987 growing season, two trials, 45370-54373 (field 2) and 45374-54377 (field 6), were performed in the same location with the treatments on the same dates. These trials are not considered independent.

Mature cabbage heads were sampled at 67–125 DAT and analysed for quintozene, PCA, PCTA, PB and HCB with or without wrapper leaves using the method CAM-24-73 (modified) with an LOQ of 0.002 mg/kg for each analyte. In all trials, analytical results of HCB were below the LOQ. Analytical results of PB were mostly below the LOQ with in some cases at the maximum 0.003 mg/kg shown in the footnotes of the table.

In the five trials performed in 1988/89, the broadcast and banded applications were conducted with ground equipment in two parallel plots each with a 750 g ai/kg WP formulation and a 100 g ai/kg GR formulation, all at a rate of 36.6 kg ai/ha. Each trial also comprised one plot where the WP formulation was applied as a soil drench application at a rate of 67.3 kg ai/ha after transplanting.

Mature cabbage heads were sampled at 70–134 DAT and analysed for quintozene, PCA, PCTA, PB, 2,3,4,5-TCNB, 2,3,5,6-TCNB and HCB with or without wrapper leaves using the method MP-PCNC-MA2 with an LOQ of 0.01 mg/kg for each analyte. In all trials, analytical results of HCB and PB were below the LOQ.

In the trials performed in 1990/91, the broadcast applications were conducted either in two parallel plots each with a 750 g ai/kg WP formulation and a 100 g ai/kg GR formulation (2 trials) or in a single plot with a 480 g ai/L flowable formulation, all at a rate of 36.6 kg ai/ha. The same setup was used for the banded application with exception that a reduced application rate of 22.4–25.2 kg ai/ha was used. Two trials, CRA-90-081 (1990/1991) and CRA-90-084 (1990) were performed in the same location. The application dates and harvest dates were available for CRA-90-081 but no date information was available for CRA-90-084. Since the harvest dates for CRA-90-081 were March and April 1091, it is likely that these dates may be more than 60 days earlier than those for CRA-90-084, and since both trials were presenting high residues, both trials were considered for estimating maximum residue level.

In the 1990/91 trials, mature cabbage heads were sampled at maturity (the DAT was reported only for one trial with 153–161 days) and analysed for quintozene, PCA, PCTA, PB and HCB with or without wrapper leaves using the method CAM-24-73 with an LOQ of 0.001 mg/kg for each analyte except HCB for which an LOQ was 0.0005 mg/kg. PB and HCB were found above the respective LOQ in some trials and some others in one of two samples from some trials, which were shown in the footnotes of the table. In one sample from one trial, HCB was found at 0.059 mg/kg but the other sample was found to contain HCB below the LOQ.

All the samples were stored frozen for periods shorter than the proven storage stability duration, except for 2 trials (shown in the following table).

Table 73 Magnitude of residues of quintozene in/on cabbage after broadcast application or banded application to soil, or soil application after transplanting in the supervised trials conducted in the United States in 1987/88, 1988/89, and 1990/91

Fruiting vegetables, other than Cucurbits

Tomato

Fourteen supervised residue trials were carried out on tomato in the United States during the growing seasons 1987 and 1988/89.

In all trials two plots were established, where in the first plot an in-furrow application of a 750 g/kg WP formulation at a rate of 8.41 kg ai/ha was performed at the time of planting. In the second plot, a soil dench application after transplanting was performed using a transplanting solution at a concentration of 0.45 kg ai/hL at rates of about 25–29 kg ai/ha. In two of the 1987 trials an additional plot each was set-up with in-furrow application at an exaggerated rate of 42 kg ai/ha to obtain samples for processing.

In the 1987 trials, tomato fruits were sampled at 69–119 DAT and analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 with an LOQ of 0.05 mg/kg for each analyte. As a follow-up, selected samples were re-analysed with a modified version of method CAM-24-73 with an LOQ of 0.002 mg/kg for each analyte. However, since samples were re-analysed after a storage of up to 574 days for which stability cannot be confirmed, the data from re-analysis were not considered for estimation of maximum residue level.

In the 1988/89 trials, mature tomato fruits were sampled at 81–108 DAT (also after planning) and analysed for quintozene, PCA, PCTA, PB, 2,3,4,5-TCNB, 2,3,5,6-TCNB and HCB using the method MP-PCNC-MA2 with an LOQ of 0.01 mg/kg for each analyte.

All the samples were stored frozen for periods shorter than the proven storage stability duration (except for re-analysis as explained above).

Table 74 Magnitude of residues of quintozene in/on tomato after in-furrow application or soil application after transplanting in the supervised trials conducted in the United States in 1987 and 1988/89 (The portions analysed were whole fruits in all trials.)

Peppers

In total nine supervised residue trials were carried out on pepper in the United States during the growing seasons 1987/88 and 1988/89. Two trials in the 1987/88 season were performed on chili peppers (non-bell shape), all other trials on sweet pepper varieties (bell shape).

In all trials, two plots were established, where in the first plot an in-furrow application of a 750 g/kg WP formulation at a rate of 8.41 kg ai/ha was performed at the time of planting. In the second plot, a soil dench application after transplanting was performed using the same WP formulation at rates of 4.20–38.1 kg ai/ha.

In the 1987/88 trials, pepper fruits were sampled at 71–104 DAT and analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 with an LOQ of 0.05 mg/kg for each analyte.

In the 1988/89 trials, mature pepper fruits were sampled at 49–105 DAT and analysed for quintozene, PCA, PCTA, PB, 2,3,4,5-TCNB, 2,3,5,6-TCNB and HCB using the method MP-PCNC-MA2 with an LOQ of 0.01 mg/kg for each analyte.

As a follow-up, selected samples were re-analysed with a modified version of method CAM-24-73 with an LOQ of 0.002 mg/kg for each analyte. However, since samples were re-analysed after a storage of up to 567 days for which stability cannot be confirmed, the data from re-analysis was not considered for estimation of maximum residue level.

All the samples, except in one trial (see in the Table), were stored frozen for periods shorter than the proven storage stability duration. Those trials with the sample storage period longer than 230 days are not included in the following Table.

Table 75 Magnitude of residues of quintozene in/on peppers after in-furrow application or soil application after transplanting in the supervised trials conducted in the United States in 1987/88 and 1988/89 (The portions analysed were whole fruits in all trials.)

[b] Stored frozen for184 days.

Legume vegetables

Beans, except broad bean and soya bean (green pods and immature seeds)–Directed band applications to soil or ground applications to soil

Twenty supervised residue trials were carried out on beans (all belong to the genus *Phaseolus*) in the United States during the growing seasons 1987 and 1988. In seventeen trials, whole green pods were sampled and in three trials, succulent seeds were sampled.

In all trials, two plots were established, where in the first plot a 750 g/kg WP formulation and in the second plot a 240 g/L EC formulation was used. In all trials/plots, except two, quintozene was applied four times at a nominal rate of 2.24 kg ai/ha with a nominal interval of 14 days. In other two trials, only three applications at rates ranging 0.56–5.60 kg ai/ha were performed.

In the 1987 trials, green pods and succulent seeds were sampled at 7–63 DALA and analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 with an LOQ of 0.05 mg/kg for each analyte.

As a follow-up, selected samples were re-analysed with a modified version of method CAM-24-73 with an LOQ of 0.002 mg/kg for each analyte. However, since samples were re-analysed after a storage of up to 557 days for which stability could not be confirmed, the data from re-analysis were not considered for estimation of maximum residue level.

In the 1988 trials, green pods were sampled at 7–57 DALA and analysed for quintozene, PCA, PCTA, PB, 2,3,4,5-TCNB, 2,3,5,6-TCNB and HCB using the method MP-PCNC-MA1 with an LOQ of 0.005 mg/kg or 0.01 mg/kg for each analyte. In trial PB-BS-2520 in which samples were obtained at 7 DALA, the last application was performed when pods were already present, which is not according to the label instructions. This trial was therefore not considered for estimating maximum residue level.

Samples in five trials (marked in the following table) were stored shorter than 3 months while all other samples were stored frozen for longer than 100 days but shorter than 250 days.

Table 76 Magnitude of residues of quintozene in/on immature bean pod after post-emergence directed band applications to soil or ground applications to soil in the supervised trials conducted in the United States in 1987 and 198. (The portions analysed were whole pods in all trials.)

Beans, except broad bean and soya bean (green pods and immature seeds)–In-furrow application

Additional three supervised residue trials were carried out on beans (all belong to the genus *Phaseolus*) in the United States during the growing season 1993 utilizing one in-furrow application at planting.

In all trials, three treated plots were established, where in the first plot a 750 g/kg WP formulation, in the second plot a 240 g/L EC formulation and in the third plot a 480 g/L FL formulation was used. In all trials/plots quintozene was applied once at a rate of 1.68 kg ai/ha.

In all three trials, green pods were sampled at 50–62 DAT and analysed for quintozene, PCA, PCTA, PB and HCB using a modified version of the method CAM-24-73 with an LOQ of 0.0005 mg/kg for each analyte. The method was validated within this study.

Table 77 Magnitude of residues of quintozene in/on immature bean pod after in-furrow application in the supervised trials conducted in the United States in 1993 (The portions analysed were whole pods in all trials.)

Pulses

Beans (dry)–Directed band applications to soil or ground applications to soil

Thirteen supervised residue trials were carried out on beans (*Phaseolus*) in the United States during the growing seasons 1987, 1988 and 1989.

In all trials, two plots were established where in the first plot a 750 g/kg WP formulation and in the second plot a 240 g/L EC formulation was used. In all trials/plots, except one, quintozene was applied four times post-emergence at a nominal rate of 2.24 kg ai/ha with a nominal interval of 14 days. In one other trial, only three applications at rates ranging 0.56–5.60 kg ai/ha were performed.

In the 1987 trials, dry beans were sampled at 45–78 DALA and analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 with an LOQ of 0.05 mg/kg for each analyte. As a follow-up, selected samples were re-analysed with a modified version of the method CAM-24-73 with an LOQ of 0.002 mg/kg for each analyte. However, since samples were re-analysed after a storage of up to 535 days for which stability could not be confirmed, the data from re-analysis were not considered for estimation of maximum residue level.

In the 1988/89 trials, dry beans were sampled at 41–64 DALA and analysed for quintozene, PCA, PCTA, PB, 2,3,4,5-TCNB, 2,3,5,6-TCNB and HCB using the method MP-PCNC-MA1 with an LOQ of 0.01 mg/kg for each analyte.

All the samples were stored frozen for periods shorter than the proven storage stability duration.

Table 79 Magnitude of residues of quintozene in/on beans (dry) after post-emergence directed band applications to soil or ground applications to soil in the supervised trials conducted in the United States in 1987, 1988 and 1989 (The portions analysed were dry seeds in all trials.)

Beans (dry)–In-furrow application

Additional three supervised residue trials were carried out on beans (*Phaseolus*) in the United States during the growing season 1993 utilizing one in-furrow application at planting.

In all trials, three treated plots were established where in the first plot a 750 g/kg WP formulation, in the second plot a 240 g/L EC formulation and in the third plot a 480 g/L FL formulation was used. In all trials/plots quintozene was applied once at a rate of 1.68 kg ai/ha.

In all three trials, dry bean seeds were sampled at 77-106 DAT and analysed for quintozene, PCA, PCTA, PB and HCB using a modified version of the method CAM-24-73 with an LOQ of 0.0005 mg/kg for each analyte. The method was validated within this study.

Table 80 Magnitude of residues of quintozene in/on beans (dry) after in-furrow application at planting in the supervised trials conducted in the United States in 1993 (The portions analysed were dry beans in all trials.)

Root and Tuber Vegetables

Potato

In total, forty-six supervised residue trials were carried out on potato in the United States during the growing seasons 1987, 1988/89, 2002, 2006 and 2019/20. Thirty-seven trials/plots utilizing an in-furrow application either at an exaggerated rate of 11.2–13.1 kg ai/ha in side-by-side plots using a 240 g ai/L EC or a 100 g ai/L GR formulation (1988/89 trials) or a 480 g ai/L FL formulation at a rate in the range of 4.12–6.04 kg ai/ha. Eight trials/plots are available utilizing two applications by chemigation at a rate of 2.8 kg ai/ha and at intervals of either 5 or 10–11 days and DALA in the range of 20–41 days.

Additional trials/plots were conducted utilizing a combination of an initial in-furrow application followed by one or two applications by chemigation. Since the United States label says, “Do not make chemigation application, if quintozene products were applied as a band application in furrow at planting”, and this type of use is not permitted by the available labels from other countries, these trials are not presented here.

In the 1987 trials, mature potato tubers were sampled at 82–140 DAT and analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 with an LOQ of 0.002 mg/kg for each analyte.

In the 1988/89 trials, mature potato tubers were sampled at 89–135 DAT and analysed for quintozene, PCA, PCTA, PB, 2,3,4,5-TCNB, 2,3,5,6-TCNB and HCB using the method MP-PCNC-MA1 with an LOQ of 0.01 mg/kg for each analyte.

In the 2002 trials, mature potato tubers were sampled at 20–41 DALA (chemigation) and analysed for parent quintozene using the published method of Zweig 1972 (Analytical Methods for Pesticides and Plant Growth Regulators, Zweig, Volume VI, pages 578–580,1972) with an LOQ of 0.01 mg/kg.

In the 2006 trials of study 900-RES-044, potato tubers were sampled at 96 and 99 DAT (in-furrow application) and 28 DALA (chemigation) and analysed for quintozene, PCA and PCTA using the method MP-PCNC-MA1 with an LOQ of 0.01 mg/kg for each analyte.

In the 2019/20 trials, potato tubers were sampled at 60–125 DAT (in-furrow application) and at 26 and 28 DALA (chemigation) and analysed for quintozene, PCA and PCTA using the Battelle 100117568 method (QuEChERS) method with an LOQ of 0.01 mg/kg for each analyte.

All the samples were stored frozen for periods shorter than the proven storage stability duration.

Table 81 Magnitude of residues of quintozene in/on potato tuber after in-furrow application at planting, chemigation applications, or other application methods, in the supervised trials conducted in the United States in 1987, 1988/89, 2002, 2006 and 2019/20 (The portions analysed were tubers in all trials.)

Notes:

[a] Mean of the analytical results of two samples. Residues scaled to the critical GAP-rate are presented in brackets

[b] The application dates were 30 days or more apart in these three trials: trial 08 to 09, 30 days; trial 09 to 20, 33 days; and trial 08 to 20, 63 days.

[c] The application rate was inadvertently low. The irrigation was about one half of the frequency of normal practice and as a result, the harvest was poor. Therefore, the result of this trial was not used.

(Residues of PB, HCB, 2,34,5-TCNB and 2,3,5,6-TCNB in potato from in-furrow application with soil at planting)

Oilseeds

Cotton seed

In total twenty-three supervised residue trials were carried out on cotton in the United States during the growing seasons 1987 to 1992.

In all trials, two or more plots were established where the granules, emulsifiable concentrates and flowable formulations were compared by use as an in-furrow application at a rate of 2.24 kg ai/ha at the time of planting. In some trials in 1991 and 1992, a reduced rate of 1.12 or 1.68 kg ai/ha was also used. In all the trials on cotton, the dates of application are the same as the dates of sowing/planting.

In the 1987 trials, cotton seeds were sampled at 137–149 DAT and analysed for quintozene, PCA, PCTA, PB, and HCB using the method CAM-24-73 with an LOQ of 0.005 mg/kg for each analyte. At two locations, Bossier City, Louisiana, and Somerton, Arizona, in two trials each, application dates were the same. In this study an additional trial was established utilizing an exaggerated application rate of 11.2 kg ai/ha in-furrow to produce samples for processing.

In the 1988 trials reported in 900-RES-021, cotton seeds were sampled at 135–173 DAT and analysed for quintozene, PCA, PCTA, PB, 2,3,4,5-TCNB, 2,3,5,6-TCNB and HCB using the method MP-PCNC-MA1 with an LOQ of 0.01 mg/kg for each analyte. In the 1988 trials reported in 900-RES-152, cotton seeds were sampled at 141–168 DAT and analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 with an LOQ of 0.005 mg/kg for each analyte.

In the 1990 trials, cotton seeds were sampled at 142–160 DAT and analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 with an LOQ of 0.002 mg/kg for each analyte.

In the 1991 trials, cotton seeds were sampled at 129–181 DAT and analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 with an LOQ of 0.002 mg/kg for each analyte.

In the 1992 trial, cotton seeds were sampled at 142 DAT and analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 with an LOQ of 0.002 mg/kg for each analyte.

All the samples were stored frozen for periods shorter than the proven storage stability duration.

Table 82 Magnitude of residues of quintozene in/on cotton seeds after in-furrow application at planting in the supervised trials conducted in the United States in 1987, 1988, 1990, 1991 and 1992 (The portions analysed were seeds in all trials.)

Notes:

[a] Mean of the analytical results of two samples. Residues scaled to the critical GAP-rate are presented in brackets

[b] The application dates are the same in these applications with three day difference in the harvest dates. Therefore, they are not regarded as independent.

[c] The application dates are the same and the harvest dates are the same. Therefore, they are not regarded as independent.

Peanut

In total, thirty-six supervised residue trials were carried out on peanuts in the United States during the growing seasons 1987 to 1992.

The trials were performed with one or more plots treated with quintozene as a 100 g ai/kg GR formulation, a 750 g ai/kg WP formulation, a 240 g ai/L EC formulation or a 480 g ai/L FL formulation at pegging stage until full seed beginning to mature. Applications were performed either as a banded granular application or directed spray (banded or broadcast), or by overhead sprinkler application or chemigation. Two trials are available where quintozene as a granular formulation was applied by aerial broadcast application. Applications were done at a nominal rate of 11.2 kg ai/ha either in one application or split equally to 2 × 5.6 kg ai/ha or in the range of 3.4–7.9 kg ai/ha.

In the 1987 trials, quintozene was applied as a split application in the range of 3.36–7.85 kg ai/ha totalling to nominally 11.2 kg ai/ha at intervals of 21–63 days. Eight trials were performed by banded application of GR and WP formulations, six trials by sprinkler application of WP and EC formulations and finally two trials were performed by aerial broadcast application of a GR formulation. Samples were stored for up to 528 days from sampling to analysis. An additional trial was established with two plots treated twice at exaggerated application rates of 28.0 kg ai/ha and 56.0 kg ai/ha to produce samples for processing.

Peanuts were sampled at 37–54 DALA, separated into nutmeat and hulls, and analysed for quintozene, PCA, PCTA, PB, and HCB using the method CAM-24-73 with an LOQ of 0.005 mg/kg for each analyte. Samples were stored for 443–535 days from sampling to analysis while the longest duration tested for storage stability for peanut was 14 months. For cotton seed, other type of high oil content matrix, however, the longest duration tested was 18 months during which quintozene, PCA, PCTA, PB and HCB were stable during this period. Perhaps the results with storage stability study with cotton seed may be extrapolated to peanut. In many of these trials, residues were detected above the LOQ in untreated samples (see in Tables 83 and 84).

In the 1988 trials, quintozene was applied as one single application at nominally 11.2 kg ai/ha. Five trials were performed by banded application of GR and WP formulations and four trials by sprinkler application of WP and EC formulations. Peanuts, whole nuts, were sampled at 45 days and analysed for quintozene, PCA, PCTA, PB, 2,3,4,5-TCNB, 2,3,5,6-TCNB and HCB using the method MP-PCNC-MA1 with an LOQ of 0.01 mg/kg for each analyte. Samples were stored for 31–70 days from sampling to analysis, shorter than the proved duration of storage stability.

In the 1990 trials reported in 900-RES-111, quintozene was applied as a split overhead sprinkler application at 4.5 and 6.7 kg ai/ha totalling to nominally 11.3 kg ai/ha at intervals of 26–27 days. Peanuts were sampled at 45 DALA, separated into nutmeat and hulls, and analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 with an LOQ of 0.001 mg/kg for each analyte. Samples were stored for 401 or 409 days from sampling to analysis.

In the 1990 trials reported in 900-RES-109, quintozene was applied by banded application split equally to 2× 5.6 kg ai/ha or in the range of 3.4–7.9 kg ai/ha at intervals of 28–37 days. Peanuts were sampled at 43–45 DALA, separated into nutmeat and hulls, and analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 with an LOQ of 0.001 mg/kg for each analyte. Samples were stored for 387 or 388 days from sampling to analysis.

In the 1991 trials, quintozene was applied by chemigation split equally to 2x 5.6 kg ai/ha at intervals of 14–30 days. Peanuts were sampled at 45–47 DALA, separated into nutmeat and hulls, and analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 with an LOQ of 0.001 mg/kg for each analyte. Samples were stored for 64–91 days from sampling to analysis.

In the 1991/1992 trials of study 900-RES-023, quintozene was applied as one single application at nominally 11.2 kg ai/ha. Four trials were performed by banded application of GR and WP formulations. In one trial an additional plot was established utilizing a sprinkler application of an EC formulation at 11.2 kg ai/ha. Peanuts were sampled at 44–50 DAT, separated into nutmeat and hulls, and analysed for quintozene, PCA, PCTA, PB, 2,3,4,5-TCNB, 2,3,5,6-TCNB and HCB using the method MP-PCNC-MA1 with an LOQ of 0.005 mg/kg for each analyte. Samples were stored for 93–182 days from sampling to analysis.

Notes:

[a] The application dates and harvest dates are the same in these trials. Trial 013 used sprinkler application while 014 and 015 used aerial broadcast application.

[b] Calculated from "whole nuts" using the respective processing factor for peeling.

n/a, Not analysed.

FATE OF RESIDUES IN STORAGE AND IN PROCESSING

The Meeting received information on the ratio of residues in peel and pulp of potato, and hulls and nutmeat of peanut, as well as on processing of tomato, green beans, potato, cotton seed and peanut.

Potato–Residues in Peel and pulp

Study 1. *(Ball, 1900, 900-RES-144)*

The effect of peeling on residue concentrations of quintozene in potato was investigated using two trials in the United States in 1988: one in Hollandale, MN and the other in Northwood, ND. Quintozene in EC formulation was applied as either in-furrow or broadcast application at 28 kg ai/ha at planting. The potato samples to be processed were collected at maturity 122–123 DAT. Potato (RAC) and all processed commodities were stored frozen for up to 4.3 months (132 days). The samples were analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 (modified) with an LOQ of 0.0005 mg/kg for each analyte.

The potatoes were processed to wet peel by abrasion, yielding about 10 percent weight of peel. Samples of the peeled potatoes and unpeeled potatoes were frozen for analysis. The wet peel samples were divided, and half were dried to about 13 percent moisture content. The wet peel and dry peel were frozen for analysis. The analytical results and calculated processing factors are summarized in the following table.

Table 85 Effect of peeling of potato on quintozene, PCA and PCTA concentrations (broadcast application at planting

Location, Year (Variety)	Application Rate Method DAT	Commodity	Residues (mg/kg)				Processing factor

[a] Sum of quintozene, PCA and PCTA expressed as quintozene

***Study 2**. (Zheng, 1992, 900-RES-206)*

The effect of peeling on residue concentrations of quintozene in potato was investigated in two trials in Bethany, IL in the United States. Quintozene in the EC formulation was applied as broadcast at a rate 140 kg ai/ha at planting. The samples were analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 (modified) with an LOQ of 0.001 mg/kg for each analyte. Detailed field trial and processing data are not available.

Residues in processed commodities

Tomato

Study 1. *(Ball, 1990, 900-RES-126 and 900-RES 084 (addendum))*

Two trials were performed in CA, United States (Madera and Fresno) during the growing season 1987. One in-furrow application of a 750 g/kg WP formulation of quintozene at a rate of 42 kg ai/ha was performed at the time of planting. The tomato samples to be processed were sampled at maturity 113 and 111 DAT.

The tomato samples were processed to canned tomato, juice, puree, paste, ketchup, as well as to the by-products, wet and dry pomace, as follows. Initially tomatoes were washed with chlorinated water to remove dirt, debris, and rotten fruit. A second chlorinated water wash preceded the final rinse with potable water.

Tomato Juice (separation of pomace (skin and seeds)): The tomatoes were fed through a disintegrator equipped with a 4 mm screen and then pumped into a plate heat exchanger for heating. The temperature of the tomato juice was raised to 107 °C and held for approximately 40 seconds. The hot tomato juice was then fed into a finisher for removal of skins and seeds (pomace). The finisher is fitted with a 0.8 mm screen for this separation. The hot juice was then collected for use in the following products.

Canned Tomato Juice: An aliquot of the hot juice was filled into cans, sealed and heated in boiling water for 10 minutes to ensure sterility.

Canned Tomato: The best red tomatoes were selected from each lot for use as whole canned tomatoes. The tomatoes were blanched in boiling water prior to removal of the skins, then received a light rinse with potable water before being packed into cans. Juice from the corresponding lots were used as cover juice. The cans were then vacuum sealed and cooked for 30 minutes in a rotary cooker before cooling.

Tomato Concentrate: The hot tomato juice from each lot was concentrated in a single pass wiped surface evaporator to the requested brix degree (about 30°). The concentrate was then filled into cans, sealed, and heated in boiling water for 30 minutes before cooling.

Sauces: Sauces were formulated to a refractive index of not less than 1.3461 and a Bostwick of not more than 14 cm in 30 seconds of 20 °C.

Ketchup: Ketchup was made to 33 percent solids and a Bostwick of 9 cm in 30 seconds at 20 °C.

Pomace: The wet pomace from juicing was weighed and divided into two equal lots. Half of the pomace was immediately frozen (wet pomace); the remaining pomace was dried in a hot air dehydrator at a temperature of 66 °C. The dry pomace was packaged to prevent rehydration.

Tomato (RAC) and all processed commodities were stored frozen up to 4 months prior to analysis. The samples were analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 with an LOQ of 0.05 mg/kg for each analyte. As a follow-up, selected samples were re-analysed with a modified version of method CAM-24-73 with an LOQ of 0.002 mg/kg for each analyte. However, since samples were re-analysed after a storage of up to 456 days for which storage stability could not be confirmed, the data from reanalysis were not considered for calculation of the processing factors.

The analytical results (4 values each) of quintozene, PCA and PCTA in tomato (RAC), washed tomato, canned tomato, tomato juice, tomato puree, tomato paste, and ketchup were all below the LOQ of 0.05 mg/kg. Quintozene was found above LOQ only in wet pomace (0.061–0.079 mg/kg) and dry pomace (0.097–0.186 mg/kg); and PCA only in dry pomace (0.063–0.098 mg/kg).

Study 2. *(LeRoy & Cassidy, 1991; 900-RES-035)*

Two separate field trials in CA (Madera and Fresno), United States, were performed during the growing season 1988. Tomatoes (var. UC-82) were treated with one 750 g/kg WP in-furrow application at transplanting at 8.4 or 84.1 kg ai/ha. Tomatoes were sampled at normal commercial harvest 113–114 days DAT.

Samples from the treatment at 84.1 kg ai/ha were used for processing to tomato juice, puree, ketchup, and wet and dry pomace in similar methods as in Study 1.

The samples were analysed for quintozene, PCA, PCTA, PB, 2,3,4,5-TCNB, 2,3,5, 6-TCNB and HCB using the method MP-PCNC-MA1 with an LOQ of 0.005 mg/kg for each analyte.

Processing factors are calculated for quintozene only and for the sum of quintozene, PCA and PCTA, expressed as quintozene in the following table. Significant concentrations of quintozene, PCA and PCTA were found in untreated wet pomace and dry pomace samples.

Table 88 Residues of quintozene, PCA and PCTA in tomato and its processed commodities following one in-furrow application at transplanting

[f] Residues in the untreated sample: quintozene, 0.022; PCA, 0.0068 mg/kg).

Study 3. *(Brunk, 1994; 900-RES-218)*

Effect of processing on residues of quintozene in tomato and processed fractions was investigated in one trial in the United States in 1991 (no information on in-life part of the trial in the study report). The samples were analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 with an LOQ of 0.0005 mg/kg for each analyte. Most of untreated samples were found to contain no PB, HCB, quintozene, PCA or PCTA above the LOQ. However, the untreated dry pomace showed trace levels of quintozene and PCA near the LOQ level and the untreated wet pomace contained quintozene at a trace level.

Table 89 Residues of quintozene, PCA and PCTA in tomato and its processed commodities following one in-furrow application at transplanting

Green beans *(LeRoy & Cassidy, 1991, 900-RES-031)*

Information on the processing of green beans to canned beans was provided utilizing different application rates in two locations. However, where RAC was analysed, processed commodities were not analysed, vice

versa. Therefore, it was not possible to use the results for calculating the processing factors, and therefore the data are not presented here.

Potato

Study 1. *(Ball, 1987, 900-RES-198)*

Potatoes were selected from a commercial lot of potatoes which had been treated with quintozene EC formulation (containing 24 percent quintozene and 0.1 percent HCB), applied broadcast at the rate of 26.9 kg ai/ha. Potatoes were grown, harvested and stored under commercial conditions. Approximately 9–11 kg of each of two varieties of treated potatoes, Russet Burbank and Norgold Russet, and an untreated sample of Russet Burbank were shipped to the processing facility for processing into French fried potatoes, potato chips (crisps) and dried flakes as follows.

French fries: Unpeeled potatoes were washed, cut into slices, and immersed in water. The slices were washed with water two times to remove excess starch and sugar, drained and divided into two lots. One batch was frozen, uncooked. The other batch was cooked in corn oil for 2.5 min. at 185 °C. After cooling, the cooked fries were packaged.

Potato chips (potato crisps): Unpeeled potatoes were washed, sliced 1.3 mm thick and immersed in water. The twice washed slices were divided into two lots. One batch was frozen, uncooked. The other batch was fried in corn oil for 2.0 minutes at 185 °C. After cooling, the chips were packaged.

Dried flakes: Potatoes were peeled and immersed in water. The washed tubers were drained and cut into slices. The twice washed potato slices were drained for a short period of time, and a portion of the slices were frozen, uncooked. The remainder of the slices were cooked in water at 78 °C to a slurry consistency. The slurry was dried at 38 °C to a final moisture content of 5–6 percent and packaged.

The samples were analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 with an LOQ of 0.002 mg/kg in raw potatoes and dried potato flakes and 0.01 mg/kg in fried potato products.

Processing factors were calculated for quintozene only and for the sum of quintozene, PCA and PCTA, expressed as quintozene in the following table.

Table 90 Residues of quintozene, PCA and PCTA in commercially available potato and its processed commodities following broadcast application.

Study 2. *(Ball, 1987, 900-RES-056)*

Two field trials were performed in CA, United States (Madera and Fresno) during the growing season 1987. Two formulations, the EC and GR formulations were selected for this potato processing study: EC formulation was applied broadcast at 140 and 280 kg ai/ha and GR formulation was applied in-furrow at 56.0 and 112 kg ai/ha at planting. The potato samples to be processed were sampled at maturity 139 or 133 DAT. Potato (RAC) and all processed commodities were stored frozen approximately one month prior to analysis.

Potato samples were processed into chips (crisps), flakes and granules as follows.

Potato chips (potato crisps): A difference from the descriptions in Study 1 is that, a portion of washed slices were fried in corn oil for 2.5–2.75 minutes at 185 °C to a final moisture content of approximately 2 percent.

Flakes and granules: Potato samples were lightly peeled in a washer/peeler for 45 seconds. The potatoes came into contact with a moving, abrasive stone which is constantly flushed with cold, running water. The amount of peel removed is proportionate to the length of contact time with the abrasive surface. In this study, peeling time was relatively short, which removed surface soil and grit with a minimal amount of peel removal. The washed, peeled potatoes were sliced to a thickness of 1.3 mm. The slices were washed and steam cooked. The cooked potato slices were immediately pulped and screened over a 2.4 mm screen recovering a smooth, uniform slurry which was utilized for the product of both flakes and granules. A portion of the slurry was dried in a thin layer on stainless steel at a temperature of 49 °C to a final moisture content of 5-6 percent. The dried flakes were packaged. Another portion of the slurry was homogenized at room temperature to a uniform consistency by being passed twice through a homogenizer. The finely divided slurry was pumped into a mixed flow spray drier, with a pressurized air feed at an inlet temperature of 150°C. The product rose in the chamber and the particles remained suspended until dry enough to drop into the collector. The final moisture content was approximately 4-6 percent. The dried granules were packaged.

The samples were analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 (modified) with an LOQ of 0.002 mg/kg for each analyte.

Processing factors were calculated for quintozene only and for the sum of quintozene, PCA and PCTA, expressed as quintozene in the following table.

Study 3. *(LeRoy & Cassidy, 1991, 900-RES-034)*

Two field trials, one in Minidoka, ID and the other in Ephrata, WA, United States, were performed during the growing season of 1988. Potatoes (var. Russet Burbank) were treated with quintozene EC formulation in-furrow at planting at 56.0 kg ai/ha in Minidoka, and at 13.5 kg ai/ha in Ephrata. Potatoes were sampled at normal commercial harvest for processing as follows. Processed commodities were frozen immediately after processing.

The tubers were stored refrigerated at approximately 7 °C until processing. Prior to processing, the tubers were washed, destoned, and inspected.

Potato chips (potato crisps), wet peel and dried peel: One batch of tubers was sent through an abrasive peeler, then sliced and fried to produce chips. This process generated both wet and dried peels. A second batch of tubers was sent through a steam peeler to produce wet peels. The resulting peels were then dried.

Potato flakes and granules: The peeled tubers were precooked for 20 minutes then divided into two batches. One batch was used to prepare flakes, and the remaining batch was used to prepare granules.

The samples were analysed for quintozene, PCA, PCTA, PB, 2,3,4,5-TCNB, 2,3,5, 6-TCNB and HCB using the method MP-PCNC-MA1 with an LOQ of 0.005 mg/kg for each analyte.

Processing factors were calculated for quintozene only and for the sum of quintozene, PCA and PCTA, expressed as quintozene in the following table.

Table 92 Residues of quintozene, PCA and PCTA in potato and its processed commodities following in-furrow application at planting

[a] Sum of quintozene, PCA and PCTA expressed as quintozene

Cotton seed

Study 1. *(Ball, 1989, 900-RES-068)*

In one field trial performed in Stoneville, MS, United States during the growing season 1988, one in-furrow application of a GR formulation at a rate of 11.2 kg ai/ha was performed at the time of planting. The cotton seed samples to be processed were collected at maturity 149 days after application.

The effect of processing on residues in cotton seed was investigated. The cotton seed samples were processed to solvent-extracted crude and refined oil and meal, as well as to the by-products hulls and linter motes.

Separation of seed, lint and gin trash: A gin was used to separate these fractions.

Delinted seed, linters and motes: A saw delinter was used to remove the majority of the lint from ginned cottonseed. The fractions are linters, motes and delinted seed. The seed has small amounts of lint adhering to each end of the seed.

Hull and kernel fractions of seed: A bar huller was used to decorticate cottonseed. Either high lint cottonseed (directly from the gin) or delinted cottonseed can be decorticated. The cracked seed was passed across a shaker screen, which separates hull and kernel fractions. An aspirator was utilized if more complete separation was required.

Cotton seed meal (hexane extraction): Kernels were preheated to 74 °C and flaked by flaking rolls to 0.2–0.3 mm thickness. Flaked kernels were then placed in a steam-jacketed, stainless steel, batch extractor. Hexane (at approximately 63 °C) was added until the flake bed was flooded. After 30 minutes, the solvent was drained, and fresh solvent added for 5 additional cycles (3 hours total extraction time). At the end of this period, warm air was forced through the flake bed for approximately 4 hours for removal of the solvent.

Crude Cotton Oil (hexane extraction): The miscella (crude oil and hexane mixture) was separated in an evaporator. During this procedure, the crude oil reaches a temperature of 85 °C.

Refined oil and soapstock (following AOCS Method Ca9a52): Prior to refining, the percent free fatty acid was determined in the crude oil. A weighed oil sample was placed in a laboratory oil refining machine. A weighed amount of sodium hydroxide (14° Baume) was added to the crude oil, as calculated on the basis of the amount of free fatty acids present. The solution was mixed at 250 rpm (20–24 °C) for

15 minutes, followed by 70 rpm for 12 minutes (63–67 °C). After a settling period (1 hour; 60–65 °C), the oil was refrigerated for at least 12 hours. At the end of this period, the refined oil was decanted and filtered. The soapstock fraction was settling to the bottom of the refrigerated container.

Cotton seed (RAC) and all processed commodities were stored frozen up to 7 months prior to analysis. The samples were analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 with an LOQ of 0.005 mg/kg for each analyte.

Processing factors were calculated for quintozene only and for the sum of quintozene, PCA and PCTA, expressed as quintozene in the following table.

Table 93 Residues of quintozene, PCA and PCTA in cotton seed and its processed commodities following in-furrow application at planting

Location, Year (Variety)	Application Rate (kg ai/ha)	Commodity	Residues (mg/kg)				Processing factor

Notes:

[a] Sum of quintozene, PCA and PCTA, expressed as quintozene

Study 2. *(LeRoy R.L., Cassidy J.E., 1991, 900-RES-032)*

Two separate field trials, one in Kerman, CA, and the other in Brookshire, TX, United States, were performed during the growing season 1988/89. Cotton (var. SJ-1 and DPL-50) were treated with quintozene EC formulation in-furrow at planting at different rates: 2.24, 5.60 and 11.2 kg ai/ha in the Brookshire trials and at 6.73 and 11.2 kg ai/ha in the Kerman trials.

Cotton balls were sampled at normal commercial harvest at 139–153 DAT. Samples from the highest treatment scheme (11.2 kg ai/ha) were used for processing as follows (see Study 1 above).

The seed cotton was first ginned which produced cottonseed, gin trash, and lint cotton. Gin trash was not collected in one trial. The cottonseed was delinted into three fractions: linters, delinted seed, and linter motes. The delinted seed was hulled and separated into kernels and hulls. The kernels were extracted with hexane into crude oil and meal. The crude oil was then refined and soapstock was generated.

The refined oil was bleached and the bleached oil was hydrogenated. The hydrogenated oil was deodorized for the final processing step. All samples generated were stored frozen until analysis.

The samples were analysed for quintozene, PCA, PCTA, PB, 2,3,4,5-TCNB, 2,3,5, 6-TCNB and HCB using the method MP-PCNC-MA1 and MP-PCNC-MA2 with an LOQ of 0.005 mg/kg for each analyte.

Quintozene, PCA, or PCTA was not detected above the LOQ in the RAC (Kerman trial only) or any processed commodities in these trials. These compounds were not analysed in the RAC sample from the Brookshire trial. It was not possible to calculate processing factors for these process commodities.

Study 3. *(Gaydosh & Smudin, 1996, 900-RES-114)*

In one field trial in Hernando, MS, United States, during the growing season 1993, one in-furrow application of a GR formulation at a rate of 6.7 kg ai/ha was performed at the time of planting. The cotton ball samples to be processed were collected at maturity 156 DAT.

Samples of cotton balls were processed into linters, linter motes, delinted seed, hulls, kernels, meal, crude oil, refined oil, and soapstock as follows.

Delinted cotton seed and lint: The cottonseed was delinted to remove a majority of the existing lint.

Hull and kernel: The delinted seed was mechanically cracked and screened to separate the majority of the hull material from the kernel material.

Crude oil (hexane extraction): The kernel material with some hull material was heated, flaked, expanded into collets and exposed to hexane for the purpose of removing crude oil from the collets. The solvent was removed from the spent collets with warm air.

Refined oil and soapstock: After the crude oil and hexane mixture was adjusted to the proper ratio, the crude oil was miscella refined. The free fatty acid is determined and a known amount of sodium hydroxide was added to the miscella and the mixture stirred by heating. After reaction, the soapstock was removed. The refined oil and hexane were separated with an evaporator under vacuum at elevated temperature.

Cotton seed (RAC) and all processed commodities were stored frozen up to 5.3 months (162 days) prior to analysis. The samples were analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 with an LOQ of 0.0005 mg/kg for each analyte.

Analysis resulted in quintozene, PCA and PCTA below the LOQ, except that in soapstock PCA was found at 0.0064 mg/kg. Therefore, no processing factors were calculated.

Study 4. *(Maselli, 1997, 900-RES-147)*

Two separate field trials, one in Tunika, MS, and the other in East Bernard, TX, United States, were conducted during the growing season 1995. Cotton (var. Delta Pine 50) were treated with quintozene EC formulation in-furrow at planting at three different rates. Cotton balls harvested at maturity from the treatment at 7.2 kg ai/ha were used for processing.

Samples of cotton balls were processed into linters, gin-trash, delinted seed, hulls, kernels, crude oil, refined oil, and soapstock, in a similar method as in previous studies.

Cotton seed (RAC) and all processed commodities were stored frozen up to 14 months (427 days) prior to analysis. The samples were analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 (modified) with an LOQ of 0.002–0.005 mg/kg for cotton seeds and 0.02–0.05 mg/kg for gin-trash.

Results were presented for quintozene in cotton seed and gin-trash only. They were below the LOQ, except in one sample of gin trash the residue was 0.062 mg/kg. Therefore, no processing factors could be calculated.

Peanuts

Study.1. *(Ball, 1990, 900-RES-078)*

One trial was conducted in Tifton, GA, United States, during the growing season 1989. Peanut plants (variety Florunner) were treated with split applications of quintozene WP formulation at either 2 × 28.0 kg ai/ha or 2 × 56.0 kg ai/ha. The first application was made at pegging and the second application about 30 days later. The whole peanuts were dug and inverted by hand 45 DALA. After drying, whole peanuts from each treatment were collected, and shipped to a processing facility, where the peanut samples were placed in frozen storage. Approximately, one week after receipt, the whole peanuts were hulled, and a week later processed. Small-scale peanut processing equipment was used to process the peanuts.

Hull and kernel (nutmeat): If the unshelled peanut (whole peanut) sample was high in moisture, it was placed in a forced air oven for 30 minutes or longer at 66 °C. The peanut sample was cleaned by aspiration and/or screening. A peanut sheller was used to dehull the peanuts. Hull and kernel fractions were separated by aspiration.

Pressed oil from expeller: After determining the percent moisture of peanut kernels, tap water was added to adjust the moisture to 10 percent. The peanuts were cooked for approximately 45 minutes or until the temperature of the peanuts reached approximately 99 °C. At the end of the cooking period, the oil was mechanically removed with an expeller.

Extracted oil with hexane and presscake (meal): The residual oil in the presscake was extracted with hexane in a steam-jacketed, stainless steel, hatch extractor. Hexane was added until the presscake was flooded. The temperature of the hexane was raised to approximately 63 °C. After 30 minutes, the solvent was drained and fresh solvent was added to repeat the cycle 6 times (3 hours). At the end of this period, the extracted sample was drained, and warm air was forced through the presscake for approximately four hours to remove residual solvent.

Crude Oil: The miscella (crude oil and hexane) was separated in an evaporator. During this procedure, the crude oil reached a temperature of 85 °C. The crude oil accounted for approximately 50 percent of the whole peanut by weight.

Refined oil and soapstock (following AOCS Method Ca9a52) and refined and deodorized oil: After the percent free fatty acid was determined in the crude oil from the expeller (using AOCS Method CaSa-40), a weighed sample was placed in a laboratory oil refining machine. A weighed amount of 16° Baume sodium hydroxide was added to the crude oil as calculated on the basis of free fatty acids present. The solution was mixed for 30 minutes at 250 rpm at 20–24 °C, and then for additional 12 minutes at 70 rpm at 63–67 °C. The neutralized oil was allowed to settle at 60–65 °C for 1 hour. The oil solution was then refrigerated overnight (minimum of 12 hours); The neutralized oil was decanted and filtered. The fraction settling to the bottom of the refrigerated container was the soapstock.

A weighed refined oil sample as obtained above was heated in a steam bath for 1 hour under an absolute vacuum of 533 Pa. The temperature of the oil was kept between 220–230 °C. At the end of the 1-hour period, the oil sample was allowed to cool to 150 °C. Citric acid solution (0.005 percent) was added to the oil (at a rate of 1 mL/100 g-oil). The sample was allowed to cool, under vacuum, to 110 °C. The cooled oil sample was immediately transferred to a shipping container.

The samples were analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 with an LOQ of 0.005 mg/kg for each analyte.

Processing factors were calculated from the residue levels in kernel for quintozene only and for the sum of quintozene, PCA and PCTA, expressed as quintozene in the following table.

Table 94 Residues of quintozene, PCA and PCTA in peanut nutmeat and its processed commodities following two applications at begging

Location, Year (Variety)	Application Rate (kg ai/ha)	Commodity	Residues (mg/kg)				Processing factor

Notes:

[a] Sum of quintozene, PCA and PCTA expressed as quintozene.

Study 2.*(LeRoy & Cassidy, 1991, 900-RES-033)*

Two separate processing trials were conducted, one in Brookshire, TX, and the other in Battleboro, NC, United States, during the 1988 growing season. Peanut plants (var. Pronto Spanish and Florigiant) were treated with quintozene WP formulation as a banded application at pegging stage at 11.2, 22.4 and 56.0 kg ai/ha in the Battleboro trial and at 11.2, 22.4 and 40.4 kg ai/ha in the Brookshire trial. Whole peanuts were harvested at normal commercial harvest 45 days after application. Samples from the trials with 40.4 and 56.0 kg ai/ha were used for processing.

The whole peanut samples (nut in shell) were kept frozen until separated into hulls and kernels, then the kernels were expelled into press-cake, crude oil, hexane-extracted press-cake, hexane-extracted

crude oil, refined oil, soapstock, dry roasted peanuts, oil roasted peanuts, deodorized oil, and hydrogenated oil. A RAC (nut in shell) sample was subsampled for analysis.

All samples generated were stored frozen until analysis. The samples were analysed for quintozene, PCA, PCTA, PB, 2,3,4,5-TCNB, 2,3,5, 6-TCNB and HCB using the method MP-PCNC-MA1 with an LOQ of 0.005 mg/kg for each analyte.

Processing factors were calculated from the residue levels in kernel for quintozene only and for the sum of quintozene, PCA and PCTA, expressed as quintozene in the following table.

Table 95 Residues of quintozene, PCA and PCTA in peanut nutmeat and its processed commodities following banded application at begging

Notes:

[a] Sum of quintozene, PCA and PCTA expressed as quintozene.

Study 3. *(Gaydosh & Smudin, 1996, 900-RES-115)*

In one field trial in Hawkinsville, GA, United States, during the 1992 growing season, two banded applications of quintozene EC formulation at a rate of 112 kg ai/ha was performed at the time of pegging and with an interval of 30 day. Whole peanuts to be processed were sampled at maturity 45 DALA.

The whole peanut samples were dried and then cleaned by aspiration and screening. A sheller was used to mechanically crack the hull surrounding the kernel (nutmeat). Aspiration was used to separate the hull and kernel fractions. The raw peanut kernels were heat conditioned and pressed in an expeller for the purpose of liberating a majority of crude oil. After pressing, the presscake was flaked. The residual crude oil remaining in the solid material (presscake) exiting the flaker was extracted with hexane. The solvent extracted presscake (meal) was desolventized. The crude oil recovered from the expeller and solvent extraction was combined and refined. Soapstock was recovered as a by-product of the refining process.

Peanuts (RAC) and all processed commodities were stored frozen up to 3.5 months (107 days) prior to analysis. The samples were analysed for quintozene, PCA, PCTA, PB and HCB using the method CAM-24-73 with an LOQ of 0.01 mg/kg for each analyte.

Processing factors were calculated from the residue levels in kernel for quintozene only and for the sum of quintozene, PCA and PCTA, expressed as quintozene in the following table.

Table 96 Residues of quintozene, PCA and PCTA in peanut nutmeat and its processed commodities following banded applications at begging

Notes:

Total residue: sum of quintozene, PCA and PCTA, expressed as quintozene.

RESIDUES ON ANIMAL PRODUCTS

Livestock Feeding Studies

Dairy Cattle *(Griffith et al., 1969, 900-ANM-055)*

Groups of three lactating cows were fed quintozene (98.2 percent quintozene containing 0.1 percent PB and 1.4 percent HCB as impurities) at nominal levels of 0.1, 1 and 10 ppm in the diet for 12–15 weeks. Samples of the milk were taken on days 0, 1, 7, and then at weekly intervals to day 56. In each group, one cow was sacrificed (time between the last dose and slaughter was not reported) after 12 weeks and two others after 16 weeks. Samples of kidneys, muscle and fat were analysed at slaughter, 16 weeks after the start of feeding. Residues in milk were analysed using the method CAM-1-69. The LOQs of PB, PCA, HCB

and quintozene in milk were 0.001, 0.001, 0.005 and 0.01 mg/kg. PCTA could not be quantified because of interference.

Milk

Throughout the study period, parent quintozene and PB were not found in milk above the LOQ in any of three feeding levels. PCA was quantified in milk only from the 10-ppm feeding level from day 14, but at most 0.008 mg/kg. The impurity HCB was quantified in the medium and high feeding levels and seems to have reached plateau at about 2 weeks with the highest concentration of 0.31 mg/kg at 5 weeks.

Table 97 Residues of quintozene, PCA, PB and HCB in cow milk after oral administration of quintozene (containing (98.2 percent quintozene with 0.1 percent PB and 1.4 percent HCB as impurities)

Day	Mean residues (mg/kg)								
	Feeding level: 0.1 ppm			Feeding level: 1 ppm			Feeding level: 10 ppm

42	<0.001		<0.017	0.003		<0.017	0.016		0.020
49	<0.001		<0.017	0.001		<0.017	0.012		<0.017
56	<0.001		<0.017	0.003		<0.017	0.015		0.018

Notes:

[a] The total concentration was calculated as the sum of quintozene, PCA and PB, not including HCB which is an impurity. Where the concentration was below the LOQ, the LOQ value was used for calculation. It should be noted that PCTA was not quantified due to interference.

Tissues

Residues in tissues were analysed using the method CAM-1-69. When the concentrations of quintozene, PCA, PB and HCB in tissues were below the respective LOQ, they are shown in the following table with the LOQ values to which "<" is attached. Like for milk, PCTA could not be quantified owing to interference.

Quintozene was not detected in any of tissues at any of three feeding levels, except that quintozene was detected at higher level than the LOD but lower than LOQ in the control fat sample. PCA and impurity HCB were found at much higher levels in fat samples than muscle, kidney or liver. Acid hydrolysis by refluxing for 2 hours, portions of kidney or liver from the 10-ppm feeding level in

concentrated H_2SO_4 increased PCA in these tissues (kidney from 0.043 to 0.120 mg/kg; and liver from ND to 0.023 mg/kg). This implies the presence of PCA conjugates before the acid hydrolysis.

Table 98 Residues of PB, HCB, quintozene and PCA in cow tissues obtained at slaughter after oral administration of quintozene (containing (98.2 percent quintozene with 0.1 percent PB and 1.4 percent HCB as impurity) at 0.1–10 ppm in the diet

Notes:

[a] One cow (sacrificed 12 weeks after the initiation of administration).

[b] Quintozene was found at 0.018 mg/kg in the control cow.

In an additional experiment, a single cow was fed at 1000 mg/kg and slaughtered after one month (time between the last administration and slaughter was not described). PCTA was detected in muscle and fat and quantified.

Table 99 Residues of PB, HCB, quintozene, PCA and PCTA in cow tissues obtained at slaughter after oral administration of quintozene (containing (98.2 percent quintozene, 0.1 percent PB, 1.4 percent HCB) at 1000 ppm in the diet. (one cow)

Laying hens *(Kuchar & Griffith, 1975, 900-RES-055)*

Hens (variety, Comet Red Chicken) were fed with quintozene (containing 98.1 percent quintozene, 0.06 percent PB, 0.2 percent 1,3,4,5-TCNB and 1.5 percent HCB and dissolved in corn oil) at levels of 0.05, 1, 5, 15, 75 and 300 ppm in the diet (commercial chicken feed) for four months. Eggs, collected every day, and fat, meat and liver, collected at slaughter, were analysed for quintozene, HCB, PB, PCA and PCTA, using the CAM-39-75 Method upon receipt or maintained at either -2.8 °C (eggs) or -29 °C (tissues) until analysis.

Residues of PB and HCB plateaued in egg yolks at about three weeks and in fat at about seven weeks, whereas quintozene, PCA and PCTA reached a plateau level in less than a week in egg yolk. All of these compounds were detected at much lower levels in egg white as anticipated from their fat solubility.

Notes:

Mean residues were calculated using values between the LOD and LOQ.

APPRAISAL

Quintozene (pentachloronitrobenzene–IUPAC name), is an aromatic fungicide, used as soil fungicide or for seed treatment of various vegetables, cereal grains, and oil seeds.

Quintozene was first evaluated by the JMPR in 1969 and reviewed under the CCPR periodic re-evaluation by the 1995 JMPR for toxicology and residues.

The Firty-third Session of the Codex Alimentarius Commission (2020) approved the new work proposals including the priority list of pesticides for evaluation by the current Meeting, including periodic reevaluation of quintozene.

The current Meeting received information on identity; chemical and physical properties; plant, rotational crop, and animal metabolism; environmental fate; residue analytical methods and storage stability; use pattern; supervised trials; processing; and animal feeding.

The following abbreviated names were used for the metabolites commonly found in plants and animals in the appraisal of quintozene.

Table 101 List of some compounds that are the basic structures of metabolites and conjugated metabolites referred to in the appraisal

 Quintozene Pentachloronitrobenzene	 PCA Pentachloroaniline	 PCTA Methyl pentachlorophenyl sulfide

 PCA glucuronide N-(pentachloroaniline) glucuronide	 PCTASO=PCTA-sulfoxide	 PCTASOO=PCTA-sulfone
 PCTP Pentachlorothiophenol	 PCP Pentachlorophenol	 PCP-MayCys or PCPT-MayCys S-(Pentachlorophenyl) malonylcysteine
 PB Pentachlorobenzene	 HCB Hexachlorobenzene a	 AM TCB sulfonic acid Aminotetrachlorobenzene sulfonic acid
 TCA Tetrachloroaniline	 TCNP-MalCys S-(Tetrachloronitrophenyl) malonylcysteine	 TCNB isomers (2,3,4,5-, or 2,3,5,6-) tetrachloronitrobenzene
 TCTA Tetrachlorothioanisole	 TCA sulfoxide Tetrachloroaniline methy sulfoxide	 MTCP-TAA S-[(methylthio)tetrachlorophenyl]-2-thioacetic acid
 C3MS Trichlorophenyl methyl sulfone		

Notes:

[a] Known impurity of quintozene. According to available information, hexachlorobenzene as an impurity is allowed up to 0.03–0.05 percent in TGAI in the countries where quintozene is registered (the 1995 JMPR reported the maximum to be 0.1 percent.).

Based on the information on physical and chemical properties, quintozene is volatile and more soluble in organic solvents than in water with a Log Pow of 5–6 at pH 7 and 25 °C. Quintozene is hydrolytically stable. Aqueous photolysis is likely to be a major degradation pathway of quintozene in the environment. Photodegradation products after irradiation were isomeric mixture of chlorinated hydroxybenzenes and/or chloronitrophenols.

Plant metabolism

The Meeting received information on the fate of quintozene labelled uniformly with ^{14}C in the phenyl ring (hereafter described as ^{14}C-quintozene) in cabbage, potato and peanut after pre-plant soil application. Residues in harvested seeds of maize, peas, sugar beet, wheat and soya bean were investigated after seed application of ^{14}C-quintozene.

Cabbage

When cabbage was grown in soil treated with ^{14}C-quintozene, the highest radioactivity levels of mature cabbage were found in the wrapper (outer) leaves in both of two studies.

In one study, 28-day old cabbage plants were transplanted in soil treated at 53.8 kg ai/ha and grown in a greenhouse. Samples were taken 49, 70 and 154 days after the application. Total radioactive residue (TRR) from combustion were 7.80, 5.24, 1.14 and 13.9 mg eq/kg in immature whole plants (48 DAT and 70 DAT), mature head and mature wrapper leaves. Extraction of wrapper leaves with methanol/water (80:20) and acetone recovered 57.5 and 14.7 percent TRR, totaling 72.2 percent of TRR). Post-extraction solids (PES) were subjected to HCl hydrolysis.

Seven metabolites were identified in the wrapper leaf extracts, among which two major metabolites were tetrachlorophenyl methyl (TCPM) sulfide (36 percent TRR) and sulfone (42 percent TRR). In this study quintozene was not found. Other identified metabolites, ring hydroxylated C3MS, NOHPA, PCTASO and PCTA, each accounted for 0.5–8.9 percent TRR.

In a second study, cabbages was sown immediately after the soil was treated at 33.7 kg ai/ha and grown outdoors. Immature cabbage samples were taken at 120 DAT and mature cabbage samples at 209 DAT. The mature cabbage samples were separated into whole head with wrapper leaves, head without wrapper leaves and wrapper leaves. TRR from combustion were 3.37, 0.28, 0.11 and 2.03 mg eq/kg for immature cabbage, mature whole cabbage, mature head and mature wrapper leaves, respectively. Extraction with hexane followed by methanol recovered 40–70 percent TRR. Samples were extracted 4.7 months and 32 months after harvest, which might affect the metabolite profile. From the cabbage extracts of immature cabbage, mature wrapper leaves and mature whole cabbage, quintozene, 5 metabolites and HCB were identified but the total identified accounted for only 5–18 percent TRR. Quintozene was the most abundant residue accounting for 9.3 percent TRR (0.327 mg/kg) in the immature cabbage and was lower in the mature wrapper leaves. The only metabolites accounting for more than 10 percent TRR were the combined TCNP-MalCys and PCP-MalCys found mostly in methanol extract (12 percent TRR and 0.34 mg/kg in the wrapper leaves and lower in other portions). In this study, quintozene, PCTA, TCNP-MalCys and PCP-MalCys were found in all three matrices. PCA and PB were in the immature cabbage and mature wrapper leaves and 6-TCNB and HCB only in immature cabbage, which accounted for at most 1.1 percent TRR in mature cabbage.

Potato

Metabolism of quintozene in potato grown in soil treated with ^{14}C-quintozene pre-plant incorporation was investigated in three studies.

In the first study, potato plants were grown outdoor in soil treated with ^{14}C-quintozene at 21.1 kg ai/ha. Potatoes were harvested at early maturity, 11 weeks after planting. Subsamples were rinsed with water and separated into peel and flesh. TRR from combustion were 11.26, 0.76 and 2.39 mg eq/kg for peel, flesh and whole potato, respectively. Sum of TRR in the extracts and PES were 16.81, 0.41 and 0.63 mg eq/kg, differing significantly from the TRR values from combustion.

The samples were extracted with 80 percent methanol, and the extracts were partitioned with chloroform, ethyl ether and water, which recovered 50 percent, 78 percent and 95 percent TRR (based on the sum of the radioactivity in the extracts) from peel, flesh and whole potato, respectively.

In the peel, the most predominant residue was quintozene at 24 percent TRR (4.1 mg/kg) followed by PCA at 18 percent TRR (3.1 mg/kg), while in the whole potato tuber, quintozene was below the LOQ. In potato tuber, the most predominant residue was PCTP-MalCys at 32 percent TRR (0.20 mg/kg) followed by PCTP-Cys at 18 percent TRR (0.11 mg/kg) and PCTA at 9.5 percent TRR (0.06 mg/kg).

In the second study, potato plants were grown outdoor in soil treated with 30 kg ai/ha. Samples were collected at 92 DAT and 122 DAT for foliage, 122 DAT (early stage) and 154 DAT (mature stage) for potato tuber. TRR from combustion were 1.13–7.07 mg eq/kg in foliage, 11.25 mg eq/kg in immature tuber, and 1.37 mg eq/kg in mature tuber.

Samples were extracted with hexane and methanol at various timings up to 26 months after harvest, which might affect the metabolite profile. Extraction rates were 53–77 percent for all matrices. PES and extracts were subject to harsh HCl hydrolysis.

In potato foliage, level of identification was low, a total of 11.7 percent of TRR. PCA, PCTA and TCNP-MalCys and PCP-MalCys were found in minor amounts up to 7.5 percent TRR (0.37 mg eq/kg). In potato tubers, quintozene, 7 metabolites and HCB were identified. Parent quintozene was only detected in 122 DAT immature tuber at low levels (0.3–0.5 percent TRR, 0.02–0.06 mg/kg). In the mature tubers, the most abundant residue was PCA at 9.5 percent TRR (0.09 mg/kg) followed by TCNP-MalCys and PCP-MalCys together at 5.2 percent TRR (0.05 mg/kg) and PB at 4.7 percent TRR (0.05 mg/kg). The total identified was 23 percent TRR. In the immature tuber, PCA, PB and the sum of TCNP-MalCys and PCP-MalCys accounted for 6.0–15 percent TRR (0.68–1.08 mg/kg), 2.7–13 percent TRR (0.48–0.60 mg/kg) and 7.0–10 percent TRR (0.32–1.8 mg/kg), respectively with the total identified was 33–38 percent TRR.

The third study was conducted outdoor using the application at 22.4 kg ai/ha or 67.3 kg ai/ha. Samples of tuber, stem and foliage were collected at 95 DAT. However, only tuber samples were subjected to analysis. TRR in the whole tubers were 1.12 mg eq/ha and 3.54 mg eq/kg for the low and high rate, respectively.

A series of extraction (methanol, aqueous methanol and water) and partitioning (hexane and ethyl ether) extracted at least 90 percent TRR. The PES were treated with a variety of enzymes. Protease released about 40 percent of the TRR in PES and much of the radioactivity was associated with substances with molecular weight > 3000. The enzymes that hydrolyze carbohydrate released minimal amount of radioactivity.

Numerous metabolites at low levels were identified in the extracts/fractions. The total of identified residues accounted for 60–64 percent TRR. No single component accounted for higher than 10 percent TRR, except for PCP-MalCys from the high-rate application (10 percent TRR, 0.36 mg/kg). Although numerous metabolites (about 60) were identified at low levels, approximately one half of the identified radioactivity attributed to five components. The most abundant residues were: parent (7.5–8.0 percent TRR) and PCP-MalCys (9.8–10 percent TRR). Three other components were PCA (2.4–4.3 percent

TRR), PCTA (2.7–3.5 percent TRR) and AM TCB sulfonic acid (3.9–4.8 percent TRR). The hexane fractions contained quintozene as the major component and 11 metabolites.

Peanut

In three studies on peanut metabolism, ^{14}C-quintozene was applied as pre-plant soil incorporation treatment. In the third study, ^{14}C-quintozene was also applied twice as band application at around pegging time.

In the first study ^{14}C-quintozene was applied at 420 kg ai/ha (incorporation into top 15 cm of the soil), higher than the rates used in all other metabolism studies. Peanut plants were harvested 21 weeks after the application and separated into roots, vines, shells and nutmeat. TRR were 1520, 42.3, 128 and 5.16 mg eq/kg in roots, vines, shells and nutmeat, respectively.

Aqueous methanol extracted most of radioactive residues from vines, shells and nutmeat (94–100 percent TRR) while from roots, only 67 percent TRR was extracted. In the extracts, a total of three metabolites were identified. In nutmeat, only one metabolite was identified, which was PCP-MalCys at 6.7 percent TRR (0.26 mg/kg). PCP-MalCys was also a predominant metabolite in roots (33 percent TRR, 320 mg/kg), vines (20 percent TRR, 6.9 mg/kg) and shells (42 percent TRR, 47 mg/kg). TCA accounted for 25 percent (240 mg/kg), 14 percent (4.9 mg/kg), and 22 percent (26 mg/kg) of TRR, respectively in roots, vines and shells. In the same matrices, MTCP-TAA accounted for 8.7 percent (85 mg/kg), 14 percent (4.7 mg/kg) and 7.4 percent (3.4 mg/kg) respectively. Acid hydrolysis in methanolic HCl liberated more than 90 percent of radioactivity in the PES of vines, shells and nutmeat but the liberated radioactivity was not subject to identification.

In the second study, ^{14}C-quintozene was applied at 37.9 kg ai/ha (incorporation into the top 7.6 cm of the soil). Immediately after the application, peanut was sown. Foliage samples were collected at 92 and 154 DAT while hulls and nutmeat samples were collected at 185 DAT. TRR were 3.50–3.97 mg eq/kg, 26.3 mg eq/kg and 2.00 mg eq/kg in foliage, hulls and nutmeat, respectively.

Extraction with hexane followed by methanol recovered 87 percent from nutmeat but 50–55 percent TRR from vines and shells.

From nutmeat extracts, a total of 66 percent TRR was identified (quintozene and 7 metabolites in hexane fraction; and quintozene and 3 metabolites in methanol fraction). PCA and PB each accounted for 17 percent TRR (0.36 mg/kg). TCNP-MalCys and PCP-MalCys together accounted for 13 percent TRR (0.27 mg/kg). Parent quintozene accounted for 5.7 percent TRR (0.12 mg/kg) and PCTA 9.5 percent TRR (0.20 mg/kg).

In hulls, 41 percent TRR was identified (quintozene and 7 metabolites, same as in nutmeat). The predominant residues were TCNP-MalCys and PCP-MalCys together accounting for 34 percent TRR (8.3 mg/kg). Other identified metabolites and quintozene each accounted for <4.0 percent TRR.

In vines, 32 percent TRR was identified (quintozene and 6 metabolites). The predominant residues were TCNP-MalCys and PCP-MalCys, together accounting for 27 percent TRR (1.09 mg/kg). Other identified metabolites and quintozene each accounted for <2.7 percent TRR.

HCl hydrolysis of the PES from vines and nutmeat did not release the significant amounts of radioactivity from the PES. HCl hydrolysis of the iso-octane or methanol extract of vines released 60 percent or 42 percent of the radioactivity respectively but released radioactivity was not identified.

In the third study, ^{14}C-quintozene was applied in two treatment regimes: preplant soil incorporation treatment at 16.8 kg ai/ha after which peanut was sown; or two banded applications at 5.6 kg ai/ha, both at pegging time (68 days and 117 days after planting). Peanut was grown in greenhouse.

Mature plants were collected either 193 DAT (preplant application) or 76 DALA (banded applications) and separated into vines (hay), shells, nutmeat and roots.

TRR from the preplant application and banded application were within 3-fold difference without clear indication about which of these two regimes gave rise to higher residues: 13.0–16.3, 1.72–2.14, 166–211, and 49–122 mg eq/kg respectively in hay, nutmeat, shells and roots.

A total of 94–100 percent of TRR was extracted from nutmeat and hay by a series of extraction with methanol/water (20:80) followed by acetone.

After two banded applications at pegging, quintozene in the extracts and after hydrolysis with methanolic HCl accounted for 97 percent TRR with trace amount of PCA in nutmeat.

In hay from the two banded applications, 92 percent TRR was identified. PCTP-MalCys was the predominant residue at 53 percent TRR followed by N-malonyl-S-(tetrachloroaminophenyl)-cysteine at 20 percent TRR and parent quintozene at 19 percent TRR.

Treated seeds

Seeds of maize, peas, sugar beet, wheat and soya bean were treated with ^{14}C-quintozene and sown and grown in an open-sided greenhouse. After harvesting at respective commercial timing, radioactivity was measured in the harvested crops. There was uptake of radioactivity by all the crops with the highest radioactivity found in dry pea vines and soya bean stems at 1.8 and 1.5 mg eq/kg, respectively. While radioactivity above the LOQ was detected in vines, roots, hay, forage, and straw, none of the harvested seeds/grains from these crops contained residues above the minimum quantifiable limits. None of the samples were subjected to identification/ characterization.

Summary of plant metabolism

Metabolism of quintozene in plants after pre-plant soil incorporation application was studied on cabbage, potato and peanut. In the case of peanut, metabolism after two banded applications at pegging was also studied. In old studies on cabbage, potato and peanut, identified compounds were not consistent with newer studies and none of the compounds in the polar fraction was identified; or extraction took place 2 years or later after the harvest.

In the newer studies on potato, numerous compounds (about 60) were identified including those in the polar fractions. About 60–64 percent TRR were identified and approximately about one half of the identified radioactivity (27–30 percent TRR) was comprised of five compounds. PCP-MalCys and its esters together accounted for 10–13 percent TRR. This compound was also found in the old studies on cabbage, potato and peanut. Parent quintozene accounted for 7.5–8.0 percent TRR. PCA and PCTA accounted for 2.4–4.3 percent and 2.7–3.5 percent TRR respectively. AM TCB sulfonic acid accounted for 3.9–4.8 percent TRR. No other metabolites accounted for more than 2.8 percent TRR while the concentrations of many metabolites were higher than 0.01 mg/kg. PB was detected up to 1.9 percent TRR (up to 0.014 mg/kg).

Based on new data, the Meeting confirmed that the metabolism of quintozene in plants occurs through three routes: (1) dechlorination, replacing chlorine by hydrogen or hydroxyl to yield metabolites with less chlorine on the phenyl ring; (2) reduction of the nitro group to NHOH or elimination; or (3) displacement of the nitro group with sulfhydryl group of glutathione to give glutathione adducts or SH-containing amino acids, which are metabolized or oxidized to become sulfoxide, sulfone and sulfonic acid. They may be further metabolized to produce conjugates with glutathione, cysteine, malonylcysteine, glucose and others or incorporated into biomolecule.

Environmental fate

Aerobic degradation in soils

Quintozene in sandy loam soil degraded showing non-linear trend. A half-life of 189 days was calculated approximating first-order kinetics. The concentration of quintozene reached less than half of the initially applied in 60 days possibly due to its volatility. The major degradation products were PCA and PCTA. Other identified degradation products were PCTA sulfone and PCTA sulfoxide which occurred from oxidization of PCTA, and PB.

Quintozene was found to leach in small amounts (2–17 percent in four soil types) and only into the adjacent untreated soil zone.

Photodegradation in soil

There was gradual decline observed through one year in soil surface under photo-irradiation. A half-life of quintozene exposed to artificial sunlight was 28.5 days in sandy loam soil.

PCA and PCTA seemed major photodegradation products but they were found not only under irradiation but also in dark control and therefore in their formation photo irradiation does not play significant role.

Field dissipation

Field dissipation studies conducted in six locations in the United States with single application at rates ranging from 2.5 to 33.6 kg ai/ha or two applications each at 36.6 kg ai/ha indicated that quintozene dissipated with a geometric mean DT_{50} of 88 days and the total of quintozene, PCA, PCTA, PB and impurity HCB dissipated with a geometric mean DT_{50} of 360 days. These compounds were found in 0–15 cm layer soil at almost all the sampling intervals (up to 546 days). They were not found, or, if found. at very low levels in depths below 15 cm. The accumulation rates of the degradates were faster than their dissipation rates. These results indicate that quintozene itself is moderately persistent while the degradates are persistent.

Rotational crop metabolism

The Meeting received information on confined rotational crop studies and a field rotational crop study.

Confined rotational crop studies

Bare soil was treated with ^{14}C-quintozene with soil incorporation, and allowed to age for 30, 120 or 365 days as the plant-back intervals (PBI) before planting lettuce, turnips and wheat.

In the first study, after the 34 kg ai/ha application, succeeding crops were grown indoor and harvested at immature and mature growth stages. The TRR in mature plants after 31-day, 121-day or 365-day PBI were: lettuce, 1.6, 0.15 or 0.73 mg eq/kg; in turnip tops and roots, 3.6 and 20.3, 1.7 and 4.8, or 0.73 and 1.5 mg eq/kg respectively; and in wheat straw, hulls and grain, 22.9, 11.1 and 0.33; 22.2, 6.1 and 0.71; or 25.9, 8.0 and 0.38 mg eq/kg respectively. The TRR in 0–15 cm soil 2 hours after the application were in a range of 6.56–14.3 mg eq/kg and showed some tendency to gradually decrease with aging.

Samples of lettuce and turnip tops and roots were centrifuged to remove water (treated as “aqueous extract”) and the remaining moist tissues were extracted with methanol/water (40:60) and the extracts were partitioned with chloroform, and the methanol fraction was combined with the “aqueous extract” for analysis. Samples of wheat materials were extracted with methanol and then water, and after adjusting to methanol/water ratio to 40/60, the extract was partitioned with chloroform. PES fractions of

wheat straw were hydrolyzed with HCl, NaOH and cellulase. The extraction with methanol and acid hydrolysis of PES together recovered a total of 36.0–53.8 percent TRR from lettuce from all the PBIs; and 76.0 percent and 62.1 percent TRR from turnip roots and tops respectively from 365-day PBI; and 49.4–53.9 percent TRR in wheat hulls. The extraction with methanol and aci[d]base hydrolysis of PES of wheat straw recovered 61.6–67.5 percent TRR. While methanol extracted 36–67 percent TRR, acid hydrolysis released additional 9.4–19 percent TRR.

Residues of quintozene, PCA or PCTA were not found in any of lettuce, turnip tops and roots, or wheat straw and hulls. Those compounds found at higher than 0.01 mg/kg were: in all crops from all PBIs, N,N'-diacetyl-S,S'-(tetrachloro-p-phenylene)-dicysteine /C4CyCy; and in wheat straw and hulls from all PBIs, PCP-GSH; PCP-MalCys; TCP-diGSH; and N-acetyl-S-(pentachlorophenyl)-cysteine. The percentage of identified compounds in the TRR was low, 5.1–6.3 percent in lettuce; 4.3 percent in turnip roots, 12.3 percent in turnip tops, 12.1–16.9 percent in wheat straw, and 33.6–34.9 percent in wheat hulls.

In the second study, after 35 kg ai/ha application, succeeding crops were grown indoor and harvested at immature and mature growth stages. The TRR in mature plants after 31-day, 121-day or 365-day PBI were: mature lettuce, 3.0, 0.13, 0.45 mg eq/kg respectively, mature turnip tops and roots, 11.9 and 11.4, 1.3 and 5.8, or 0.91 and 1.9 mg eq/kg respectively; and mature wheat straw, hulls and grain, 27.7, 21.5 and 0.63, 13.4, 2.0 and 0.07 and 6.28, 19.3 and 1.2 mg/kg respectively. The TRR in soil immediately after treatment was in a range of 2.6–12.7 mg eq/kg.

Samples were extracted with hexane followed by methanol. These solvents extracted 77–80 percent TRR in lettuce from 121-day and 365-day PBI while only 10.8 percent TRR in lettuce from 30-day PBI; 47.1–67.0 percent and 50.1–71.8 percent TRR respectively from turnip tops and roots from all the PBIs; and 35.2–62.5 percent, 41.5–49.7 percent, and 29.6–34.2 percent TRR in wheat grain, hulls and straw respectively from all the PBIs. PES of turnip roots and tops from all PBIs and wheat matrices 365-day PBI were acid hydrolyzed. Acid hydrolysis released 5.6–7.9 percent TRR and <5 percent TRR from the PES of turnip tops and turnip roots, respectively; and <1 percent to 30 percent TRR from the PES of wheat matrices.

Detailed identification was performed only on turnip roots from 31-day PBI. Quintozene, PCA, PCTA and PB were identified in the hexane extract at the maximum of 4.1 percent TRR and 0.69 mg/kg. In the methanol extract, S-(tetrachlorothiophenol)-N-malonylcycteine and PCP-MalCys together accounted for 16 percent TRR and 2.7 mg/kg. The identified residue accounted for 11.8 percent TRR in hexane fraction and 15.6 percent TRR in methanol fraction, totalling 27.9 percent TRR.

In the third study, after application at rates of 2.2, 11 and 34 kg ai/ha, succeeding crops were grown outdoor and harvested at immature and mature growth stages. The application rate of 11 kg ai/ha was used for all crops. After the 11 kg ai/ha application, TRR in mature plants after 30-, 120- or 365-day PBI (only 365-day PBI for turnip) were: lettuce, 0.15, 0.10 or 0.43 mg eq/kg; turnip tops and roots, 1.1 and 0.77 mg eq/kg (1st retrial results); and wheat forage, grain, and straw, 3.0, 0.79 and 10.7; 3.4, 0.94 and 16.8; or 0.64, 0.14 and 4.6 mg eq/kg. The TRR in soil immediately after application of quintozene at 33.6 kg ai/ha were within a range of 2.6–12.7 mg eq/kg.

Samples were extracted using methanol followed by methanol/water (1:1), or methanol/water (1:1) alone, and the extracts were partitioned with chloroform, hexane followed by chloroform, or dichloromethane. Methanol and methanol/water, or methanol/water extracted a total of 56–77 percent TRR (27–44 percent TRR in chloroform fraction and 22–38 percent TRR in aqueous fraction) in lettuce; and 52 -76 percent and 59–70 percent TRR respectively from wheat forage and wheat straw. However, from wheat grain, only 9.8–33 percent TRR were released.

The PES remaining after extraction were treated with sequential digestions with three groups of enzymes (pH 5 compatible enzymes, pH 7 compatible or pH 6 compatible enzymes and proteases) followed by base hydrolysis. The hydrolysis with enzymes and strong acid and or base released <10 percent TRR in each fraction, except protease and base treatment released up to 10.1 percent TRR and 16.8 percent TRR respectively from lettuce PES; pH 5 compatible enzyme, pH 6 compatible enzyme and base treatment released up to 42.0 percent TRR, 13.7 percent TRR and 23.6 percent TRR from the wheat grain PES. After these treatments, < 10 percent TRR remained in the PES of these commodities.

Residues of quintozene were found in lettuce at 21 percent TRR (max conc. 0.032 mg/kg) from 30-day PBI and decreased in terms of percent TRR and concentration as the aging of soil got longer (after 365-day PBI, around 1 percent TRR and < 0.01 mg/kg). It was also found in wheat straw (2.2 kg ai/ha, 120-day PBI) at 0.023 mg/kg but not in turnip. PCA was found in all three cops. There were numerous compounds identified in lettuce and wheat matrices but most of them at very low levels.

Field rotational crop study

Unlabelled quintozene was applied to bare soil simulating the maximum US GAP for peanut (2 × 5.6 kg ai/ha; not valid at the time of this evaluation). Lettuce and wheat were planted 30, 120 and 365 days after the second application, and turnip 365 days after the second application. Samples were obtained at mature growth stage, except that wheat forage was obtained at immature stage. Samples were extracted with acetone/hexane (50:50) and partitioned with water to obtain the hexane layer which was cleaned up using Florisil column for analysis of quintozene, PCA, PCTA, PB, HCB, TCA, PCTASO and TCTASOO.

Quintozene was detected above the LOQ of 0.005 mg/kg in the 30-day PBI and 120-day PBI lettuce at a maximum 0.013 mg/kg. Quintozene was not found in any of wheat and related samples from any PBI or in turnip roots or tops from 365-day PBI (only PBI tested for turnip).

PCA was mostly below the LOQ but found above the LOQ in 30-day PBI lettuce (highest, 0.0092 mg/kg), 30-day PBI and 365-day PBI wheat forage (highest, 0.016 mg/kg) and turnip roots from 365-day PBI (highest, 0.014 mg/kg). PCTA was not found above the LOQ in any of the samples. PB, HCB, TCA, PCTASO, or TCTASOO were not found above the LOQ of 0.005 mg/kg in lettuce, turnip or wheat from all PBIs, except in 365-day PBI turnip roots TCA was found above the LOQ (highest, 0.010 mg/kg).

From 366- or 367-day PBI, no residues above the LOQ of 0.005 mg/kg of quintozene, PCTA, PCTASO, TCTASOO, PB or HCB were found in any portions of lettuce, turnip or wheat tested. PCA and TCA were found in the turnip roots at levels up to 0.014 mg/kg, PCA in wheat forage at the maximum 0.016 mg/kg.

Summary of rotational crop studies

In the confined rotational crop studies using the high application rates (up to 34.6 kg ai/ha pre-plant), similar metabolites as plant metabolism studies were identified showing complex metabolite profile, except that parent quintozene was either not found or found at low levels.

In the field study with unlabelled quintozene (2 × 5.6 kg ai/ha), quintozene was detected above the LOQ of 0.005 mg/kg in the 30-day PBI and 120-day PBI lettuce at a maximum 0.013 mg/kg. Quintozene was not found in any of wheat and related samples from any PBI or in turnip roots or tops from 365-day PBI (only PBI tested for turnip). PCA was mostly below the LOQ with sporadic detection up to 0.0092 mg/kg in 30-day PBI in lettuce and up to 0.016 mg/kg in wheat forage. PCTA was not found above the LOQ in any of the samples. PB, HCB, TCA, PCTASO, or TCTASOO were not found above the LOQ of 0.005 mg/kg in lettuce, turnips or wheat from all PBIs, except that up to 0.01 mg/kg TCA was found in

365-day PBI turnip roots. At higher single application rate to the soil (such as 25 kg ai/ha on the provided label for cabbage and broccoli), residues of quintozene were expected above 0.01 mg/kg in lettuce and other leafy vegetable.

The metabolism of quintozene in rotational crops seems to follow similar pathway as in the plant metabolism.

Animal metabolism

The Meeting received information on metabolism in lactating goats and laying hens, in addition to metabolism in rats.

Rat

Metabolism studies on laboratory animals including rats were reviewed in the framework of toxicological evaluation by the current JMPR.

Lactating goats

In three studies with goats, ^{14}C-quintozene was orally administered to lactating goats once daily for five consecutive days. The goats were sacrificed approximately 6 hours after the final dose.

In the first study, two goats were dosed orally with ^{14}C-quintozene in capsules at levels 25 or 50 mg/kg bw (equivalent to 714 and 947 ppm in the diet). The administered dose was eliminated in feces (36/41 percent of the total dose for 25 mg/kg bw goat/50 mg/kg bw goat) and urine (30/20 percent of total dose) within 48 h. A small amount was excreted in milk (0.34/0.21 percent of total dose). TRR in milk reached the highest level of 6.0/3.6 mg eq/kg on day 2 pm, after which TRR decreased. Liver, kidney and fat contained 13/13, 10/11, and 15–16/9.4–12.8 mg eq/kg respectively. Muscle contained much lower radioactivity of 0.54/0.48 mg eq/kg.

The samples of tissues were extracted with a mixture of chloroform, methanol and water, and the chloroform fraction was partitioned between acetonitrile and hexane. The milk samples and a portion of liver sample were extracted with chloroform/methanol (1:1) and the chloroform extracts were cleaned up with gel permeation column. From milk, kidney, muscle and fat following the administration of 25 mg/kg bw., 70.8–84.0 percent TRR were extracted in chloroform fraction while 4.3–18.0 percent TRR were found in the methanol/water fraction and PES contained 0–29.9 percent TRR. From liver using two slightly different extraction and partition systems, 24.2/31.4 percent TRR were extracted in chloroform fraction with 5.8/29.5 percent TRR in methanol/water fraction and PES contained 69.4/42.4 percent TRR, showing that the extraction system with chloroform/methanol was more efficient.

Chloroform fractions from the 25 mg/kg bw dose goat were subject to identification. Quintozene was extensively metabolized and it was not found in milk or tissues. PCA was identified as the main metabolite in milk (50 percent TRR, 3.0 mg/kg), kidney (31 percent TRR, 3.2 mg/kg), muscle (59 percent TRR, 0.32 mg/kg) and fat (49 percent TRR, 7.7 mg/kg). PCTA was identified at lessor amounts in milk (4.7 percent TRR, 0.28 mg/kg), kidney (2.8 percent TRR, 0.29 mg/kg), muscle (6.4 percent TRR, 0.04 mg/kg) and fat (1.5 percent TRR, 0.23 mg/kg). In liver, the majority of the radioactivity (40 percent TRR) was associated with an unknown polar metabolite released by base hydrolysis. As a result, PCA and PCTA accounted for 9.6 percent (1.3 mg/kg) and 1.3 percent (0.18 mg/kg) of TRR, respectively.

In the second study, two goats were dosed orally with ^{14}C-quintozene in capsule at 20 or 50 mg/kg bw. The administered dose was eliminated in urine (33/38 percent of total dose for 20 mg/kg bw goat/50 mg/kg bw goat) and feces (25/19 percent of the total dose). A small amount is excreted in milk (0.4 percent of total dose). TRR in milk reached a plateau on Day 2. Only 1.3/1.1 percent of total dose

remained in tissues, bile and urine in bladder. Kidney, liver, renal fat contained 32/49, 26/46 and 18–33 mg eq/kg. Muscle contained much lower levels of 1.1/2.3 mg eq/kg.

In milk from lower dose, hexane extracted 55 percent TRR with 31 percent TRR remaining in PES. In kidney and liver from lower dose, extraction with water/methanol/chloroform (1:2:1) recovered a total of 68 percent and 60 percent TRR leaving 16 percent and 46 percent TRR in the respective PES. Base hydrolysis of the PES released 10.0 percent and 4.8 percent TRR, respectively. In renal fat and omental fat from the lower dose, chloroform extracted 72.9 percent and 70.9 percent TRR respectively with 1.6 percent and 1.7 percent TRR in the PES. No extraction was conducted on muscle samples.

The extracts of kidney and liver of lower dose goat were subject to identification and characterization. The chloroform fraction of kidney contained quintozene (9.1 percent TRR, 2.9 mg/kg), followed 2,3,4,5-TCNB (0.5 percent TRR, 0.16 mg/kg). In the aqueous fraction, a smaller amount of quintozene was identified (0.5 percent TRR). The chloroform fraction of liver contained parent quintozene and PCA (together 8.3 percent TRR, 2.2 mg/kg), PCTA (5.4 percent TRR, 1.4 mg/kg) and 2,3,4,5-TCNB (1.0 percent TRR, 0.26 mg/kg). In the aqueous fraction, a smaller amount of quintozene and 2,3,4,5-TCNB were identified. Radioactivity in milk was not characterized.

In the third study, one goat was orally dosed with ^{14}C-quintozene at 50 mg/kg bw. The TRR in milk, kidney, liver, fat and muscle were 59, 49, 46, 22 and 2.2 mg eq/kg respectively.

Extraction of the 2nd day milk sample with ethyl acetate recovered 87 percent TRR. The kidney, liver and muscle samples were extracted with a mixture of methanol, chloroform and water and the PES was treated with protease. For kidney, chloroform fraction accounted for 46 percent TRR, aqueous fraction 28 percent TRR and PES 26 percent TRR of which 19 percent TRR was solubilized with protease (total of 93 percent TRR extracted). For liver, chloroform fraction accounted for 24 percent TRR, aqueous fraction 20 percent TRR and PES 56 percent TRR which was solubilized with protease. For muscle, 98 percent TRR was extracted. The renal and omental fat samples were extracted with chloroform and, after evaporation of chloroform, partitioned with acetonitrile and hexane. The acetonitrile fraction contained 84 percent of TRR. For milk, kidney, liver, muscle and fat, extractability was high from 84 to 100 percent TRR.

In kidneys, six metabolites were identified, among which PCA and PCA glucuronide accounted for 26 and 55 percent of the extracted residue. The four other metabolites were PCTP, tetrachloro(methylthio)benzenethiol, TCTA and TCA sulfoxide, each < 4.5 percent. In liver, also six metabolites were identified, mainly PCA (17 percent) and PCA-glucuronide (73 percent). Other four identified metabolites were PCPT dimer, N-pentachlorophenylhydroxyamine, PCPT and teterchloro(methylthio) benzenethiol, each < 4.7 percent. In muscle, four metabolites were identified: PCA (46 percent), PCTA (11 percent) and TCTA/tetrachlorophenyl methyl sulfoxide (together, 42 percent). In fat and milk, only one metabolite was identified as PCA, 96–100 percent of the extracted. In this study, quintozene was not detected in milk or tissues.

Laying hens

Laying hens were orally dosed with ^{14}C-quintozene for five (first study) or six (second study) consecutive days. Birds were sacrificed approximately 6 hours after the final dose.

In the first study, two groups of hens were dosed orally with ^{14}C-quintozene in capsule at 25 or 50 mg/kg bw (equivalent to 309 or 554 ppm in the diet). The majority of the total dose was recovered in excreta (65/71 percent TAR for 25 mg/kg bw group/50 mg/kg bw group) in four days, followed by GI tract and its contents (6.5/9.2 percent). Liver, kidneys, all eggs contained 0.03/0.04 percent, 0.02 percent and 0.01–0.02 percent of the total dose. In eggs, most of the radioactivity was found in egg yolk (1.2/2.7 mg eq/kg at sacrifice), much higher than that in corresponding egg white (0.038/0.071 mg eq/kg).

Kidneys, liver, abdominal fat and skin with fat contained 4.5/5.5, 2.0/2.4, 2.1/4.2 and 1.1–2.2 mg eq/kg respectively. Breast muscle contained 0.16/0.31 mg eq/kg, significantly lower than fat, as in the case of lactating goats.

Egg yolk, liver, kidney, fat and muscle were extracted with a mixture of chloroform, methanol and water. After evaporation, chloroform fraction was partitioned between acetonitrile and hexane. From liver of lower dose hens, 86.3 percent TRR were extracted and additional 10.8 percent TRR were released from PES by acid hydrolysis (total, 97.1 percent TRR). From kidney of the lower dose hens, 72 percent TRR was extracted and additional 19.1 percent TRR was released by base hydrolysis (total, 91.4 percent TRR). From fat, breast muscle and egg yolk at sacrifice, 103.5 percent, 97.0 percent and 33.5 percent TRR were extracted.

In liver extracts, quintozene, PCA and PCTA, each accounted for 3.2 percent, 0.45 percent and 1.5 percent TRR respectively. In kidney extracts, also quintozene, PCA and PCTA were detected, each accounting for 0.80 percent, 2.7 percent and 0.23 percent TRR respectively. The concentrations of these compounds were >0.01 mg/kg. The majority of the radioactivity in liver and kidney was not adequately identified or characterized.

In the second study, three groups of hens were dosed orally with ^{14}C-quintozene in capsule at rates equivalent to 105, 273 and 512 ppm in the diet. The majority of the total dose was eliminated in the excreta (87–94 percent of administered dose) for three dose groups. The TRR in liver, kidneys, thigh muscle and fat in three dose groups were 0.87/2.72/3.81, 1.84/5.05/7.29, 0.13/0.36/0.71, 2.64/6.17/10.1 mg eq/kg respectively. TRR in day-5 egg yolk and white were 1.74/3.52/5.75, and 0.06/0.24/0.29 mg eq/kg, respectively.

The tissue and egg yolk samples were extracted with a mixture of chloroform, methanol and water. Except for fat sample, significant radioactivity remained in PES: 32.8 percent TRR for kidney, 35.2 percent TRR for liver, 25.9 percent TRR for thigh muscle, and 75.3 percent TRR for egg yolk obtained from the highest dose. In order to solubilize the radioactivity in the PES, acid and base hydrolysis and proteolytic enzyme treatment were attempted. Base hydrolysis was the most efficient in solubilizing radioactivity in PES, releasing: 79.9 percent in kidney, 104 percent in liver, 75.9 percent in thigh muscle but only 38.2 percent in egg yolk. Among proteolytic enzymes with different optimal pH, 116 percent, 55 percent and 81 percent of radioactivity in kidney PES were released by pepsin, trypsin and protease treatment respectively. These enzymes released only up to 17.1 percent of radioactivity in liver PES and up to 7.4 percent in egg yolk PES.

In fat, quintozene was the predominant residue accounting for 48 percent of extracted radioactivity. Other major metabolites included PCA (16 percent) and teterchloromethylsulfinylaniline (31 percent). In liver, PCTP (71 percent) and PCTASO (21 percent) were identified. Base hydrolysis of the liver PES released PCA and PCTA. In egg yolks, PCA (70 percent), PCTA (9 percent) and PCTP (18 percent) were identified. In muscle, the major radioactive residues were PCP thioacetate or TCTA sulfone (88 percent) with minor amounts of PCTA (8 percent). Quintozene was found only in fat.

Summary of animal metabolism

The metabolism of quintozene was investigated in lactating goats and laying hens. In general, the metabolic pathways in these species were similar to that in rats.

In goats, quintozene was metabolized mainly to PCA and its glucuronide conjugates. Other metabolites were formed in much smaller amounts. They were TCTA, PCTA, C4MX. Parent quintozene was not detected in any of the tissues.

In hens, PCA, PCTA, PCTP, PCTP conjugated with cysteine, malonylcysteine, pyruvate and acetate were identified. Other metabolites identified included TCTA, TCTASOO, PCTASO and tetrachloromethylsulfinylaniline. Parent quintozene was detected in muscle (55.8 percent TRR) and fat (59.8 percent TRR) as predominant residue and in kidney and liver at low levels in one study, but detected only in fat at 48 percent of the extracted residue in another study.

The major metabolic pathway in animals involves (1) displacement of the nitro group by the sulfhydryl group of glutathione or SH-containing amino acids/peptides, followed by catabolic cleavage of the peptide, or by hydroxyl group; (2) reduction of the nitro group to produce N-hydroxypentachloroaniline and conjugated PCA; (3) dechlorination to yield tetrachloro- trichloro- phenyl compounds. The pathway has some commonality with the metabolism in plants.

Methods of analysis

The Meeting received information on the analytical methods using GC-ECD or GC-MS for the determination of residues of quintozene for data development and enforcement for broccoli, cabbage, peppers, tomato, green bean, dry bean, lettuce, potato, turnip roots and tops, wheat (forage, grain and straw), cotton seed and its processed products, peanut (whole, shell and nutmeat), cattle milk and tissues, and poultry eggs and tissues. The analytes include quintozene, PCA, PCTA, PB and impurity HCB. Some methods are capable of determining 2,3,4,5-TCNB and 2,3,5,6-TCNB.

In general, the methods for plant commodities employed extraction by homogenization with solvents containing hexane, such as 2-propanol/hexane, acetone/hexane or hexane alone, or acetonitrile/water, ethyl acetate and then partitioned into hexane fraction. After clean-up using either of Florisil, gel permeation, silica gel or SPE column, the hexane phase or reconstituted phase in other organic solvent was separated and quantified by GC-ECD or GC-MS. These methods were validated through recovery tests with the acceptable range of mean recoveries and RSD.. For the analytes mentioned above, the validated LOQ were in a range of 0.0005–0.01 mg/kg for each analyte.

One method for monitoring using the QuEChERS extraction, clean-up with SPE column, and GC-MS analysis was also validated for quintozene, PCA and PCTA with the LOQ of 0.01 mg/kg for broccoli and potato.

For quintozene, PCA, PCTA PB and HCB in animal commodities, the methods employed extraction by either acetone and then partitioned into hexane, or hexane alone, and without clean-up, analysis was conducted using GC-ECD with the LOQ in a range of 0.001–0.01 mg/kg. There was no full validation data provided to the Meeting. For analysis of these compounds in bovine and poultry commodities, procedural recovery data of the methods used in cattle and poultry feeding studies were available. In most of animal matrices, except bovine milk and egg yolk, recovery was examined by only single test on one or two fortification levels. For milk and egg yolk, four or five fortification levels were tested mostly in single or duplicate. In milk, quintozene showed recovery lower than 70 percent in 2 of 4 fortification levels. Therefore, the Meeting considered that the methods were not sufficiently validated and not fit-for-purpose.

Stability of pesticide residues in stored analytical samples

The Meeting received information on storage stability of quintozene, PCA, PCTA and PB and HCB in various commodities of high water content (broccoli, peppers, tomato, lettuce, snap bean, turnip tops and wheat immature whole plant), high protein content (kidney bean and soya bean), high starch content (potato, turnip root, corn and wheat grain), high oil content (cotton seed and peanut) and dry sample (wheat straw).

Table 102 Summary of frozen storage stability of quintozene, PCA, PCTA, PB and HCB is shown below

Category	Commodity	Duration of study (month)	Stable period (months) [a]				
			Quintozene	PCA	PCTA	PB	HCB
High water content	Broccoli	14	14	14	14	14	14

Notes:

[a] Where the value of stable period is the same as the duration of study, this indicates that the fortified compound was stable at least for the months in this table. Where the term "up to" precedes the value of stable period, the fortified compound would not be stable after the months specified. The month value with the "<" symbol indicate that significant degradation occurred by the months described.

The storage periods in the storage stability studies on plant commodities cover the sample storage intervals in the residue trials.

Storage stability data were not available on animal commodities.

Definition of residue

Plant commodities

The plant metabolism of quintozene was studied in cabbage, potato and peanut. As for cabbage, there were inconsistent results in two studies. In the first study, quintozene or PCA were not detected but two metabolites were identified which were not detected in the other study. In the other study, quintozene, PCA and PCTA were detected in immature cabbage and mature wrapper leaves at the maximum 0.05 mg/kg and 1.6 percent TRR. The total identified radioactivity was only up to 18 percent TRR. The highest reported component was the sum of TCNP-MalCys and PCP-MalCys at the maximum 12 percent TRR and 0.34 mg/kg but no separate values were available for each of them.

As for potato, a new metabolism study identified numerous compounds, including conjugates with GSH, cysteine, malonylcysteine, sulfoxide, sulfone, and others, at low levels. A total of 60–64 percent TRR was identified. Quintozene, PCA and PCTA were identified and quantified but PCP-MalCys was the most abundant residue (10–12 percent TRR).

A new metabolism study on peanuts identified a total of 62 percent of TRR. Quintozene was the most abundant residue in nutmeat at 62 percent TRR. In the older studies, PCP-MalCys was identified as the predominant residue (20–42 percent TRR) with smaller amount of quintozene, PCA and PCTA.

In the supervised residue trials, quintozene was detected generally at higher concentrations than PCA and PCTA, or at similar or slightly lower concentrations than PCA. PCTA was detected generally at lower levels than quintozene or PCA. In the trials on potato, in addition to quintozene, PCA and PCTA, PB, HCB, 2,3,4,5-TCNB and 2,3,5,6-TCNB were analysed. 2,3,4,5-TCNB and 2,3,5,6-TCNB were, when analysed, below the LOQ. Quintozene was also detected at slightly higher than the LOQ of 0.005 mg/kg in succeeding lettuce in the field rotational crop study with the treatment of bare soil at a rate which is about one third of the maximum rate in available GAP.

Analytical methods were available to determine quintozene in plant commodities.

The Meeting therefore concluded that quintozene was a suitable marker for MRL-compliance.

For the residue definition for dietary risk assessment, the Meeting considered likely occurrence and toxicological relevance. While more than 80 compounds including many conjugates were identified, most of which were at low concentrations and contributions. The Meeting noted that while parent quintozene is not regarded as genotoxic, possibility of genotoxicity could not be excluded for all the metabolites, due to the lack of toxicological information on these metabolites and quantification of metabolites in rat metabolism. The Meeting considered that these metabolites could be assessed using the TTC approach for genotoxic compounds (0.0025 µg/kg bw/day).

The Meeting was unable to reach conclusion on residue definition for dietary risk assessment for plant commodities. due to concern of potential genotoxicity of all the metabolites.

Animal commodities

In the animal metabolism studies, parent quintozene was not detected in milk or any tissue of lactating goats in two of three studies. In laying hens, quintozene was detected at significant levels in tissues in one study but not in tissues other than fat in the other study. Therefore, quintozene alone is not a suitable marker.

PCA was the most predominant residue in tissues and milk, and egg yolk and fat. In chicken muscle, quintozene or PCA was not detected and the most predominant residue was PCP thioacetate or TCTA sulfone (88 percent of the extracted residue) followed by PCTA (8 percent of the extracted residue).

GC-ECD methods provided were not supported by full validation data and the Meeting considered it was not certain that these methods were fit-for-purpose to determine quintozene, PCA and PCTA in animal commodities. Therefore, it was not possible for the Meeting to establish residue definition for compliance with MRLs for animal commodities.

For the residue definition for dietary risk assessment, the Meeting considered likely occurrence and toxicological relevance. In the animal commodities, except egg yolk, the total of metabolites identified was relatively high in percentage of TRR, and comparing with plant commodities, the number of identified metabolites was relatively small. The Meeting noted that possibility of genotoxicity could not be excluded for all the metabolites, due to the lack of toxicological information on these metabolites and quantification of metabolites in rat metabolism. The Meeting considered that these metabolites could be assessed using the TTC approach for genotoxic compounds (0.0025 µg/kg bw/day).

The Meeting was unable to reach a conclusion on residue definition for dietary risk assessment for animal commodities. due to concern that exposure would exceed the TTC for genotoxicity of all the metabolites.

Conclusion

Based on the above, the Meeting recommended the following residue definition.

Definition of the residue for compliance with the MRL for plant commodities: *Quintozene*.

Results of supervised residue trials on crops

The Meeting received supervised trial data for quintozene residues on broccoli; cabbage, head; tomato; peppers; beans with and without pods; beans (dry); potato; cotton seed; and peanut conducted in the United States.

At the time of this evaluation, there were Codex MRLs for the following commodities but the current Meeting withdrew the previous recommendations: for barley; barley straw and fodder, dry; maize; maize fodder (dry); pea hay or pea fodder (dry); peas (dry); soya bean (dry); soya bean fodder; sugar beet; wheat; and wheat straw and fodder, dry since no GAP information or residue data were provided for these commodities.

The Meeting decided to withdraw the previous recommendations for quintozene on spices, fruits and berries; spices, roots and rhizomes, based on monitoring data .

Due to genotoxic concerns of all the metabolites, the Meeting estimated maximum residue levels based on provided supervised residue trials but they were not recommended for use as MRLs.

Broccoli

The critical GAP in the United States for broccoli (among the list of various Cole crops, but not for a group) allows one application of pre-plant banded soil application or broadcast application at 25 kg ai/ha.

The Meeting received 12 supervised trials conducted on broccoli in the United States during the growing season of 1988/89 and 2018/19.

In the trials, broadcast application and banded application of WP and GR formulations were used at rates (shown below for each residue value) that differ from the GAP rate. There were also direct seed treatment and transplant solution applications.

Since a number of the application rates used in the trials differed by more than 25 percent of the GAP rate, the Meeting decided to use the proportionality approach to estimate a maximum residue level and an STMR. Scaled residues were calculated using the formula below.

Scaled residue (mg/kg) = (residue in the trial, mg/kg) × 2.025 (kg ai/ha) / (rate used in the trial, kg ai/ha).

After each scaled residue value, the residue found in each trial and respective application rate are indicated in a pair of parentheses, e.g., (residue value in mg/kg, application rate in kg ai/ha).

Residues of quintozene from trials with banded application approximating the GAP in the United States were in rank order (n=7 scaled residues): 0.006 (0.005, 22.4), 0.008 (0.007, 22.4), 0.009 (0.008, 22.4), < 0.01 (< 0.01, 36.6), < 0.01 (0.13, 36.6), 0.024 (0.032, 36.6), and 0.026 (0.023, 22.4) mg/kg.

Residues of quintozene from trials with broadcast application approximating the GAP in the United States were in rank order (n=7 scaled residue): 0.005 (0.006. 33.6), 0.005 (0.006, 33.6), 0.006 (0.007, 33.6), < 0.01(< 0.01, 36.6), < 0.01(< 0.01, 36.6), 0.018 (0.024, 36.6), and 0.020 (0.027, 33.6) mg/kg.

Mann-Whitney U-test indicates that residues of quintozene from banded application and broadcast application were not significantly different. Therefore, the Meeting used the highest residue levels of quintozene from either banded or broadcast application in independent trials. Residues from independent trials were in rank order (n=7): 0.006, 0.008, 0.009, < 0.01, < 0.01, 0.024, and 0.026 mg/kg.

In a field rotational crop study with two applications each at 5.6 kg ai/ha, quintozene was detected above the LOQ of 0.005 mg/kg in lettuce from 30-day and 120-day PBI. The mean value was calculated using the residue data from all PBIs to be 0.0065 mg/kg (assuming that values < 0.005 mg/kg were at 0.005 mg/kg). After applying quintozene at 30 kg ai/ha, the highest maximum rate among available GAP, the mean residue in succeeding lettuce would be 0.017 mg/kg.

Adding 0.017 mg/kg, residue of quintozene from banded and broadcast application were: 0.023, 0.025, 0.026, < 0.027, < 0.027, 0.041 and 0.043 mg/kg.

The Meeting estimated a maximum residue level of 0.09 mg/kg for broccoli. The Meeting withdrew its previous recommendation of 0.05 mg/kg.

Cabbage, head

The critical GAP in the United States for cabbage (among the list of various Cole crops, but not for a group) is for one pre-plant banded soil application or broadcast application at 25 kg ai/ha.

The Meeting received 16 supervised trials conducted on cabbage in the United States during the growing season of 1987/88, 1988/89 and 1990/91.

In the trials, broadcast application and banded application of WP and GR formulations were used. There were also transplant solution applications.

Residues of quintozene from trials with banded application approximating the GAP in the United States were in rank order (n=15 including scaled residues): < 0.002, < 0.002, 0.002, 0.003, 0.003 (0.003,24.7), 0.007, 0.009 (0.009, /24.7), < 0.01, < 0.01, < 0.01, < 0.01, < 0.01, 0.010 (0.009, 22.4), 0.013 (0.013, 24.7) and 0.042 (0.038, 22.4) mg/kg.

Residues of quintozene from trials with broadcast application approximating the GAP in the United States were in rank order (n=15 scaled residue): < 0.002 (0.002, 33.6), < 0.002 (0.003, 33.6), < 0.002 (0.003, 33.6), 0.003 (0.004, 33.6), 0.004 (0.005, 33.6), 0.007 (0.009, 33.6), 0.008 (0.010, /33.6), 0.008 (0.011, 33.6), < 0.01, < 0.01, < 0.01, < 0.01, < 0.01 (0.013, 33.6), 0.022 (0.030, 33.6), and 0.028 (0.037, 33.6) mg/kg.

Mann-Whitney U-test indicates that residues of quintozene from banded application and broadcast application were not significantly different. Therefore, the Meeting used the highest residue levels of quintozene from either banded or broadcast application in independent trials. Residues from independent trials were in rank order (n=15): < 0.002, < 0.002, 0.003, 0.004, 0.007, 0.008 0.009, < 0.01, < 0.01, < 0.01, < 0.01, < 0.01, 0.013, 0.028 and 0.042 mg/kg.

In a field rotational crop study with two applications each at 5.6 kg ai/ha, quintozene was detected above the LOQ of 0.005 mg/kg in lettuce from 30-day and 120-day PBI, with the mean value of 0.0065 mg/kg calculated assuming that values < 0.005 mg/kg were at 0.005 mg/kg. After applying quintozene at 30 kg ai/ha, the highest maximum rate among available GAP, the mean residue in succeeding lettuce would be 0.017 mg/kg.

Adding 0.017 mg/kg, residues from independent trials according to GAP in the United States were: 0.019, 0.019, 0.020, 0.021, 0.024, 0.025, 0.026, 0.027, 0.027, 0.027, 0.027, 0.027, 0.030, 0.045 and 0.059 mg/kg.

The Meeting estimated a maximum residue level of 0.08 mg/kg for cabbages, head. The Meeting withdrew its previous recommendation of 0.1 mg/kg for cabbages, head.

Tomato

Critical GAP for tomato was from Mexico, for a single application of quintozene at a maximum rate of 14.4 kg ai/ha in nursery. No trials matching this GAP were available.

GAP for tomato in Thailand allows spraying to soil, immediately after planting young tomato plant and repeating spraying every 14 days at least two times at a maximum spray concentration of 1.50 kg ai/hL. No trials matching this GAP were available.

GAP in Ecuador for kidney tomato allows the use of quintozene in greenhouse at 0.56 kg ai/ha with a PHI of 1 day (number of applications not specified). No trials matching this GAP were available.

The Meeting therefore decided to withdraw the previous recommendation of 0.02 mg/kg for tomato.

Peppers

The critical GAP for chili peppers is in Mexico which allows a single application in nursery situations.

The Meeting received nine supervised trials conducted in the United States during the growing seasons of 1987/1988 and 1988/89. In the trials, quintozene was applied to soil at the time of planting and only in two trials chili peppers were grown and harvested.

The Meeting considered that the trials did not match the GAP in Mexico. The Meeting withdrew the previous recommendation of 0.05 (*)mg/kg for peppers, sweet. Consequently, the Meeting also withdrew the previous recommendations on dried chili peppers (0.1 mg/kg).

Beans with pods, Beans, shelled and Beans (dry)

Critical GAP for beans in Mexico allows a single application at 8.64 kg ai/ha as band application at the beginning of flowering.

The Meeting received 20 supervised trials on beans with pods, three trials on shelled beans, 13 trials on beans (dry) conducted in the United States. Except for three trials on beans with pods using in-furrow application, other trials used 4 or 3 post-emergence applications. Finite residues were found in four trials on beans with pods and five trials on beans (dry). The Meeting considered that these trials did not match the critical GAP and could not be used for estimating a maximum residue level.

For in-furrow application at planting, critical GAP was from Mexico that allows a single banded application of 1.44 kg ai/ha at sowing.

In three in-furrow trials, the application was made once at 1.68 kg ai/ha and beans with pod were sampled. Residues of quintozene from trials approximating this GAP were: < 0.0005, 0.017 and 0.074 mg/kg. Since there were only three trials, the Meeting considered the information was not sufficient for estimating a maximum residue level.

The Meeting withdrew its previous recommendations for common bean (pods and/or immature seeds) at 0.1 mg/kg and for common beans (dry) at 0.02 mg/kg.

Potato

For in-furrow applications, the critical GAP is from the United States, which allows one application of quintozene at the maximum rate of 5.6 kg ai/kg, sprayed as a 22-cm band in the seed furrow at planting.

The Meeting received 37 supervised trials conducted on potato in the United States using in-furrow application at rates 11.2–13.1 kg ai/ha.

Residues of quintozene from the in-furrow application approximating US GAP with scaling (scaling factors from 5.6/14.0–5.6/4.12) were (n=37): < 0.01, < 0.01, 0.013, 0.013, 0.015, 0.020, 0.037, 0.038, 0.049, 0.056, 0.064, 0.068, 0.073, 0.081, 0.090, 0.093, 0.095, 0.099, 0.10, 0.10, 0.14, 0.14, 0.15, 0.16, 0.16, 0.16, 0.17, 0.18, 0.20, 0.22, 0.27, 0.35, 0.36, 0.38, 0.39, 0.44 and 0.79 mg/kg.

For chemigation, the critical GAP of United States allows two applications at the maximum rate of 2.8 kg ai/ha with a PHI of 28 days.

The Meeting received eight supervised trials conducted on potato in the United States using two chemigation applications at a rate of 2.8 kg ai/ha each.

Residues of quintozene from the chemigation application matching the US GAP were (n=8): < 0.01, < 0.01, 0.011, 0.017, 0.019 (0.037, 5.6), 0.026, 0.039 and 0.080 mg/kg.

For broadcast application, cGAP in Mexico allows one application at the maximum rate of 30.0 kg ai/ha. PHI was not specified. Twenty independent trials were conducted in the United States. Residues of quintozene from independent trials using the broadcast application and matching the GAP in Mexico were (n=20): < 0.002, 0.007, 0.007, 0.009, 0.014, 0.018, 0.044, 0.048, 0.067, 0.070, 0.074, 0.078, 0.087, 0.098, 0.11, 0.12, 0.14, 0.15, 0.19 and 0.66 mg/kg.

Among these three data populations, residues from chemigation were significantly lower than the other two populations. Residues from in-furrow application and those from broadcast applications were different according to Mann-Whitney U-test. As the residues from in-furrow application would lead to a higher maximum residue level, using this data population, the Meeting estimated a maximum residue level of 0.8 mg/kg for potato.

Cotton seed

Critical GAP in South Africa for cotton allowed one application of quintozene into furrow at the maximum rate of 5.25 kg ai/kg.

The Meeting received 23 supervised trials conducted on cotton in the United States during the growing seasons of 1987 to 1992. The trials used in-furrow application at planting or in five trials banded soil application at planting at a rate of 2.24 kg ai/ha. Residues of quintozene from the trials with banded soil application at 2.24 kg ai/ha were all below the LOQ of 0.01 mg/kg. The maximum residue level of quintozene from in-furrow application at 2.24 kg ai/ha was 0.012 mg/kg. Since residue levels were below the LOQ in most of the trials, there were only 3 finite values for scaling up to the GAP rate in South Africa. The Meeting concluded that information was insufficient to estimate maximum residue level for cotton seed.

Therefore, the Meeting decided to withdraw the previously recommended maximum residue level of 0.01 (*) mg/kg for cotton seed.

Peanut

Critical GAP for peanuts was from Mexico, which allows a single banded application at a rate of 1.92 kg ai/ha at sowing.

The Meeting received 36 supervised trials conducted on peanut in the United States conducted during the growing seasons of 1987 to 1992. In all the trials in the United States, two applications with quintozene were made during pegging time. The Meeting concluded that the trials did not match this GAP and decided to withdraw the previous recommendation of 0.5 mg/kg for peanut.

Residues arising from crop rotation

In a field rotational crop study using two applications of 5.6 kg ai/ha, quintozene was detected above the LOQ of 0.005 mg/kg in lettuce. Residues of quintozene were expected to occur in leafy vegetables and Brassica vegetables from crop rotation. Residues found from 30, 120 and 365-day PBI were: < 0.005 × 15, 0.053, 0.075, 0.0080, 0.0096, 0.0120, 0.0126 and 0.0133 mg/kg.

The critical maximum seasonal rate according to the available GAP is 30 kg ai/ha (Mexico). Finite residues were scaled to the rate of 30 kg ai/kg using the scaling factor of 30/11.2: 0.014, 0.020, 0.021, 0.026, 0.032, 0.034 and 0.037 mg/kg. Assuming that residues < 0.005 mg/kg were at 0.005 mg/kg, scaled residue of < 0.005 mg/kg would be 0.013 mg/kg

The Meeting estimated a maximum residue level of 0.08 mg/kg for a group of leafy vegetables and a group of Brassica vegetables (except Brassica leafy vegetables) (except broccoli and cabbage).

Fate of residues during processing

No information was available on high temperature hydrolysis.

Processing

The Meeting received information on residues in edible portions of potato and peanut, and processing of tomato, green beans, potato, cotton seed and peanut to various processed commodities.

Processing factors of quintozene for potato, for which maximum residue level was estimated, to its processed commodities potato are shown below.

Table 103 Potato processing factors

Commodity	n	Processing factor for quintozene	
		Individual	Best estimate
Potato		-	
Wet peel	8	2.0, 3.3, 5.6, 5.8, 7.6, 10, 11, 13	6.7
Dried peel	8	2.3, 13, 13, 14, 25, 16, 65, 75	19.5
Peeled potato	4	0.06, 0.10, 0.10, 0.14	0.10
French fries	2	1.9, 2.8	2.35
Crisps	10	0.13, 0.16, 0.23, 0.47, 0.80, 0.99, 1.3, 1.7, 1.8, 1.9	0.90
Dried flakes	2	0.14, 0.18	0.16
Flakes	8	0.02, 0.04, 0.04, 0.06, 0.06, 0.07, 0.09, 0.10,	0.06
Granules	8	0.00, 0.00, 0.01, < 0.02, < 0.02, < 0.02, 0.02, 0.04	0.02

Residues in animal commodities

Livestock feeding studies on lactating cows and laying hens were provided. However, due to the lack of full validation data on the analytical methods used, it was not possible to use the data for evaluation. Therefore, it was not possible to estimate maximum residue levels for animal commodities.

The Meeting withdrew its previous recommendations on chicken commodities: 0.1(*) mg/kg (fat) for chicken meat, 0.01(*) mg/kg for chicken, edible offal of, and 0.03 (*) mg/kg in eggs.

RECOMMENDATIONS

On the basis of the data from supervised trials, the Meeting agreed to the following residue definition.

Definition of the residue for compliance with the MRL for plant commodities: *Quintozene*.

The Meeting was unable to establish residue definition for compliance with MRLs for animal commodities.

The Meeting was also unable to reach a conclusion on residue definition for dietary risk assessment for plant and animal commodities. due to concern that exposure would exceed the TTC for genotoxicity of all the metabolites.

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The Meeting confirmed an ADI of 0–0.01 mg/kg for quintozene and ARfD was unnecessary.

As the Meeting was unable to conclude on the toxicological relevance of all the metabolites, the Meeting could not reach a conclusion on a residue definition for dietary risk assessment. As a result, long-term dietary exposure assessments could not be conducted.

Threshold of toxicological concern (TTC) consideration for metabolites

The Meeting noted that possibilities of genotoxicity could not be excluded from all the metabolites. They could be assessed using the TTC approach for genotoxicity (threshold of 0.0025 µg/kg bw per day for genotoxic compounds).

In one potato metabolism study and one confined rotational crop study, numerous non-polar and polar metabolites were identified. However, the percentage of identified radioactivity in confined rotational crop studies was relatively low mostly below 50 percent of TRR, except that in turnip roots about 80 percent TRR was identified. In a field rotational crop study, quintozene, PCA, PCTA, TCA TCTASOO and PCTASO, PB and HCB were analysed, among which quintozene, PCA and TCA were detected in food commodities.

PCA and PCTA were also analysed in supervised residue trials provided to the Meeting.

Dietary exposure was calculated for a number of the metabolites using the rotational crop studies and the IEDI spreadsheet and compared with the threshold of 0.0025 µg/kg bw per day. The calculated exposure may be underestimated due to the low percentage of identification. For the metabolites calculated, TTC for genotoxic compounds was exceeded. Two examples are shown below.

1. PCA

PCA was detected in many of metabolism studies and confined rotational crop studies. PCA concentrations in the extracts in the confined rotational crop studies were scaled from the application rates used in the studies to the highest possible application rate of 30 kg ai/ha.

PCA was detected in turnip roots and lettuce at 0.023–0.155 mg/kg and 0.018–0.12 mg/kg, respectively, after scaling.

Using the lowest quantified concentrations, the calculated chronic exposure from root and tuber vegetables, leafy vegetables and Brassica vegetables were in a range of 0.063–0.24 ug/kg bw, higher than the TTC for genotoxic compounds (0.0025 ug/kg bw).

2. TCA

TCA was detected in the field rotational crop study in turnip root at < 0.005–0.010 mg/kg. Since in the study the application rate was 2 × 5.6 kg ai/ha, while the highest possible application rate was 30 kg ai/ha, the Meeting applied the proportionality principle to scale up the residues. The scaled finite residues were: 0.0134, 0.0169, 0.190 and 0.0279 mg/kg. TCA was < 0.005 mg/kg in other rotated crops and not detected in confined rotational crop studies.

Using the lowest quantified residue after scaling, the calculated chronic exposure from root and tuber vegetables were in a range of 0.021–0.15 µg/kg bw, higher than the TTC for genotoxic compounds (0.0025 ug/kg bw).

The Meeting concluded that the chronic dietary exposure of many of metabolites arising from uses of quintozene considered by the Meeting exceeded the TTC for genotoxic compounds of 0.0025 µg/kg bw/day and they may present a public health concern.

SPIROMESIFEN (294)

The first draft was prepared by Dr Chris Anagnostopoulos, Benaki Phytopathological Institute, Greece

EXPLANATION

Spiromesifen is a contact insecticide-acaricide belonging to the titronic acid class of compounds. The mode of action is inhibition of lipid biosynthesis, especially triglycerides and free fatty acids.

Spiromesifen was first evaluated by the 2016 JMPR where an ADI of 0–0.03 mg/kg bw was established and an ARfD was determined to be unnecessary. The residue definition for compliance with MRLs for plant and animal commodities and for dietary risk assessment for animal commodities is sum of spiromesifen and spiromesifen-enol, expressed as spiromesifen. For dietary risk assessment for plant commodities, the residue definition is sum of spiromesifen, spiromesifen-enol and 4-hydroxymethyl-spiromesifen-enol (free and conjugated), expressed as spiromesifen. The residue is fat-soluble.

Spiromesifen was scheduled at the Fifty-second Session of the CCPR for evaluation of additional uses by the 2022 JMPR. The Meeting received information on GAP, analytical methods, storage stability data, processing studies and residue trials on oranges, mango, papaya, legume vegetables and pulses.

RESIDUE ANALYSIS

Analytical methods

Method 00631 was evaluated by the 2016 JMPR and successfully validated in high water content (broccoli, cucumber, pepper, melon, beans and tomato), high starch content (corn/maize, sugar beet), high oil content (cotton), high acid content (strawberry) commodities and tea. Additional method validation data are available as part of the supervised residue trials relied upon in this submission, these data are summarised in Table 1. The initial method did not use a clean-up step if analysis was occurring using HPLC -MS/MS (due to high sensitivity of the instrument used). Modifications to the Method 00631, resulting in Method 00631/M001, were the inclusion of the clean-up step regardless of the instrumentation being used, with the addition of the deuterated internal standard occurring.

Method BS001-P09-01 is a modification of analytical method 00631. The method was evaluated by the 2016 JMPR and successfully validated in high starch content commodities (wheat: grain, aspirated grain fractions, bran, flour, germ, middling's, shorts; and sorghum: grain and aspirated grain fractions). Additional method validation data for the modified method BS001-P09-02 are available as part of the citrus fruit and soybean supervised residue trials relied upon in this submission and are summarised in Table 1.

Method BS001-P09-02

An analytical method was developed to determine the residues of BSN2060 (spiromesifen) and BSN2060-enol (spiromesifen-enol) in crop matrices. This analytical method encompasses minor modifications and best practices adopted since the original analytical method (Method 00631) was developed.

Spiromesifen and spiromesifen-enol residues were extracted from all orange matrices except oil by blending with an acetonitrile/water mixture (4/1, v/v) as the extraction solvent. The extract was filtered into a centrifuge tube. The filtered solids were washed with an additional aliquot of acetonitrile/water (4/1, v/v) and the solvent was added to the extract. The extract was amended with

stable isotopically labelled internal standards. A 0.5 mL aliquot of the extract was transferred to a HPLC vial and diluted with 0.75 mL of water. The samples were analysed by high performance liquid chromatography/tandem mass spectrometry (LC/MS/MS).

For the orange oil, a 0.5 g aliquot of sample was diluted with acetone and vortexed to mix. The extract was amended with stable isotopically labelled internal standards and further diluted with acetonitrile and mixed. An aliquot of the extract was purified by passing through tandem C18 cartridges, evaporated to dryness, and reconstituted in ACN/water (1:1) and analysed by LC/MS/MS.

The method was successfully validated by analysis of blank untreated control (UTC) orange whole fruit samples and blank untreated control (UTC) orange processed samples fortified with 0.010 ppm of BSN2060 and BSN2060-enol. Additionally, blank untreated control (UTC) orange oil samples fortified with 0.10 and 0.50 ppm of BSN2060 and BSN2060-enol were validated. These data support a method limit of quantitation (LOQ) of 0.010 ppm for BSN2060 and BSN2060-enol in orange fruit and all orange-processed commodities except oil, and an LOQ for both analytes of 0.1 ppm in orange oil. The LOQ is the lowest fortification level at which acceptable recovery was achieved.

The calibration was validated for spiromesifen (BSN2060) and BSN2060-enol with linear response in solvent over the range of 0.0050 ppm to 1.0 ppm, in parent equivalents (solution concentrations equivalent to 0.00020 to 0.040 µg/mL) ($R^2 \geq 0.99$). This validation was carried out alongside the analysis of residues in orange processed commodities. As part of this study procedural recoveries were carried out for whole fruit and processed commodities at the LOQ (n = 3-7) and a higher level (n = 4-5). These results are summarised in Table 1.

Table 1 Summary of validation data for methods BS001-P09-01, BS001-P09-02 and 00631

Notes:

[a] Fortification values were often given in the reports expressed as analyte – here the fortification levels are expressed as parent spiromesifen – were appropriate, values have been calculated using a molecular weight correction factor of 1.36 (derived from the respective molecular weights of spiromesifen (370.5 g/mol) and spiromesifen-enol (272.3 g/mol))

STABILITY OF RESIDUES IN STORED ANALYTICAL SAMPLES

The Meeting received additional data on the storage stability of spiromesifen and spiromesifen-enol under frozen conditions (Sarti, A., 2016, M-553911-01-2).

The stability of total residues (sum of spiromesifen and spiromesifen-enol) on dry bean, coffee beans and citrus fruit is submitted for evaluation and summarised below. In this study, samples of dry

bean, coffee and citrus fruit were homogenised and fortified at 0.1 mg/kg with spiromesifen and Spiromesifen-enol, before being stored at <-18 °C for approximately 24 months. Samples were analysed at appropriate intervals using the validated analytical method 00631. Analysis of the samples showed that there also appeared to be a conversion of spiromesifen to spiromesifen- enol; up to 80 percent until 741 days of storage for dry bean samples and up to 27 percent until 755 days of storage for coffee samples. This conversion was not observed for citrus samples up to 728 days. Nevertheless, after a storage period of 24 months under deep-freezer conditions, the total residues of spiromesifen and spiromesifen-enol were well recovered from all matrices tested. Storage stability data on dry bean, coffee and citrus area summarised in Tables 2 to 10 below.

Table 2 Storage Stability Data for Spiromesifen in Dry bean (seed)

Sample Material	Storage Period [days]	Residue Level in Stored Samples				Day-0 Normalized Recovery [%][a]	Average of Fresh Concurrent Recoveries [%]	Average Corrected Recovery [%][b]
		mg/kg (ppm)	% of nominal spiking level	Average recovery [%]	RSD [%]

Notes:

[1]For false spider mite, sample on a periodic basis and apply when the presence of mites is found in 3% of fruits or branches examined. For citrus rust mite, sample on a periodic basis and apply when the presence of mites is found in 20 to 30 mites/cm^2 in 5% of fruits examined.

[2]Applications must be started soon after crop emergence or transplantation, according to monitoring of leaves and inflorescences, early in the infestation.

[3]Lupinus spp., includes grain lupin, sweet lupin, white lupin, and white sweet lupin; Phaseolus spp., includes: field bean, kidney bean, lima bean, navy bean, pinto bean, runner bean, snap bean, tepary bean, wax bean; Vigna spp., includes: adzuki bean, asparagus bean, blackeyed pea, catjang, Chinese longbean, cowpea, Crowder pea, moth bean, mung bean, rice bean, southern pea, urd bean, yardlong bean; broad bean (fava), chickpea (garbanzo bean), guar, jackbean, lablab bean (hyacinth bean), lentil, soybean (immature seed), sword bean.

[4]For broad mite, the application must be made early in the infestation, when the first forms of pest development are seen in monitoring. For white fly, monitor and start applications early in the infestation, when the presence of eggs, first "nymphs" or young forms is found, or 7-10 days after crop emergence with the presence of the pest. The lowest dose must be used in preventive applications, i.e., when the occurrence of the pest is anticipated in the crop, however, it is not present yet in the crop. The highest dose must be used under higher pressure conditions or when there is a history of pest occurrence. In case of reinfestation, re-apply within a 5-7-day interval.

[5]For two-spotted spider mite, the application must be made early in the infestation, when the first forms of pest development are seen in monitoring. For white fly, monitor and start applications early in the infestation, when the presence of eggs, first "nymphs" or young forms is found. The lowest dose must be used in preventive applications, i.e., when the occurrence of the pest is anticipated in the crop, however, it is not present yet in the crop. The highest dose must be used under higher pressure conditions or when there is a history of pest occurrence. In case of reinfestation, re-apply within a 5-7-day interval.

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received residue trials on oranges, mango, papaya, legume vegetables and pulses. The detailed information is summarised below.

Citrus fruit

A total of 13 supervised trials were carried out on oranges in Brazil during 2015-2018 (Ref: M-571855-02-1, M-627001-01-1 and M-764414-01-1). Each trial consisted of 2 plots; a control untreated plot and a plot treated with a single broadcast spray application of an SC (suspension concentrate formulation) containing 230–240 g ai/L. Each treated plot received a single application at a nominal rate of 144 g ai/ha. No adjuvants were added to the formulation prior to application.

Samples of fruit were collected from all trials 21 days after the last application. Samples were also collected from 11 trials at 7, 14, 27-28 and 33-37 days after the last application, to provide residue decline data. Whole fruits were collected and placed into frozen storage.

Samples were maintained frozen at <-20 °C for a maximum of 302 days (*ca* 10 months) prior to analysis. The storage stability of spiromesifen residues has been sufficiently investigated (see Section 4.0), therefore, it can be assumed that residues (sum of spiromesifen and its metabolites) were stable when analysed.

Residues of spiromesifen and its metabolite spiromesifen-enol were determined by LC- MS/MS, using the validated analytical method 00631 (study M-571855-02-1 and M-764414-01-1) or method BS001-P09-01 (M-627001-01-1). These methods have been validated with an LOQ of 0.01 mg/kg for both analytes (expressed as analyte, resulting in an LOQ of 0.014 mg/kg for spiromesifen-enol, expressed as spiromesifen). Procedural recoveries carried out concurrently with the analyses of trial samples showed recoveries were within the acceptable range of 70–120 percent, with relative standard deviation <20 percent. The results of the trials are presented in Table 12 below. Two of the trials were co-located, in these cases the highest value has been selected for MRL calculations.

Table 12 Residue concentration of spiromesifen from residue trials on oranges in Brazil

Study, Trial Country, Year, Location (Variety)	Application					PHI (days)	Commodity	Residues (mg/kg)			Reference

Notes:

(1) Mean residue values from duplicate samples presented in parenthesis.

Mango

A total of five supervised trials were carried out on mango in Brazil during 2019 (M-675094-01-1). Each trial consisted of 2 plots; a control untreated plot and a plot treated with broadcast spray applications of

Oberon® 2 SC (a suspension concentrate formulation containing 240 g ai/L). Each plot received 3 applications at a nominal rate of 144 g ai/ha, applications were made with an interval of 7 days. No adjuvants were added to the formulation prior to application. For the five trials, two were conducted in Petrolina region (007SRBR18R03-01 and 007SRBR18R03-02) and two in Juazeiro region (007SRBR18R03-04 and 007SRBR18R03-05), however trials are more than 20 km from one another and different varieties were used, thus can be considered as independent.

Samples of mango were collected from all trials 5 days after the 1st application, 5 days after the 2nd application and then 3, 5, 7, 10 and 14 days after the last application. After collection of whole fruit, the stones were removed and samples separated into peel and pulp fractions, before being placed into frozen storage.

Samples were maintained frozen at <-20 °C for a maximum of 150 days (*ca* 5 months) prior to analysis. The storage stability of spiromesifen residues has been sufficiently investigated (see Stability section), therefore, it can be assumed that residues (sum of spiromesifen and its metabolites) were stable when analysed.

Residues of spiromesifen and its metabolite spiromesifen-enol were determined by LC- MS/MS, using the validated analytical method 00631. The method has been validated with an LOQ of 0.01 mg/kg for both analytes (expressed as analyte, resulting in an LOQ of 0.014 mg/kg for spiromesifen-enol, expressed as spiromesifen). Procedural recoveries carried out concurrently with the analyses of trial samples showed recoveries were within the acceptable range of 70–120 percent, with relative standard deviation <20 percent. The results of the trials are presented in Table 13 below.

Table 13 Residue concentration of spiromesifen from residue trials on mangoes in Brazil

Notes:

(1) – mean residue values from duplicate samples presented in parenthesis

(2) - For whole fruit samples, the stones were not analysed but the residue level is calculated assuming that they are included but contain no residue. For this, a conversion factor is calculated from the mass of the whole fruit and the mass of fruit without stone according to the equation that follows: CF = Mass without stone/Mass without fruit; The concentration of the whole fruit is calculated using the conversion factor as follows: Reportable values (mg/kg) = concentration x CF

DAA1 – Days after application 1

DAA2 – Days after application 2

Papaya

A total of five supervised trials were carried out on papaya in Brazil during 2017 (M-632116-01-1). Each trial consisted of 2 plots, a control untreated plot and a plot treated with broadcast spray applications of Oberon (a suspension concentrate formulation containing 240 g ai/L). Each plot received 3 applications at a nominal rate of 144 g ai/ha, applications were made with an interval of 7 days. No adjuvants were added to the formulation prior to application.

Samples of papaya were collected from all trials 3, 5, 7, 10 and 14 days after the last application. After collection, samples of fruit were placed into frozen storage.

Samples were maintained frozen at <-20 °C for a maximum of 212 days (*ca* 7 months) prior to analysis. The storage stability of spiromesifen residues has been sufficiently investigated (see Stability section), therefore, it can be assumed that residues (sum of spiromesifen and its metabolites) were stable when analysed.

Residues of spiromesifen and its metabolite spiromesifen-enol were determined by LC- MS/MS, using the validated analytical method 00631. The method has been validated with an LOQ of 0.01 mg/kg for both analytes (expressed as analyte, resulting in an LOQ of 0.014 mg/kg for spiromesifen-enol, expressed as spiromesifen). Procedural recoveries carried out concurrently with the analyses of trial samples showed recoveries were within the acceptable range of 70–120 percent, with relative standard deviation <20 percent. The results of the trials are presented in Table 14 below.

Beans with pods

A total of 8 supervised trials were carried out on beans with pods in the United States during 2005 (Ref: M-282963-01-1). Each trial consisted of 2 plots; a control untreated plot and a plot treated with a broadcast spray application of Oberon® 2 SC (a suspension concentrate formulation containing 2 lb ai/gal, equivalent to 240 g ai/L). Each treated plot received 3 applications at a nominal rate of 0.19 lb ai/A (equivalent to 213 g ai/ha), applications were made with an interval of 6–14 days. In one trial, two additional applications were made at approximately 213 g ai/ha. No adjuvants were added to the formulation prior to application.

Samples of beans with pods and bean foliage (vines) were collected from all trials 1 day after the last application. Foliage samples were shaken to minimize the inclusion of loose soil in the samples. Additional samples of beans in pods were collected from 1 trial 3, 7, 10 and 14 days after the last application to provide residue decline data. All samples were then placed into frozen storage.

Samples were maintained frozen at <-20 °C for a maximum of 498 days (*ca* 16 months) prior to analysis. The storage stability of spiromesifen residues has been sufficiently investigated (see Section 4.0), therefore, it can be assumed that residues (sum of spiromesifen and its metabolites) were stable when analysed.

Residues of spiromesifen and its metabolite spiromesifen-enol were determined by LC-MS/MS, using the validated analytical method 00631. The method has been validated with an LOQ of 0.05 mg/kg for both analytes (expressed as analyte, resulting in an LOQ of 0.07 mg/kg for spiromesifen-enol, expressed as spiromesifen). Procedural recoveries carried out concurrently with the analyses of trial samples showed recoveries were generally within the acceptable range of 70–120 percent, with relative standard deviation <20 percent. The results of the trials are presented in Table 15 below. Two of the trials were co-located in Wooster, OH, therefore the highest residue value from this location has been selected for MRL calculations.

Notes:

(1) – mean residue values from duplicate samples presented in parenthesis

(2) – where applicable

(3) – Trial received an additional 2 applications to allow the crop time to mature – since the terminal residue in seed with pod is less than in all other trials it is clear that the additional 2 applications do not affect the terminal residue – the trial is considered acceptable and residues have been scaled according to total application rate

Beans without pods

A total of seven supervised trials were carried out on beans without pods in the United States during 2005 (Ref: M-282963-01-1). Each trial consisted of 2 plots; a control untreated plot and a plot treated with a broadcast spray application of Oberon® 2 SC (a suspension concentrate formulation containing 2 lb ai/gal, equivalent to 240 g ai/L). Each treated plot received 3 applications at a nominal rate of 0.19 lb ai/A (equivalent to 213 g ai/ha), applications were made with an interval of 6–14 days. No adjuvants were added to the formulation prior to application.

Samples of beans and bean foliage (vines) were collected from all trials 1 day after the last application. Foliage samples were shaken to minimise the inclusion of loose soil in the samples. All samples were then placed into frozen storage.

Samples were maintained frozen at <-20 °C for a maximum of 468 days (*ca* 15 months) prior to analysis. The storage stability of spiromesifen residues has been sufficiently investigated (see Section 4.0), therefore, it can be assumed that residues (sum of spiromesifen and its metabolites) were stable when analysed.

Residues of spiromesifen and its metabolite spiromesifen-enol were determined by LC-MS/MS, using the validated analytical method 00631. The method has been validated with an LOQ of 0.05 mg/kg for both analytes (expressed as analyte, resulting in an LOQ of 0.07 mg/kg for spiromesifen-enol, expressed as spiromesifen). Procedural recoveries carried out concurrently with the analyses of trial samples showed

recoveries were generally within the acceptable range of 70–120 percent, with relative standard deviation <20 percent. The results of the trials are presented in Table 16 below.

Dry beans

A total of 10 supervised trials were carried out on dry shelled beans in the United States during 2005 (Ref: M-282963-01-1). Each trial consisted of 2 plots; a control untreated plot and a plot treated with a broadcast spray application of Oberon® 2 SC (a suspension concentrate formulation containing 2 lb ai/gal, equivalent to 240 g ai/L). Each treated plot received 3 applications at a nominal rate of 0.19 lb ai/A (equivalent to 213 g ai/ha), applications were made with an interval of 6–14 days. No adjuvants were added to the formulation prior to application. One trial (05-ID15) received an additional 4th application in error, and another trial (05-CO16) received 3 applications that were approximately 13–14 percent over the target rate.

Samples of beans were collected from all trials 9–10 days after the last application. The beans were dried on the vine or in the field after the plants were pulled. Dry beans were then shelled by hand or *via* a mechanical thresher or sheller, and then the dry, shelled beans were placed into frozen storage.

Samples were maintained frozen at <-20 °C for a maximum of 346 days (*ca* 11 months) prior to analysis. The storage stability of spiromesifen residues has been sufficiently investigated (see Section 4.0), therefore, it can be assumed that residues (sum of residues of spiromesifen and its metabolites) were stable when analysed.

Residues of spiromesifen and its metabolite spiromesifen-enol were determined by LC- MS/MS, using the validated analytical method 00631. The method has been validated with an LOQ of 0.01 mg/kg for both analytes (expressed as analyte, resulting in an LOQ of 0.014 mg/kg for spiromesifen-enol, expressed as spiromesifen). Procedural recoveries carried out concurrently with the analyses of trial samples showed recoveries were generally within the acceptable range of 70–120 percent, with relative standard deviation <20 percent. These low recoveries for parent spiromesifen are consistent with the conversion of parent into the enol metabolite occurring in dry bean, as demonstrated in the storage stability study of Sarti (2016).

The results of the trials are presented in Table 17 below. Eight of the trials were co- located, in 4 different locations, in these cases the highest value from each location has been selected for MRL calculations.

Soya bean

A total of nine supervised trials were carried out on soybeans (dry) in Brazil during 2016 (Ref: M-600100-01-1). Each trial consisted of 2 plots; a control untreated plot and a plot treated with a broadcast spray application of Oberon 240 SC (a suspension concentrate formulation containing 240 g ai/L). Each treated plot received 2 applications at a nominal rate of 144 g ai/ha, applications were made with an interval of 5 days. No adjuvants were added to the formulation prior to application.

Samples of soybeans (dry seed) were collected from all trials 21 days after the last application. Additionally, at five trial sites samples were collected 6–7, 13–14, 26–28 and 34–35 days after the last application. All samples were placed into frozen storage.

Samples were maintained frozen at <-20 °C for a maximum of 263 days (*ca* 9 months) prior to analysis. The storage stability of spiromesifen residues has been sufficiently investigated (see Section 4.0), therefore, it can be assumed that residues (sum of spiromesifen and its metabolites) were stable when analysed.

Residues of spiromesifen and its metabolite spiromesifen-enol were determined by LC- MS/MS, using the validated analytical method BS001-P09-01. The method has been validated with an LOQ of 0.01 mg/kg for both analytes. Procedural recoveries carried out concurrently with the analyses of trial samples showed recoveries were within the acceptable range of 70–120 percent, with relative standard deviation <20 percent. The results of the trials are presented in Table 18 below.

FATE OF RESIDUES IN STORAGE AND IN PROCESSING

In Storage

Further data were not provided.

In Processing

Three processing studies for orange and one for soybeans were provided, investigating the fate of residues in processed commodities.

Oranges Study 1

The processing of oranges to dried pulp, oil, juice, raw juice and marmalade was performed in two field residues trials carried out in the United States (Ref: M-635467-01-1).

Each trial consisted of two plots; a control untreated plot, and a plot treated with a single airblast application of Oberon 240 SC (a suspension concentrate formulation containing 240 g spiromesifen/L). The test substance was applied to orange trees (BBCH 83–89) at an exaggerated rate of approximately 720 g ai/ha, with an application volume of approximately 1800–2200 L/ha. Samples of mature oranges were harvested 2 days after the last application, samples of RAC (oranges whole fruit, unwashed) were placed in frozen storage and an additional bulk sample was shipped at ambient temperature to the processing facility. Oranges were processed using processes representative of industrial practices into dried pulp, oil, juice, raw juice and marmalade. Samples of the RAC and processed commodities were stored frozen prior to analysis for a maximum of 253 days (*ca* 8 months).

Residues of spiromesifen and spiromesifen-enol were determined by LC-MS/MS using the validated analytical method BS001-P09-02. The method was validated with an LOQ of 0.01 mg/kg for all matrices, with the exception of orange oil, which has an LOQ of 0.1 mg/kg (expressed as spiromesifen). Procedural recoveries carried out concurrently with the analyses of trial samples were within the range of 70–120 percent, with relative standard deviation of <20 percent.

The results of the trials are presented in Table 19 below. These results indicate that residues of total spiromesifen only concentrate when oranges are processed into orange oil, in all other processed commodities a dilution of residues was observed.

							Oil	31.8, 33.4, 32.2 (32)	<0.1, <0.1, <0.1 (<0.1)	32.9, 33.5, 32.3 (33.1)	183

Notes:

Values are reported to 3 significant figures where possible.

Mean values are presented in parenthesis.

For orange whole fruit RAC, the results are individual analyses of three separate samples. For the other processed commodities, the results are three analyses of a single sample.

Oranges Study 2

The processing of oranges to peel (washed), pulp, juice, oil, pomace (wet and dry), dry pulp and marmalade was performed in two field residues trials carried out in the United States (Ref: M-762109-03-1).

Each trial consisted of three plots; a control untreated plot, and two plots treated with two airblast applications of Oberon Speed (an SC formulation containing 228.6 g spiromesifen/L). The test substance was applied at an exaggerated rate of approximately 875 g ai/ha (plot TRTHI) or 525 g ai/ha (plot TRTLO), applications were made to orange trees at BBCH 83 with an interval of 10 days, with an application volume of approximately 2000–2500 L/ha. An adjuvant, crop oil concentrate (COC), was used in all applications at a rate of 1.0 percent v/v. The plot TRTLO was conducted as a reserve, however this was later not needed and therefore fruit were not harvested from this plot.

Samples of mature oranges (BBCH 83–85) were harvested from in each trial 7 days after the last application, samples of RAC (oranges whole fruit, unwashed) were placed in frozen storage and an additional bulk sample was shipped at ambient temperature to the processing facility. Oranges were processed using processes representative of industrial practices into washed fruit, peel (unwashed and washed), pulp, pasteurized juice, oil, pomace (wet and dry), dried pulp and marmalade. Samples of the

RAC and processed commodities were stored frozen prior to analysis for a maximum of 391 days (*ca* 13 months).

Residues of spiromesifen and spiromesifen-enol were determined by LC-MS/MS using the validated analytical method BS001-P09-02. The method was validated with an LOQ of 0.01 mg/kg for all matrices, with the exception of orange oil, which had an LOQ of 0.5 mg/kg in this study (expressed as spiromesifen). Procedural recoveries carried out concurrently with the analyses of trial samples were within the range of 70–120 percent, with relative standard deviation of <20 percent.

The results of the trials are presented in Table 20 below. These results indicate that residues of total spiromesifen concentrate when oranges are processed into orange oil, peel (washed and unwashed), dry pulp and pomace (wet and dry). In all other processed commodities, a dilution of residues was observed.

Table 20 Summary of spiromesifen residues in processed oranges from study M-762109-03-1

Notes:

Values are reported to 3 significant figures where possible

Mean values are presented in parenthesis

For whole fruit samples (RAC and washed), the results are individual analyses of three separate samples. For the other processed commodities, the results are three analyses of a single sample.

Oranges Study 3

The processing of oranges to juice was performed in four field residues trials carried out in Brazil (Ref: M-754191-01-1).

Each trial consisted of two plots; a control untreated plot, and a plot treated with a single airblast application of Oberon 240 SC (a suspension concentrate formulation containing 240 g spiromesifen/L). The test substance was applied to orange trees (BBCH 83–89) at a nominal rate of approximately 144 g ai/ha, with an application volume of approximately 2000 L/ha. Samples of mature oranges were harvested 1, 3, 7, 14 and 21 days after the last application. Analysis of both the RAC and the processed juice was only carried out on days 1 and 3, therefore the processing values derived from these have been presented here. Samples of RAC (oranges whole fruit) were processed into raw juice at the test site and stored frozen (<-20 °C) prior to analysis.

Samples of the RAC and processed commodities were stored frozen prior to analysis for a maximum of 98 days (*ca* 3 months).

Residues of spiromesifen and spiromesifen-enol were determined by LC-MS/MS using the validated analytical method 00631, as described in Section 3.1 of this document. The method was validated with an LOQ of 0.01 mg/kg for all matrices (expressed as analyte, resulting in an LOQ of 0.014 mg/kg for spiromesifen-enol, expressed as spiromesifen). Procedural recoveries carried out concurrently with the analyses of trial samples were within the range of 70–120 percent, with relative standard deviation of <20 percent.

The results of the trials are presented in Table 21 below. These results indicate that residues of total spiromesifen are diluted when oranges are processed into orange juice.

Notes:

Values are reported to 2 significant figures where possible.

Soya beans

The processing of soya beans to aspirated grain fractions, meal, hulls, flour, milk, solvent extracted RBD (refined, bleached and deodorized) oil and cold-pressed RBD oil was performed in two field residues trials carried out in the United States (Ref: M-631397-01-1).

Each trial consisted of two plots; a control untreated plot, and a plot treated with two spray applications of Oberon 240 SC (a suspension concentrate formulation containing 240 g spiromesifen/L). The test substance was applied to soya bean crop at BBCH 78–79 at an exaggerated rate of approximately 720 g ai/ha, with an application volume of approximately 200–300 L/ha. Samples of mature soya beans were harvested 21 days after the last application and shipped frozen to the processing facility. Soya beans were processed using processes representative of industrial practices into aspirated grain fractions, flour, hulls, meal, milk, solvent extracted RBD oil and cold-pressed RBD oil.

Samples of the RAC and processed commodities were stored frozen prior to analysis for a maximum of 339 days (*ca* 11 months).

Residues of spiromesifen and spiromesifen-enol were determined by LC-MS/MS using the validated analytical method BS001-P09-01. The method was validated with an LOQ of 0.01 mg/kg for all matrices, with the exception of aspirated grain fractions, which has an LOQ of 1.0 mg/kg (expressed as spiromesifen). Procedural recoveries carried out concurrently with the analyses of trial samples were within the range of 70–120 percent, with relative standard deviation of <20 percent.

The results of the trials are presented in Table 22 below. These results indicate that residues of total spiromesifen concentrate when soya beans are processed into aspirated grain fractions and hulls. In all other processed commodities, a dilution of residues was observed.

Notes:

(a) – Mean of 6 analysis.

Values are reported to 3 significant figures where possible.

Mean values are presented in parenthesis.

For soya bean seed samples (RAC), the results are individual analyses of three separate samples. For the processed commodities, the results are three (or six) analyses of a single sample.

APPRAISAL

Spiromesifen is a contact insecticide-acaricide belonging to the titronic acid class of compounds. The mode of action is inhibition of lipid biosynthesis, especially triglycerides and free fatty acids.

Spiromesifen was first evaluated by the 2016 JMPR where an ADI of 0–0.03 mg/kg bw was established and an ARfD was determined to be unnecessary. The residue definition for compliance with MRLs for plant and animal commodities and for dietary risk assessment for animal commodities is *sum of spiromesifen and spiromesifen-enol, expressed as spiromesifen*. For dietary risk assessment for plant commodities, the residue definition is *sum of spiromesifen, spiromesifen-enol and 4-hydroxymethyl-spiromesifen-enol (free and conjugated), expressed as spiromesifen*. The residue is fat-soluble.

Spiromesifen was scheduled at the Fifty-second Session of the CCPR for evaluation of additional uses by the 2022 JMPR. The Meeting received information on GAP, analytical methods, storage stability data, processing studies and residue trials on oranges, mango, papaya, legume vegetables and pulses.

Methods of analysis

The Meeting received additional information on analytical methods for spiromesifen and spiromesifen-enol in plant commodities for data gathering.

LC-MS/MS method 00631 was evaluated by the 2016 JMPR and successfully validated in high water content (broccoli, cucumber, pepper, melon, beans, tomato), high starch content (corn/maize, sugar beet), high oil content (cotton), high acid content (strawberry) commodities and tea. Additional method validation data for the modified method 00631/M001 are available as part of the supervised residue trials relied upon in this submission. The Meeting concluded that this method is valid for the determination of spiromesifen and spiromesifen-enol with LOQ values at 0.01 mg/kg in mango, dry beans and at 0.05 mg/kg in succulent shelled beans and edible podded beans for each compound individually.

Another LC-MS/MS method BS001-P09-01, a modification of analytical method 00631, was evaluated by the 2016 JMPR and successfully validated in high starch content commodities (wheat: grain, aspirated grain fractions, bran, flour, germ, middling's, shorts; and sorghum: grain and aspirated grain fractions). Additional method validation data for the modified method BS001-P09-02 are available as part of the supervised residue trials relied upon in this submission. The Meeting concluded that this method is valid for the determination of spiromesifen and spiromesifen-enol with LOQ values at 0.01 mg/kg in orange whole fruit, pomace, dry pulp, juice, marmalade, peel, wet pulp and at 0.10 mg/kg in orange oil for each compound individually.

Stability of pesticide residues in stored analytical samples

The stability of spiromesifen spiromesifen-enol and metabolite 4-hydroxymethyl-Sp-enol residues under frozen conditions was investigated in high protein, high oil, high acid, high water and high starch content commodities by the 2016 JMPR. The total residues of spiromesifen and spiromesifen-enol were stable for at least 24 months in all matrices tested.

The current Meeting received additional storage stability data for spiromesifen and spiromesifen-enol under freezer storage conditions for dry beans, coffee beans and citrus fruits The total

residue (sum of spiromesifen and spiromesifen-enol) and spiromesifen-enol (per se) were demonstrated to be stable for at least 24 months in all matrices investigated. Parent spiromesifen (per se) was stable for at least 24 months in coffee beans and citrus fruits, but degraded significantly in dry beans within 30 days, resulting from the formation of spiromesifen-enol.

The samples analysed in the supervised residue trials included in this submission were stored for up to a maximum of 498 days (ca. 16 months) prior to analysis, therefore, the available data for the sum of spiromesifen and spiromesifen-enol is sufficient to cover these frozen storage intervals.

Results of supervised residue trials on crops

Oranges sweet, sour (subgroup)

The critical GAP for the use of spiromesifen on citrus fruits in Brazil is a single foliar spraying with 0.144 kg ai/ha and 21 days PHI.

Thirteen supervised field trials on oranges conducted in Brazil, matching the cGAP were provided. In whole fruits, residues for the sum of spiromesifen and spiromesifen-enol, expressed as spiromesifen were (n = 13): 0.021, < 0.024(2), 0.025, 0.041, 0.042, 0.043, 0.045, 0.047(2), 0.049, 0.100 and 0.103 mg/kg.

As oranges covered by the registered use correspond to the Codex subgroups for subgroup 1C (Oranges, Sweet, Sour) the Meeting decided to extrapolate the estimates from oranges to subgroup 1C (Oranges, Sweet, Sour).

The Meeting estimated a maximum residue level of 0.15 mg/kg and an STMR of 0.043 mg/kg for Subgroup of Oranges, Sweet, Sour.

Mango

The critical GAP for mango is from registrations in Brazil with three applications (minimum application interval of 7 days) at 0.144 kg ai/ha and a 5-day PHI.

Five supervised field trials conducted in Brazil, matching the cGAP were provided. In whole fruits, residues for the sum of spiromesifen and spiromesifen-enol, expressed as spiromesifen were (n = 5): 0.079, 0.115, 0.135, 0.200 and 0.225 mg/kg. All residue values in pulp were (n = 5): < LOQ (< 0.024(5) mg/kg).

The Meeting estimated a maximum residue level of 0.5 mg/kg for mango and an STMR of 0.024 mg/kg based on the residue values in mango pulp.

Papaya

The critical GAP for papaya is from registrations in Brazil with three applications (minimum application interval of 7 days) at 0.144 kg ai/ha and a 5-day PHI.

Five supervised field trials conducted in Brazil, matching the cGAP were provided. In whole fruits, residues for the sum of spiromesifen and spiromesifen-enol, expressed as spiromesifen were (n = 5): 0.046, 0.099, 0.13, 0.23, 0.33 mg/kg.

The Meeting estimated a maximum residue level of 0.7 mg/kg and an STMR of 0.13 mg/kg for papayas.

Beans with pods

The critical GAP for beans with pods is from registrations in Canada with three applications (minimum application interval of 7 days) at 0.144 kg ai/ha and a 1-day PHI.

Seven supervised field trials conducted in United States using a higher application rate (3 × 0.213 kg ai/ha) were provided. The Meeting agreed to use proportionality to scale down residues to the cGAP.

In beans with pods, unscaled residues of sum of spiromesifen and spiromesifen-enol expressed as spiromesifen were (n = 7): < 0.12, < 0.13, 0.14, 0.24, 0.28, 0.3, 0.44 mg/kg.

In beans with pods, scaled residues of sum of spiromesifen and spiromesifen-enol, expressed as spiromesifen were (n = 7): < 0.053, 0.091, < 0.12, 0.16, 0.18, 0.20 and 0.30 mg/kg.

The Meeting estimated a maximum residue level of 0.5 mg/kg and an STMR of 0.16 mg/kg for beans with pods.

Beans without pods

The critical GAP for beans without pods is from registrations in Canada with three applications (minimum application interval of 7 days) at 0.144 kg ai/ha and a 1-day PHI.

Seven supervised field trials conducted in United States using a higher application rate (3 × 0.213 kg ai/ha) were provided.

In beans without pods, residues of sum of spiromesifen and spiromesifen-enol, expressed as spiromesifen were (n = 7): < 0.12 (7)mg/kg.

The Meeting estimated a maximum residue level of 0.15(*) mg/kg and an STMR of 0.12(*) mg/kg for beans with pods.

Dry beans and soya beans

For dry beans, the critical GAP for dry beans is from registrations in Canada with three applications (minimum application interval of 7 days) at 0.144 kg ai/ha and a 10-day PHI.

Six supervised field trials conducted in United States using a higher application rate (3 × 0.213 kg) were provided. In dry seeds residues for the sum of spiromesifen and spiromesifen-enol, expressed as spiromesifen were (n = 6): < 0.024 (6)mg/kg.

For soya beans, the critical GAP for soya beans is from registrations in Brazil with two applications (minimum application interval of 5 days) at 0.144 kg ai/ha and a 21-day PHI.

Nine supervised field trials conducted in Brazil, matching the cGAP were provided. In dry seeds residues for the sum of spiromesifen and spiromesifen-enol, expressed as spiromesifen were (n = 9): < 0.024 (9)mg/kg.

The Meeting noted that all residues in dry beans and soya beans were below the LOQ (0.024 mg/kg) and decided to propose estimates for the whole subgroup of dry beans.

The Meeting estimated a maximum residue level of 0.03(*) mg/kg and an STMR of 0.024 mg/kg for the subgroup of dry beans.

Animal feed

Bean forage (green)

The critical GAP for beans is from registrations in Canada with three applications (minimum application interval of 7 days) at 0.144 kg ai/ha and a 1-day PHI.

Seven supervised field trials conducted in United States at a higher application rate GAP (3 × 0.213 kg ai/ha, same treatment regime) were provided.

In foliage, unscaled residues of sum of spiromesifen and spiromesifen-enol expressed as spiromesifen (n = 7): 0.38, 0.43, 0.54, 0.58, 0.60, 0.82 and 0.86 mg/kg.

In foliage, scaled residues of sum of spiromesifen and spiromesifen-enol, expressed as spiromesifen were (n = 7): 0.26, 0.29, 0.37, 0.39, 0.41, 0.55 and 0.58 mg/kg.

The Meeting estimated a median residue of 0.39 mg/kg and a highest residue of 0.58 mg/kg for bean forage (as received) based on the scaled data set.

Fate of residues during processing

The Meeting received new processing studies on oranges and soya bean. Processed commodities from oranges (dry pulp, juice, marmalade, oil, dry pomace) and soya bean (flour, hulls, meal, milk, oil) were derived using simulated commercial practices. Processing factors and residue estimates are summarized below.

Table 23 Processing factors, STMR-Ps and HR-Ps for the sum of spiromesifen and spiromesifen-enol expressed as spiromesifen and used for dietary risk assessment and livestock dietary burden calculation

Raw commodity	Processed commodity	Individual processing factors	Median or best estimate processing factor	STMR-P (Median-P) = STMR RAC × PF (mg/kg)	Maximum residue level for RAC (mg/kg)	Maximum residue level for processed commodity = maximum residue level × PF (mg/kg)[a]
Oranges	Pulp, dry	0.7, 1.05, 2.9, 7.3	2	0.043 × 2 = 0.086	0.15	0.15 × 2 = 0.3
	Raw juice	< 0.03,< 0.11, < 0.2, < 0.2, < 0.2, < 0.3, 0.3, < 0.5, < 0.6, < 0.6, < 0.7	0.3	-		-
	Pasteurize Juice	< 0.03, < 0.06, < 0.1, < 0.11	< 0.08	0.043 × 0.08 = 0.0034		-
	Marmalade	0.04, < 0.1, 0.1, 0.12,	0.1	0.043 × 0.1 = 0.0043		-
	Orange oil, edible	133, 183, 218, 221	201	0.043 × 201 = 8.6	0.15	0.15 × 201 = 30
	Fruit, raw, without peel	< 0.06, < 0.1	< 0.08	0.043 × 0.08 = 0.0034		-
	Pomace, dry	2.9, 7.3	5.1	0.043 × 5.1 = 0.22		-

	flour	0.14, < 0.3	0.22	0.024 × 0.22 = 0,0053		-
	Oil (refined)[b]	< 0.1, < 0.3	0.2	0.024 × 0.2 = 0.005		-
	Oil (crude)[c]	0.2, < 0.3	0.25	0.024 × 0.25 = 0.006	0.03(*)	0.03(*)
	aspirated grain	194, 203	199	0.024 × 199 = 4.8		-

Raw commodity	Processed commodity	Individual processing factors	Median or best estimate processing factor	STMR-P (Median-P) = STMR RAC × PF (mg/kg)	Maximum residue level for RAC (mg/kg)	Maximum residue level for processed commodity = maximum residue level × PF (mg/kg)[a]
	Meal	< 0.1, < 0.3	< 0.2	0.024 × 0.2 = 0.005	0.03(*)	0.03(*)
	Hulls	1.1, 1.4	1.25	0.024 × 1.25 = 0.03	0.03(*)	0.03(*)

Notes:

[a] calculated values are rounded according to the OECD rounding classes.

[b] Solvent extracted RBD.

[c] Cold pressed RBD.

The Meeting estimated a maximum residue level of 30 mg/kg for orange oil edible, 0.3 mg/kg for citrus pulp, dry and of 0.03(*) mg/kg for soya bean oil (crude), hulls, and meal.

Residues in animal commodities

Farm animal feeding studies

No additional information on transfer of residues to livestock was provided to the current Meeting. Please refer to the 2016 JMPR Report.

Estimated maximum and mean dietary burdens of livestock and animal commodities maximum residue levels

Dietary burdens were calculated for beef cattle, dairy cattle, broilers and laying poultry based on feed items evaluated by the Meeting. The dietary burdens, estimated using the most recent version of the OECD livestock dietary burden calculator, are presented in Annex 6 and summarised below. In the 2016 JMPR the calculations were made according to the animal diets listed in Appendix IX of the 2016 edition of the FAO manual. Results of the estimated maximum and mean dietary burdens are summarised in Table 24.

Table 24 Estimated maximum and mean dietary burdens of farm animals

	Animal dietary burden: spiromesifen, ppm of dry matter diet							
	United States-Canada		European Union		Australia		Japan	
	max	mean	max	mean	max	mean	max	mean
Beef cattle	2.6	1.3	25.5	6.8	9.6	4.7	0.01	0.01
Dairy cattle	5.0	2.3	23.6	6	39.9❶	8.6❷	5.50	2.50
Poultry – broiler	0.01	0.01	0.02	0.02	0.07	0.07	0.002	0.002
Poultry – layer	0.01	0.01	0.62❸❺	0.1❹	0.07	0.07	0.001	0.001

Notes:

❶ Suitable for estimation of maximum residue levels in meat and milk.

❷ Suitable for estimation of median residue levels in meat and milk

❸Suitable for estimation of maximum residue levels in poultry meat

❹ Suitable for estimation of median residue levels in poultry meat and eggs

❺ Suitable for estimation of maximum residue levels in eggs

The spiromesifen dietary burden reached a maximum level of 25.5 ppm of dry matter diet in beef cattle, 39.9 ppm diet in dairy cattle and 0.62 mg/kg diet in poultry. The mean dietary burdens were

6.8 mg/kg in beef cattle, 8.6 mg/kg diet in dairy cattle and 0.1 mg/kg in poultry. These results are similar to the previous livestock dietary burden calculations performed by the 2016 JMPR (highest maximum dietary burden was 25 ppm of dry matter diet in beef cattle, 40 ppm diet in dairy cattle and 5.3 mg/kg diet in poultry). The meeting confirmed its previous recommendations for animal commodities.

RECOMMENDATIONS

On the basis of the data from supervised trials, the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessment.

The definition of the residue for compliance with the MRL for plant and animal commodities and for dietary risk assessment for animal commodities: *sum of spiromesifen and spiromesifen-enol, expressed as spiromesifen*.

The definition of the residue for dietary risk assessment for plant commodities: *sum of spiromesifen, spiromesifen-enol and 4-hydroxymethyl-spiromesifen-enol (free and conjugated), expressed as spiromesifen*.

The residue is fat-soluble.

Table 25 Residue levels suitable for establishing maximum residue limits and for IEDI assessment

CCN	Commodity name	Recommended Maximum residue level (mg/kg)		STMR or STMR-P mg/kg
		New	Previous	
FC 0004	Subgroup of oranges, Sweet, Sour	0.15	-	0.043
FI 0345	Mango	0.5	-	0.024
FI 0350	Papaya	0.7	-	0.13
VP 0061	Beans with pods (Phaseolus spp.) immature pods and succulent seeds)	0.5	-	0.16
VP 0062	Beans without pods (Phaseolus spp.) (succulent seeds)	0.15*	-	0.12
VD 2065	Dry beans, subgroup	0.03*	-	0.024
JF 0004	Orange Juice	-	-	0.0034
OR 0004	Orange oil, edible	30	-	8.6[a]
OC 0541	Soya bean oil, crude	0.03*	-	0.006
OR 0541	Soya bean oil, refined	-	-	0.005 [a]
	Soya bean milk	-	-	0.005 [a]
DM 0541	Soya bean flour	-	-	0.0053
AL 1030	Bean forage (green)	-	-	0.39 (ar)
AB 0001	Citrus pulp, dried	0.3	-	0.086
AL 3538	Soya bean, hulls	0.03*	-	0.03
AL 3539	Soya bean meal	0.03*	-	0.005

[a] Value not relevant for IEDI assessment calculations.

CCN	Commodity name	Median residue (-P) mg/kg	highest residue (-P) mg/kg
	Soybean aspirated grain	4.8	-

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The ADI for spiromesifen is 0–0.03 mg/kg bw. The International Estimated Daily Intakes (IEDIs) for spiromesifen were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the JMPR. The results are shown in Annex 3 of the 2022 JMPR Report.

The IEDIs were 3–20 percent of the maximum ADI. The Meeting concluded that long-term dietary exposure to residues of spiromesifen from uses considered by the JMPR is unlikely to present a public health concern.

Short-term dietary exposure

The Meeting determined that an ARfD is not necessary for spiromesifen. The Meeting therefore concluded that the short-term dietary exposure to residues of spiromesifen resulting from uses that have been considered by the JMPR is unlikely to present a public health concern.

SULFOXAFLOR (252)

EXPLANATION

Sulfoxaflor was evaluated for the first time by JMPR 2011 when an acceptable daily intake (ADI) of 0–0.05 mg/kg bw and an acute reference dose (ARfD) of 0.3 mg/kg bw were established. Sulfoxaflor underwent subsequent evaluations by the JMPR in 2014, 2016, and 2021 (Extra).

The definition of the residue in plants and animals for both compliance with MRLs and for dietary assessment is sulfoxaflor. The residue is not fat-soluble.

The current Meeting received information on residues in globe artichoke and sunflower to supplement trials evaluated at the 2021 Extra Meeting.

Table 1 Metabolites of sulfoxaflor referenced in this document

Common or code name	Chemical name	Structure
X11719474	1-[methyl(oxido){1-[6-(trifluoromethyl)pyridin-3-yl]ethyl}-λ^6-sulfanylidene]urea	
METHODS OF RESIDUE ANALYSIS

QuEChERS

Field trial samples of globe artichoke flower heads and sunflower seeds were analysed for residues of sulfoxaflor and X11719474 using a standard QuEChERS method. Briefly, residues of sulfoxaflor and X11719474 were extracted from homogenized samples by shaking for 30 minutes with water + acetonitrile + QuEChERS salts. An aliquot of the acetonitrile layer was cleaned up by dispersive SPE (globe artichoke only). The extract was diluted with 0.1 percent formic acid and then analysed for residues by LC-MS/MS. Concurrent recovery data are summarized below.

Table 2 Summary of concurrent recovery of sulfoxaflor and its main metabolite from avocado, blueberry, caneberry, globe artichoke, asparagus, and sunflower commodities

Matrix	Analyte	Fortification level [mg/kg]	Individual recoveries [%]	Mean recovery [%]	RSD [%]	Reference
Globe artichoke flower heads	Sulfoxaflor	0.01	86, 93, 95, 106, 107, 109, 124	103	12	210115
		0.1	91, 93, 96, 104, 111	99	8.4	
		1	77, 79, 84, 101, 108	90	15	
	X11719474	0.01	89, 95, 98, 99, 99, 101, 117	100	8.6	
		0.1	91, 93, 93, 98, 110	97	8.0	
		1	73, 78, 84, 100, 104	88	15	
Sunflower seed	Sulfoxaflor	0.01	87, 93, 94, 96, 98, 103, 110	97	7.6	210116

	X11719474	0.01	93, 96, 96, 98, 101, 106, 111	100	6.4	

Matrix	Analyte	Fortification level [mg/kg]	Individual recoveries [%]	Mean recovery [%]	RSD [%]	Reference
		0.1	98, 100, 100, 100, 106	101	3.0	
		1	96, 99, 100, 100, 102	99	2.2	

STABILITY OF RESIDUES IN STORED SAMPLES

New data on the stability of sulfoxaflor and its two main metabolites in frozen stored samples were not provided. Field trial samples were stored at ca. -20 °C for up to 104 days for globe artichoke and up to 133 days for sunflower seed.

USE PATTERN

Registered labels describing the use of sulfoxaflor were submitted to the present Meeting for globe artichoke and sunflower (Table 3). For both uses, the timing of application is triggered by pest pressure, and applications are broadcast spray.

Table 3 Registered uses of sulfoxaflor submitted to the 2020/2022 JMPR

Use site	Country	Formulation		Application					PHI, days
		Conc.	Type	Rate, g/ha/applic	Rate, g/ha/year	Water, L/ha	Max No.	Interval, days	
Artichoke (globe)	United States	50%	WG	101	298	ns	4	7	3
Sunflower subgroup [a)]	United States	50%	WG	96	193	ns	2	7	14

Notes:

[a)] Calendula, castor oil plant, Chinese tallowtree, euphorbia, evening primrose, jojoba, niger seed, rose hip, safflower, stokes aster, sunflower, tallowwood, tea oil plant, vernonia.

RESULTS OF SUPERVISED RESIDUE TRIALS ON CROPS

The Meeting received data from supervised residue trials conducted on globe artichoke and sunflower.

The field trial reports included method validation data, as recoveries from spiked samples at levels reflecting those observed in the field trial samples; dates from critical events during the study, including application, harvest, storage, and analysis; as well as detailed information on the field site and treatment parameters. Analytical reports were sufficiently detailed and included example chromatograms and example calculations. Samples were analysed by the method described above for plant commodities.

The field trial study designs included control plots. Measured residues from control plots were <LOQ and are not included in the summary tables in this evaluation.

When calculating average residues, values below the LOQ were assumed to be at the LOQ. In the summary tables, residue values leading to maximum residue estimations and used for long-term dietary risk assessment are underlined. The highest individual values selected for estimating acute dietary risks are bolded.

Although the submitted study reports include analysis of X11719474, that compound is not part of the residue definitions for sulfoxaflor. Therefore, field trial results for X11719474 are not included in this evaluation.

Oilseeds	Sunflower	Table 5

Globe artichoke

One trial was conducted in the United States during the 2021 season (Shepard, E. 2022, Report 210115). Treatment consisted of three foliar broadcast applications of ca. 100 g ai/ha, on a 7-day interval. Harvest occurred 0, 1, 3, 8, 14, and 21 days after the last application (DALA).

Following harvest, samples (12–14 flower heads, *ca*. 4–6 kg) were placed into frozen storage within 4 hours of collection and shipped frozen to the analytical facility. Upon arrive at the facility, samples were put into frozen storage. Prior to analysis, samples were homogenized in the presence of dry ice and then returned to frozen storage. Samples were stored for a maximum of 3.4 months prior to analysis. This duration is supported by available storage stability data reviewed by the 2021 Extra JMPR.

Samples were analysed for residues of sulfoxaflor using a QuEChERS analytical method. Concurrent recovery data indicate that the method is suitable.

Note:

[A)] Side-by-side trials using different spray volume/ha. Trials are not independent.

Sunflower seed

Five field trials were conducted in United States during the 2021 season (Shepard, E. 2022, Report 210116). Treatment consisted of two broadcast applications of sulfoxaflor each at *ca* 102 g ai/ha. The retreatment interval was 6–8 days. Harvest occurred 0 to 21 DALA.

Following harvest, samples (1–2.7 kg) were placed into frozen storage within 3 hours of collection and shipped frozen the analytical facility. Upon arrive at the facility, samples were put into frozen storage. Prior to analysis, samples were homogenized in the presence of dry ice and then returned to frozen storage. Samples were stored for a maximum of 4.4 months prior to analysis. This duration is supported by available storage stability data reviewed by the 2021 Extra JMPR.

Samples were analysed for residues of sulfoxaflor using a QuEChERS analytical method. Concurrent recovery data indicate that the method is suitable. Residues of X11719474 were not detectable in any sample of sunflower seed.

APPRAISAL

Sulfoxaflor (ISO common name) is a broad-spectrum, sulfoximine insecticide with registered uses on multiple crops. It was evaluated for the first time by JMPR 2011, which established an acceptable daily intake (ADI) of 0–0.05 mg/kg bw and an acute reference dose (ARfD) of 0.3 mg/kg bw. Sulfoxaflor underwent subsequent evaluations by the JMPR in 2014, 2016, and 2021 (Extra). The 2022 JMPR agreed to consider additional residue data provided to support uses on globe artichoke and sunflower, for which the 2021 Extra Meeting was unable to make recommendations.

The definition of the residue in plants and animals for both compliance with MRLs and for dietary risk assessment is sulfoxaflor. The residue is not fat-soluble.

The current Meeting received information on residues in globe artichoke and sunflower to supplement trials evaluated at the 2021 Extra Meeting.

Methods of analysis

The Meeting received concurrent recovery data for use of a standard QuEChERS multiresidue method. The method was demonstrated to have adequate performance for sulfoxaflor from concurrent recovery samples of globe artichoke and sunflower seed, with an LOQ of 0.01 mg/kg. Metabolism studies evaluated by the 2011 JMPR showed high extraction efficiency (73–97 percent TRR) with similar solvent as that used in the QuEChERS method.

Stability of pesticide residues in stored analytical samples

Based on data provided to it, the 2021 Extra Meeting concluded that residues of sulfoxaflor are stable for at least 24 months in globe artichoke and in sunflower seeds during frozen storage. In the studies provided to the current Meeting, samples were stored at -20 °C for up to 3.4 months (globe artichoke) and 4.4 months (sunflower seed).

Results of supervised residue trials on crops

The Meeting received data from supervised residue trials in globe artichoke and sunflower. These data were to supplement studies reviewed by the 2021 Extra Meeting, which concluded that the numbers of trials for those crops were insufficient to make recommendations.

Globe artichoke

The critical GAP for globe artichoke is from the United States. The label provides for up to four applications, each at 101 g ai/ha, on a 7-day interval, with a 3-day PHI. The label also specifies an annual limit of 298 g ai/ha; thus, the critical GAP is three applications at the maximum rate.

Residue of sulfoxaflor in globe artichoke from the additional trial provided to the meeting was (n=1): 0.41 mg/kg. In independent trials evaluated by the 2021 Extra JMPR, residues were (n=3): 0.22, 0.23, and 0.26 mg/kg. Altogether, residues of sulfoxaflor in globe artichoke from independent trials matching the critical GAP were (n=4): 0.22, 0.23, 0.26, and 0.41 mg/kg.

The Meeting estimated a maximum residue level of 0.9 mg/kg, an STMR of 0.245 mg/kg, and an HR of 0.45 mg/kg (from a single sample) for sulfoxaflor in globe artichoke.

Subgroup of sunflower seeds

Sunflower seed

The critical GAP is from the United States on the sunflower subgroup of oilseeds and consists of two applications, each at 96 g ai/ha, with a 7-day re-treatment interval and a 14-day PHI.

Residues of sulfoxaflor in sunflower seeds from independent trials approximating the critical GAP were (n=5): 0.024, 0.047, 0.076, 0.092, and 0.19 mg/kg. In independent trials approximating the critical GAP and evaluated by the 2021 Extra JMPR, residues were (n=4): < 0.01, 0.013, 0.018, and 0.15 mg/kg. Altogether, residues of sulfoxaflor in sunflower seeds from independent trials approximating the critical GAP were (n=9): < 0.01, 0.013, 0.018, 0.024, 0.047, 0.076, 0.092, 0.15, and 0.19 mg/kg.

The Meeting estimated a maximum residue level of 0.4 mg/kg and a STMR of 0.047 mg/kg for residues of sulfoxaflor in sunflower seed. Noting that the registered use includes all commodities in the Codex Subgroup of sunflower seeds (SO 2091) and that sunflower seed is the recommended representative commodity, the Meeting agreed to extrapolate the recommendations to Subgroup 023B Sunflower Seeds.

Fate of residues during processing

The 2021 Extra Meeting evaluated a sunflower seed processing study and derived best-estimate processing factors of 0.71 for both sunflower meal and refined oil. Based on the STMR of 0.047 mg/kg in seed, the STMR-Ps for both meal and refined oil were 0.033 mg/kg.

Residues in animal commodities

The only animal feed item considered by the current Meeting was sunflower meal. Inclusion of sunflower meal in the animal dietary calculations did not change the maximum and mean burdens for cattle or poultry from those calculated by the 2014 JMPR (3.22 and 1.26 ppm respectively for cattle and 0.93 and 0.31 ppm respectively for poultry); therefore, the Meeting confirmed is previous recommendations for residues in animal commodities.

RECOMMENDATIONS

On the basis of the data obtained from supervised trials, the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessments.

Definition of the residue for compliance with the MRL and for dietary risk assessment for plant and animal commodities: *sulfoxaflor.*

The residue is not fat-soluble.

Table 7 Recommendations for residues of sulfoxaflor from the 2022 JMPR

CCN	Crop/Commodity	MRL, mg/kg		STMR or STMR-P, mg/kg	HR or HR-P, mg/kg
		New	Previous		
VS 0620	Globe artichoke	0.9		0.245	0.45
SO 2091	Subgroup of sunflower seeds	0.4	--	0.047	--
For dietary risk assessment and/or dietary burden calculations					
AM 0702	Sunflower seed, meal	--	--	0.033	--
OR 0702	Sunflower seed oil, edible	--	--	0.033	--

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The ADI for sulfoxaflor is 0–0.05 mg/kg bw. The International Estimated Daily Intakes (IEDIs) for sulfoxaflor were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the JMPR. The results are shown in Annex 3 of the 2022 JMPR Report.

The IEDIs ranged from 1–7 percent of the maximum ADI. The Meeting concluded that long-term dietary exposure to residues of sulfoxaflor from uses considered by the JMPR is unlikely to present a public health concern.

Acute dietary exposure

The ARfD for sulfoxaflor is 0.3 mg/kg bw. The International Estimate of Short-Term Intakes (IESTIs) for sulfoxaflor were calculated for the food commodities and their processed commodities for which HRs/HR-Ps or STMRs/STMR-Ps were estimated by the present Meeting and for which consumption data were available. The results are shown in Annex 4 of the 2022 JMPR Report.

The IESTIs varied from 0–2 percent of the ARfD for children and 0–1 percent for the general population. The Meeting concluded that acute dietary exposure to residues of sulfoxaflor from uses considered by the present Meeting is unlikely to present a public health concern.

TETRANILIPROLE (324)

First draft prepared by K. Mahieu and T. van der Velde-Koerts, Centre for Nutrition, Prevention and Health Services (VPZ), National Institute for Public Health and the Environment (RIVM), The Netherlands

EXPLANATION

Tetraniliprole (ISO name) is a broad spectrum fast acting insecticide that belongs to the anthranilic diamide chemical class. The mode of action of anthranilic diamides involves activating ryanodine receptors, which play a critical role in muscle function.

Tetraniliprole was scheduled at the Fifty-first Session of the CCPR (2019) for evaluation as a new compound by the 2020 JMPR, which was postponed to the 2021 JMPR for toxicology and to the 2022 JMPR for residues. The 2021 JMPR estimated and ADI of 0–2 mg/kg bw and concluded that an ARfD was not necessary.

The Meeting received information on identity, physical chemical properties, plant and animal metabolism, aerobic soil degradation, residue analysis, storage stability, use patterns, supervised trials on citrus fruits, pome fruits, stone fruits, grapes, head and stem brassica vegetables, fruiting vegetables, leafy vegetables, soya beans, root and tuber vegetables, cereal grains, tree nuts, and rice, fate of residues during processing, and livestock feeding studies.

IDENTITY

ISO common name:	Tetraniliprole
IUPAC name:	1-(3-chloropyridin-2-yl)-N-[4-cyano-2-methyl-6-(methyl¬carbamoyl) phenyl]-3-{[5-(trifluoromethyl)-2H-tetrazol-2-yl]methyl}-1H-pyrazole-5-carboxamide
CAS name:	1H-pyrazole-5-carboxamide, 1-(3-chloro-2-pyridinyl)-N-[4-cyano-2-methyl-6-[(methylamino)carbonyl]phenyl]-3-[[5-(trifluoromethyl)-2H-tetrazol-2-yl]methyl]-(9CI)
CAS Registry No:	1229654-66-3
CIPAC No:	not allocated
Structural formula:	Molecular formula	$C_{22}H_{16}ClF_3N_{10}O_2$
Molecular weight:	544.88 g/mol

Parameter	Result	References	Guidelines/method
	pH 9 0.04 days at 50 °C At normal temperatures tetraniliprole is stable at pH 4, hydrolyses slowly at pH 7 and rapidly at pH 9. One degradation product was identified as tetraniliprole-N-methyl-quinazolinone with a maximum amount of 99.6% AR. At higher temperatures tetraniliprole degrades more rapidly.		
Photolysis in sterile water: Sample ID: KML 9532 Radiolabel: [pyrazole-carboxamide-^{14}C]	(Radio)chemical purity: >98% Photodegradation tetraniliprole was studied under simulated sunlight in sterile aqueous acetate buffer solution (pH 4) at 25 ºC for 11 days with 0.48 mg ai/L, with a mean irradiance of 694 Watts/m^2. Under these conditions tetraniliprole was rapidly degraded with an experimental DT_{50} value of 3.4 days and DT_{90} value of 11.3 days. The predicted environmental DT_{50} value is calculated to be e.g. 10.5 solar summer days at Phoenix, Arizona, United States. Tetraniliprole was stable under dark conditions (a DT_{50} of 188.5 days and a DT_{90} of 626.2 days). One major degradation product was identified as tetraniliprole-deschloro-oxazine with a maximum amount of 72.7% AR. The sum of five minor unidentified metabolites increased to 12.5% AR at day 11, with max individual levels of 1.9-6.6% AR. The mean material balances were 98.9% AR for irradiated samples and 102.6% AR for dark samples	Heinemann & Kasel, 2014, M-484185-01-1, Report EnSa-13-0320	OECD 316, OPPTS 835.2240

Formulations

Tetraniliprole has not been evaluated by JMPS and therefore no FAO specifications for technical and formulated tetraniliprole have been published.

A suspension concentrate (SC) formulation containing 200 g ai/L is commercially available in Australia, Canada, Guatemala, Korea, New Zealand, Peru and the United States. A flowable concentrate for seed treatment (FS) formulation containing 480 g ai/L is commercially available in the Australia, Canada, Japan and the United States as well as a granule box 15 g/kg in Japan.

Tetraniliprole - quinazolinone-carboxylic acid Code: BCS-CU81056		2-[1-(3-chloropyridin-2-yl)-3-{[5-(trifluoromethyl)-2H-tetrazol-2-yl]methyl}-1Hpyrazol-5-yl]-8-methyl-4-oxo-3,4-dihydroquinazoline-6-carboxylic acid Molecular formula: $C_{21}H_{13}ClF_3N_9O$ Molecular weight: 531 g/mol	soil

METABOLISM AND ENVIRONMENTAL FATE

Plant metabolism

The meeting received plant metabolism studies for tetraniliprole after application on tomatoes (soil drench), apples (foliar), potatoes (foliar applications or seed treatment in furrow), lettuce (foliar a), paddy rice (foliar application or granular treatment in planting holes) and maize (seed treatment) using either [pyrazole-carboxamide-^{14}C]- or [phenyl-carbamoyl-^{14}C]-labelled tetraniliprole, as shown below.

Pyrazole-carboxamide label	Phenyl-carbamoyl label
	[pyrazole-carboxamide-^{14}C]-tetraniliprole	[phenyl-carbamoyl-^{14}C]-tetraniliprole

Notes:

* = Position of ^{14}C-radiolabel.

Seed treatments and soil treatments (soil drench, in-furrow, granular)

Tomato–Indoor soil drench application

The metabolic fate of tetraniliprole after a single soil drench application was investigated in tomato plants (*Lycopersicon esculentum* Mill., variety: Philona) in two studies (Bongartz and Schmeling, 2014a, M-495009-01-1, Report EnSa-14-0485 and Bongartz and Schmeling, 2014b, M-495019-01-1, Report EnSa-14-0484). Plants were grown individually in pots in a greenhouse in Germany (Monheim am Rhein). Radiolabelled tetraniliprole was formulated as SC 200 and applied to two tomato plants at growth stage BBCH 15–16 (fifth to sixth leaf on main shoot unfolded) as a single drench application to Einheitserde T soil (characteristics not reported). The application rate with pyrazole-carboxamide label was 7.81 mg ai/plant, equivalent to 156.3 g ai/ha based on a plant density of 20,000 plants/ha (Report EnSa-14-0485). The application rate with phenyl-carbamoyl labelwas 7.65 mg ai/plant, equivalent to 153.1 g ai/ha based on a plant density of 20,000 plants/ha (Report EnSa-14-0484).

Tomatoes were picked from the plants during the whole ripening period (BBCH 81–89), between 83 to 99 days after application. In intervals of 2–3 days the fruits which appeared fully ripe were picked and stored. At the end of the ripening period, after all fruits were harvested (BBCH 89) a leaf sample was taken from each plant. The tomato and leaf samples were extracted three times with a mixture of acetonitrile/water/formic acid (8/2/0.1, pH determined but not reported) followed by a partitioning step of the combined extracts against dichloromethane.

The total radioactive residue (TRR) values of the extracted samples were quantified by LSC and were calculated based on the radioactivity determined in the extracted phases and the remaining solids.

Pyrazole-carboxamide label: The extraction efficiency was >90 percent TRR for both fruit and leaf samples. For tomatoes, the main portion of the radioactivity (67.8 percent TRR) partitioned into the organic phase and 22.9 percent TRR into the aqueous phase. Similar to the fruit, the main portion of the radioactivity (75.7 percent TRR) in the leaf samples partitioned into the organic phase and 18.3 percent TRR into the aqueous phase.

Phenyl-carbamoyl label: The extraction efficiency was >86 percent TRR for both fruit and leaf samples. For tomatoes, the main portion of the radioactivity (55.5 percent TRR) partitioned into the organic phase and 31.0 percent TRR into the aqueous phase. Similarly in leaves, the main portion of the radioactivity (77.9 percent TRR) partitioned into the organic phase and 16.6 percent TRR into the aqueous phase.

The distribution of radioactivity in the tomato fruit and leaf samples is presented in Table 2.

Table 2 Distribution of radioactivity in the extracts of tomato fruits and leaves following indoor drench application of pyrazole-carboxamide and of phenyl-carbamoyl labelled tetraniliprole

The organic phases of both leaf and fruit samples were cleaned up by SPE. The measurement of the radioactivity in liquid samples was carried out by liquid scintillation counting (LSC). All solid samples were combusted in an oxygen atmosphere using an oxidiser. The released $^{14}CO_2$ was trapped in an alkaline scintillation cocktail and the radioactivity was determined by LSC. HPLC-radioactivity analysis was performed with radiometric and UV-detection. Non-radiolabelled reference compounds (tetraniliprole and tetraniliprole-N-methyl-quinazolinone) were used.

Parent tetraniliprole was a major compound in both fruit and leaves and amounted to 22 percent TRR (<0.001 mg eq/kg) and 24 percent TRR (0.001 mg eq/kg), respectively with the pyrazole-carboxamide label and amounted to 34 percent (<0.001 mg eq/kg) and 27 percent (0.002 mg eq/kg) TRR, respectively with the phenyl-carbamoyl label. Tetraniliprole-N-methyl-quinazolinone was a major metabolite and amounted to 11 percent TRR (<0.001 mg eq/kg) for fruit and 34 percent TRR (0.002 mg eq/kg) for leaves with the pyrazole-carboxamide label and amounted to 20 percent (<0.001 mg eq/kg) TRR for fruit and 37 percent (0.002 mg eq/kg) TRR for leaves with the phenyl-carbamoyl label. All other detected metabolites in leaf extracts each amounted to ≤ 4.1–4.4 percent TRR (0.001 mg eq/kg) with both labels. The metabolic profile of tetraniliprole in tomato fruit and leaf samples is presented in Table 3.

Notes:
[a] Characterised by extraction, partitioning and chromatographic behaviour.
[b] Characterised by extraction and partitioning (most likely polar compounds).
[c] Total extracted = total identified + total characterised + losses of the organic phase during SPE + aqueous phase of the extract.

Only little radioactivity was taken up in the plants, indicating little translocation from soil to the plants. Pyrazole-carboxamide and phenyl-carbamoyl labelled tetraniliprole were moderately metabolised in tomatoes following soil application. The only observed metabolic reaction was an intra-molecular condensation (cyclisation) leading to tetraniliprole-N-methyl-quinazolinone.

Potato – outdoor seed treatment in furrow

A study was conducted to investigate the distribution and metabolism of pyrazole-carboxamide labeled tetraniliprole in potatoes after an in furrow seed treatment (Piskorski, 2015a, M-508350-01-1, Report EnSa-14-1306). The study was carried out in a Swiss (Witterswil) outdoor testing facility. Potato plants (*Solanum tuberosum* L, variety: Agri Bio) were cultivated under natural temperature and light conditions in the outdoor facility. Treated potato plants were grown in a single compartment surrounded with control potato plants. The soil used for the study was Spaniergrund (sandy loam). Radiolabelled pyrazole-carboxamide tetraniliprole was formulated as FS380P and applied to the seed in the furrow directly before covering the seed tubers with soil at an actual application rate of 199.8 g ai/ha.

Tubers from all the potato plants were collected 151 days after the application (BBCH 99). Aliquots of homogenized potato tubers were combusted and TRR amounted to only 0.001 mg eq/kg, indicating little translocation from soil to tubers. The investigation of the metabolic pathway was not possible due to the very low amount of radioactivity in the samples and the high matrix content.

Rice–Indoor granular soil application

The metabolism of tetraniliprole in paddy rice after a single granular treatment was investigated, using two different radiolabels in two different studies (Bongartz & Schallau, 2014a, M-496790-01-1, Report EnSa-14-0487 and Bongartz & Schallau, 2014b, M-496783-01-1, Report EnSa-14-0486). The studies were carried out in the greenhouse in Monheim am Rhein in Germany. Paddy rice (*Oryza sativa L.* var. Balilla) was cultivated under artificial temperature and light conditions in the greenhouse. Plants were pre-grown in a Japanese nursery box. The pre-grown seedlings (BBCH13-14, three to four leaves unfolded) were transplanted into a plant container (0.5 m^2) after addition of granular test compound in 11 planting holes. The containers were filled with sandy loam (Monheim 4). The pyrazole-carboxamide and phenyl-carbamoyl labelled tetraniliprole were applied onto Sepiolite carrier granules, at rates of was 205 and 211 g ai/ha, , respectively.

Samples of rice forage (BBCH 34–35, PHI 64 days), kernels, husks and straw (BBCH 89–92, PHI 150 days) were collected for analysis. All samples were extracted three times with a mixture of acetonitrile/water/formic acid (8/2/0.1, pH 3.5–3.8). The combined extracts were concentrated by rotary evaporation (40 °C bath temperature).

The measurement of the radioactivity in the liquid samples was carried out by LSC. All solid samples were combusted in an oxygen atmosphere using an oxidiser. The released $^{14}CO_2$ was trapped in an alkaline scintillation cocktail and the radioactivity was determined by LSC. The TRRs were low for all commodities with both labels (0.003–0.004 mg eq/kg for kernels, 0.008–0.0011 mg eq/kg for forage, 0.018–0.026 mg eq/kg for husks and 0.069–0.098 mg eq/kg for straw).

The extraction efficiency for straw, husks and forage was >75 percent for all commodities with the pyrazole-carboxamide label. The extraction efficiency with the phenyl-carbamoyl label was >87percent for all commodities except for kernels (49 percent). The post extraction solids (PES) of all commodities amounted to ≤0.009 mg eq/kg and were not further investigated. The distribution of radioactivity in rice samples is presented in Table 4.

Notes:
[a] Pyr-car = [pyrazole-carboxamide-^{14}C]-label; Phen-car= [phenyl-carbamoyl-^{14}C]-label.

Forage, husk and straw extracts were analysed by HPLC with radiometric- and UV-detection. HPLC method ANTAM was used for metabolite profiling and quantitation. Kernel extracts were analysed by one-dimensional thin-layer chromatography (TLC). The identification of parent compound and metabolites was performed by TLC co-chromatography with non-labelled reference compounds that were visualised by UV. The main compound found with the pyrazole-carboxamide label in the extracts was parent tetraniliprole (81.0 percent TRR (0.009 mg/kg) for forage, 48.4 percent TRR (0.001 mg/kg) for kernels, 77.9 percent TRR (0.020 mg/kg) for husks and 76.9 percent TRR(0.075 mg/kg) for straw). A minor metabolite was tetraniliprole-N-methyl-quinazolinone and amounted to 5.2 percent TRR (0.001 mg eq/kg) for forage, 9.9 percent TRR (<0.001 mg eq/kg) for kernels and 13.9 percent TRR (0.014 mg eq/kg) for straw. Tetraniliprole-N-methyl-quinazolinone was not detected in the kernel extracts. Similarly, the main compound found with the [phenyl-carbamoyl-^{14}C]-label in the extracts was parent tetraniliprole (78.9 percent TRR (0.007 mg/kg) for forage, 21.8 percent TRR (0.001 mg/kg) for kernels, 83.2 percent TRR (0.015 mg/kg) for husks and 77.3 percent TRR (0.054 mg/kg) for straw). A minor

metabolite was tetraniliprole-N-methyl-quinazolinone, which amounted to 12.3 percent TRR (0.001 mg eq/kg) for forage, 6.2 percent TRR (<0.001 mg eq/kg) for kernels, 3.9 percent TRR (0.001 mg eq/kg) for husks and 10.8 percent TRR (0.007 mg eq/kg) for straw. The metabolic profile of tetraniliprole in rice is presented in Table 5.

Maize–Outdoor seed treatment

The distribution and metabolism of pyrazole-carboxamide label formulated as FS 380P with maize after seed treatment was investigated in an outdoor facility in Witterswil in Switzerland. Maize plants (*Zea mays*, variety: Mezdi) were cultivated under natural temperature and light conditions in the outdoor facility of the test facility. The soil used for the study was Spaniergrund (soil type: sandy loam) (Piskorski, 2015b, Report EnSA-15-0013, M-525419-01-2). The seeds were placed in the soil and volumes of 72 and 172 µL application solution were carefully loaded onto each seed to achieve actual application rates of 62.8 and 150.1 g ai/ha, respectively (two separate treated plots with individual rates), based on a seed density of 80000 seeds/ha. Directly after the application, the seeds were covered with soil.

For each treatment plot, forage was sampled at BBCH 79–83 and mature plants at BBCH 89, corresponding with a PHI of 98 and 145 days, respectively. The mature plants were separated into kernel and stover samples. TRR values for forage, stover and kernels; determined by combustion/LSC analysis, were low for both treatment plots (<0.001 mg eq/kg for kernels, ≤0.006 mg eq/kg for forage, and 0.004 mg eq/kg for stover (62.8 g ai/ha plot)). As an exception, the TRR for the stover high rate (150 g ai/ha) sample was calculated as a sum of radioactivity found in extracts and PES (0.008 mg eq/kg). Due to the low TRRs, the stover sample from the high dose treatment plot was the only sample subjected to further analysis.

For analysis, the stover sample was homogenized and repeatedly (three times) extracted by with a mixture of acetonitrile/water/ formic acid (8/2/0.1). The extraction efficiency was determined as 75.8 percent TRR. The extracts were combined and concentrated before partition against ethyl acetate. The organic phase amounted to 70.1 percent TRR (0.005 mg eq/kg) and the aqueous phase 5.7 percent TRR (<0.001 mg eq/kg). The aqueous phase was not further investigated. The PES accounted for 0.002 mg eq/kg and was not investigated further. The distribution of radioactivity in maize stover is presented in Table 6.

Table 6 Distribution of radioactivity in the extracts of maize stover following seed treatment with [pyrazole-carboxamide -^{14}C]-tetraniliprole

The partition organic phase of the stover extract was analysed by one-dimensional TLC with UV-detection. The extracted residues were identified as parent tetraniliprole and tetraniliprole-N-methyl-quinazolinone representing 26.1 percent TRR (0.002 mg eq/kg) and 17.4 percent TRR (0.001 mg eq/kg), respectively. All other metabolite peaks represented ≤0.001 mg eq/kg. The main observed metabolic reaction was the cyclisation in the parent molecule leading to tetraniliprole-N-methyl-quinazolinone (Table 7).

Foliar treatments

Apples–Indoor foliar application

The metabolic fate of tetraniliprole was investigated in apple fruit and leaves after two spray applications in apple trees (*Malus domesticus*, variety: James Grieve) in two studies (Bongartz & Kluxen, 2015a, M-514517-01-1, Report EnSa-14-0492 and Bongartz & Kluxen, 2015b, M-514503-01-1, Report EnSa-14-0490). The apple trees were cultivated under natural temperature and light conditions in a greenhouse building (6682) in Germany (Monheim am Rhein), each tree in its own planting container in sandy soil (Monheim 4). Radiolabelled tetraniliprole was formulated as an SC 200 and applied twice to two apple trees at growth stages BBCH 71 (start of fruit development) and BBCH 73 (after the second fruit fall) with a retreatment interval of 33 days. The actual individual spray applications ranged from 86–88 g ai/ha with the pyrazole-carboxamide label, resulting in a total application rate of approximately 53 mg ai/tree, equivalent to a total application rate of 159.1 g ai/ha based on a plant density of 3,000 trees/ha (Report EnSa-14-0492). The individual spray applications with the phenyl-carbamoyl label were 85 and 86 g ai/ha, resulting in a total application rate of approximately 54 mg ai/tree, equivalent to a total application rate of 161.4 g ai/ha based on a plant density of 3,000 trees/ha (Report EnSa-14-0490).

Apple fruit (both labels) and leaves (pyrazole-carboxamide label only) were harvested from the trees at the end of the fruit ripening period (BBCH 89) at PHI of 64 days (fruits) and 66 days (leaves). A subset of apple fruits were dipped and subsequently rinsed with dichloromethane (=surface washing), diced, and homogenized under nitrogen and stored frozen until extraction. For determination of the extraction efficiency of the residue method, another subset of the fruits (without surface wash) was homogenised as described above. Leaves were not surface washed and stored in the freezer until homogenisation and extraction. Samples were extracted three times with a mixture of acetonitrile/water/formic acid (8/2/0.1; pH not reported). The surface wash solution and the first extract of the fruit samples were concentrated. The extracts of the leaves were combined and concentrated.

The measurement of radioactivity in liquid samples was carried out by LSC. All solid samples were combusted in an oxygen atmosphere using an oxidiser. The released $^{14}CO_2$ was trapped in an alkaline scintillation cocktail and the radioactivity was determined by LSC.

TRR in apple fruits was calculated based on the radioactivity in the surface wash solution and the fruit sample and amounted to 0.18 mg eq/kg in total (pyrazole-carboxamide label) to 0.25 mg eq/kg in total (phenyl-carbamoyl label).

Pyrazole-carboxamide label: The extraction efficiency (sum of surface wash and solvent extract) in the fruit samples was 98 percent TRR. The largest portion TRR was found in the surface wash solution (0.18 mg eq/kg, 97 percent TRR). The distribution of radioactivity in apple fruit and leaves is presented in Table 8.

Phenyl-carbamoyl-^{14}C] label: The extraction efficiency (sum of surface wash and solvent extract) in the fruit samples was 99.6 percent.

Table 8 Distribution of radioactivity at PHI 64-66 days in the extracts of apple fruit and leaves following 2 foliar indoor applications each of pyrazole-carboxamide or phenyl-carbamoyl labelled tetraniliprole, with a retreatment interval of 33 days

	% TRR	mg eq/kg	% TRR	mg eq/kg	% TRR	mg eq/kg
Dichloromethane surface wash	96.7	0.177	-	-	92.1	0.232
Acetonitrile/water/formic acid extraction	3.0	0.005	99.5	98.9	7.5	0.019
Total extracted	99.6	0.183	99.5	98.9	99.6	0.251
PES	0.4	0.001	0.5	0.541	0.4	0.001
Accountability	100	0.183	100	99.4	100	0.252

All sample extracts were analysed by HPLC with radiometric and UV-detection. The identification of the compounds detected in the fruit extract was performed by HPLC co-chromatography with the non-radiolabelled reference compound. Parent tetraniliprole was the main compound in the apple fruit sample. The highest amount of parent compound (0.18 mg/kg eq, 99.2 percent TRR with the pyrazole-carboxamide label and 0.25 mg/kg eq, 99.3 percent TRR with the phenyl-carbamoyl label) was found in apple fruits (surface wash and extract combined). Besides parent compound, there were no other metabolites detected in the fruit extract with either label. Two very minor compounds (<0.001 mg eq/kg, ≤ 0.3 percent TRR) were found in the surface wash solution of the pyrazole-carbamoyl label and only one minor compound (0.001 mg eq/kg, 0.2 percent TRR) was detected in the surface wash solution of the phenyl-carbomoyl label.

Parent tetraniliprole was the main compound in the apple leaves sample and amounted to 98 mg eq/kg, 98.6 percent TRR. Six minor compounds were detected in the leaf extract and ranged from 0.051 to 0.32 mg eq/kg (0.1 to 0.3 percent TRR).

These results show that minimal metabolism of [pyrazole-carboxamide-^{14}C] and [phenylcarbamoyl-^{14}C] tetraniliprole occurs in apple fruit and leaves after foliar application of tetraniliprole. Only parent compound was identified (Table 9).

Lettuce – indoor foliar application

The distribution and metabolism of pyrazole-carboxamide label (Piskorski, 2014a, M-496411-01-1, Report EnSa-14-0613) or phenyl-carbamoyl label (Piskorski, 2014b, M-496407-01-1, Report EnSa-14-0612) in lettuce after two foliar spray applications was investigated. Lettuce plants (*Lactuca sativa* L, variety: Reine de Mai) were cultivated under artificial temperature and light conditions in the greenhouse of a Swiss (Witterswil) test facility. Plants were grown in three plastic containers using Spaniergrund (sandy loam soil). Radiolabelled tetraniliprole was formulated as SC 200 and applied to the plants. The two applications were performed as a spray foliar treatment at approximately BBCH 44–45 (40–50 percent of the expected head size reached), 14 days before harvest and again 7 days later, 7 days before harvest. The actual application rates were 2 × 59–60 g ai/ha (total rate 119 g ai/ha in both studies).

A total of six lettuce heads (leaves) were collected 7 days after the second application (BBCH 49). Aliquots of homogenized lettuce leaves were repeatedly (three times) extracted with acetonitrile/water/formic acid (8/2/0.1). Extracts were combined and concentrated.

The measurement of the radioactivity in liquid samples was carried out by LSC. All solid samples were combusted using an oxidiser, the released $^{14}CO_2$ was trapped in an alkaline scintillation cocktail and the radioactivity was determined by LSC.

In the lettuce leaf samples, the TRR amounted to 4.0 mg eq/kg and 4.1 mg eq/kg with the respective labels. The PES amounted to 0.020 mg eq/kg (0.5 percent TRR) and 0.038 mg eq/kg (0.9 percent TRR) with both labels respectively. The distribution of radioactivity in lettuce leaves is presented in Table 10.

Table 10 Distribution of radioactivity in the extracts of lettuce leaves following two foliar application of pyrazole-carboxamide and of phenyl-carbamoyl labelled tetraniliprole

Extracts were analysed by HPLC with radiometric and UV-detection and one-dimensional TLC with UV detection (at 254 nm). The identification of the compounds was performed with non-radiolabelled test item. Nearly all radioactivity (99.5 percent TRR) could be extracted and all extracted residues were identified as parent tetraniliprole. No metabolic degradation was observed, see Table 11.

Potato–Indoor foliar application

The metabolic fate of tetraniliprole in potatoes was investigated after two foliar applications with pyrazole-carboxamide (Bongartz & Junge, 2015a, M-508626-01-1, Report EnSa-14-0493) or with phenyl-carbamoyl (Bongartz & Junge, 2015b, M-508624-01-1, Report EnSa-14-0491) labelled tetraniliprole. Potato plants (*Solanum tuberosum* L, cv. Cilena) were cultivated under artificial temperature and light conditions in a greenhouse in Germany (Monheim am Rhein). Plants were grown in planting containers filled with Monheim 4 soil (sandy loam). Two foliar applications ranging from 101-105 g ai/ha each were applied at a 49 day interval at growth stages BBCH 38 and BBCH 97–99 (last application 14 days before harvest). The total application rate corresponded to 207 g ai/ha and 206 g ai/ha, respectively, based on an average seed density of 55,000 seed potatoes/ha.

Potato plants were harvested at maturity (BBCH 99) and separated into tubers and leaves. The leaves were not further processed/analysed. Soil was removed by hand and the potato tubers were washed with water. The radioactivity in the washing water was determined by LSC. The potato tubers were air dried, cut into four aliquots and mixed thoroughly. Potato tubers were homogenized and extracted three times with a mixture of acetonitrile/water (8/2) plus 0.1 percent formic acid (pH was determined but not reported). The solids were separated from the extract by centrifugation. The extracts

were combined and the radioactivity was determined by LSC (three aliquots) after volume measurement. PES were air-dried and homogenized. Aliquots were radio assayed by combustion followed by LSC.

TRR for potato tubers was very low (0.001 mg eq/kg). The tuber solvent extract and PES amounted to 74.6–79.3 percent TRR (0.001 mg eq/kg) and 20.7–25.4 percent TRR (< 0.001 mg eq/kg), respectively with both labels. The distribution of radioactivity in potato tubers is presented in Table 12.

Table 12 Distribution of radioactivity in the extracts of potato following indoor foliar applications of [pyrazole-carboxamide-^{14}C]- and of [phenyl-carbamoyl-^{14}C]-labelled tetraniliprole.

Parent compound and metabolites were quantified after multiple purification (partitioning 3 × ethyl acetate) and concentration steps in the organic phase (59 percent TRR, 64.6 percent TRR) of the potato tubers extract by TLC. The aqueous phase (20.3 percent TRR and 10.1 percent TRR, respectively) was not further explored. Potato tuber extracts were analysed by TLC with UV_{254} -detection using non-radiolabelled reference compounds (tetraniliprole and tetraniliprole-N-methylquinazolinone). Parent tetraniliprole was the main compound in the extract and represented 29 percent TRR (< 0.001 mg eq/kg) with the pyrazole-carboxamide label and 42 percent TRR (< 0.001 mg eq/kg) with the phenyl-carbamoyl label. Tetraniliprole-N-methyl-quinazolinone was the only identified metabolite in the extract and represented 9.0 percent TRR (<0.001 mg eq/kg) and 13 percent TRR (<0.001 mg eq/kg) for both labels, respectively. All other metabolite peaks represented <0.001 mg eq/kg. The metabolic profile of tetraniliprole in potato is presented in Table 13.

The only observed metabolic reaction was the intra-molecular condensation (cyclisation) of parent compound leading to tetraniliprole-N-methyl-quinazolinone.

Paddy rice–Indoor foliar treatment

The metabolism of tetraniliprole in paddy rice after two foliar treatments was investigated in two studies using either pyrazole-carboxamide label (Bongartz and Schallau, 2015a, M-496793-02-1, Report EnSa-14-0489) or phenyl-carbamoyl label (Bongartz and Schallau, 2015b, M-496787-02-1, Report EnSa-14-0488). Paddy rice (*Oryza sativa*, variety: Balilla) was cultivated under artificial temperature and light conditions in a greenhouse in Germany (Monheim am Rhein). Plants (11 plants/pot) were grown in planting containers filled with Monheim 4 soil (soil type: sandy loam). Two foliar applications ranging from 101–105 g ai/ha were applied at a 42-day interval. The radiolabelled tetraniliprole was formulated as SC 200 and applied onto the plants at BBCH 14 (four leaves unfolded) and BBCH 73–77 (early to late milk stage). Actual application rates were 52.3 g ai/ha for the first and 50.9 g ai/ha for the second treatment with the pyrazole-carboxamide label and 50.6 g ai/ha for the first and 49.9 g ai/ha for the second treatment with the phenyl-carbamoyl label.

Samples of rice forage, kernels, husks and straw were collected for analysis at BBCH 34–35 (rice forage) and BBCH 89–92 (husks, kernels and straw including panicles), corresponding with PHI of 13 and 56 days, respectively. All samples were extracted three times with a mixture of acetonitrile/water/formic acid (8/2/0.1; pH 3.5–3.8). The solids were separated from the extract by suction through a filter and the extracts were combined. The solids of husks and straw were additionally extracted twice with acetonitrile/water/formic acid (8/2/0.1) using microwave assistance and the extracts combined. The volume of each extract was determined and three aliquots radio-assayed by LSC. The extraction solids were air-dried and aliquots were radio assayed by LSC following combustion. The combined extracts were concentrated by rotary evaporation (40°C bath temperature).

TRR was found to be low in kernels (0.040 mg eq/kg and 0.024 mg eq/kg, for the respective labels). The TRRs of forage, husks and straw were higher due to their exposed surfaces during foliar treatment (1.3, 2.5 and 4.3 mg eq/kg, respectively for the pyrazole-carboxamide label and 2.6, 2.1 and 4.6 mg eq/kg, respectively for the phenyl-carbamoyl label).

The extraction efficiency for all commodities was >92 percent with both labels. PES of husks and straw were further extracted using microwave assistance; releasing 1.8 percent TRR (0.047 mg eq/kg) and 1.2 percent TRR (0.050 mg eq/kg), respectively with the pyrazole-carboxamide label and releasing 5.0 percent (0.106 mg/kg) and 2.1 percent (0.094 mg/kg), respectively with the phenyl-carbamoyl label. The PES of forage and kernels amounted to ≤0.022 mg eq/kg with both labels and were not further investigated. The distribution of radioactivity in forage, kernel, husk and straw samples is presented in Table 14.

[a] Pyr-car = [pyrazaole-carboxamide-^{14}C]-label; Phen-car= [phenyl-carbamoyl-^{14}C]-label

The concentrated extracts were used for HPLC analysis with radiometric- and UV-detection. HPLC method ANTAM was used for metabolite profiling and quantitation. The main compound found in the extracts was parent tetraniliprole (97 percent TRR (1.27 mg/kg) TRR for forage, 92 percent (0.037 mg/kg) for kernels, 96 percent (2.42 mg/kg) for husks and 95.3 percent (4.11 mg/kg) for straw). A minor metabolite was tetraniliprole-N-methyl-quinazolinone and amounted to 1.1 percent (0.014 mg eq/kg) TRR for forage, 1.5 percent (0.001 mg eq/kg) for kernels, 2.1 percent (0.052 mg eq/kg) for husks and 2.6 percent (0.112 mg eq/kg) for straw. All other metabolite peaks represented $\underline{<}$ 0.7 percent TRR. With the [phenyl-carbamoyl-^{14}C]-label a similar profile was observed. The main compound detected in the extracts was parent tetraniliprole (98 percent (2.54 mg/kg) TRR for forage, 91 percent (0.022 mg/kg) for kernels, 93 percent (1.95 mg/kg) for husks and 94.4 percent (4.31 mg/kg) for straw). A minor metabolite was tetraniliprole-N-methyl-quinazolinone and amounted to 0.7 percent (0.018 mg eq/kg) TRR for forage, 1.8 percent (<0.001 mg eq/kg) for kernels, 3.7 percent (0.078 mg eq/kg) for husks and 3.3 percent (0.151 mg eq/kg) for straw. All other metabolite peaks represented ≤ 0.8 percent TRR. Tetraniliprole was hardly metabolised in the rice after foliar treatment. The only observed metabolic reaction was an intra-molecular condensation (cyclisation) leading to tetraniliprole-N-methyl-quinazolinone (Table 15).

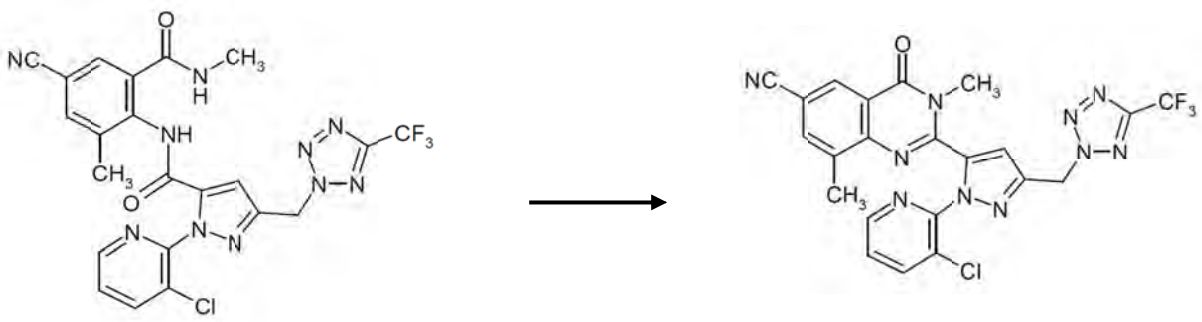
Overview of the metabolic pathway in plants

No metabolism in apples (foliar application) or lettuce (foliar application) was observed. One metabolism step could be identified in the metabolism studies in other crops, including tomato (soil drench application), potato (foliar application), paddy rice (foliar application as well as granular soil application), and maize (seed treatment) was the cyclisation in the parent molecule leading to tetraniliprole-N-methyl-quinazolinone (Figure 1).



tetraniliprole tetraniliprole-N-methyl-quinazolinone

Figure 1 Metabolism of tetraniliprole observed in tomato, potato, rice and maize

Environmental fate in water/sediment systems

Hydrolysis in sterile water buffers

The abiotic hydrolytic degradation of [pyrazole-carboxamide-^{14}C]-tetraniliprole was studied at 20, 25 and 50 °C in sterile buffer solutions with pH values of 4, 7 or 9 in the dark in the laboratory (Hein&Kasel, 2016, M-565616-01-1, Report EnSa-14-0308).

A study application rate of 0.3 mg/L was applied, considering the low water solubility of the test item and its degradation products.

Duplicate samples were processed and analysed. The radioactivity in the test solutions was determined by LSC, and HPLC-ESI-MS/MS and radio-detection was used for confirmation of the test item identity and for structure elucidation of the degradation product. Additionally, test item identity was confirmed by NMR.

At 50 °C and pH 4 and pH 7 samples were processed and analysed after 0.25, 1.04, 2.25, 7, 14, 21 and 30 days. The pH 9 samples were processed 0.04, 0.08, 0.17, 0.25, 1.04 and 2.04 days after treatment (DAT) corresponding to 1, 2, 4, 6, 25 and 49 hours. At 25 °C and pH 4 and pH 7 samples were processed after 1.04, 2.25, 7, 14, 21 and 30 days. The pH 9 samples were processed after 0.125, 0.25, 1.04, 2.25, 7,

14, 21 and 30 days. At 20 °C and pH 4 and pH 7 samples were processed after 1.04, 2.25, 7, 14, 21 and 30 days. The pH 9 samples were processed after 0.25, 1.04, 2.25, 7, 14, 21 and 30 days.

On incubation at 50 °C the amount of tetraniliprole in test solution decreased at pH 4 from 100 percent ofapplied radioactivily (AR) at DAT-0 to 16.3 percent AR at DAT-30. At pH 7, the values were 100 and 1.6 percent AR, and at pH 9 were 97.2 and 2.9 percent AR, respectively. At 25 °C, tetraniliprole decreased at pH 4 from 100 to 89.6 percent AR, at pH 7 from 100.0 to 56.5 percent AR, and at pH 9 from 97.2 to 1.8 percent AR. At 20 °C, the amount decreased at pH 4 from 100.0 to 91.5 percent AR, at pH 7 from 100 to 68.1 percent AR, and at pH 9 from 97.2 to 1.5 percent AR at DAT-30.

One degradation product was identified as tetraniliprole-N-methyl-quinazolinone with a maximum amount of 99.6 percent AR at DAT-30 (pH 9, optional test, 20 °C). The total unidentified residues amounted to a maximum of 3.3 percent AR and no single unidentified component exceeded 3.3 percent AR at any sampling interval of all conducted tests.

Following incubation at 50 °C, the material balances at pH 4 ranged from 92.5 to 100 percent AR, at pH 7 from 92.5 to 100.9 percent AR, and at pH 9 from 93.2 to 101.1 percent AR. Following incubation at 25 °C, material balances at pH 4 ranged from 93.0 to 100 percent AR, at pH 7 from 92.2 to 100 percent AR, and at pH 9 from 98.7 to 103.1 percent AR. Following incubation at 20 °C, material balances at pH 4 ranged from 93.7 to 101.8 percent AR, at pH 7 from 93.4 to 100 percent AR, and at pH 9 from 97.1 to 103.9 percent AR.

The degradation rate of tetraniliprole for all pH values at all temperatures was calculated using first order kinetics (SFO). The hydrolytic degradation of tetraniliprole was observed to be pH dependent. Results are summarised in Table 16.

Table 16 Kinetic evaluation of hydrolysis of tetraniliprole at different pH values and at different temperatures

Temperature (^{o}C)	pH	SFO		
		DT_{50} (d)	DT_{90} (d)	χ^2 error ( )
50	4	10.9	36.0	2.7
50	7	3.74	12.4	3.1
50	9	0.04	0.13	5.5
25	4	287	953	1.7
25	7	38.8	129	2.3
25	9	0.75	2.48	3.8
20	4	265	882	1.8
20	7	58.0	193	1.7
20	9	1.27	4.21	4.2

In summary, the hydrolytic degradation of tetraniliprole strongly depended on the temperature and the pH conditions. Tetraniliprole degraded rapidly at pH 9 and well at pH 7 at all temperatures in the laboratory. For pH 4, it was degraded rapidly at 50 °C and slowly at 20 and 25 °C. The calculated half-lives of tetraniliprole were between 0.04 and 10.9 days at 50 °C, between 0.75 and 287 days at 25 °C and between 1.27 and 265 days at 20 °C. One degradation product was identified as tetraniliprole-N-methyl-quinazolinone with a maximum amount of 99.6 percent AR (at DAT-30; pH 9, optional test, 20 °C).

Phototransformation in natural water

The photolytic route and rate of degradation of [pyridinyl-2-^{14}C]-tetraniliprole was studied in sterile natural water (pH 8.5) from the river Rhine under exposure to simulated sunlight in the laboratory for 11 days at 25 ± 2 °C (Heinemann&Kasel, 2016a, M-568022-01-1, Report EnSA-16-0158).

A study application rate of 0.5 mg/L was applied due to the low water solubility of the test item. 11 days of incubation under exposure to simulated sunlight were equivalent to 69.6 days of solar summer days in Japan. Control samples were incubated in the dark.

Mean material balances were 101 and 103 percent AR for irradiated and dark samples, respectively. The maximum amounts of carbon dioxide were 38.9 and ≤0.1 percent AR in irradiated and dark samples, respectively. Formation of volatile organic compounds (VOC) was insignificant as demonstrated by values of ≤0.2 percent AR at all sampling intervals for both, irradiated and dark samples.

The amount of tetraniliprole in the test solution decreased from 97.7 percent AR at study start (DAT-0) to non-detectable amounts and 4.8 percent AR at DAT-11 in irradiated and dark samples, respectively. Besides the formation of carbon dioxide two degradation products were identified in irradiated samples with the following maximum occurrences: tetraniliprole-N-methyl-quinazolinone with 39.2 percent AR at DAT-1 and tetraniliprole-deschloro-pyrazine with 38.8 percent AR at DAT-2. The total unidentified residues amounted to a maximum of 62.4 percent AR and no single component exceeded 7.3 percent AR at any sampling interval. In dark samples tetraniliprole was degraded to tetraniliprole-N-methyl-quinazolinone with the maximum occurrence of 99.0 percent AR at DAT-11. A summary of the degradation results is presented in Table 17.

Table 17 Photodegradation of [pyridinyl-2-^{14}C]-tetraniliprole in natural water with mean values expressed as percent AR (± SD)

Notes:
ND = Not Detected; NA = Not Analysed.
[a] Time zero analysis for both irradiated and non-irradiated experiments.
[b] Refers to radioactivity not associated with specific compounds, the maximum amount of a single degradation product was 7.3% applied radioactivity.

The experimental data could be well described by a SFO kinetic model. The half-life of tetraniliprole in irradiated samples was 0.77 days with a predicted environmental DT_{50} calculated values of 4.9 solar summer days at Tokyo, Japan. Under dark conditions, DT_{50} was 0.75 days. A summary of the kinetics data is presented in Table 18

Table 18 Kinetic parameters for the photodegradation of [pyridinyl-2-^{14}C]-tetraniliprole in sterile natural water (SFO model)

Test system	DT_{50} (days)	DT_{90} (days)	χ^2 Error(%)	Rate Constant (day^{-1})	DT_{50} under natural conditions(days)	Net Photodegradation Rate Constant[a] /DT^{50} ($days^{-1}$ / days)
Irradiated	0.77	2.6	6.1	0.90	4.9 (Tokyo, Japan)[b]	Degradation under dark conditions was faster than under irradiated conditions
Dark	0.75	2.5	9.5	0.93	No conversion	

Notes:

[a] Net rate constant = rate constant of irradiated samples – rate constant of dark samples.

[b] Since the experimental degradation rates of tetraniliprole were identical under irradiated and dark conditions, it is assumed that the DT_{50} value determined for dark samples also applies for natural conditions.

In another study, the photolytic route and rate of degradation of [pyrazole-carboxamide-^{14}C]-tetraniliprole was studied in sterile natural water (pH 8.0) from the river Rhine under exposure to simulated sunlight in the laboratory for 10 days at 25 ± 2 °C (final study temperature 24.9 °C (mean irradiated) and 24.4 °C (mean dark)) (Heinemann&Junge, 2014, M-489424-01-1, Report EnSA-13-0321).

A study application rate of 0.45 mg/L was applied due to the low water solubility of the test item. 10 days of incubation under exposure to simulated sunlight were equivalent to 69.1 days of solar summer days in Japan. Control samples were incubated in the dark.

Mean material balances were 95.6 and 97.6 percent AR for irradiated and dark samples, respectively. The maximum amounts of carbon dioxide were 10.9 and ≤0.1 percent AR in irradiated and dark samples, respectively. Formation of VO was insignificant as demonstrated by values of ≤0.1 percent AR at all sampling intervals for both, irradiated and dark samples. The amount of tetraniliprole in the test solution decreased from 97.2 percent AR at study start (DAT-0) to 1.2 and 4.1 percent AR at DAT-10 in irradiated and dark samples, respectively.

Besides the formation of carbon dioxide four degradation products were identified in irradiated samples with the following maximum occurrences: tetraniliprole-N-methyl-quinazolinone with 34.5 percent AR at DAT-0.25, tetraniliprole-despyridyl-N-methyl-quinazolinone with 7.2 percent AR at DAT-2, tetraniliprole -deschloro-pyrazine with 37.2 percent AR at DAT-2 and tetraniliprole -pyrazole-5-carboxylic acid with 18.0 percent AR at DAT-10. The total unidentified residues amounted to a maximum of 56.3 percent AR and no single component exceeded 9.4 percent AR at any sampling interval. In dark samples tetraniliprole was degraded to tetraniliprole -N-methyl-quinazolinone with the maximum occurrence of 95.0 percent AR at DAT-10 (Table 19).

Table 19 Photodegradation of [pyrazolecarboxamide-^{14}C]-tetraniliprole in natural water with mean values expressed as percent AR (± standard deviatin)

Compound	Sample	Days exposed to simulated sunlight						
		0 [a]	0.25	1	2	4	7	10

Notes:
ND – Not Detected; NA – Not Analysed.
[a] Time zero analysis for both irradiated and non-irradiated experiments.
[b] 'Others' refers to radioactivity not associated with specific compounds, the maximum amount of a single degradation product was 9.4% applied radioactivity.

The experimental data could be well described by a SFO kinetic model. The half-life of tetraniliprole in irradiated samples was 0.7 days, with a predicted environmental DT_{50} calculated values to be e.g. 4.7 solar summer days at Tokyo, Japan. Under dark conditions, a DT_{50} was 0.3 days. A summary of the kinetics is presented in Table 20.

Table 20 Kinetic parameters for the photodegradation of [pyrazolecarboxamide-^{14}C]-tetraniliprole in sterile natural water (SFO model)

Test system	DT_{50} (days)	DT_{90} (days)	Chi^2 Error (%)	Rate Constant (day^{-1})	DT_{50} under natural conditions(days)	Net Photodegradation Rate Constant [a] /DT_{50} [$days^{-1}$ / days]
Irradiated	0.7	2.2	18.2	1.0	4.7 (Tokyo, Japan)	Degradation under dark was faster than under irradiated conditions
Dark	0.3	1.1	16.8	2.2	No conversion	

Notes:
[a] Net rate constant = rate constant of irradiated samples – rate constant of dark samples.

It is concluded that photodegradation contributes to the overall degradation of tetraniliprole under aqueous conditions in natural water.

Environmental fate in soil

Photodegradation on the soil surface

The photodegradation of [pyrazole-carboxamide-^{14}C]-tetraniliprole under exposure to simulated sunlight and aerobic conditions was studied in one German soil in the laboratory for 11 days at 20 ± 2 °C (König& Beckmann, 2014, M-493228-01-1, Report EnSa-14-0217). Soil characteristics are reported in Table 21. Soil was kept in a Suntest® unit containing a Xenon lamp simulating natural sunlight. The light emission was filtered with a 290 nm cut-off UV-filter, which eliminated all wavelengths <290 nm. The intensity of the Xenon lamp was determined at the beginning and the end of the overall test period using a radiometer and photodetector assembly and was calculated as 1089 W/m2 for 300 to 2450 nm. At this light intensity, it takes 8.0 and 5.1 hours in the Suntest® unit to equal one solar summer day at Phoenix and Athens, respectively.

[Pyrazole-carboxamide-^{14}C]-tetraniliprole was applied to thin layers of soil at an application rate of 7.3 mg/kg dry soil weight (equivalent to a field application rate of 200 g tetraniliprole/ha) in individual photolysis vessels. The test was performed in static systems consisting of quartz glass vessels each containing 3 g soil (dry weight equivalents) and equipped with traps for the collection of carbon dioxide and volatile organic compounds. The test systems were continuously exposed to irradiation with artificial sunlight (Xenon lamp with a < 290 nm cut-off filter). 11 days of continuous irradiation were equivalent to 33.4 and 51.8 solar summer days in Phoenix (Arizona, United States) and Athens (Greece), respectively. Control samples were incubated in the dark.

Duplicate test systems were processed and analysed 0, 1, 2, 4, 7, 9 and 11 days after treatment (DAT) for both irradiated and dark samples.

Table 21 Soil characteristics of a German soil

Soil and location	Hoefchen am Hohenseh 4a, Burscheid,
Soil texture (USDA) [a]	silt loam
-- Sand (%)	26
-- Silt (%)	57
-- Clay (%)	17

Organic Matter (%)	3.1
CEC (meq/100 g)	11.5
pH (soil/water 1/1)	6.8
pH (soil/1 N KCl 1/1)	6.1
pH ($CaCl_2$)	6.4
Maximum Water Holding Capacity H_2O ad 100 g soil dry weight [%]	53.5
Water Holding Capacity at pF 2.0 (0.1 bar) [%]	39.5
Disturbed bulk density (g/cm^3)	1.12
Microbial biomass (mg microbial C/kg)	888

Notes:
[a] Classification according to United States Department of Agriculture (USDA).
[b] Organic C = organic matter/1.724 based on the certificate values.

At each sampling interval, the soil was extracted twice at ambient temperature using acetonitrile/water (4/1) and once using acetonitrile. Furthermore, two microwave-accelerated extraction steps were performed using acetonitrile/water (1/1) at 70 °C and acetone/water (1/1) at 50 °C. Degradation products in soil extracts were determined by LSC and by HPLC-radiodetection analysis. Vvolatiles and non-extracted residues were determined by LSC and combustion/LSC, respectively. Compound identity was confirmed by HPLC-MS(/MS) including accurate mass determination and by 1H-

NMR. The LOD for the HPLC-radio-detection method was 0.5 percent AR and the corresponding LOQ was 1.6 percent AR. Volatiles and non-extracted residues were determined by LSC and combustion/LSC, respectively.

The identity of the test item and its degradation product was elucidated by LC-MS/MS and/or assigned by comparison of the retention times with those of unlabelled tetraniliprole and tetraniliprole-N-methyl-quinazolinone.

Overall mean material balances were 98.7 percent AR for irradiated samples and 100 percent AR for dark samples. The maximum amount of carbon dioxide was 0.8 and <0.1 percent AR at study end (DAT-11) in irradiated and dark samples, respectively. Formation of organic volatiles was insignificant (< 0.1 percent AR) at all sampling intervals for both irradiated and dark samples.

Extracted residues ranged from 94.7 to 102.1 percent AR in irradiated samples and from 96.1 to 102.6 percent AR in dark samples. Non-extracted residues (NER) increased from <0.1 percent AR at DAT-0 to 1.3 and 0.4 percent AR at DAT-11 in irradiated and dark samples, respectively.

The amount of tetraniliprole decreased from 101.5 percent AR at DAT-0 to 77.4 percent AR at DAT-11 in irradiated samples and from 101.5 percent AR to 86.5 percent AR in dark samples, indicating degradation in irradiated samples. Tetraniliprole-N-methyl-quinazolinone was identified as a degradation product in irradiated samples (7.0 percent AR at DAT-11) and in the dark samples (5.7 percent AR at DAT-11). The unidentified residues amounted to a maximum of 12.9 percent AR in the irradiated samples with no single component exceeding 1.9 percent AR and the total unidentified residue in the dark samples amounted to 7.5 percent AR with no single component exceeding 2.9 percent AR.

The summary of the amount of [pyrazole-carboxamide-^{14}C]-tetraniliprole and its degradation products is presented in Table 22.

Aerobic degradation in soil – laboratory studies

[Pyrazole-carboxamide-^{14}C] – German soils

The degradation and time-dependence of sorption of [pyrazole-carboxamide-^{14}C]-tetraniliprole under aerobic laboratory conditions was studied in four terrestrial German soils (Hellpointer & Junge, 2015, M-465975-02-1, Report EnSa-113-0244). Soil characteristic are reported in Table 24 and Table 25.

Soil was treated with [pyrazole-carboxamide-^{14}C]-tetraniliprole, at an application rate of 54.9 µg/100 g soil (dry weight), equivalent to a single field application of 200 g ai/ha. The test was performed in static systems consisting of Erlenmeyer flasks each containing 100 g soil dry weight and equipped with traps for the collection of [^{14}C]-carbon dioxide and volatile organic compounds. The active substance was dispensed on the soil surface and mixed with the soil. Soil samples were incubated under aerobic conditions in the dark at 20 ± 2°C for 119 days. Duplicate soil samples were taken and analysed at 0.5 hours, 24 hours, 2, 6, 9, 16, 22, 29, 62, 91and 119 days of incubation. Soil moisture was adjusted to the maximum water holding capacity (WHC) every 30 days.

Microbial biomass at DAT = 62[a]	301	1885	429	602
Microbial biomass at DAT = 212[a][b]	172	1207	202	283

Notes:

[a] mg microbial carbon/kg soil dry weight.

[b] Scheduled termination date was 119 days, however, the measurements were undertaken later. This had no negative impact on the results.

Soil samples were extracted with aqueous 0.01 M $CaCl_2$ solution. After shaking for 24 hours to gain equilibrium, the suspension was centrifuged and the supernatant was removed. The remaining soil was extracted with organic solvents (two extractions with acetonitrile/water (80/20), followed by 2 extractions with acetonitrile) at room temperature and once under elevated temperature conditions (70 °C with acetonitrile/water and 50 °C with acetone to obtain elevated temperature organic extracts).

After the extraction steps the suspensions were centrifuged for $CaCl_2$ and organic extractions, respectively. The radioactivity content of these extracts was determined by LSC. The elevated temperature extracted soils were air-dried, homogenized by a planetary mill and NER were determined by combustion/LSC.

Soil extracts were characterised by LSC and HPLC/radio-detection. The LOD and the LOQ for the HPLC/radio-detection method were 0.3 and 0.9 percent AR, respectively. The amount of volatiles and non-extracted residues were determined by LSC and combustion/LSC, respectively. Recovery of the applied activity ranged from 97.2–98.5 percent AR.

The identity of the test item and its degradation products was elucidated by HPLC-MS/MS and/or assigned by comparison of the retention times with those of reference items. Reference standards used were FIX12121 (Reg 4-tetraniliprole-carboxylic acid or tetraniliprole-carboxylic acid), FIX11773 (Reg 2 (BCS-CQ63359 or tetraniliprole-N-methyl-quinazolinone), FIX12014 (BCS-CN61675).

Maximum amounts of $^{14}CO_2$ detected at DAT-119 (study end) ranged from 0.6 percent AR to 2.5 percent AR. Formation of volatile organic compounds was not significant (≤0.1 percent AR at all sampling intervals).

Total extracted residues decreased from 94.1–95 percent AR at DAT-0 to 84.3–94.4 percentAR at DAT-119 in the four soils. Non-extracted residues (NER) increased from 0.2, 0.7, 0.3 and 0.3 percent AR at DAT-0 to maximum amounts of 5.2, 13.9, 9.3 and 8.1 percent AR at DAT-119 in soils AX, DD, HN and HF, respectively.

The amount of tetraniliprole in the soil extracts decreased from 91.2 percent AR at DAT-0 to 41.9 percent AR at DAT-119 in soil AX, from 87.7 to 4.9 percent AR in soil DD, from 92.1 to 55.9 percent AR in soil HN and from 88.8 to 17.1 percent AR in soil HF. Six degradation products were identified above 5 percent AR: tetraniliprole-quinazolinone-carboxylic acid (maximum of 6.5 percent AR at DAT-119 in soil DD), tetraniliprole-N-methyl-quinazolinone (maximum of 14.6 percent AR at DAT-91 in soil HF), tetraniliprole-amide (maximum of 6.9 percent AR at DAT-62 in soil HN), tetraniliprole-carboxylic acid (maximum of 47.8 percent AR at DAT-62 in soil DD), tetraniliprole-desmethyl-amidecarboxylic acid (maximum of 12.0 percent AR at DAT-119 in soil HF), and tetraniliprole-N-methyl-quinazolinone-carboxylic acid (maximum of 10.6 percent AR at DAT-119 in soil DD). Furthermore, five degradation products were found with no component exceeding 3.5 percent AR at any sampling interval.

The amount of [pyrazole-carboxamide-^{14}C]-tetraniliprole and its degradation products as percent of applied radioactivity is summarised in Table 26.

Notes:

T = Tetraniliprole; n.d.: not detected, n.a.: not analysed, DAT: days after treatment, SD: standard deviation.

[a] Samples shaken on mechanical overhead shaker for 0.5 h or 24 h with $CaCl_2$ solution.

[b] Samples shaken on mechanical overhead shaker for 24 h with $CaCl_2$ solution.

[b] Taken from Material Balance, values may differ due to rounding.

The data were evaluated according to the FOCUS guidance document on degradation kinetics (2006) using the software KinGUI 2 to derive the DT_{50} and DT_{90} values of tetraniliprole. The results are summarised in Table 27.

Table 27: Best-fit degradation kinetics of tetraniliprole in soils under aerobic conditions

Soil (soil type)	Kinetic model	DT_{50} (days)	DT_{90} (days)	χ^2 error (%)	Visual assessment
Laacher Hof AXXa (Loamy Sand)	DFOP	94.5	959.1	1.0	Good
Dollendorf II (Loam)	FOMC	18.4	83.4	1.9	Good
Hanscheiderhof (Silt Loam)	FOMC	183	> 1000	0.7	Good
Hoefchen Am Hohenseh 4a (Silt Loam)	FOMC	43.8	176.8	1.3	Good

Notes:
DFOP = Double first order in parallel; FOMC = first order multi compartment

.

Additionally, at each sampling interval, the soils were extracted with aqueous $CaCl_2$ solution (24 hours for determination of desorption behaviour) to determine the time-dependent sorption. The sorption of tetraniliprole to soil increased in the course of the study. The calculated RTDS values (Ratio of concentration of test item in soil (µg/g)/ concentration of test item in solution (µg/mL) were 4.61, 11.69, 6.71 and 8.04 mL/g for soils Laacher Hof AXXa, Dollendorf II, Hanscheiderhof and Hoefchen Am Hohenseh 4a, respectively, at the beginning of the study (DAT-0). With time of aging in soil, values increased to 13.91, 38.62, 19.39, and 28.82 mL/g on DAT-119 for the four soils.

United States soils

The degradation and time-dependence of sorption of [pyrazole-carboxamide-^{14}C]-tetraniliprole under aerobic dark laboratory conditions was investigated in six US for 120 days (Mislankar & Haddix, 2016, M-557172-01-1, Report MEFVP098). Soil characteristics are reported in Table 28 and Table 29.

Soil (50 g) was treated at a nominal application rate of 0.5 mg tetraniliprole/kg soil (dry weight), equivalent to a field rate of 200 g ai/ha (2.5 cm depth, 1.5 g/cm^3 bulk density) based on a single field application rate of 200 g tetraniliprole/ha. The test was performed in flow through system consisting of Erlenmeyer flasks each containing 50 g soil dry weight and equipped with traps for the collection of [^{14}C]-carbon dioxide and volatile organic compounds. The active substance was dispensed on the soil surface and mixed with the soil. Soil samples were incubated under aerobic conditions in the dark at 20 ± 2°C for 120 days. Duplicate soil samples were taken and analysed at 0.5 hours, 24 hours and 2, 7, 14, 28, 42, 63, 91, and 120 days after treatment for soils KS, NE, CA and ND. For CAH and HCB soils, duplicate samples were analysed after 0.5 and 24 hours, and 2, 7, 21, 30, 42, 63, 91, and 120 days after treatment. Soil moisture was adjusted to the maximum water holding capacity (WHC) 4-10 times on days 7/13, 18, 28, 37, 49, 56/58/64, 72/73, 81/84/87, 102/111, and/or 116.

Table 28 Soil characteristics of six soils in the United States of America

Soil name	KS	NE	CA	NF	CAH	HCB
Location	Stilwell, Kansas	Louisville, Nebraska	Sanger, California	Grand Forks County, North Dakota	Hughson California	Northwood, North Dakota
Soil texture (USDA) [a]	Silt loam	Silt loam	Sandy loam	Clay loam	Loamy sand	Clay loam
-- Sand (%)	4.7	15.5	68.5	32.0	78.6	22.4

Hughson, CA (CAH)	Actinomycetes	61,000	6,180	318,000	306,000
	Fungi	1,460	8,240	8,220	11,000
	Bacteria	488,000	2,750,000	651,000	721,000
Northwood, ND (HCB)	Actinomycetes	169,000	41,800	388,000	287,000
	Fungi	260	2,630	4,490	4,190
	Bacteria	109,000	1,540,000	466,000	747,000

At each sampling interval, the soil was extracted first with aqueous 0.01 M $CaCl_2$ solution, followed by four shake extractions at ambient temperature and two microwave- accelerated extractions at elevated temperature. Acetonitrile/water (80/20) was used for the first two ambient extractions and acetonitrile for the third and fourth extractions. The first microwave-accelerated extraction was performed at 70 °C using acetonitrile/water (80/20) and the second was performed at 50° C using acetone. Soil extracts were characterised by LSC and HPLC-radio-detection. The LOQ for the HPLC-radio-detection method was 1 percent AR. The amount of volatiles and non-extracted residues was determined by LSC and combustion/LSC, respectively. The tetraniliprole residues were analysed by HPLC coupled to a

radio-detector. Identification of the degradation products was accomplished by co-chromatography with authentic standards and LC-ESI/MS with exact mass capability. Reference items used were tetraniliprole-N-methyl-quinazolinone, tetraniliprole-N-methyl-quinazolinone-carboxylic acid, tetraniliprole-carboxylic acid, tetraniliprole-desmethyl-amide-carboxylic acid, and tetraniliprole -amide.

Mean material balances were 95.2, 93.4, 97.1, 99.5, 95.0 and 95.8 percent AR for KS, NE, CA, ND, CAH and HCB soils, respectively. The maximum amount of $^{14}CO_2$ formed was 1.3, 0.8, 1.0, 0.7, 0.8 and 2.1 percent AR at study end (DAT-120) in KS, NE, CA, ND, CAH and HCB soils, respectively. Formation of organic volatiles was insignificant (≤ 0.3 percent AR) at all sampling intervals for all soils.

Total extracted residues decreased from DAT-0 to DAT-120 from 99.2–100 percent AR to 75.2–91.4 percent AR in the six soils. Non-extracted residues increased from 0.3, 0.3, 0.3, 0.8, <LOQ and 0.3 percent AR at DAT-0 to 10.4, 8.4, 3.2, 12.3, 3.5 and 18.9 percent of AR at DAT-120 in soils KS, NE, CA, ND, CAH and HCB soils, respectively.

The amount of tetraniliprole in the soil extracts decreased from DAT-0 to DAT-120 from 98.7–98.8 percent to 23.5–50.7 percent AR in the six soils. Two degradation products, tetraniliprole-carboxylic acid and tetraniliprole-N-methylquinazolinone were identified with a maximum of 34.8 percent AR at DAT-120 in HCB soil and 33.4 percent AR at DAT-120 in CAH soil, respectively. Additionally, three degradation products were found, but with a maximum concentration not exceeding 4.9 percent AR at any sampling interval. The amount of [pyrazole-carboxamide-^{14}C]-tetraniliprole and its degradation products as percent of applied radioactivity is summarised in Table 30.

Table 30 Degradation of tetraniliprole in six United States soils under aerobic conditions (percent AR; mean value of duplicates)

Notes:

T=tetraniliprole; n.a.: not analysed, DAT: days after treatment, ± SD: standard deviation.

[a] Samples shaken on benchtop shaker for 0.5 h with $CaCl_2$ solution.

[b] Samples shaken on benchtop shaker for 24 h with $CaCl_2$ solution.

[c] Taken from Material Balance, values may differ due to rounding

[d] One replicate only, replicate 2 data not used, test system did not have enough moisture for proper metabolism.

[e] One replicate only, centrifuge bottle broke and sample lost for replicate 2.

[f] One replicate only, for replicate 2 flask may not have received correct dose.

The rate of degradation of tetraniliprole was calculated using kinetic modelling. The data were evaluated according to the FOCUS guidance document on degradation kinetics (2006) using the software KinGUI 2 to derive the DT_{50}, DT_{75} and DT_{90} values of tetraniliprole. The best-fit degradation kinetics of tetraniliprole in soil are summarized in Table 31.

Table 31 Best-fit degradation kinetics of tetraniliprole in soils under aerobic conditions

Soil (soil type)	Kinetic model	DT_{50} (d)	DT_{75} (d)	DT_{90} (d)	χ^2 error (%)	Visual assessment
KS (silt loam)	DFOP	91.8	202	348	1.22	Good
NE (silt loam)	DFOP	58.3	134	234	3.09	Good
ND (clay loam)	DFOP	90.1	200	345	1.62	Good
CA (sandy loam)	DFOP	117	267	465	2.99	Good
CAH (loamy sand)	DFOP	82.5	197	346	1.58	Good
HCB (clay loam)	DFOP	45.8	111	198	1.82	Good

Notes:
DFOP = double first order in parallel.

Additionally, at each sampling interval, the soils were extracted with aqueous $CaCl_2$ solution (24 hours for determination of desorption behaviour) to determine the time-dependent sorption. The sorption of tetraniliprole to soil increased in the course of the study. The calculated RTDS values (Ratio of concentration of test item in soil [µg/g]/ concentration of test item in solution [µg/mL]) were 4.67, 6.87, 1.45, 14.86, 0.58 and 14.91 mL/g for soils KS, NE, CA, ND, CAH and HCB, respectively, at the beginning of the study (DAT-0). With time of aging in soil, these values increased throughout the study in all soils to 12.11, 15.12, 4.64, 80.53, 1.86 and 51.24 mL/g for soils KS, NE, CA, ND, CAH and HCB, respectively, on DAT-120.

Italian paddy soil

The route and rate of degradation of [pyrazole-carboxamide-^{14}C]-tetraniliprole under dark laboratory conditions was investigated in an Italian paddy sandy loam soil at 25 ± 2 °C for 181 days (Heinemann & Kasel, 2016b, M-545810-01-1, Report EnSa-14-1369). Soil characteristics are given in Table 32.

Paddy conditions were re-created using static test systems consisting of cylindrical flasks (5 cm diameter) containing 100 g soil (dry weight equivalent) and 100 mL of de-ionised water (water layer approximately 3.5 cm height). Incubation vessels were equipped with traps (permeable for oxygen) for the collection of carbon dioxide and volatile organic compounds. Untreated test vessels were equilibrated to study conditions for 15 days prior to application (to establish reductive conditions in the deeper soil layer, E_H <200 mV).

The application rate used in the study was 58.9 µg/100g soil (dry weight) based on a single field application rate of tetraniliprole at 200 g/ha (assuming a soil mixing depth of 0.1 m and a soil bulk density of 1.0 g/cm^3). Due to analytical reasons, a 3-fold application rate was used resulting in a nominal study application rate of 600 µg/kg (soil dry weight). Applications were made via pipette drops to the water surface of each pre-equilibrated test system prior to the water and soil in each sample being completely mixed.

Duplicate samples were processed and analysed at 0, 3, 7, 14, 30, 62, 100, 140 and 181 days after treatment (DAT). At each sampling interval, the water was decanted and the remaining soil extracted at ambient temperature, twice using acetonitrile/water (4/1) and twice using acetonitrile. Following this, two microwave-assisted extraction steps were performed using acetonitrile/water (4/1) at 70 ˚C and acetone at 50 ˚C.

[a] Classification according to United States Department of Agriculture (U± SDA).

[b] Organic C = organic matter/1.724 based on the certificate values.

The water and soil extracts were analysed by LSC and HPLC-radio-detection analysis. The LOD and the LOQ for the HPLC/radio-detection method were 0.3 and 0.9 percent of applied radioactivity (percent AR), respectively, for the water phase and 0.6 and 1.7 percent AR, respectively, for the combined extract (the maximum LOD and LOQ values for the combined extract were the values taken into account for calculations). The amount of volatiles and non-extracted residues was determined by LSC and combustion/LSC, respectively.

The identity of the test item and its degradation products were identified by HPLC-MS/MS including accurate mass determination. Reference standards used were parent tetraniliprole and tetraniliprole--N-methyl-quinazolinone.

Overall, the material balance ranged from 101 to 109 percent AR with a mean material balance, throughout the study, of 102 percent AR. The maximum amount of $^{14}CO_2$, detected at the end of the study (DAT-181), was only 0.1 percent AR and formation of volatile organic compounds (VOCs) was also insignificant (≤0.2 percent AR at all sampling intervals).

Residues in the water compartment decreased from 54.9 percent AR (0-DAT) to 2.6 percent AR (181-DAT). Extractable residues in the soil increased from 47.4 percent AR at DAT-0 to 94.0 percent AR at DAT-140 and then decreased to 85.9 percent AR at DAT-181. Extracted residues in the total system (water and soil extracts) decreased from 102 percent AR at DAT-0 to 88.5 percent AR at DAT-181. Non-extracted residues increased from 0.1 percent AR (DAT-0) to 12.1 percent AR (DAT-181).

The amount of tetraniliprole in the water decreased from 54.3 percent AR (DAT-0) to 0.9 percent AR (DAT-181). The amount of tetraniliprole in the soil extracts increased from DAT-0 to DAT-30, from 46.9 to 55.9 percent AR, and then decreased to 34.4 percent AR at the end of the study (DAT-181). The amount of tetraniliprole in the total system decreased from 101 (DAT-0) to 35.3 percent AR (DAT-181).

One degradation product was identified. Tetraniliprole-N-methyl-quinazolinone was found to have a maximum occurrence in the total system of 47.6 percent AR at DAT-140. Other unidentified residues in

the total system amounted to a total maximum of 6.3 percent AR and no single component exceeded 3.6 percent AR at any sampling interval.

The mean recoveries of radioactivity in the Satirana Lomellina soil under paddy conditions are presented in Table 33. The amount of [pyrazole-carboxamide-^{14}C]-tetraniliprole and its degradation product as percent of applied radioactivity is summarised in Table 34.

Table 33 Material balance and distribution of radioactivity in the sandy loam soil Satirana Lomellina under paddy (mixed anaerobic/aerobic) conditions (expressed as percent of applied radioactivity; mean value of duplicate samples)

Notes:

n.d.: not detected, LOD: limit of detection; ± SD: standard deviation.

[a] Minor components are summed up to sum of unidentified / diffuse residues. None of the unidentified minor components individually exceeded 4% AR.

[b] These values may differ to the material balance values due to rounding errors as well as clean up and chromatographic losses.

[c] Values taken from Material Balance.

[d] Mean values of the entire system could be unequal compared to the sum of the mean values of water and soil, because mean values of the entire system were calculated.

The data for the test item were evaluated according to the FOCUS guidance document on degradation kinetics (2006) using the software KinGUI 2 to derive the DT_{50} and DT_{90} values of tetraniliprole. The degradation of tetraniliprole under paddy conditions best followed double first order in parallel (DFOP) kinetics in both the water and the total system based on the lowest chi^2 error values and visual assessments of fits. The best-fit degradation kinetics of tetraniliprole are summarized in Table 35.

Table 35 Best-fit degradation kinetics of tetraniliprole in a Satirana Lomellina paddy soil system under paddy conditions and overlying water using the double first order in parallel model

Satirana Lomellina sandy loam soil	DT_{50} (d)	DT_{90} (d)	χ^2 error (%)	Visual assessment
Water	4.4	46.0	7.3	Good
Entire System	84.5	548	1.3	Good

The proposed degradation pathway for tetraniliprole in soils under aerobic conditions is presented in Figure 2.

Rotational crops

The Meeting received information on confined and field rotational crops.

Confined rotational crop studies

The metabolism of tetraniliprole was investigated in confined rotational crops after one spray application onto bare soil in two studies [Bongartz&Schallau, 2014c, Report EnSA-14-0494, M-500569-01-1 and Bongartz&Schallau, 2014d, Report EnSA-14-0495, M-500576-01-1]. The soil was treated with 213.1 g phenyl-carbamoyl label/ha according to the envisaged use pattern (Report EnSA-14-0494) and in the second study [pyrazole carboxamide-^{14}C]-labelled tetraniliprole at an application rate of 209.4 g ai/ha was applied (EnSa-14-0495).Turnips (root vegetables), Swiss chard (leafy vegetables) and wheat (cereals) were sown 30 days (1st rotation), 168 days (2nd rotation) and 286 days (3rd rotation) after soil treatment. A sample of immature Swiss chard was harvested at BBCH 45. Wheat forage was sampled at BBCH 29

and wheat hay at BBCH 75-83. Turnip leaves, turnip roots, Swiss chard, wheat straw and wheat grain were harvested at maturity.

The TRRs obtained in the different crop commodities are presented in Table 36.

Table 36 TRR values in confined rotational crops after spray application onto bare soil with [phenyl-carbamoyl-^{14}C]- and [pyrazole carboxamide-^{14}C]- tetraniliprole

Notes:

TRR values were determined by combustion/LSC analysis.

[a] Phen-car = [phenyl-carbamoyl-^{14}C]-label and Pyr-car = [pyrazole-carboxamide-^{14}C]-label.

[b] Samples were not further extracted.

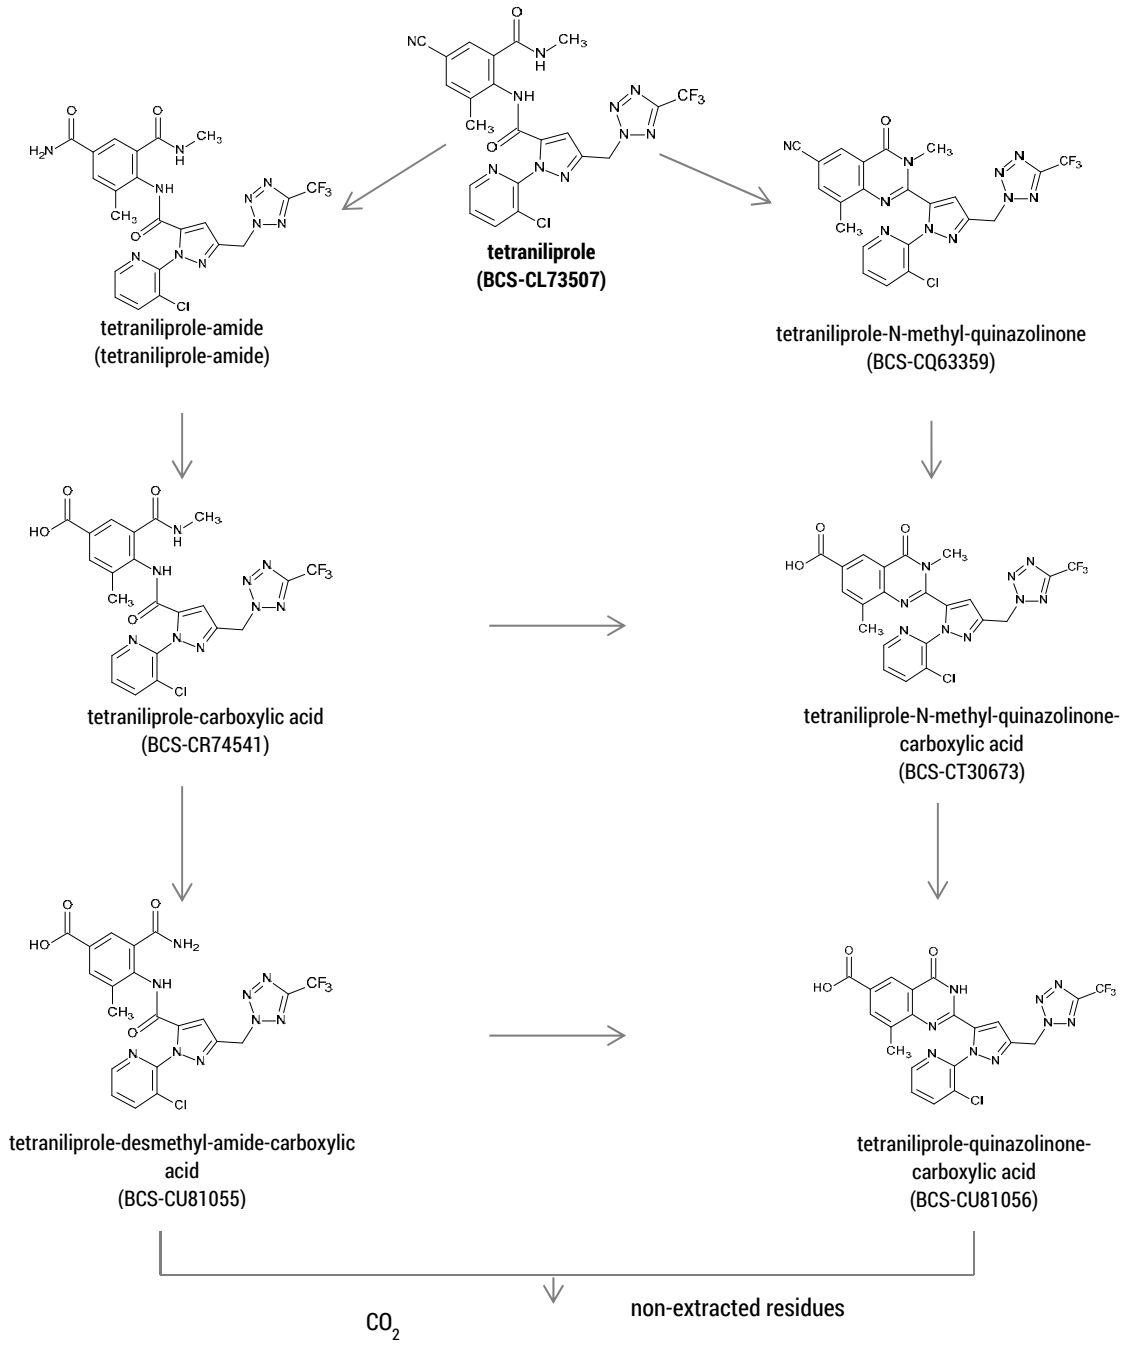

Figure 2 Overview of the degradation pathway of tetraniliprole in aerobic soil

The majority of the radioactive residue of all RACs was extracted with a mixture of acetonitrile/water (8/2) and 10 mL/L formic acid. The residues in the extracts ranged from 77 to 99 percent TRR with [phenyl-carbamoyl-^{14}C]-tetraniliprole and from 79 to 99 percent TRR with [pyrazole-carboxamide-^{14}C]-tetraniliprole. PES of wheat hay of the 1st and 2nd rotation and straw of the 1st rotation were further extracted using microwave assistance with a mixture of acetonitrile/water (1/1) and 3 percent formic acid and, in case of wheat hay of the 2nd rotation, subsequently with 0.1 N hydrochloric acid ([pyrazole-carboxamide-^{14}C]-label only). Microwave assisted solvent extracted residues in the acetonitrile/water mixture were further characterised by partition against ethyl acetate. The radioactive

residues in the organic and aqueous phases in wheat hay and straw amounted to ≤0.010 mg eq/kg (6.4–10.5 percent TRR) and to ≤0.016 mg eq/kg (7.7–15.1 percent TRR) with the respective labels.

Table 37 Distribution of the radioactivity in the extracts of the RACs in the different rotations

Extracts were analysed by HPLC. A summary of the rotational crop metabolism data is presented in Table 37. Parent tetraniliprole was the most prominent compound in all RACs. Other identified compounds were tetraniliprole-despyridyl-N-methyl-quinazolinone-pyrazole-3-carboxylic acid, tetraniliprole-dihydroxy, tetraniliprole -amide, tetraniliprole -desmethyl-amide-carboxylic acid, tetraniliprole-carboxylic acid and tetraniliprole-N-methyl-quinazolinone. Low residues of tetraniliprole-pyrazole-5-carboxylic acid (≤0.005 mg/kg) were also detected; this metabolite is specific for the pyrazole-carboxamide label. Each of these identified metabolites amounted to ≤0.023 mg eq/kg (phenyl-carbamoyl label) or to ≤0.028 mg eq/kg (pyrazole-carboxamide label). All unknown metabolites were present in negligible amounts (≤0.002 mg eq/kg and ≤0.006 mg eq/kg with the respective labels).

Notes:
PBI: Plant back interval.
NA – Not Analysed.
[a] Samples were not subjected to further extraction and identification due to the low total residue values.
Wheat grain samples contained low (<0.01 mg eq/kg) TRR for all PBIs in both labels, therefore samples were not subjected to further extraction and identification.

Field rotational crop studies

According to the confined rotational crop studies, it is possible that rotational crops could take up residues of tetraniliprole from the soil. The Meeting received field rotational crop studies on onions, cucurbits, alfalfa, legumes, soya bean, wheat, barley, sorghum, rape seed, and sunflowers (23B).

Twelve field rotational crops studies were conducted in the growing seasons 2014 and/or 2015 to measure the magnitude of tetraniliprole residues in onions, cucurbits (melon, summer squash, cucumber), alfalfa, peas and beans (fresh with pods), peas and beans (fresh without pods), beans and peas (dried), wheat, barley , sorghum, rape seed, sunflower, wheat and soya bean.

In all studies, residues were determined in plants planted at a target 30-day plant back interval (actual PBI ranged from 25-31 days) following one broadcast application of tetraniliprole to bare soil. Applications were made at a nominal rate of 200 g ai/ha, with actual rates ranging from 170 (onion) to 220 g ai/ha (garden peas, shelled).

Samples of onion from 11 field trials were collected at normal commercial maturity (BBCH 48-49). Samples were stored for a maximum of 453 days (ca 15 months) (Lam, 2016, Report RAFVN039/M-562968-01-1).

Samples of melons, summer squashes, and cucumbers from twenty-seven field trials (Netzband & Beedle, 2016, Report RAFVP101-01/M-563500-02-1) were collected at commercial maturity (BBCH 71-89). Samples were stored for a maximum of 670 days (*ca* 24 months).

Samples of alfalfa forage and hay from a total of eleven field trials (Veal, 2016, Report RAFVP100/M-563135-01-1) were collected at commercial maturity (BBCH 59-61). Once cut, the alfalfa was allowed to re-grow and samples were again collected a second time at commercial maturity (BBCH

55-61). This was repeated once more for a third cutting (BBCH 51-62). Samples were stored for a maximum of 450 days (ca 15 months).

Samples from snow peas and snap beans, both with pods, from sixteen field trials (Dallstream, 2016, Report RAFVN033/M-560245-01-1) were collected at normal commercial maturity and stored frozen for a maximum of 654 days (ca 22 months).

Samples from lima beans and garden peas, both shelled, from 16 trials (Gould and Jerkins, 2016, Report RAFVN035-01/M-560729-02-1) were collected at normal commercial maturity (BBCH 75-89) and stored frozen for a maximum of 643 days (*ca* 21 months).

Samples from dried shelled peas and beans, forage and hay from 16 trials (Miller & Roberts, 2016, Report RAFVN037-01/M560950-02-1) were collected at maturity. Samples were stored frozen for a maximum of 633 days (*ca* 21 months).

Samples of wheat forage, hay, grain, and straw from twelve field trials (Veal & Jerkins, 2016, Report RAFVP086, M-558449-01-1) were collected at commercial maturity. Samples were stored for a maximum of 467 days (*ca* 15 months).

Samples of barley hay, straw and grain from nine field trials (Dallstream & Jerkins, 2016, Report RAFVP085, M-555094-01-1) were collected at commercial maturity. Samples were stored for a maximum of 414 days (*ca* 14 months).

Samples of sorghum forage, grain and fodder from seven field trials (Murphy & Jerkins, 2016a, Report RAFVN029, M-559018-01-1) were collected at commercial maturity. Samples were stored for a maximum of 405 days (*ca* 13 months).

Seed samples from oilseed rape, from seven field trials (Lam & Jerkins, 2016, Report RAFVP085, M-556294-01-1) were collected at commercial maturity (BBCH 89). Samples were stored for a maximum of 385 days (*ca* 13 months).

Samples of sunflower seed from six field trials (Murphy and Jerkins, 2016b, Report RAFVN030/M-558451-01-1) were collected at commercial maturity (BBCH 89). Samples were stored for a maximum of 323 days (*ca* 11 months).

The last field rotation crop study was designed slightly different. In this study six field trials (3 wheat and 3 soya bean) residues in/on wheat or soya bean planted at targeted 30-, 120-, and 365-day plant-back intervals (PBI), each following one application of tetraniliprole to either a target crop of potatoes or to bare soil (Krolski & Jerkins, 2016, Report RAFVP051, M-568415-01-1). Applications were made at an actual rate of 200–210 g ai/ha and were made in-furrow at planting of the primary crop (potatoes) or to bare soil at actual plant intervals ranging from 22–29 days, 108–119 days, and 334–365 days.

In trials that made applications to a primary crop of potatoes, the potatoes were grown to maturity or until the time of rotational crop planting. For the 4-month and 12-month PBI plots, potatoes were harvested after approximately 4 months or at maturity, respectively; for the 1-month PBI plots, the potato plants were disked or tilled into the plot. Samples of wheat forage, hay, grain and straw, soya bean forage, hay and seed were collected at commercial maturity. Samples were stored for a maximum of 604 days (*ca* 20 months).

Samples were analysed for residues of tetraniliprole and metabolite tetraniliprole-N-methyl-quinazolinone using the validated analytical method 01414 (see analytical section). The acceptability of the method was confirmed with procedural recoveries within the acceptable range of 70–120 percent. The LOQ was 0.01 mg/kg for both analytes in all commodities.

Storage periods for the various crops were within the demonstrated stability periods for tetraniliprole and tetraniliprole-N-methyl-quinazolinone in high water content, high protein, high oil content and dry and high starch commodities (see section on storage stability).

Considering all twelve field rotational crop studies, the residues in human consumable commodities of the rotational crops with a 30 day PBI were all below the LOQ of <0.01 mg/kg. Quantified residues were observed in samples of animal feed commodities at plant-back intervals up to 365 days. The results are presented in Table 39 and Table 40.

Table 39 Residues of tetraniliprole in rotated feed commodities, using an application rate of 200 g ai/ha to bare soil and a plant back interval (PBI) of 30-days

Trial	PBI (days)	Application rate (g ai/ha)	Tetraniliprole (mg/kg)	Tetraniliprole-N-methyl-quinazolinone (mg/kg)

Overview of the metabolic pathway in rotational crops

In the confined rotational crops studies the following metabolic reactions were observed:

- hydroxylation of parent compound leading to tetraniliprole-dihydroxy,

- stepwise oxidation of the cyano group of parent compound leading via tetraniliprole-amide to tetraniliprole-carboxylic acid,
- demethylation of tetraniliprole-carboxylic acid leading to tetraniliprole-desmethylamide-carboxylic acid,
- intra-molecular condensation (cyclisation) of parent compound leading to tetraniliprole-N-methyl-quinazolinone, and
- cleavage of the pyridyl and tetrazolyl moiety and a subsequent oxidation forming tetraniliprole-despyridyl-N-methyl-quinazolinone-pyrazole-3-carboxylic acid.

The potential for uptake of residues from soil in practice seems to be negligible for human food commodities (all <0.01 mg/kg, grain, potatoes etc.) and low in livestock feed items. These metabolic pathways are depicted in Figure 3.

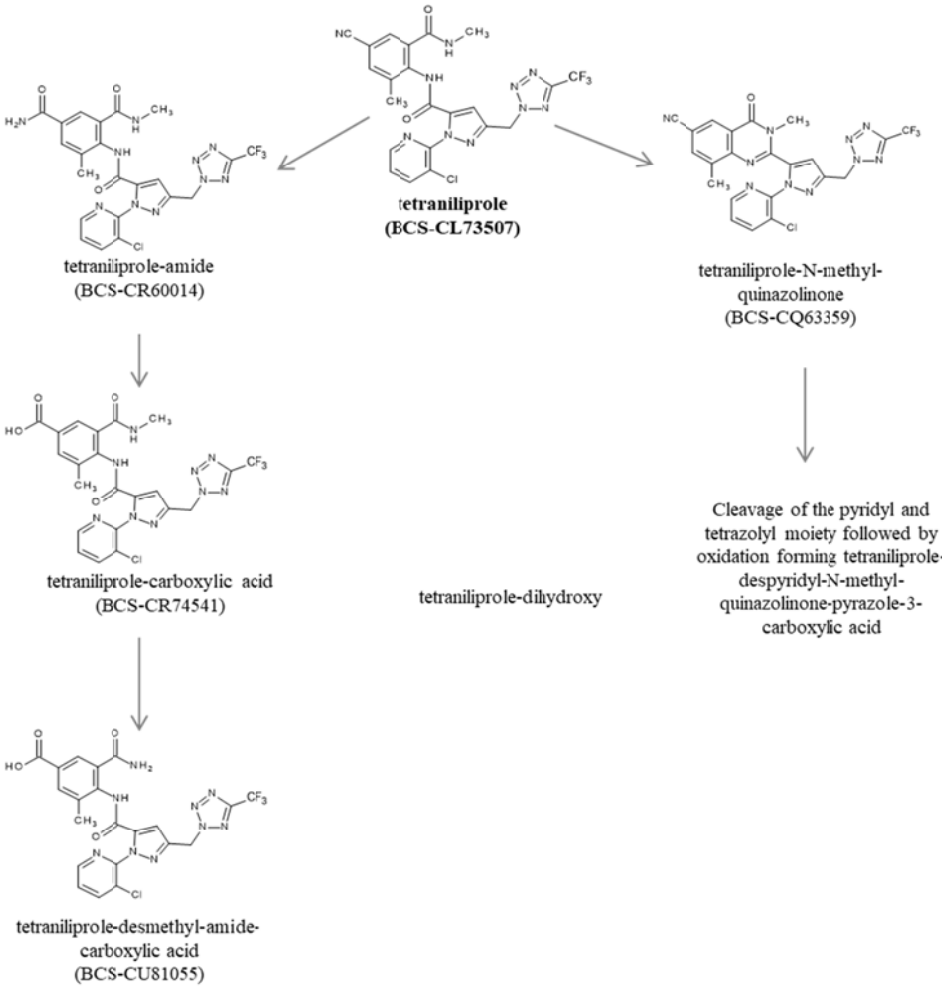

Figure 3 Metabolic pathway of tetraniliprole in rotational crops

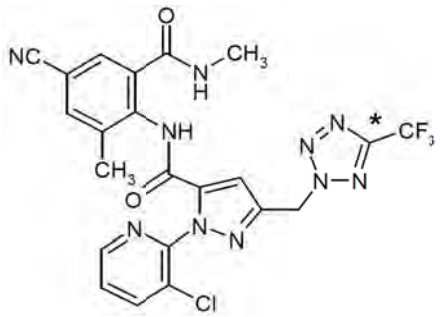
Animal metabolism

The Meeting received information on the metabolic fate of tetraniliprole in ruminants (lactating goats) and poultry (laying hens). The metabolism in other mammalian animals was summarized and evaluated by the WHO panel of the JMPR in parallel in 2020.

For livestock metabolism, studies were conducted with either [pyrazole-carboxamide-^{14}C]-, [pyridinyl-2-^{14}C]-, or [tetrazolyl-^{14}C]-labelled tetraniliprole, as shown below.

Pyrazole-carboxamide label	Pyridinyl label
	[pyrazole-carboxamide-^{14}C]-tetraniliprole	[pyridinyl-2-^{14}C]-tetraniliprole
Tetrazolyl label	
	


[tetrazolyl-^{14}C]-tetraniliprole	

Lactating goat

Pyrazole-carboxamide-label

The metabolism and excretion of [pyrazole-carboxamide-^{14}C]-tetraniliprole was investigated in the lactating goat (Bongartz et al, 2017, M-525616-02-1, Report EnSa-14-0579). The test compound was orally administered in gelatin capsules at a dose of *ca.* 1 mg/kg body weight. Based on the daily feed consumption, the dose level corresponded to 27.04 ppm (mg ai/kg dry feed/day). The goat, Weiße deutsche Edelziege (*Capra Hircus*), received five consecutive doses at 24-hour intervals in the morning after milking and was sacrificed *ca.* 5.5 hours after the last dose.

Throughout the experiment, the goat was housed in a metabolism cage, which permitted separate collection of urine and faeces. The goat was milked in the morning immediately prior to each administration, about eight hours later in the afternoon and *ca.* 1 hour before sacrifice. TRRs were determined in each milk sample and in dissected organs and tissues (muscle, fat, liver and kidney) at sacrifice. The total radioactivity (percent of total dose administered) were additionally determined in each urine and faeces sample. The radioactivity measurement in liquid samples was carried out by LSC. All solid samples were combusted and the radioactivity determined by LSC.

The overall recovery accounted for *ca.* 73 percent of the total applied dose/radioactivity (TAR). Up to the time of sacrifice, *ca*. 2.13 percent TAR was excreted with the urine and *ca.* 67.3 percent TAR with faeces. The daily renal and faecal excretion rates of radioactivity started shortly after the first dosing before plateauing at about 0.6 percent and 13 percent–20 percent TAR for urine and faeces, respectively. Radioactivity in the GI tract and cage washes were not investigated. Approximately 1.24 percent TAR was

secreted with the milk. At sacrifice, radioactive residues in the organs and tissues were *ca.* 2.36 percent TAR (0.42 percent TAR in liver, 0.01 percent TAR in kidney, 0.56 percent TAR in muscle, and 1.36 percent TAR in fat).

The TRR values in milk samples ranged from 0.16 mg eq/kg at 24 hours after the first administration to 0.51 mg eq/kg *ca*. 0.5 hours before sacrifice. The radioactive residues increased significantly during the eight-hour period after each administration followed by a small decrease measured prior to the delivery of the next dose, except for the period from 60 – 96 h, at which the plateau-level (0.42 mg eq/kg) was reached. Regarding organs and tissues, the TRR values amounted to 0.099 mg eq/kg for muscle (composite of round and loin muscle), 0.60 mg eq/kg for fat (composite of perirenal and omental fat), 1.0 mg eq/kg for liver and 0.25 mg/kg for kidney.

The majority of the residues in the milk, organs and tissues were efficiently (90.3–100 percent TRR) extracted three times with a mixture of acetonitrile/water (8/2), using 1 mL formic acid in the first extraction step. In case of fat, 150 mL n-heptane were added to every extraction step and subsequently separated from the aqueous phases. All n-heptane phases and aqueous phases were unified before further processing/ analysis. Solids after extraction of the liver were further extracted using two microwave assisted extractions with mixtures of acetonitrile/water (1/1) using microwave assisted solvent extraction. Formic acid was added to the last extraction step. An additional 9.7 percent TRR was released. Low amounts of radioactivity (≤0.7 percent TRR) remained in the PES of all commodities.

Most of the metabolites were isolated from urine and faeces by HPLC using the methods “ANTAM”, “antam1” and “MI9916”. They were identified in the isolated fractions by LC-MS and LC-MS/MS. Following structure elucidation, the identified metabolites were re-assigned in the profile by HPLC co-chromatography using the isolated fractions. Other metabolites were identified by HPLC co-chromatography with radiolabelled reference compounds taken from the rat ADME study: tetraniliprole-pyrazole-5-N-methylamide, tetraniliprole-hydroxypyridyl-glucuronide, tetraniliprole-desmethyl-amide, and tetraniliprole-hydroxy. Furthermore, the assignment and identification of parent compound and metabolites were achieved by comparison of HPLC metabolite profiles of the analysed samples among each other. Unknown metabolites were characterised based on their extraction and chromatographic behaviour.

Identification rates were very high and ranged between 86 and 96 percent of the TRR in milk, and edible organs and tissues. Parent tetraniliprole was the predominant residue in milk, muscle, liver and kidney and ranged from 55 to 71 percent TRR. For fat, 28 percent TRR was quantified as parent compound. Tetraniliprole-N-methyl-quinazolinone was the main metabolite in fat (67 percent TRR) and a major metabolite in muscle (27.9 percent TRR). A prominent metabolite was tetraniliprole-benzylalcohol (11 percent TRR in milk, 8.0 percent TRR in liver and 6.2 percent TRR in kidney). Metabolite tetraniliprole-hydroxy-N-methyl was found in milk (5.0 percent TRR), liver (8.9 percent TRR) and kidney (3.7 percent TRR).

All other minor metabolites, such as tetraniliprole-N-methyl-quinazolinone-pyrazole-3-carboxylic acid, tetraniliprole-pyridinyl-pyrazole-5-carboxylic acid, tetraniliprole-N-methyl quinazolinone-benzylalcohol, tetraniliprole-desmethyl-amide and tetraniliprole-quinazolinone accounted for ≤2.6 percent TRR (≤0.007 mg eq/kg).

Pyrazole-carboxamide label specific metabolites were tetraniliprole-pyrazole-5-amide, tetraniliprole-pyrazole-5-N-methyl-amide and tetraniliprole-5-carboxylic acid. They were found at low amounts in milk and liver (≤1.8 percent TRR, ≤0.018 mg eq/kg). Several unknown metabolites were characterised by extraction and chromatographic behaviour. And since the exact position of the hydroxy group or the glucuronic acid group could not be determined, due to the general low amount of the

metabolites tetraniliprole-hydroxypyridyl-Gluc, tetraniliprole-N-methyl-quinazolinonehydroxy-Gluc, tetraniliprole-quinazolinone-hydroxy, and tetraniliprole- hydroxy, these metabolites were considered as characterised, only. The metabolic profile of tetraniliprole in milk and edible tissues is presented in Table 41.

Table 41 Distribution of parent compound and metabolites in the extracts of milk and edible tissues of goats following oral administration of [pyrazole-carboxamide-^{14}C]-tetraniliprole for 5 consecutive days at 27 ppm ai in feed.

Notes:

[a] Milk collected over 32-101 hours.

[b] Characterised by extraction and partition behaviour.

[c] Comprised of 8 separate regions, the largest of which contained 3.1% TRR, 0.012 mg eq/kg.

[d] Comprised of 3 separate regions, the largest of which contained 1.3% TRR, 0.001 mg eq/kg.

[e] Comprised of 5 separate regions, the largest of which contained 3.3% TRR, 0.020 mg eq/kg.

[f] The initial extract comprised of 14 separate regions, the largest of which contained 6.7% TRR, 0.067 mg eq/kg; in the microwave assisted extract 5 unknown regions were characterised, the largest of which contained 0.5% TRR, 0.05 mg eq/kg.

[g] Comprised of 5 separate regions, the largest of which contained 6.1% TRR, 0.015 mg eq/kg.

Pyridinyl-2-label

The metabolism and excretion of [pyridinyl-2-^{14}C]-tetraniliprole was investigated in the lactating goat (Bongartz *et al*., 2015a, M-525622-01-1, Report EnSa-14-1311). The test compound was orally administered in gelatin capsules at a dose of *ca.* 1 mg/kg body weight. Based on the daily feed consumption, the dose level corresponded to 20.62 ppm (mg ai/kg dry feed/day). The goat, Weiße deutsche Edelziege (*Capra Hircus*), received five consecutive doses at 24-hour intervals in the morning after milking and was sacrificed *ca.* 6 hours after the last dosing.

Throughout the experiment, the goat was housed in a metabolism cage, which permitted separate collection of urine and faeces. The goat was milked in the morning immediately prior to each administration, about eight hours later in the afternoon and *ca.* 20 min before sacrifice. TRRs were determined in each milk sample and in dissected organs and tissues (muscle, fat, liver and kidney) at sacrifice. The total radioactivity (percent TAR) was additionally determined in each urine and faeces sample. The radioactivity measurement in liquid samples was carried out by LSC. All solid samples were combusted and the radioactivity determined by LSC.

The overall recovery accounted for *ca.* 74 percent TAR. Up to the time of sacrifice*, ca.* 2.0 percent of the total dose was excreted with the urine and *ca.* 69 percent TAR with faeces. The daily renal and faecal excretion rates of the radioactivity started shortly after the first dosing before plateauing at about 0.5 percent and 14–18 percent TAR for urine and faeces, respectively. Radioactivity in the GI tract and cage washes were not investigated. Approximately 1.3 percent TAR was secreted with the milk. At sacrifice, radioactive residues in the organs and tissues were *ca*. 1.8 percent TAR (0.44 percent TAR in liver, 0.02 percent TAR in kidney, 0.49 percent TAR in total body muscle, 0.89 percent TAR in total bod fat).

The TRR values in milk samples ranged from 0.14 mg eq/kg at 24 hours to 0.33 mg/kg at 80 hours after the first administration. The radioactive residues increased significantly during the eight-hour period after each administration followed by a decrease prior to the delivery of the next dose. A residue plateau-level in milk of 0.28 mg/kg was reached at about day 4 after the first administration. Regarding organs and tissues, the TRR-values amounted to 0.086 mg eq/kg for muscle (composite of round and loin muscle), 0.39 mg eq/kg for fat (composite of perirenal and omental fat), 0.88 mg eq/kg for liver and 0.24 mg eq/kg for kidney.

The majority of the residues in the milk, organs and tissues were efficiently (91-100 percent TRR) extracted three times with a mixture of acetonitrile/water (8/2), using 1 mL formic acid in the first extraction step. Solids after extraction of the liver were further extracted two times with mixtures of

acetonitrile/water (1/1) using microwave assistance. Formic acid was added to the last extraction step. An additional 8.8 percent TRR was released. Negligible amounts of radioactivity (≤1.0 percent TRR) remained in the PES of all commodities.

Parent compound and metabolites were quantified in the initial and microwave assisted extracts by HPLC. Parent compound and metabolites were identified as in the goat study with the pyrazole-carboxamide label (Bongartz *et al.*, 2017, M-525616-02-1, Report EnSa-14-0579) by spectroscopic methods and co-chromatography with radiolabelled reference compounds. They were assigned to the profiles of the current study based on their retention times and the metabolite pattern in the corresponding extracts.

Identification rates were very high and ranged between 91.6 and 97.6 percent of the TRR in milk, and edible organs and tissues. Parent tetraniliprole was the main residue in milk, muscle, liver and kidney and ranged from 62–69 percent TRR. For fat, 24 percent TRR was quantified as parent compound. Tetraniliprole-N-methyl-quinazolinone was the main metabolite in fat and amounted to 72 percent TRR. Tetraniliprole-N-methyl-quinazolinone was also a major metabolite in milk, muscle and kidney and accounted for 11 percent, 28 percent and 14 percent TRR, respectively. Additionally, metabolite tetraniliprole-benzylalcohol amounted to 9.0 percent TRR in milk and 6.9 percent TRR in liver. Metabolites tetraniliprole-hydroxy-N-methyl and tetraniliprole-desmethyl-amide (both approx. 7 percent TRR) were also found in the liver.

All other minor metabolites, such as tetraniliprole-N-methyl-quinazolinone-pyrazole-3-carboxylic acid, tetraniliprole- pyridinyl-pyrazole-5-carboxylic acid, tetraniliprole-N-methylquinazolinone-benzylalcohol and tetraniliprole-quinazolinone accounted for ≤ 3.6 percent TRR (≤ 0.030 mg eq/kg). Pyridinyl label specific metabolites were not detected in milk or edible organs and tissues. Several unknown metabolites were characterised by extraction and chromatographic behaviour. And since the exact position of the hydroxy group or the glucuronic acid group could not be determined, due to the general low amount of the metabolites tetraniliprole-hydroxypyridyl-Gluc, tetraniliprole-N-methyl-quinazolinonehydroxy-Gluc, tetraniliprole-quinazolinone-hydroxy, and tetraniliprole- hydroxy, these metabolites were considered as characterised, only. The metabolic profile of tetraniliprole in milk and edible tissues is presented in Table 42.

[a] Milk collected over 32-101 hours.

[b] Characterised by extraction and partition behaviour.

[c] Comprised of 3 separate regions, the largest of which contained 2.2% TRR, 0.005 mg eq/kg.

[d] Comprised of 4 separate regions, the largest of which contained 0.8% TRR 0.001 mg eq/kg.

[e] Comprised of 3 separate regions, the largest of which contained 1.8% TRR, 0.007 mg eq/kg.

[f] Comprised of 8 separate regions, the largest of which contained 3.4% TRR, 0.030 mg eq/kg in the first extraction series and of 1 region in the microwave assisted solvent extract.

[g] Comprised of 4 separate regions, the largest of which contained 3.6% TRR, 0.009 mg eq/kg.

[h] Total characterised is the sum of unknowns from both extraction series.

[i] Losses during concentration procedures or extracts not analysed.

Tetrazolyl-label

The metabolism and excretion of [tetrazolyl-^{14}C]-tetraniliprole was investigated in the lactating goat (Bongartz et al, 2015b, M-525625-02-1, Report EnSa-1321). The test compound was orally administered in gelatin capsules at a dose of *ca.* 1 mg/kg body weight. Based on the daily feed consumption, the dose level corresponded to 37.64 ppm (mg ai/kg dry feed/day). The goat, Weiße deutsche Edelziege (*Capra Hircus*), was given five consecutive doses at 24-hour intervals in the morning after milking and was sacrificed *ca.* 6 hours after the last dosing.

Throughout the experiment, the goat was housed in a metabolism cage, which permitted separate collection of urine and faeces. The goat was milked in the morning immediately prior to each administration, about eight hours later in the afternoon and *ca*. 40 min before sacrifice. TRRs were determined in each milk sample and in dissected organs and tissues (muscle, fat, liver and kidney) at sacrifice. The total radioactivity (percent TAR) was additionally determined in each urine and faeces

sample. The radioactivity measurement in liquid samples was carried out by LSC. All solid samples were combusted and the radioactivity determined by LSC.

The overall recovery accounted for *ca.* 68 percent TAR. Up to the time of sacrifice, *ca.* 3.3 percent TAR was excreted with the urine and ca. 60.9 percent TAR with faeces. The daily renal and faecal excretion rates of the radioactivity started shortly after the first dosing before plateauing at about 0.9 percent and 15-21 percent TAR for urine and faeces, respectively. Radioactivity in the GI tract and cage wash was not investigated. Approximately 1.1 percent TAR was secreted with the milk. At sacrifice, radioactive residues in the organs and tissues were *ca.* 2.4 percent TAR, with 0.57 percent TAR in liver, 0.02 percent TAR in kidney, 0.72 percent TAR in total body muscle, and 1.1 percent TAR in total body fat.

The TRR values in milk samples ranged from 0.12 mg eq/kg at 8 hours to 0.49 mg eq/kg at 72 hours after the first administration. At *ca.* 0.6 hours before sacrifice, the TRR value amounted to 0.43 mg eq/kg. The time course TRR-values of the evening and morning milk samples indicated a more or less steady increase until the fourth dosing, after which a residue plateau-level of 0.43 mg eq/kg was reached.

Regarding organs and tissues, the TRR values amounted to 0.12 mg eq/kg for muscle (composite of round and loin muscle), 0.47 mg eq/kg for fat (composite of perirenal and omental fat), 1.2 mg eq/kg for liver and 0.33 mg eq/kg for kidney.

The majority of the residues in the milk, organs and tissues were efficiently (89.4-100 percent TRR) extracted three times with a mixture of acetonitrile/water (8/2), using 1 mL formic acid in the first extraction step. In case of fat, 150 mL n-heptane were added to every extraction step and subsequently separated from the aqueous phases. All n-heptane phases and aqueous phases were unified before further processing/ analysis. Solids after extraction of the liver were further extracted two times with mixtures of acetonitrile/water (1/1) using microwave assistance. Formic acid was added to the last extraction step. An additional 10.6 percent TRR was released. Low amounts of radioactivity (≤1.0 percent TRR) remained in the PES of all commodities.

Parent compound and metabolites were quantified in the extracts by HPLC. Parent compound and metabolites were identified in the goat study with the pyrazole-carboxamide label (Bongartz et al, 2017, M-525616-02-1, Report EnSa-14-0579) by spectroscopic methods and co-chromatography with radiolabelled reference compounds. They were assigned to the profiles of the current study based on their retention times and the metabolite pattern in the corresponding extracts.

Identification rates were very high and ranged between 86 and 96 percent of the TRR in milk, and edible organs and tissues. In addition tetraniliprole-tetrazole was isolated from urine and identified by spectroscopic methods. Parent tetraniliprole was the main residue in milk (55.4 percent TRR, 0.23 mg/kg), muscle (68 percent TRR, 0.083 mg/kg), liver (53 percent TRR, 0.64 mg/kg, fat (30 percent TRR, 0.14 mg/kg) and kidney (59 percent TRR, 0.20 mg/kg). In fat, the metabolite tetraniliprole-N-methyl-quinazolinone was the main residue and amounted to 0.29 mg eq/kg (62 percent TRR). Tetraniliprole-N-methyl-quinazolinone was also a major metabolite in milk, muscle, kidney and liver and amounted to 0.056 mg eq/kg (13 percent TRR), 0.029 mg eq/kg (23 percent TRR), 0.044 mg eq/kg (13 percent TRR) and 0.067 mg eq/kg (5.6 percent TRR) respectively3.

An additional metabolite in milk, liver and kidney was tetraniliprole-benzylalcohol, and amounted to 0.045 mg eq/kg (11 percent TRR) in milk, 0.11 mg eq/kg (8.9 percent TRR) in liver and 0.020 mg eq/kg (6.0 percent TRR) in kidney. Metabolites tetraniliprole-hydroxy-N-methyl and tetraniliprole-desmethyl-amide were also detected in the liver (0.078 mg eq/kg (6.4 percent TRR) and 0.055 mg eq/kg (4.5 percent TRR), respectively).

All other metabolites, such as tetraniliprole-pyridinyl-pyrazole-5-carboxylic acid, tetraniliprole-N-methyl-quinazolinone-benzylalcohol, tetraniliprole-N-methyl-quinazolinone hydroxypyridyl, tetraniliprole-quinazolinone and tetraniliprole-pyrazole-5-N-methyl-amide were minor and accounted for ≤3.3 percent TRR (≤ 0.040 mg eq/kg). Tetrazolyl label specific metabolites were not identified in milk or edible organs/tissues. Several unknown metabolites were characterised by extraction and chromatographic behaviour. And since the exact position of the hydroxy group or the glucuronic acid group could not be determined, due to the general low amount of the metabolites tetraniliprole-hydroxypyridyl-Gluc, tetraniliprole-N-methyl-quinazolinonehydroxy-Gluc, tetraniliprole-quinazolinone-hydroxy, and tetraniliprole- hydroxy, these metabolites were considered as characterised, only. The metabolic profile of tetraniliprole in milk and edible tissues is presented in Table 43.

Table 43 Distribution of parent compound and metabolites in the extracts of milk and edible tissues of goats following oral administration of [tetrazolyl-^{14}C]-tetraniliprole for 5 consecutive days at 38 ppm ai in feed

Notes:

[a] Milk collected over 32-101 hours.

[b] Characterised by extraction and partition behaviour.

[c] Comprised of 5 separate regions, the largest of which contained 3.1% TRR, 0.013 mg eq/kg.

[d] Comprised of 2 separate regions, the largest of which contained 1.8% TRR, 0.002 mg eq/kg.

[e] Comprised of 1 single region.

[f] Comprised of 13 separate regions, the largest of which contained 4.3% TRR, 0.052 mg eq/kg; the microwave assisted extract contained 2 unknown regions, containing 1.0 and 0.7% TRR, 0.012 and 0.009 mg eq/kg, respectively.
[g] Comprised of 3 separate regions, the largest of which contained 5.7% TRR, 0.019 mg eq/kg.
[h] Total characterised is the sum of unknowns from both extraction series.
[i] Losses during concentration procedures or extracts not analysed.

Laying hens

Pyrazole-carboxamide-label

The metabolism and excretion of [pyrazole-carboxamide-^{14}C]-tetraniliprole was investigated in laying hens (Bongartz, 2017, M-535432-02-1, Report EnSA-5-0411). The test compound was orally administered to six hens as an aqueous 0.5 percent tragacanth suspension by gavage using a syringe at a dose of *ca.* 1 mg/kg body weight. Based on the daily feed consumption, the dose level corresponded to *ca.* 18.64 ppm (mg ai/kg dry feed/day). The hens received 14 consecutive doses at 24-hour intervals in the morning and were sacrificed *ca.* 6 hours after the last dose.

The eggs were collected once daily and before sacrifice. TRR were determined in each egg (mixed sample from egg white and yolk) and in dissected organs and tissues (muscle, fat, liver, kidney, skin and eggs from ovary/ oviduct) at sacrifice. The total radioactivity (percent TAR) was additionally determined in each excreta sample. The radioactivity measurement in liquid samples was carried out by LSC. All solid samples were combusted and the radioactivity determined by LSC.

The overall recovery amounted to *ca.* 93 percent TAR. At sacrifice, radioactive residues in the organs and tissues were *ca.* 0.2 percent TAR. Up to the time of sacrifice, *ca.* 92 percent TAR was excreted. After the third administration the daily excretion rate plateaued at 6-7 percent TAR within 24 hours. GI tract and cage wash was not investigated. An average amount of *ca* 0.2 percent TAR was measured in the eggs.

The TRR-values in eggs ranged from 0.005 mg eq/kg at day one to 0.091 mg eq/kg at sacrifice. Following a linear increase a residue plateau-level of 0.088 mg eq/kg was reached approx. at day nine after the first administration. Regarding organs and tissues, the TRR-values amounted to 0.48 m eq/kg in liver, 0.098 mg eq/kg in kidney, 0.046 mg eq/kg in subcutaneous fat, 0.035 mg eq/kg in skin and 0.017 mg eq/kg in skeletal muscle.

Aliquots from eggs, muscle, fat, liver and excreta were extracted three times with a mixture of acetonitrile/ water (8/2). A volume of 1 mL formic acid was added to the first extraction step. In case of fat, 100 mL n-heptane were added to every extraction step and subsequently separated from the aqueous phases. All n-heptane phases and aqueous phases were unified before further processing/ analysis. Solids after initial extraction of eggs and liver were further extracted two times with mixtures of acetonitrile/water (1/1) using microwave assistance (5 min to 120 °C, 20 min at 120 °C). Formic acid was added to the last extraction step. The combined extracts were concentrated by rotary evaporation. Afterwards the distribution and quantities of parent compound and metabolites were determined by HPLC with the profiling method “ANTAM”, except for the microwave assisted extract from eggs, which, due to its very low amount of radioactivity (0.010 mg eq/kg), was further characterised by partition against ethyl acetate and radioactivity measurement of the resulting aqueous and organic phases by LSC.

The majority of the residues in the eggs as well as organs and tissues were efficiently extracted (88.6 to 100 percent TRR). Final PES for all commodities was ≤11.4 percent TRR, 0.002 mg eq/kg. The distribution of radioactivity in eggs and edible tissues is presented in Table 44.

Table 44 Distribution of radioactivity in the extracts of eggs and edible tissues of hens following oral dosing with [pyrazole-carboxamide -^{14}C]-tetraniliprole for 14 consecutive days at 19 ppm in feed

Notes:
[a] Day 6–13.25.

Parent compound and metabolites were quantified in the extracts by HPLC-chromatography based on the profiling method ANTAM. Metabolites in the extracts were assigned to each other by comparison of the metabolite profiles and their retention times. Parent compound and metabolites were isolated from the extract of eggs (day 6–13.25) and the extract of liver and identified in the isolated fractions either by spectroscopic methods or by HPLC co-chromatography with radiolabelled reference compounds taken from the ADME study with rats using the profiling method "ANTAM". Reference compounds were: tetraniliprole-pyrazole-5-N-methylamide-hydroxy, tetraniliprole-pyrazole-5-carboxylic acid, tetraniliprole-benzylalcohol-Gluc, tetraniliprole-dihydroxy, and tetraniliprole-despiridyl, tetraniliprole-benzylalcohol, and tetraniliprole-hydroxy-N-methyl. Additionally, tetraniliprole-despyridyl and tetraniliprole-pyrazole-5-carboxylic acid were identified by TLC analysis using the corresponding radiolabelled reference compounds.

Parent tetraniliprole was present in eggs, muscle and fat and amounted to 0.008 mg/kg (10 percent TRR) for eggs, 0.002 mg/kg (10 percent TRR) for muscle and to 0.012 mg/kg (26 percent TRR) for fat. Parent compound was also detected in liver and amounted to 0.023 mg/kg (4.8 percent TRR). Metabolite tetraniliprole-despyridyl-N-methyl-quinazolinone was the major compound in eggs, fat and liver and amounted to 0.030 mg eq/kg (36 percent TRR) for eggs, 0.029 mg eq/kg (63 percent TRR) for fat and 0.060 mg eq/kg (12 percent TRR) for liver, while the metabolite amounted only to 0.002 mg eq/kg (8.6 percent TRR) in muscle. In muscle, the metabolite tetraniliprole -pyrazole-5-N-methyl-amide was the main residue and amounted to 0.007 mg eq/kg (40 percent TRR). Tetraniliprole -pyrazole-5-N-methyl-amide was also a prominent portion in liver (0.022 mg eq/kg; 4.6 percent TRR).

Another prominent metabolite was tetraniliprole-pyrazole-5-amide in muscle (0.002 mg eq/kg; 13 percent TRR). In liver, the metabolites were tetraniliprole-pyrazole-5-N-methyl-amide-hydroxy (0.016 mg eq/kg; 3.2 percent TRR), tetraniliprole-pyrazole-5-carboxylic acid (0.037 mg eq/kg; 7.6 percent TRR), tetraniliprole-benzylalcohol-Gluc (0.027 mg eq/kg; 5.6 percent TRR), tetraniliprole-despyridyl (0.042 mg eq/kg; 8.6 percent TRR), tetraniliprole-benzylalcohol (0.024 mg eq/kg; 5.0 percent TRR), tetraniliprole-despyridyl-N-methylquinazolinone-hydroxy and tetraniliprole-despyridyl-hydroxy (0.045 mg eq/kg; 9.3 percent TRR (mixture of both metabolites)), tetraniliprole-hydroxy-N-methyl (0.019 mg eq/kg; 3.8 percent TRR) and tetraniliprole-despyridyl-quinazolinone (0.034 mg eq/kg; 7.0 percent TRR).

All other identified metabolites, such as tetraniliprole-dihydroxy and tetraniliprole-quinazolinone accounted for ≤6.3 percent TRR, only. The metabolic profile of tetraniliprole in eggs and the edible tissues of hens is presented in Table 45.

Notes:

T= Tetraniliprole.

[a] Eggs collected at day 6-13.25.

[b] Characterised by extraction and partition behaviour.

[c] Comprised of 12 separate regions, the largest of which contained 6.3% TRR, 0.005 mg/kg.
[d] Comprised of one single region.
[e] Comprised of 17 separate regions, the largest of which contained 5.1% TRR, 0.025 mg/kg; In the microwave assisted extract the unknowns represented only 1 region.
[f] For eggs: sum of aqueous and organic phase and first series of extractions; for liver: sum of unknowns from both extraction series.

Pyridinyl-2-label

The metabolism of [pyridinyl-2-^{14}C]-tetraniliprole was investigated in laying hens (Bongartz *et al*., 2015c, M-539048-01-1, Report M1854600-4). The test compound was orally administered to six hens ("LB Lohmann Brown") as aqueous 0.5 percent Tragacanth suspension by gavage using a syringe at a dose of *ca.* 1 mg/kg body weight. Based on the daily feed consumption, the dose level corresponded to *ca.* 17.94 ppm (mg ai /kg dry feed/day). The hens were given 14 consecutive doses at 24-hour intervals in the morning and were sacrificed *ca*. 6 hours after the last dosing.

The hens were housed in metabolism cages, which permitted separate collection of eggs and excreta. The eggs were collected once daily and before sacrifice. TRRs were determined in each egg (mixed sample from egg white and yolk) and in dissected organs and tissues (muscle, fat, liver, kidney, skin and eggs from ovary/ oviduct) at sacrifice. The total radioactivity (percent TAR) was additionally determined in each excreta sample. The radioactivity measurement in liquid samples was carried out by LSC. All solid samples were combusted and the radioactivity determined by LSC.

The overall recovery amounted to *ca.* 93 percent TAR. Up to the time of sacrifice, the excretion products accounted for *ca.* 92 percent TAR. The daily excretion rate plateaued after the third administration at 6–8 percent TAR within 24 hours. Radioactivity in GI tract and cage wash was not investigated. An average amount of *ca*. 0.2 percent TAR was measured in the eggs. At sacrifice, the test compound-related residues in the organs and tissues dissected from the bodies were calculated or estimated to be about 0.3 percent TAR

The TRR-values in eggs ranged from 0.006 mg eq/kg at day one to 0.10 mg eq/kg at sacrifice. Following a linear increase, a residue plateau-level of 0.084 mg eq/kg was reached approx. at day eight after the first administration. Regarding organs and tissues, the TRR-values amounted to 0.73 mg eq/kg in liver, 0.33 mg eq/kg in kidney, 0.028 mg eq/kg in subcutaneous fat, 0.047 mg eq/kg in the skin and 0.025 mg eq/kg in skeletal muscle.

Aliquots from eggs, muscle, liver and excreta were extracted three times with a mixture of acetonitrile/ water (8/2). Fat was extracted three times with methanol. In all cases, 1 mL formic acid was added to the first extraction step. Solids and extracts were separated after each extraction step by filtration. In case of fat, only a liquid fat phase remained. Solids after extraction of eggs, muscle and liver were additionally extracted two times with mixtures of acetonitrile/water (1/1) using microwave assistance (5 min to 120 °C, 20 min at 120 °C). Formic acid was added to the last extraction step. The combined extracts were concentrated by rotary evaporation. Afterwards, the distribution and quantities of parent compound and metabolites were determined by HPLC with the profiling method "ANTAM".

After extraction of fat, a liquid phase remained. The liquid fat phase and the microwave assisted extract from muscle were not further analysed due to low radioactivity (0.004 mg eq/kg for fat and 0.014 mg eq/kg for muscle). The distribution of radioactivity in eggs and edible tissues is presented in Table 46.

Table 46 Distribution of radioactivity in the extracts of eggs and edible tissues of hens following oral dosing with [pyridinyl-2 -^{14}C]-tetraniliprole for 14 consecutive days at 18 ppm ai in feed

Notes:
[a] Day 6–13.25.

Parent compound and metabolites were quantified in the extracts by HPLC based on the profiling method ANTAM. Parent compound and metabolites were assigned in the profiles of the current study by comparison with the profiles analysed in the study with the pyrazole-carboxamide label (Bongartz, 2017, M-535432-02-1, Report EnSA-5-0411). Unknown metabolites were characterised based on their extraction and chromatographic behaviour. One metabolite was isolated from the extract of liver and identified in the isolated fraction by LC-MS/MS.

Parent tetraniliprole was the main residue in eggs, muscle and fat and amounted to 0.012 mg/kg (14 percent TRR) for eggs, 0.001 mg/kg (3.7 percent TRR) for muscle, 0.015 mg/kg (55 percent TRR) for fat, and 0.012 mg/kg (1.6 percent TRR) for liver. The main compound in liver was metabolite tetraniliprole-benzylalcohol-Gluc, which amounted to 0.047 mg eq/kg (6.5 percent TRR) and was not detected in eggs, muscle or fat. Other prominent metabolites in liver were tetraniliprole-benzylalcohol (0.024 mg eq/kg; 3.3 percent TRR), tetraniliprole-deschloro-desmethyl-amide (0.033 mg eq/kg; 4.5 percent TRR) and tetraniliprole-hydroxy-N-methyl (0.013 mg eq/kg; 1.7 percent TRR). Tetraniliprole-dihydroxy was a prominent metabolite in fat (0.004 mg eq/kg; 15 percent TRR). A minor metabolite was tetraniliprole-N-methyl-quinazolinone and accounted for 7.4 percent TRR (0.006 mg eq/kg) in eggs.

The main part of identified metabolites in the corresponding laying hen studies with the pyrazole-carboxamide label and tetrazolyl label consisted of metabolites formed after cleavage of the pyridinyl moiety. The corresponding pyridine label specific metabolites could not be identified in the current study. Therefore, it can be assumed that the significant amount of characterised radioactivity in the current study can be assigned to metabolites originating from the cleavage of the pyridinyl moiety most likely followed by degradation and/or binding to sample matrix, resulting in a large number of unknown metabolites. For example, a large portion of these unknown metabolites were found in the polar HPLC region of eggs and liver after TLC subquantification. There were no metabolites detected in the microwave assisted solvent extract of muscle (0.014 mg eq/kg, 56 percent TRR) by HPLC analysis, due to the low radioactivity in the sample and the high number of metabolites, as demonstrated in liver. The metabolic profile of tetraniliprole in eggs and edible tissues is presented in Table 47.

Notes:
T = Tetraniliprole.
[a] Day 6-13.25.
[b] Characterised by extraction and partition behaviour.
[c] Comprised of 15 separate regions, 9 in the first extraction series and 6 in the second series, the largest of which contained 12.4% TRR, 0.010 mg eq/kg.
[d] Comprised of 5 separate regions, the largest of which contained 19.9% TRR, 0.005 mg eq/kg.
[e] Comprised of 3 separate regions, the largest of which contained 4.8% TRR, 0.001 mg eq/kg.
[f] Comprised of 30 separate regions, the largest of which contained 6.9% TRR, 0.050 mg eq/kg.
[g] Sum of unknowns [b] from both extraction series and organic phase in case of fat.

Tetrazolyl-label

The metabolism of [tetrazolyl-^{14}C]-tetraniliprole was investigated in laying hens (Bongartz *et al*., 2015d, Report M1854608-2, M-539074-01-1). The test compound was orally administered to six hens ("LB Lohmann Brown") as an aqueous 0.5 percent Tragacanth suspension by gavage using a syringe at a dose level of *ca.* 1 mg/kg body weight. Based on the daily feed consumption, the dose level corresponded to *ca.* 18.66 ppm (1.03 mg ai /kg dry feed/day). The hens were given 14 consecutive doses at 24-hour intervals in the morning after and were sacrificed *ca.* 6 hours after the last dosing.

Throughout the experiment, the hens were housed in metabolism cages, which permitted separate collection of eggs and excreta. The eggs were collected once daily and before sacrifice. TRRs

were determined in each egg (mixed sample from egg white and yolk) and in dissected organs and tissues (muscle, fat, liver, kidney, skin and eggs from ovary/ oviduct) at sacrifice. The total radioactivity (percent of TAR) was additionally determined in each excreta sample. The radioactivity measurement in liquid samples was carried out by LSC. All solid samples were combusted and the radioactivity determined by LSC.

The overall recovery amounted to *ca.* 92 percent TAR. The remaining amount of radioactivity (Approx. 8 percent TAR) was expected to still be present in the gastro-intestinal tract at sacrifice, likely due to the short period of time between last administered dose and sacrifice (Approx. 6 hours). An average amount of *ca.* 0.2 percent TAR was measured in the eggs. At sacrifice, residues in the organs and tissues were about 0.4 percent TAR. Up to the time of sacrifice, the excretion products accounted for *ca.* 91.3 percent TAR. The daily excretion rate plateaued after third dose to 6-7 percent TAR within 24 hours.

The TRR-values in eggs ranged from 0.011 mg eq/kg at day one to 0.100 mg eq/kg at sacrifice. Following a linear increase a residue plateau-level of 0.089 mg eq/kg was reached approximately at day nine after the first administration. Regarding organs and tissues, the TRR-values amounted to 0.766 mg eq/kg in liver, 0.172 mg eq/kg in kidney, 0.095 mg eq/kg in subcutaneous fat, 0.078 mg eq/kg in skin and 0.031 mg eq/kg in skeletal muscle.

Aliquots from eggs, muscle, liver and excreta were extracted three times with a mixture of acetonitrile/ water (8/2). In all cases, 1 mL formic acid was added to the first extraction step. In case of fat, 100 mL n-heptane were added to every extraction step and subsequently separated from the aqueous phases. All n-heptane phases and aqueous phases were unified before further processing/ analysis. Solids after the first extraction series of liver were further extracted two times with mixtures of acetonitrile/water (1/1) using microwave assistance (5 min to 120 °C, 20 min at 120 °C). Formic acid was added to the last extraction step. The combined extracts were concentrated by rotary evaporation. Afterwards, the distribution and quantities of parent compound and metabolites were determined by HPLC with the profiling method “ANTAM”.

The majority of the residues in the eggs as well as organs and tissues were efficiently extracted (90.3 to 100 percent TRR) using acetonitrile/water mixtures. In case of liver, post extracted solids were further extracted using microwave treatment. Only up to 9.7 percent (0.008 mg eq/kg) TRR of the residues remained in the PES from all commodities. The distribution of radioactivity in eggs and edible tissues is presented in Table 48.

Table 48 Distribution of radioactivity in the extracts of eggs and edible tissues of hens following oral dosing with [tetrazolyl -^{14}C]-tetraniliprole for 14 consecutive days at 19 ppm ai in feed

Notes:
[a] Day 6 – 13.25.

Parent compound and metabolites were quantified in the extracts by HPLC- based on the profiling method ANTAM. Parent compound and metabolites were assigned in the profiles of the current study by comparison with the profiles analysed in the study with the pyrazole-carboxamide label (Bongartz, 2017, M-535432-02-1, Report EnSA-5-0411). Unknown metabolites were characterised based on their extraction and chromatographic behaviour.

For the isolation of label specific conjugates of tetraniliprole-tetrazole, an additional amount of 100 g egg pool and 50 g liver pool were extracted with acetonitrile/water mixture (8/2). The conjugates were isolated from concentrated extracts by HPLC using the profiling method ANTAM. Due to acidic conditions, the conjugates were cleaved during sample preparation. The common exocon tetraniliprole-tetrazole was identified in the isolated fractions by LC-MS/MS analysis.

To evaluate the impact of acidic conditions on the stability of the conjugates in the extracts during isolation and sample preparation, 500 µL of the initial extracts from eggs and liver were treated with 200 µL 1N HCl and stirred at 70 °C for 30 min and analysed by HPLC.

Parent tetraniliprole was a major compound in fat (0.025 mg/kg, 26 percent TRR). Tetraniliprole was also detected in eggs, muscle and liver (0.004 mg/kg (4.2 percent TRR) in eggs, 0.003 mg/kg (9.4 percent TRR) in muscle and 0.032 mg/kg (4.2 percent TRR) in liver). Metabolite tetraniliprole-despyridyl-N-methyl-quinazolinone was the predominant residue in eggs and fat (0.023 mg eq/kg (27 percent TRR) for eggs and 0.059 mg eq/kg (62 percent TRR) for fat), while the metabolite amounted to 0.002 mg eq/kg (6.8 percent TRR) in muscle and 0.065 mg eq/kg (8.5 percent TRR) in liver. In muscle, the metabolite tetraniliprole-pyrazole-5-N-methyl-amide was the main residue and amounted to 0.005 mg eq/kg (18 percent TRR). Tetraniliprole-pyrazole-5-N-methyl-amide was also a prominent portion in the liver (0.044 mg eq/kg; 5.8 percent TRR). The main compound in liver was metabolite tetraniliprole-despyridyl (0.074 mg eq/kg, 9.6 percent TRR) and was detected in minor amounts in eggs, muscle and fat.

Other metabolites in liver were tetraniliprole-pyrazole-5-carboxylic acid (0.039 mg eq/kg; 5.0 percent TRR), tetraniliprole-benzylalcohol (0.062 mg eq/kg; 8.1 percent TRR), tetraniliprole-despyridyl-N-methyl-quinazolinone-hydroxy and tetraniliprole-despyridyl-hydroxy (0.069 mg eq/kg; 9.0 percent TRR) and tetraniliprole-despyridyl-quinazolinone (0.044 mg eq/kg; 5.8 percent TRR).

The label specific metabolite tetraniliprole-tetrazole and its conjugates were detected in eggs, muscle, fat and liver with levels ranging from (0.8-15 percent TRR). The sum of tetraniliprole-tetrazole and its conjugates amounted to 0.019 mg eq/kg (23 percent TRR) for eggs, 0.009 mg eq/kg (29 percent TRR) for muscle, 0.005 mg eq/kg (5.5 percent TRR) for fat and 0.025 mg qe/kg (3.3 percent TRR) for liver.

All other minor identified metabolites, such as tetraniliprole-pyrazole-5-amide and tetraniliprole-N-methyl-quinazolinone accounted for ≤0.027 mg eq/kg. The metabolic profile of tetraniliprole in eggs and edible tissues is presented in Table 49.

Table 49 Distribution of parent compound and metabolites in the extracts of eggs and edible tissues of hens following oral administration of [tetrazolyl-^{14}C]-tetraniliprole for 14 consecutive days at 19 ppm ai in feed

Notes:

[a] Sum of tetraniliprole-tetrazole and its 3 conjugates.

[b] Characterised by extraction and partition behaviour.

[c] Comprised of 9 separate regions, the largest of which contained 2.2% TRR, 0.002 mg/kg.

[d] Comprised of 2 separate regions, the largest of which contained 13.4% TRR, 0.004 mg/kg.

[e] Comprised of 13 separate regions, the largest of which contained 4.8% TRR, 0.037 mg/kg.

Overview of the metabolic pathway in livestock

The principal metabolic reactions of tetraniliprole in the lactating goat are listed below:

- intra-molecular condensation (cyclisation) of parent compound leading to quinazolinone compounds;
- hydroxylation in the methyl group of the phenyl moiety leading to tetraniliprole-benzylalcohol and the N-methyl moiety leading to tetraniliprole hydroxy-N-methyl;

- demethylation of the N-methyl group to form tetraniliprole-quinazolinone and tetraniliprole-desmethyl-amide;
- cleavage of the pyridine ring leading to tetraniliprole-pyrazole-5-amide (PC- and tetra-label) followed by further oxidation to a tetraniliprole-pyrazole-5-carboxylic acid or by methylation leading to tetraniliprole-N-methyl-amide;
- cleavage of the phenyl ring to form tetraniliprole-pyridinyl-pyrazole-5-carboxylic acid;
- cleavage of the tetrazole ring followed by oxidation leading to tetraniliprole-N-methyl-quinazolinone-3-carboxylic acid.

A proposed metabolic pathway for tetraniliprole in the lactating goat is presented in Figure 4.

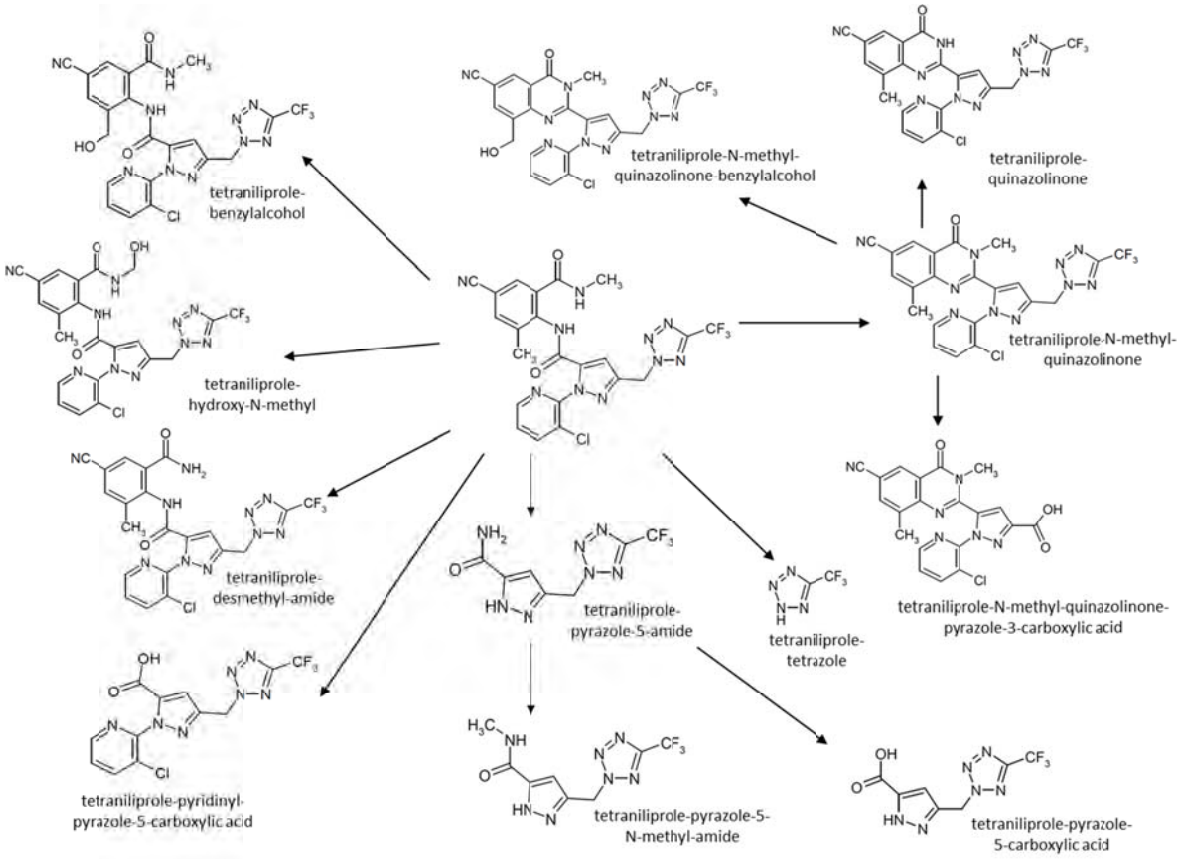

Figure 4 Proposed metabolic pathway for tetraniliprole in the lactating goat

The principal metabolic reactions of tetraniliprole in the laying hen are:

- cleavage of the pyridine ring, leading to despyridyl compounds;
- intra-molecular condensation of despyridyl compounds and parent compound leading to the quinazolinone compounds;
- cleavage of the tetrazole ring, followed by conjugation (tetra-label only);
- hydroxylations, leading to mono- and/or dihydroxy compounds such as tetraniliprole-dihydroxy, tetraniliprole-despyridyl-hydroxy, tetraniliprole-despyridyl-N-methyl-quinazolinone-hydroxy, and tetraniliprole-pyrazole-5-N-methyl-amide-hydroxy;
- conjugation with glucuronic acid after hydroxylation to tetraniliprole-benzylalcohol;

- cleavage of the phenyl moiety, leading to tetraniliprole-5-amide followed by methylation into tetraniliprole-pyrazole-5-N-methyl-amide followed by hydroxylation (tetraniliprole-pyrazole-5-N-methyl-amide-hydroxy);
- demethylation of the N-methyl group after intra-molecular condensation (cyclisation) of tetraniliprole-despyridyl to form tetraniliprole-despyridyl-quinazolinone.

A proposed metabolic pathway for tetraniliprole in the laying hen is presented in Table 5 and Figure 6 shows the positions involved in the metabolic pathway of tetraniliprole in livestock.

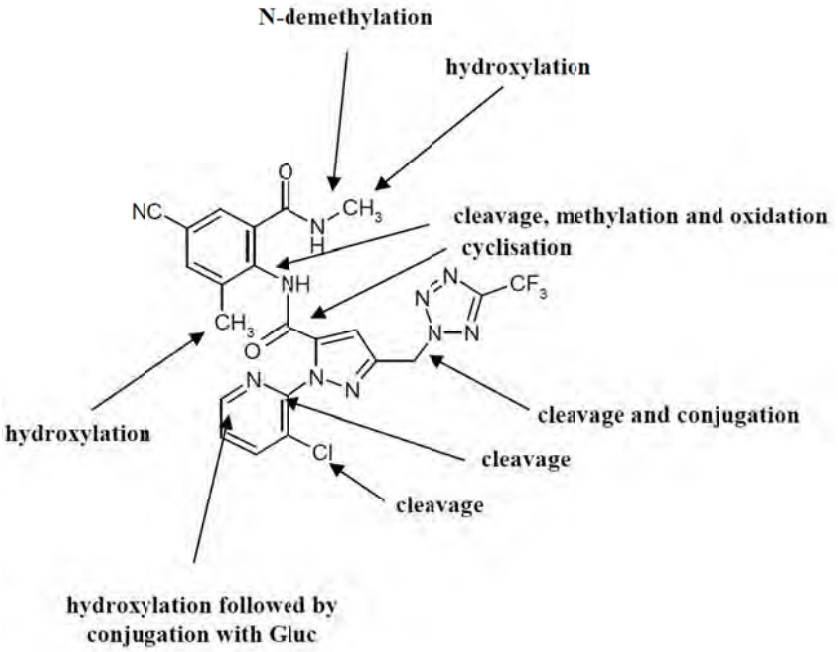

Figure 6 Positions involved in the metabolic pathway of tetraniliprole in livestock

RESIDUE ANALYSIS

Plant commodities

Enforcement methods

LC-MS/MS multi-residue method QuEChERS

The method 01463 (modification RTP-01) was validated for the determination of tetraniliprole and its metabolites tetraniliprole-N-methylquinazolinone and tetraniliprole-benzylalcohol in tomato (watery) and rapeseed (oilseed) (Reed, 2016a, M-564377-01-1, Report 035053).

The tomato and rapeseed seed were dry ice ground and stored frozen before use. Rapeseed (5 g) or tomato (10 g) of the homogenized and deep frozen samples were taken. Depending on the sample 10 mL of water was added as well as acetonitrile. The tube was shaken (15 minutes), 4 g of magnesium sulfate anhydrous, 1 g of sodium chloride, 1 g of trisodium citrate dihydrate and 0.5 g of disodium hydrogencitrate sesquihydrate was added, as well as a mixed internal standard solution and the tube was shaken strongly by hand for 1 minute. After centrifugation (4750 rpm for 5 minutes) about 1 mL supernatant was transferred into a 96 well plate and filtered through a 0.45 µm single syringe filter and analysed for tetraniliprole and both metabolites by LC-MS/MS, operated in electrospray positive mode without any further clean-up step. Transition for tetraniliprole in the primary method used was m/z 545.1 to 356.1 and for the confirmatory method m/z 545.1 to 376.1. For tetraniliprole-N- methylquinazolinone transitions m/z 527.0 to 389.1 and 527.0 to 374.0 (confirmation) were used. Similarly, the two transitions used for metabolite tetraniliprole-benzylalcohol were m/z 561.1 to 356.1 (primary) and 561.1–392.0 (confirmation). Calibration was applied with internal or matrix matched external standards solvent or matrix and using linear regression. The reported LOQ of the method was 0.01 mg/kg for parent and both metabolites.

A validation study was also carried out for tomato, grape (bunches of grapes), wheat (grain), dry bean (seed) and rape (seed) using matrix-matched external standards (tetraniliprole and tetraniliprole-N-methylquinazolinone only) (Stuke&van Berkum, 2016, M-544119-01-2, Report MR-15/091). An independent method validation (ILV) for method 01463 for tetraniliprole and metabolite tetraniliprole-N-methylquinazolinone in food of plant origin by QuEChERS was performed in tomato and rapeseed (seed) (Lakaschus& Lau, 2016, M-554622-01-1, Report S16-00229). The extraction method was performed as described by Reed (2016, M-564377-01-1, Report 035053).

Validation results are shown in Table 50 and Table 52.

Analytical methods used in study reports

HPLC-MS/MS method 1414 determines tetraniliprole and tetraniliprole-methylquinazolinone in various plant matrices. The method was first described by Stuke & Santiago (2014, M-488453-01-2, Report P602145509). An independent laboratory validation of the method for determination of tetraniliprole and tetraniliprole-N-methylquinazolinone was performed in citrus and broccoli (Claussen, 2016, M-564116-01-1, Report 122G1313).

Residues are extracted from the different matrices (2 g of sample) using water (8 mL) and acetonitrile (10 mL) along with automated shaking. After shaking, an internal standard solution is added. The extract is then filtered and the extracted residue levels are determined by LC-MS/MS. Residues of tetraniliprole and tetraniliprole-N-methylquinazolinone (are quantified using external calibration with standards in solvent containing stable isotope labelled standards.

The linearity range of the used detector was determined for tetraniliprole and its metabolite tetraniliprole-N-methylquinazolinone, as well as metabolites tetraniliprole carboxilic acid and tetraniliprole-desmethyl-amide-carboxylic acid using calibration standards containing 0.2, 1 (LOQ), 5, 10 and 25 µg/L of tetraniliprole and its metabolites tetraniliprole-N-methylquinazolinone, tetraniliprole-carboxylic acid, and tetraniliprole-desmethyl-amide-carboxylic acid and 10 µg/L of stable isotope labelled ISTD of each analyte. The correlation coefficients of the 1/× weighted linear regression were in all cases ≥ 0.99. The reported LOQ was 0.01 mg/kg. Validation results are shown in Table 53 and Table 54.

Recovery rates were determined after fortification of control samples with tetraniliprole and tetraniliprole-N-methylquinazolinone at fortification levels (expressed as parent equivalent) of 0.01 mg/kg and 0.1 mg/kg in all sample materials tested. Repeatability (precision) of the method, is given as relative standard deviation (% RSD) for all samples (n = 5) at both fortification levels. Analysis was performed LC-MS/MS.

Analytical Method 01414 for the determination of tetraniliprole and tetraniliprole-N-methylquinazolinone in orange whole fruit and broccoli stems and heads, representing citrus and Brassica crops, respectively, was successfully validated by an independent laboratory (Claussen, 2016, M-564166-01-1, Report 122G1313/RAFVP035).

Additional procedural recoveries obtained from the residue field trials have also been summarised here to support the suitability of the method in all plant matrices included in this evaluation.

Mean recovery values for each matrix were within the range of 70–120 percent, and RSD were generally less than 20 percent for tetraniliprole and tetraniliprole-N-methylquinazolinone at the LOQ and 10 × LOQ fortification levels.

Table 53 Recoveries for the validation of method 01414: tetraniliprole in plant matrices

Animal commodities

Enforcement methods

LC-MS/MS Method FV-002-A16-01 determines tetraniliprole, and its metabolites in animal commodities (Williams, 2016a, M-545487-01-2, Report FV-002-A16-01). The method was described and validated by in house validation studies in ruminant matrices and poultry muscle (Williams, 2016b, M-563847-01-1, Report RAFVP046) and in poultry matrices (Williams & Jerkins, 2016, M-569448-01-1, Report RAFV0033).

Samples of 5 ± 0.05 g were weighed into a 50-mL conical tube and fortified with the appropriate mixed standard solution. A mixture of 4:1 acetonitrile:water (~20 mL) was added to each sample as well as ~0.20 mL of formic acid. The samples were left to macerate for ~2 minutes prior to centrifugation (~5 minutes at ~3000 G). The extract was decanted and filtered with a SPE reservoir, filter paper, or other equivalent. Another ~20 mL of 4:1 acetonitrile:water was added to each sample, followed again by maceration, centrifugation and filtering. A Mixed Internal Standard Solution (0.250 mL of the 1.0 µg/mL) was added and the sample was further diluted to ~50 mL 4:1 v/v acetonitrile:water. For fat samples a slightly different approach was used with the first extraction step. In addition to the acetonitrile:water and formic acid also ~50 mL of hexane was added. After centrifugation at 2000G the hexane layer was discarded and the bottom layer was transferred to the filter.

For further sample preparation a 2 mL aliquot was transferred to a culture tube and dried to completeness in a turbovap at 50 °C, reconstituted in approximately 1 mL of 0.1 percent aqueous formic acid, mixed well and transferred to a C18 cartridge prewashed with about 1 mL of acetonitrile followed by water. The sample was eluted into an HPLC vial with 0.5 mL 4:1 v/v acetonitrile:water and 0.5 mL 0.1 percent aqueous formic acid, capped and mixed.

Samples were analysed by LC-MS/MS at m/z 545.1 to 356.1 (parent) and m/z 527.0 to 389.1 (tetraniliprole-N-methyl-quinazolinone), and 561.1 to 356.1 (tetraniliprole-benzylalcohol). Calibration was applied with internal standards in solvent (20/80/2 (v/v) water/acetonitrile/acetic acid) using linear regression with 1/× weighting. The reported LOQ for each analyte was 0.01 mg/kg. Validation results are shown in Tables 55 to Table 57.

An independent laboratory validation (ILV) was performed on ruminant milk and liver (Reed, 2016b, M-564372-01-1, Report number 034822-1/RAFVP0033). Furthermore, concurrent recoveries for parent and both metabolites tetraniliprole-N-methylquinazoline and tetraniliprole-benzylalcohol in cream, skim milk, milt, fats, kidney, liver and muscle from a dairy feeding study were available (Williams, 2016c, M-569181-01-1, Report RAFVP037). All results are shown in Table 55 to Table 57.

Average recoveries for the confirmation mass transitions at m/z 545.1 to 376.1 (tetraniliprole) and m/z 527.0 to 248.1 (tetraniliprole-N-methyl-quinazoline), and 561.1 to 392.0 (tetraniliprole-benzylalcohol) ranged from 75–107 percent for parent, 76–111 percent for tetraniliprole-benzylalcohol, and 76–107 percent for tetraniliprole-N-methylquinazoline in all animal tissues at 0.01-0.10 mg/kg (n=5 at each level). Control samples at these transitions were below 0.3 LOQ. Linearity at these transitions was confirmed in the range 0.1–100 µg/L.

Soil

HPLC-MS/MS method 01373 (Freitag & Koch, 2015, M-486110-02-1, Amendment to Report MR-13/100, Report RAFVP019) determines tetraniliprole and its metabolites tetraniliprole-N-methylquinazoline, tetraniliprole-amide, tetraniliprole-carboxylic acid, tetraniliprole-desmethyl-amide-carboxylic acid, tetraniliprole-N-methyl-quinazolinone-carboxylic acid and tetraniliprole-quinazolinone-carboxylic acid in soil and sediment.

Residues in 20 g soil samples are extracted for 15 minutes in a microwave extractor with a mixture (40 mL) of acetonitrile/water/acetic acid (400/100/3). The extracts are centrifuged to remove fine particles of the soil. Acetic acid (0.9 mL at 0.1 percent) is added to 0.1mL of sample. After further centrifugation to remove fine particle, the sample solution is ready for injection. Identification and quantitation of the active substance is done by high performance liquid chromatography using MS/MS detection in the Multiple Reaction Monitoring mode. The method was validated using three different soils "Höfchen", "Laacher Hof", "Dollendorf" and sediment. The recovery rates were determined for all analytes at fortification levels of 0.002 mg/kg (LOQ) and 0.02 mg/kg (10×LOQ).

Analytical method 01373 was successfully validated by an independent laboratory (ILV), analysing soil from Florida and Washington (Netzband&Jenks, 2016, M-554130-01-1, Report RAFVP017). The results are summarized in Table 58. The mean recovery values for each matrix were generally within the range of 70–120 percent, and RSD were generally less than 20 percent for all analytes at the LOQ and 10× LOQ fortification levels. The validation results for the determination of each of the analytes in soil are summarized in Table 58.

Table 58 Recoveries for the validation of method 01373 for determination of tetraniliprole and metabolites in soil with reported LOQ of 0.002 mg/kg (n=5)

Notes:
ILV = Independent Laboratory Validation.
[a] n=4.
[b] Due to a not given sensitivity this fortification level could not be used.
[c] Due to poor sensitivity at this fortification level no acceptable data was generated.
[d] Value of 155% is not included in calculations.
[e] Value of 143% is not included in calculations.

STABILITY OF PESTICIDE RESIDUES IN STORED ANALYTICAL SAMPLES

Storage stability of spiked residues in plant commodities

Storage stability was investigated by spiking tomato, dry bean (seed), wheat (grain), rape (seed) and grape (bunch of grapes) with 0.20 mg/kg of parent and metabolite tetraniliprole-N-methylquinazolinone [Uceda, 2016, M-565221-01-1, Report 14-10]. The samples stored in High Density Poly Ethylene (HDPE) Nalgene containers at an average temperature of -18 °C or below, were analysed at the nominal storage intervals of 0, 3, 6, 9, 12, 18 and 24 months using analytical method 01414 (see section on analytical methods). The LOQ of the method was 0.01 mg/kg for each compound. Average concurrent fresh recoveries were within the range of 70–110 percent, with RDS <20 percent, except for one recovery mean of 111 percent at the storage interval of 196 days for parent tetraniliprole in dry bean (seed). Control samples had residues below the 0.3LOQ.

Storage stability results (not corrected for concurrent recovery) and concurrent recoveries for the tetraniliprole and tetraniliprole-N-methylquinazolinone are shown in Table 59 and Table 60, respectively.

Table 59 Storage stability at ≤ -18 °C in commodities spiked with 0.2 mg/kg of tetraniliprole and tetraniliprole-N-methylquinazolinone

Residues of tetraniliprole and its metabolite tetraniliprole-N-methylquinazolinone are stable for at least 24 months in crop commodities representative of high water (tomato), high oil (oilseed rape), high protein (dry bean), high starch (wheat grain) and high acid (grape) commodity groups when stored under frozen at or below -18 °C.

Storage stability of residues in animal commodities

All samples obtained from livestock feeding studies (see section on farm animal feeding) were extracted and analysed within 30 days of their frozen storage and therefore it was not necessary to conduct freezer storage stability studies for animal products. Additionally, in the animal metabolism studies, samples were extracted and analysed within 5 months.

USE PATTERNS

Tetraniliprole is used as an insecticide on various crops grown under field conditions, applied either by foliar spray, soil applications, in-furrow, or drip chemigation. Tetraniliprole is toxic to bees and should therefore never be applied during bloom.

The Canadian and United States labels for foliar and seed treatments indicate a replanting interval for rotational crops of 30 days for root vegetables, leaves of root and tuber vegetables, bulb vegetables, legume vegetables (except soybeans); foliage of legume vegetables (except soybeans); cucurbits; cereal grains (except corn); forage, fodder, and straw of cereal grains (except corn); rapeseeds; sunflowers, and alfalfa. For all other rotational crops an interval of 120 days is advised. No restrictions or recommendations for the use of adjuvants are given in either the Canadian or United States labels. The registered use patterns that are supported with data are summarized in Table 61.

Table 61 Registered uses of tetraniliprole in the field

Crop	Country	Form	Application method and field or glass house					PHI, days

Notes:

n.a. = Not applicable.

[a] Including: Australian desert lime, Australian finger lime, Australian round lime, Brown River finger lime, calamondin, citron, citrus hybrids, grapefruit, Japanese summer grapefruit, kumquat, lemon, lime, Mediterranean mandarin, Mount White lime, New Guinea wild lime, orange (sour and sweet), pummel, Russell River lime, Satsuma mandarin, sweet lime, tachibana orange, Tahiti lime, tangelo, tangerine (mandarin), tangor, trifoliate orange, uniq fruit and cultivars, varieties, and/or hybrids of these commodities.

[b] Apply post bloom only. Do not make foliar application less than20 days following a soil or drip application.

[c] Apply >21 days prior to bloom or post blooming.

[d] Including: apple, azarole, crabapple, loquat*, mayhaw, medlar, pear, Asian pear, quince, Chinese quince, Japanese quince, tejocote and cultivars, varieties, and/or hybrids of these commodities. * Not in Canadian label.

[e] Apply post-bloom only.

[f] Stone fruit, including apricot, Japanese apricot, capulin*, cherry (black, sweet, tart, and Nanking), Chinese jujube*, nectarine, peach, plum, American plum, beach plum, Canada plum, plum, cherry plum, Chickasaw plum, Damson plum, Japanese plum, Klamath plum, prune, plumcot, sloe and cultivars, varieties, and/or hybrids of these commodities. Canadian label also includes chokecherry. * Not in Canadian label.

[g] Apply at infestation.

[h] Small fruit vine climbing, including amur river grape*, gooseberry, grape, hardy kiwifruit, maypop, schisandra berry, and cultivars, varieties, and/or hybrids of these commodities. Canadian label describes grape as: Grape (American bunch, Muscadine and Vinifera). * Not in Canadian label.

[i] Including: broccoli, Brussels sprouts, cabbage, Chinese cabbage (napa), cauliflower and cultivars, varieties, and/or hybrids of these commodities.

[j] Fruiting vegetables, including African eggplant, bush tomato, cocona, currant tomato, eggplant, garden huckleberry, goji berry, ground cherry, martynia, naranjilla, okra, pea eggplant, pepino, pepper (bell & nonbell), roselle, scarlet eggplant, sunberry, tomatillo, tomato; tree tomato, cultivars, varieties and hybrids of these commodities.

[k] Do not make applications less than 12 days prior to bloom or while plants are blooming.

[l] Leafy vegetables, including amaranth (leafy and Chinese), arugula, Indian aster, blackjack, broccoli raab, Chinese broccoli, abyssinian cabbage, bok choy, seakale cabbage, cat's whiskers, cham-chwi, cham-na-mul, chervil (fresh leaves), chipilin, chrysanthemum (garland), cilantro (fresh leaves), collards, corn salad, cosmos, garden cress, upland cress, dandelion leaves, dang-gwi leaves, dillweed, dock, dol-nam-mul, ebolo, endive, escarole, fameflower, feather cockscomb, Good King Henry, Hanover salad, huauzontle, jute leaves, kale, lettuce (bitter, head and leaf (Romaine)), maca leaves, mizuna, mustard greens, orach, parseley (fresh leaves), plantain (buckhorn), English primrose, purslane (garden and winter), radicchio, radish leaves, rape greens, wild rocket, shepherd's purse, spinach, Malabar spinach, New Zealand spinach, Swiss chard, tanier spinach, turnip greens, Chinese violet leaves, watercress, and cultivars, varieties and/or hybrids of these commodities. Note that for applications made to watercress, production fields must be drained of water at least 24 hours prior to application and water must not be reapplied to the field for a minimum of 24 hours following application. Canadian label also includes Italian corn salad, lamb's lettuce and tree spinach. It is noted that, according to the Codex classification, some of the leafy vegetables mentioned here belong to the fresh herbs.
Restriction for watercress: "For applications made to watercress, production fields must be drained of water at least 24 hours prior to application and water must not be reapplied to the field for a minimum of 24 hours following the application.
[m] Tuberous and corm vegetables, including arracacha, arrowroot, edible canna, cassava (bitter and sweet)*, chayote root*, Chinese artichoke, chufa, dasheen (taro), ginger, Jerusalem artichoke, leren, potato, sweet potato, tanier, true yam, turmeric, yam bean*. * Not in Canadian label. It is noted that, according to the Codex classification, ginger and turmeric belong to the spices.
[n] Apply pre- or post-blooming.
[o] Tree nuts, including: African nut-tree, almond, beechnut, Brazil nut*, Brazilian pine*, bunya*, bur oak nut, butternut, cajou nut*, candle nut*, cashew*, chestnut, chinquapin, coconut*, coquito nut*, dika nut*, ginkgo nut, Guiana chestnut, hazelnut (filbert), heartnut, hickory nut, Japanese horse-chestnut, macadamia nut*, mongongo nut*, monkey-pot*, monkey puzzle nut, Okari nut*, Pachira nut*, peach palm nut*, pecan, pequi*, Pili nut*, pine nut, pistachio*, Sapucaia nut*, tropical almond*, walnut (black & English), yellowhorn and cultivars, varieties, and/or hybrids of these commodities. * Not in Canadian label.
[p] Do not make a subsequent foliar application for a minimum of 60 days after planting the treated seed.
[q] Before soaking and before seeding (seed treatment dressing with coating agent) or after soaking and before seeding (seed treatment dressing during or after seed coating).
[r] For all application methods; only apply up to the V15 (when 15th leaf collar is visible), or after pollen shed (around 1 week after tassel is fully emerged).

RESIDUE RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received information on supervised residue trials for citrus fruit (orange, mandarin, lemon, and grapefruit), pome fruit (apple and pear), stone fruit (cherry, peach plum), grapes, flowerhead brassicas (broccoli and cauliflower) and head brassicas (head cabbage), fruiting vegetables (tomato, peppers), leafy vegetables (lettuce head, lettuce leaf, spinach, mustard greens), pulses (dry soya beans), tuberous and corm vegetables (potato),cereal grains (rice, maize, sweet corn), tree nuts (almonds and pecans). Table 62 summarizes the trials submitted to the Meeting

Table 62 Overview of the crops considered within the framework of this submission.

Application rates, spray concentrations and total residues have been rounded to two figures. Residue data are recorded unadjusted for percentage recoveries or for residue values in control samples unless otherwise stated. Unquantifed residues are shown as below the LOQ of 0.01 mg/kg.

Where multiple analyses were conducted on a single sample, the average value is reported. Where multiple samples were taken from a single plot, the individual and average values are reported. Results are therefore sometimes presented as single values or as duplicate/triplicate values with the (mean) value between brackets. Where results from separate plots with distinguishing characteristics such as different formulations, crop varieties or treatment schedules were reported, results are listed separately for each plot.

Residues from the trials conducted according to the critical GAP, which have been used for the estimation of maximum residue levels, STMR and HR values are underlined.

The residues presented in the tables are given as tetraniliprole and tetraniliprole-N-methylquinazolinone. Tetraniliprole-N-methylquinazolinone was either not found in matrices for human consumption or in quantities <1 percent of the parent (leafy vegetables and incidentally in rice grain). In some animal feed commodities significant levels of the metabolite were observed. In those tables a column with total residues was included. The total column reflects the sum of parent and tetraniliprole-N-methyl-quinazolinone, expressed as parent. The total residues, expressed as parent equivalents are not corrected with a molecular weight conversion factor, since molecular weight deviates only 3 percent.

Citrus fruit

Twenty-three field trials were conducted in the United States to measure the magnitude of tetraniliprole residues in/on grapefruit (6), lemon (5), mandarin (4), and orange (8) following treatment with a tetraniliprole 200 SC formulation (Gould&Dallstream, 2017, M-563131-03-1, Report RAFVP089-02). At each site one plot received a single soil (directed chemigation) plus a single foliar application and two replicate plots received three foliar applications with either concentrated or a dilute spray application, both with equal total rates. Different soil types were included (sand, loam, and clay). Trials were carried out in 2014/2015. Applications were made at actual rates of 115–121 g ai/ha (soil application) or 58–62 g ai/ha each (foliar application), with an application interval of 19–21 days between the soil and foliar applications and an application interval of 4–6 days between the three foliar applications. No adjuvants were used.

Duplicate samples of mature fruit (BBCH 83–89) were harvested from the soil + foliar treatment plots at 5–7 days following soil application, being 12–13 days prior to the foliar application (-12 to -13 DALA), shortly before foliar applications (DALA -0) and at DALA 1 after the foliar application. Single samples of mature fruit (BBCH 83–89) were harvested at the foliar application plots on DALA 0 prior to the final application and at DALA 1 after the third foliar application. Additional decline data were collected from 10 sites, where samples were taken nominally -14, -0, 0 (immediately after the final foliar

application), 1, 7, 14 and 21 days following the final application. Samples were collected from the centre of four trees, from all areas of the plot. Each sample consisted of at least 24 fruits, weighing at least 2 kg, except for one sample of trial FV143-14DA, which consisted of 17 fruits (sample weight was not reported). Which of the samples was smaller was not reported. Since the location consisted of replicate plots using different spraying volumes, but showing similar residue levels and decline rate, the highest value at PHI 1 days was considered suitable for MRL setting.

Samples were stored frozen for a maximum of 489 days prior to residue analysis. Samples were analysed for residues of tetraniliprole and metabolite tetraniliprole-N-methylquinazolinone using the LC-MS/MS method 01414. The LOQ was 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent. Totals were only calculated where residues of parent tetraniliprole and tetraniliprole-N-methylquinazolinone are above LOQ of 0.01 mg/kg. In the trials summarized below, levels of the metabolite were always below the LOQ. Therefore, no totals were added to the tables for citrus fruits.

The results of the trials are summarised in Table 63 to Table 66.

Lemons

Table 63 Residues of tetraniliprole in lemons (whole fruits) after a single soil application followed by a single foliar application [a] or three foliar applications using a 200 SC formulation (no adjuvants used) in the United States of America (Study RAFVP089-02)

Notes:

RTI = Retreatment Interval; DALA = Days after last application.

Mean residue values presented in parenthesis.

[a] Chemigation application followed by foliar application.
[b] Residues expressed in parent equivalents.
[c] PHI notation of 'X/-X/' represents sampling X days after the chemigation application and -X represents the corresponding number of days before the final foliar; '-0' represents sampling just prior to the final application; '0' represents sampling immediately after the final application.

Mandarins

Notes:

RTI = Retreatment Interval.

DALA = Days After Last Application.

[a] Chemigation application followed by foliar application.

[b] Residues expressed as parent equivalents.

[c] at the last application

[d] The report mentioned that one sample of trial FV143-14DA consisted of 17 fruits (sample weight was not reported). Which of the samples was smaller was not reported. The location consisted of replicate plots for triple foliar treatment with the same concentration of active substance, but two using different spraying volumes. Since both show similar residue levels and decline rates, the highest value at PHI 1 days was considered suitable for MRL setting.

Grapefruits

Table 66 Residues of tetraniliprole in grapefruits (whole fruits) after a single soil application followed by a single foliar application or three foliar applications using a 200 SC formulation in the United States in 2014 (Study RAFVP089-02)

Pome fruit–Canada and the United States

Twenty-five field trials were conducted in Canada and the United States (Fischer & Roberts, 2016, M-561106-02-1, Report RAFVP104-01) to measure the magnitude of tetraniliprole residues in/on apples (15 trials) and pears (10 trials) following three foliar air-blast applications of tetraniliprole 200 SC. Trials were carried out in 2014/2015. Applications were made at an actual rate of 57–62 g ai/ha, with application intervals of 5–8 days. Applications were made between growth stages BBCH 72–89. There were no adjuvants added to the spray mixture, except in trial FV190-14DA in which a silicone de-foamer was added to the three TRTDC applications (0.005 percent) and one of the TRTDD applications (0.003 percent).

Across all trials, apple fruit and pear fruit were harvested when the RAC was at BBCH 81 to 89. In the harvest trials, samples were collected from plots with a concentrated spray solution (TRTDC) and a diluted spray solution (TRTDD) a day before (-1) or immediately prior to the third treatment (-0), and after the 3rd application at a nominal 7-day pre-harvest interval. Additional decline data was collected from 8 sites, where samples were taken nominally -0, 0, 3, 7, 10 and 14 days following the final application. Each composite pome fruit sample contained a minimum of 24 whole fruit (2 kg), collected from all four quadrants of at least four trees per plot.

Samples were stored frozen for a maximum of 314 days prior to residue analysis. Samples were analysed for residues of tetraniliprole and metabolite tetraniliprole-N-methylquinazolinone using LC-MS/MS method 01414. The LOQ was 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent.

Pome fruit–Australia

Ten field trials were conducted in Australia (Massault, 2017, M-598808-01-1, Report BCS-0531 and Massault, 2018, M-631139-01-1, Report BCS-0532.01) to measure the magnitude of tetraniliprole residues in/on apples (6 trials) and pears (4 trials) following various foliar treatments with tetraniliprole 200 SC. Trials were carried out in 2017/2018. At each test site, multiple treatment plots were established that

received applications of tetraniliprole at various rates and timings. A non-ionic organic surfactant (Agral) was used at all trial sites.

Across all trials, apple and pear fruit were collected at commercial maturity, with additional decline samples also collected from some treatment plots. With exception of trial 532-2, where only 6 fruits were collected (indicated with [SS]), at least 12 fruits (1–2 kg) were sampled from several places on each tree within the centre of the plot.

Samples were stored frozen for a maximum of 85 days (*ca* 3 months) prior to residue analysis. Samples were analysed using the LC-MS/MS method ATM-0071 and ATM-0071B (see section on analytical methods). The LOQ was 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent. The specific recovery data are summarised in the analytical section.

Totals were only calculated where residues of parent tetraniliprole and tetraniliprole-N-methylquinazolinone are above LOQ of 0.01 mg/kg. In the trials summarized below, levels of the metabolite were always below the LOQ. Therefore, no totals were added to the tables for pome fruits.

The results of the trials in apples and pears are summarised in Tables 67 to 72.

Apples

Notes:

RTI = Retreatment Interval; DALA = Days After Last Application; T = tetraniliprole.

ADJ = adjuvant used (silicone de-foamer (FoamBuster, Helena Chemical Co.)), trial was not considered for MRL estimation; NIS= Non-ionic organic surfactant Agral.

[SS] = Sample size too small, consisting of 6 instead of 12 fruits; but trials were considered for MRL estimation, since total sample weight was >1 kg.

[a] At last treatment.

[b] Residues expressed as parent equivalents.

Stone fruit

Thirty-eight field trials were conducted to measure the magnitude of tetraniliprole residues in/on cherry (12 trials; Greenland, 2016a, M-570651-01-1, Report SARS-15-15), peach (16 trials; Greenland, 2016b, M-572119-01-1, Report SARS-15-16) and plum (10 trials; Greenland, 2016c, Document M-572124-01-1, Report SARS-14-01) following three foliar air-blast applications of tetraniliprole 200 SC. Trials were carried out in 2014/2015. Applications were made at an actual rate of 58-62 g ai/ha, with application intervals of 5–9 days. Applications were made between growth stage BBCH 74–89. In some trials an adjuvant (non-ionic surfactant (NIS) or crop oil concentrate (COC)) was added. At two of the plum test sites, additional treatment plots were established that were treated at an exaggerated rate to provide samples for processing.

Fruit were harvested when the RAC was at BBCH 81 to 89 (normal commercial harvest), 5 days after the last application (DALA)). Additional decline data was collected from five sites, where samples were taken nominally 0, 3, 5, 7 and 10 days following the final application. For each cherry sample a composite sample, weighing at least 1 kg, from several places on at least four trees within each plot was collected. The cherries were pitted and destemmed and the remaining fruit processed to a fine consistency in the presence of dry ice using a food processor prior to extraction. Samples of peach fruit or plums (a minimum of 24 fruit per sample) weighing at least 2 kg were taken from several places from at least four trees across the plot. Peach and plum stems and stones (pits) were removed prior to sample homogenization

Samples were stored frozen for a maximum of 344 days (*ca* 11 months) prior to residue analysis. Samples were analysed for residues of tetraniliprole and metabolite tetraniliprole-N-methylquinazolinone using LC-MS/MS method 01414 (LOQ of 0.01 mg/kg). The concurrent recoveries were within the acceptable range of 70–120 percent.

Totals were only calculated where residues of tetraniliprole and tetraniliprole-N-methylquinazolinone are above LOQ of 0.01 mg/kg. Except for one trial in plums, which was not considered for MRL estimation, levels of the metabolite were always < LOQ. Therefore, no totals were added to the tables for stone fruits. The results of the trials are summarised in Table 73 to Table 75.

Cherries

Berries and other small fruits

Grapes

Fifteen field trials were conducted in Canada and the United States to measure the magnitude of tetraniliprole residues in/on grapes (Greenland, 2016d, M-572121-01-1, Report SARS-14-7) following four foliar applications of a tetraniliprole 200 SC formulation. Trials were carried out in 2014/2015. Applications were made at an actual rate of 44–54 g ai/ha, with application intervals 6– days. Some trials were carried out without the use of adjuvants and in other trials an adjuvant was used (COC or NIS).

At two trial sites (trials SARS-14-07-CA8-3 and -NY-3) additional treatment plots were established that received an exaggerated application (5×) to provide samples for processing.

Samples of grape (a minimum of 12 bunches or parts of 12 bunches) weighing at least 1 kg were taken from random areas across the plots at normal commercial harvest, nominally 14 days after the last application. Additional decline data was collected from 1 site, where samples were taken 0, 7, 14, 21 and 28 days following the final application.

Samples were stored frozen for a maximum of 212 days (*ca* 7 months) prior to residue analysis. Samples were analysed for residues of tetraniliprole and metabolite tetraniliprole-N-methylquinazolinone using LC-MS/MS method 01414. The LOQ was 0.01 mg/kg for both analytes. The concurrent recoveries were within the acceptable range of 70–120 percent. The results of the trials are summarised in Table 77.

[b] At the last application.

Brassica vegetables, except brassica leafy vegetables

Twenty field trials were conducted to measure the magnitude of tetraniliprole residues in/on broccoli, cabbage, and cauliflower following four applications of a tetraniliprole 200 SC formulation (Netzband & Roberts, 2016, M-565724-02-1, Report RAFVP096-01). Trials were carried out in 2014. Applications were made at actual rates of 43–47 g ai/ha, with application intervals of 4–5 days without addition of an adjuvant.

Samples of florets (cauliflower), curd with stalks (broccoli) and heads with or without wrapper leaves (head cabbage) were collected at maturity, 1-day after the final application. Additional decline data was collected from eight sites, where samples were generally taken 0, 1, 5, 10 and 14 days following the final application. Each sample of broccoli, cauliflower, and head cabbage consisted of a composite from at least 12 individual plants and, for broccoli and cauliflower, weighed a minimum of 1 kg (with the exception of the residue reduction samples and trials FV262-14DA and FV267-14DA, indicated with [SS]).

For broccoli and cauliflower samples, the flower head and stem were collected by hand. For cabbage, the head was collected by hand, and if applicable, wrapper leaves were manually removed.

Samples were stored frozen for a maximum of 633 days (broccoli), 617 days (cauliflower), and 699 days (*ca* 23 months, cabbage) prior to residue analysis. Samples were analysed for residues of tetraniliprole and metabolite tetraniliprole-N-methylquinazolinone using LC-MS/MS method 01414. The LOQ was 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent. In the trials summarized below, levels of the metabolite were always below the LOQ. Therefore, no totals were added to the tables for flowerhead brassicas.

The results of the trials are summarised in Table 77 to Table 79.

Fruiting vegetables, other than cucurbits

Tomato

Nineteen field trials were conducted in the United States in 2014/2015 to measure the magnitude of tetraniliprole residues in/on tomato following four foliar applications of a tetraniliprole 200 SC formulation (Greenland, 2016e, M-572627-01-1, Report SARS-14-19). Applications were made at an actual rate of 43–47 g ai/ha, with application intervals of 4–6 days. Three trials included an additional plot which was treated with one soil drench application of tetraniliprole 200 SC at the maximum label rate (200 g ai/ha). Data on the soil types were not reported. At two of the trial sites (NY-3 and GA-3) additional treatment plots were established that received an exaggerated application rate (4 times 222–231 g ai/ha), to provide samples for processing.

Samples of fruit (a minimum of 24 medium (or 12 large) fruits weighing at least 2 kg, taken from random areas across the plots) were collected at maturity, nominally 1-day after the last foliar application. Additional information provided by the applicant showed that the typical fruits size varied from small sized varieties 28–81 g, medium sized varieties (170–280 g), to large varieties (up to 900 g). For the plots treated with a soil application, samples were harvested at maturity (14 days after treatment). Additional decline data was collected from 2 sites, where samples were taken 0, 1, 3, 5 and 10 days following the final foliar application, and 3, 7, 14, 21 and 28 days following the soil application.

Samples were stored frozen for a maximum of 299 days (*ca* 10 months) prior to residue analysis. Samples were analysed for residues of tetraniliprole and metabolite tetraniliprole-N-methylquinazolinone using LC-MS/MS method 01414. The LOQ was 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent. In the trials summarized below, levels of the metabolite were always below the LOQ. Therefore, no totals were added to the tables for tomatoes.

The results of the trials are summarised in Table 80 and Table 81.

Peppers

Thirteen field trials were conducted in the United States to measure the magnitude of tetraniliprole residues in/on pepper (sweet and chili) following four foliar applications of a tetraniliprole 200 SC formulation (Greenland, 2016f, M-570122-01-1, Report SARS-14-20). Applications were made at an actual rate of 43–47 g ai/ha with application intervals of 5–6 days. Trials were carried out in 2014/2015. The field trials were carried out with (+COC or +NIS) or without (indicated by ^) use of adjuvants.

Samples of fruit (a minimum of 24 medium (or 12 large) fruits weighing at least 2.4 kg, taken from random areas across the plots) were collected at maturity, nominally 1-day after the last foliar application. Additional decline data was collected from 1 site, where samples were taken 0, 1, 3, 5 and 10 days following the final application.

Samples were stored frozen for a maximum of 285 days (*ca* 9 months) prior to residue analysis. Samples were analysed for residues of tetraniliprole and metabolite tetraniliprole-N-methylquinazolinone using LC-MS/MS method 01414. The LOQ was 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent. The specific recovery data are summarised in the analytical section.

Totals were only calculated where residues of parent tetraniliprole and tetraniliprole-N-methylquinazolinone are above LOQ of 0.01 mg/kg. In the trials summarized below, levels of the metabolite were always below the LOQ. Therefore, no totals were added to the tables for peppers.

The results of the trials in sweet peppers and chili peppers are summarised in Table 82.

[b] At the last application

Leafy vegetables (including Brassica leafy vegetables)

Leafy greens

Twenty-six field trials were conducted in the United States to measure the magnitude of tetraniliprole residues in/on leaf lettuce (11 trials) (Greenland, 2016g, M572118-01-1, Report SARS-14-11), head lettuce (six trials) (Greenland, 2016h, M570646-01-1, Report SARS-15-12) and spinach (nine trials) (Greenland, 2016i, M5720124-01-1, Report SARS-14-14), following four foliar applications of a tetraniliprole SC formulation. Applications were made at an actual rate of 43–50 g ai/ha with application intervals of 2–4 days. Trials were carried out in 2014/2015. The field trials were carried out with (+COC or +NIS) or without (indicated by ^) use of adjuvants. At three of the spinach trial sites, an additional treatment plot was established that received a single soil application at the base of the spinach plants at a rate of 201–202 g ai/ha, 14 days prior to harvest.

Samples of lettuce leaves, lettuce heads (with and without wrapper leaves) and spinach leaves were collected at maturity, nominally 1 day following the final foliar application at BBCH 47-49 and were taken from random areas across the plots. Samples of leaf lettuce consisted of above ground portions of a minimum of 12 plants, weighing at least 1 kg. Samples of lettuce heads consisted of a minimum of 12 heads (or sections of 12 heads) with wrapper leaves or twelve heads (or sections of 12 heads) without wrapper leaves) weighing at least 1 kg. Samples of spinach leaves, weighing at least 1 kg, were taken from at least 12 plants. Following the soil application, spinach leaves were collected after 14 days (at maturity).

Additional decline data was collected from 3 foliar treated plot sites, where samples were taken 0, 1, 3, 5 and 10 days following the final application. Decline samples were also collected from the soil treated plot at 3, 7-, 14-, 21-, and 28-days following application.

Samples were stored frozen for a maximum of 268 days prior to residue analysis. Samples were analysed for residues of tetraniliprole and metabolite tetraniliprole-N-methylquinazolinone using LC-MS/MS method 01414. The LOQ was 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent. The results of the trials are summarised in Tables 83 to Table 86.

Brassica leafy vegetables

Mustard greens

Five field trials were conducted to measure the magnitude of tetraniliprole residues in/on mustard greens following four applications of a tetraniliprole 200 SC formulation (Miller & Jerkins, 2016, M-557177-01-1, Report RAFVN036). Applications were made at a rate of 45–49 g ai/ha, with application intervals of 4–5 days. Trials were carried out in 2014/2015. No adjuvants were used.

Samples of leaves weighing at least 1 kg were collected at maturity from at least 12 separate areas of the plot, nominally 1-day after the final application. One bulk sample of 4 kg was collected from plot FV306-14HA for processing purposes. Additional decline data were collected from 2 sites, where samples were taken nominally 0, 1, 5, 10 and 14 days following the final application.

All samples were stored frozen for a maximum of 427 days (*ca* 14 months) prior to residue analysis. Samples were analysed for tetraniliprole and tetraniliprole-N-methylquinazolinone using LC-MS/MS method 01414. The LOQ was 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent. Totals were only calculated where residues of parent tetraniliprole and tetraniliprole-N-methylquinazolinone are above LOQ of 0.01 mg/kg. In the trials summarized below, levels of the metabolite were always below the LOQ.

The results of the trials are summarised in Table 87.

Pulses

Soya bean (dry)

Twenty-one field trials were conducted in Canada and the United States to measure the magnitude of tetraniliprole residues in/on soya bean raw agricultural commodities following four foliar applications of a tetraniliprole 200 SC formulation (Greenland, 2016j, M-574330-02-1, Report SARS-15-03). Applications were made at an actual rate of 48–52 g ai/ha, with application intervals of 2–4 days. Three trials also included a separate plot where soya bean was treated with one in-furrow soil application of tetraniliprole 200 SC at an actual rate of 203–240 g ai/ha. Trials were carried out in 2014/2015.

An additional treatment plot was established at two sites that was treated at an exaggerated rate (5×) to provide samples for processing. Samples of seed were collected at normal maturity (BBCH not reported), nominally 14 days after the last foliar application. Additional decline data was collected from 2 sites, where samples were taken 0, 7, 14, 21 and 28 days following the final foliar application.

Seed samples, weighing at least 1 kg, were collected from a mechanical harvester in at least twelve areas within the plot as the harvester proceeded through the plot, or plants were harvested from at least twelve areas within the plot by hand and then threshed.

Soybean seed samples for processing and aspirated grain fractions (AGF) were collected at the normal commercial harvest time, fourteen (14) days after the last test substance foliar application. Samples were stored frozen for a maximum of 227 days (*ca* 7 months) prior to residue analysis. Samples were analysed for tetraniliprole and metabolite tetraniliprole-N-methylquinazolinone using LC-MS/MS method 01414. The LOQ was 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent.

The results of the trials are summarised in Table 88 (Foliar applications) and Table 89 (In-furrow treatments). In the trials summarized below, levels of the metabolite were always below the LOQ. Therefore, no totals were added to the tables for soya bean seeds.

Root and tuber vegetables

Potato

Twenty-six field trials were conducted in Canada and the United States to measure the magnitude of tetraniliprole residues in/on potato following one in furrow or four foliar applications of a tetraniliprole 200 SC formulation (Dallstream & Jerkins, 2016b, M-557979-01-1, Report RAFVP074). Foliar applications were made at an actual rate of 25–32 g ai/ha, with application intervals of 3–7 days. In-furrow treatments were made at a nominal rate of 200 g ai/ha. Trials were carried out in 2014/2015. No adjuvants were used.

Samples of tubers were collected at maturity, generally 14 days after the final foliar application. Samples were also collected at maturity following the in-furrow applications. Additional decline data was collected from 4 sites, where samples were taken nominally 3, 7, 14, 21 and 28 days following the final foliar application.

Samples were stored frozen a maximum of 455 days (*ca* 15 months) prior to residue analysis. Samples were analysed for tetraniliprole and metabolite tetraniliprole-N-methylquinazolinone using LC-MS/MS method 01414. The LOQ was 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent.

The results of the trials are summarised in Table 90 (Foliar applications) and Table 91 (In-furrow treatments). In the trials summarized below, levels were always below the LOQ.

Notes:

DALA = Days After Last Application; T = tetraniliprole.

[a] Residues are expressed as parent equivalents.

[b] Five of the trials were carried out at the same time in Phelps (1) and Sodus (1), and Lyons (3); The cities are geographically <30 km apart. When considering the application dates, the trials in Phelps and Sodus were not considered independent, nor were the three trials in Lyons.

Cereal grains

Rice–Thailand, India and Vietnam

Twelve field trials were conducted throughout Thailand, India and Vietnam to measure the magnitude of tetraniliprole and tetraniliprole-N-methylquinazolinone residues in/on paddy rice following 2 foliar applications of a thiacloprid 480 SC formulation containing 120 g tetraniliprole/L (Woodard, 2019a, Report RAFV0085, Document M-669757-01-1). Applications were made at actual rates of 38–42 g ai/ha, with application intervals of 7–17 days. In addition, twelve field trials were conducted in the same countries to measure the magnitude of tetraniliprole and tetraniliprole-N-methylquinazoline residues in/on paddy rice following either 1 seed treatment (TRTD1), 1 seed treatment followed by on foliar treatment (TRTD2) or 3 foliar treatments (TRTD3) with a tetraniliprole 480 FS formulation or a tetraniliprole 200 SC formulation (Woodard, 2019b, Report RAFV0014, Document M-667200-01-1). Seed treatments were made at application rates ranging from 240 to 244 g ai/ha, foliar treatments were made at actual rates of 58–68 g ai/ha. All the trials were carried out in 2018/2019. No adjuvants were used in either study.

In both studies samples of rice grain and brown rice were collected from each site at normal commercial harvest (*ca* 43 days after the final application). Several sites in both studies included additional samples of grain, collected approximately 38, 43, 50 and 53 days following the final application to provide residue decline data.

For the whole grain (paddy rice) samples, collected at 40 (actual 38–40 days), 45 (actual 43 – 45 days), 50 (actual 48 – 50 days), 55 days (actual 53 days), and normal commercial harvest (NHC), sample fractions were generated according to local practice. At crop maturity (approximately BBCH 89), sufficient paddy rice plants were harvested from the control plot first and then from the treated plot to obtain minimum sample sizes for all commodities (1 kg grain). In a clean area away from the test plots, the whole grain rice was separated from the rice straw and allowed to dry by sun drying up to 5 days if needed, according to local practice. The rice grain was then dehulled and milled, using a dehulling machine, by hand or other method. The dehulling process produced unpolished, brown rice and rice hulls. Brown rice samples were collected and the rice hulls were discarded.

Samples were stored frozen for a maximum of 261 days and 136 days. In both studies samples were analysed for residues of tetraniliprole and metabolite tetraniliprole_N-methylquinazolinone using LC-MS/MS method 01414. The LOQ was 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent.

The results of the trials are summarised in Table 92 and Table 95 (Whole grain/paddy rice) and Table 96 and Table 97 (Brown rice).

Rice–Brazil

Six field trials were conducted in Brazil to measure the magnitude of tetraniliprole and tetraniliprole-N-methylquinazolinone residues in/on paddy rice following 3 foliar applications with a tetraniliprole 200 SC formulation (Carvalho, 2016, M-567467-02-1, Report I14-046). Applications were made at actual rates of 40–43 g ai/ha, with application intervals of 14 days. All the trials were carried out in 2015.

Samples of rice (grain) were collected from each site at normal commercial harvest (*ca* 14 days after the final application). Additional samples were collected from three sites to provide residue decline data (PHI 7, 14 and 21 days). Samples were analysed for residues of tetraniliprole and metabolite tetraniliprole_N-methylquinazolinone using LC-MS/MS method 01414. The LOQ was 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent. The period of the storage of the frozen samples to tetraniliprole and its metabolite tetraniliprole-N-methylquinazolinone was at maximum 95 days. Totals were only calculated where residues of parent tetraniliprole and tetraniliprole-N-methylquinazolinone are above LOQ of 0.01 mg/kg.

The results of the trials on rice are summarised in Tables 92 to 95..

Table 92 Residues of tetraniliprole paddy rice (grain) after foliar treatment using SC formulation in trials performed in Brazil, India, Thailand and Vietnam

[a] Residues are expressed in parent equivalents.

[b] At the last application.

Maize/field corn

Twenty one field trials were conducted in Canada and the United States to measure the magnitude of tetraniliprole residues in/on field corn raw agricultural commodities following four foliar applications of a tetraniliprole 200 SC formulation (Stewart & Greenland, 2016, M-574645-01-2, Report SARS-15-06).

Foliar applications were generally made at applications rates ranging between 49 and 52 g ai/ha, with application intervals of 6–8 days, except for one trial that had 13 days between the 2nd and 3rd applications to plot 2. Three trials also included a separate plot where field corn was treated with one in-furrow soil application of a tetraniliprole 200 SC formulation, at application rates ranging from 198 to 202 g ai/ha. Three trials also included two additional plots that were each planted with field corn seed that was treated with a tetraniliprole 480 FS formulation, corresponding with 30–48 g ai/ha. One of these seed treated plots was also treated with three foliar applications of a tetraniliprole 200 SC formulation at 50–51 g ai/ha. In some trials adjuvants (NIS or COC) were used.

At two of the sites, an additional treatment plot was established that received four foliar applications at an exaggerated rate (5×) of nominally 250 g ai/ha, to provide samples for processing. All trials were carried out in 2015.

Samples were collected for analysis at the normal commercial harvest time, fourteen (14) days after the last test substance application. Foliar applications in plots designated for grain sampling (plots 3 and 6) were scheduled so that the last application occurred fourteen (14) days before crop maturity–normal grain harvest. Additional decline samples were collected for analysis at 0, 7, 14 (normal harvest), 21, and 28 days after the last application (DALA).

Grain samples, weighing at least 1 kg, were collected from a mechanical harvester in at least twelve areas within the plot as the harvester proceeded through the plot, or ears were removed from the plants by hand and then shelled. Treated bulk grain samples weighing >200 kg for processing were mechanically harvested.

Samples were stored frozen for a maximum of 158 days (*ca* 5 months) prior to residue analysis. Samples were analysed for residues of tetraniliprole and metabolite tetraniliprole-N-methylquinazolinone (BCS-CQ63359) using LC-MS/MS method 01414. The LOQ was 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent. The results on grain are summarised in Table 37.

Totals were only calculated where residues of parent tetraniliprole and tetraniliprole-N-methylquinazolinone are above LOQ of 0.01 mg/kg. In the trials summarized below, levels of the metabolite were always below the LOQ therefore, no totals were added to the table.

Maize/sweet corn

Fifteen field trials were conducted in the United States and Canada to measure the magnitude of tetraniliprole residues in/on sweet corn raw agricultural commodities following four foliar applications of a tetraniliprole 200 SC formulation at an actual rate of 48–54 g ai/ha, with application intervals of 6–10 days (Greenland&Stewart, 2016, M-574351-01-2, Report SARA-15-05). Three trials also included a separate plot where sweet corn was treated with one in-furrow soil application of tetraniliprole 200 SC at an application rate of 199–202 g ai/ha. Furthermore, three trials also included two separate plots that were planted with sweet corn seed that was treated with a tetraniliprole 480 FS formulation at a rate of

49–63 g ai/ha. One of these seed treated plots was also treated with three foliar applications of tetraniliprole 200 SC at a rate of 48–52 g ai/ha. Trials were carried out in 2015. In some trials adjuvants (NIS or COC) were used.

All sample collection dates were collected on normal harvest of sweet corn for fresh market, the milk stage. Forage and kernel plus cob with husk removed (K+CWHR) samples were collected at normal harvest, one (1) day after the last foliar application (DALA). Stover samples were collected one month later (1 DALA + one month), corresponding to about 80 to 85 percent dry matter, except at the NE site stover samples were not collected due to technician error of destroying plants before stover sampling date. Forage and K+CWHR samples from the seed treatment only plot were collected on the same day as the other plots. Decline samples of forage and K+CWHR were collected at 0, 1 (normal harvest), 3, 7, and 14 DALA. Stover decline samples were collected at 0 DALA + one month, 1 (normal harvest) DALA + 1 month, 3 DALA + 1 month, 7 DALA + 1 month, and 14 DALA + 1 month. Forage and stover samples were composites of 12 plants. Each stem, with leaves attached, was divided into three (3) equal lengths. Top, middle and bottom portions were randomly selected from each of the three groups of four stems to ensure that parts of all 12 stems were included in the sample. The exception was at the ND site where the entire plant was harvested instead of dividing it into three parts (see Deviation 1). K+CWHR samples consisted of at least 12 ears from different plants in each plot and weighed at least 2 kg.

Samples were stored frozen for a maximum of 316 days (*ca* 10 months) prior to residue analysis. Samples were analysed for residues of tetraniliprole and metabolite tetraniliprole-N-methylquinazolinone using LC-MS/MS method 01414. The LOQ was 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent. In the trials summarized below, levels of tetraniliprole-N-methylquinazolinone were always below the LOQ. The results on kernels (cobs with husks removed) are summarised in Table 98 and Table 99.

Table 98 Residues of tetraniliprole in sweet corn kernel with cobs with husks removed (K+CWHR) after foliar treatments with a 200 SC formulation in trials performed in Canada and the United States in 2015 (Study SARS-15-05)

Tree nuts

Almonds

Five field trials were conducted in the United States to measure the magnitude of tetraniliprole residues in/on almond, following four foliar applications of a tetraniliprole 200 SC formulation (Greenland, 2016k, M-572123-01-1, Report SARS-15-17). Applications were made at an actual rate of 44–46 g ai/ha with application intervals of 7 days. Trials were carried out in 2015. In some trials an adjuvant (NIS or COC) was used.

Samples of nutmeat were collected at maturity, 10 days after the final application. Additional decline data was collected from 1 site, where samples were taken 0, 5, 10, 15 and 20 days following the final application. Almonds were taken by hand, taking care to avoid the plot boundaries, from several places from upper, middle and lower portions of the trees across the plot. The nutmeats were separated from the hulls. Samples of almond nutmeats (weighing at least 1 kg) were kept cool until they were placed in freezers

Samples were stored frozen for a maximum of 176 days (*ca* 6 months) prior to residue analysis. Samples were analysed for residues of tetraniliprole and metabolite tetraniliprole-N-methylquinazolinone (BCS-CQ63359) using LC-MS/MS method 01414. The LOQ was 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent. The results of the trials are summarised in Table 100.

Totals were only calculated where residues of parent tetraniliprole and tetraniliprole-N-methylquinazolinone are above LOQ of 0.01 mg/kg. In the trials summarized below, levels of the metabolite were always below the LOQ therefore, no totals were added to the table.

Table 100 Residues of tetraniliprole in almond (nutmeat) after foliar treatment using a 200 SC formulation in trials performed in the United States in 2015 (Study SARS-15-17)

Pecan

Eight field trials were conducted in the United States to measure the magnitude of tetraniliprole residues in/on pecan, following four foliar applications of a tetraniliprole 200 SC formulation [Greenland, 2016l, M-570119-01-1, Report SARS-14-02]. Applications were made at a rate of 44–47 g ai/ha with application intervals of 7–8 days. The trials were carried out in 2014/2015.

Samples of nutmeat were collected at maturity, generally 10 days after the final application. Additional decline data was collected from 1 site, where samples were taken 0, 5, 10, 15 and 20 days following the final application. Samples of pecan nutmeat weighing at least 1 kg were taken from several places from at least four trees across the plot, except the treated samples from the SARS-14-02-TX3 site were only 0.79 and 0.90 kg.

Samples were stored frozen for a maximum of 245 days (*ca* 8 months) prior to residue analysis. Samples were analysed for residues of tetraniliprole and tetraniliprole-N-methylquinazolinone using LC-MS/MS method 01414. The LOQ was 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent.

In the trials summarized below, levels of tetraniliprole and tetraniliprole-N-methylquinazolinone were always below the LOQ. The results of the trials are summarised in Table 101.

Table 101 Residues of tetraniliprole in pecan (nutmeat) after foliar treatment using a 200 SC formulation in trials performed in the United States (Study SARS-14-02)

[b] At the last application.

Animal feed items

Soya bean forage and soya bean hay

A total of three field trials on soya bean were conducted in the United States in the 2014/2015 growing season [Greenland, 2016j, M-574330-02-1, Report SARS-15-03] resulting in residue data of tetraniliprole in soya bean forage and soya bean hay. In separate plots soya bean was treated with one in-furrow soil application of tetraniliprole 200 SC at an actual rate of 203–240 g ai/ha. Trials were carried out in 2014/2015. Forage and hay samples were cut at approximately BBCH 70 (mid-to-full bloom to pods 50 percent developed). Forage was collected immediately after cutting and hay was collected after drying to about 10 to 20 percent moisture. Samples of soya bean forage weighing at least 1 kg and soya bean hay weighing at least 0.5 kg were taken from random areas across the plots.

Samples were stored frozen for a maximum of 224 days prior to residue analysis. Samples were analysed for residues of tetraniliprole and tetraniliprole-N-methylquinazolinone (BCS-CQ63359) using LC-MS/MS method 01414. The LOQ was 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent. The results are presented in Table 104 and Table 105.

Notes:

[a] Residues are expressed in parent equivalents.

Rice straw, and whole plant silage

Twelve field trials were conducted throughout Thailand, India and Vietnam to measure the magnitude of tetraniliprole and tetraniliprole-N-methylquinazolinone residues in/on paddy rice following 2 foliar applications of a thiacloprid 480 SC formulation containing 120 g tetraniliprole/L (Woodard, 2019a, Report RAFV0085, Document M-669757-01-1). Applications were made at actual rates of 38–42 g ai/ha, with application intervals of 7–17 days. In addition, twelve field trials were conducted in the same countries following either 1 seed treatment, 1 seed treatment followed by on foliar treatment or 3 foliar treatments with a tetraniliprole 480 FS formulation or a tetraniliprole 200 SC formulation (Woodard, 2019b, Report RAFV0014, Document M-667200-01-1). Seed treatments were made at application rates ranging from 240 to 244 g ai/ha, foliar treatments were made at actual rates of 58–68 g ai/ha. All the trials were carried out in 2018/2019. No adjuvants were used in either study.

For the whole plant (no roots), panicles removed and panicles samples at 33 (actual 31-33 days) day interval, sufficient paddy rice plants were harvested from the control plot first and then from the treated plot to obtain minimum sample sizes (minimum of 12 plants and 0.5 kg) for each whole plant (no roots, panicles removed) and panicles sample. The rice plant was cut about 2 cm above the surface of the water. Panicles were separated from the rest of the plant to create 2 samples; panicles and whole plant (no roots) panicles removed. BBCH growth stage varied between the samples.

For straw samples at 40 (actual 38–40 days), 45 (actual 43–45 days), 50 (actual 48–50 days), 55 days (actual 53 days), and normal commercial harvest samples (NHC). At crop maturity (approximately BBCH 89), sufficient paddy rice plants were harvested from the control plot first and then from the treated plot to obtain minimum sample sizes for all commodities (0.5 kg straw). Sample fractions were generated according to local practice. In a clean area away from the test plots, the whole grain rice was separated from the rice straw. The separated rice grain and straw from both plots was then sun dried up to 5 days, if necessary.

Samples were stored frozen for a maximum of 261 days prior to residue analysis. Samples were analysed for residues of tetraniliprole and tetraniliprole_N-methylquinazolinone using LC-MS/MS method 01414. The LOQ was 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent.

The results on paddy rice straw and paddy rice whole plant silage are presented in Table 103 to Table 106.

Notes:
DALA = Days After Last Application; [FT] = Foliar Treatment; [ST] = Seed Treatment
[a] Residues are expressed in parent equivalents.
[b] At the last application.

Maize forage and stover

Supervised field residue trials on maize/field corn were conducted in Canada and the United States in the 2018/2019 growing season (Stewart & Greenland, 2016, M-574645-01-2, Report SARS-15-06).

At all locations plots received four foliar applications of a tetraniliprole 200 SC formulation. Foliar applications were generally made at applications rates ranging between 49 and 52 g ai/ha, with application intervals of 6–8 days, except for one trial that had 13 days between the 2nd and 3rd applications to plot 2. Three trials also included a separate plot where field corn was treated with one in-furrow soil application of a tetraniliprole 200 SC formulation, at application rates ranging from 198 to 202 g ai/ha. Three trials also included two additional plots that were each planted with field corn seed that was treated with a tetraniliprole 480 FS formulation, corresponding with 30–48 g ai/ha. One of these seed treated plots was also treated with three foliar applications of a tetraniliprole 200 SC formulation at 50–51 g ai/ha. In some trials adjuvants (NIS or COC) were used.

Samples were collected for analysis at the normal commercial harvest time, fourteen (14) days after the last test substance application. Foliar applications in plots designated for forage sampling (plot 2) were scheduled so that the last application occurred fourteen (14) days before the late dough/early

dent stage–normal forage harvest. Foliar applications in plots designated for stover sampling (plots 3 and 6) were scheduled so that the last application occurred fourteen (14) days before crop maturity–normal stover harvest. Forage and stover samples from in-furrow treatment (plot 4) and seed only treatment (plot 5) were harvested at the same time as the forage and stover were harvested in plots 2 and 3. Additional decline data was collected from 2 sites, where samples were taken nominally 0, 7, 14, 21 and 28 days following the final foliar application. Decline samples were collected for analysis at 0, 7, 14 (normal harvest), 21, and 28 days after the last application (DALA).

Forage and stover samples were composites of twelve plants. Treated bulk grain samples for generating aspirated grain fractions were mechanically harvested.

Samples were stored frozen for a maximum of 158 days prior to residue analysis. Samples were analysed for residues of tetraniliprole and metabolite tetraniliprole-N-methylquinazolinone using LC-MS/MS method 01414. The LOQ was 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent.

In a second study, fifteen field trials were conducted in Canada and the United States to measure the magnitude of tetraniliprole residues in/on sweet corn raw agricultural commodities following four foliar applications of a tetraniliprole 200 SC formulation at an actual rate of 48–54 g ai/ha, with application intervals of 6–10 days [Greenland&Stewart, 2016, M-574351-01-2, Report SARA-15-05]. Three trials also included a separate plot where sweet corn was treated with one in-furrow soil application of tetraniliprole 200 SC at an application rate of 199–202 g ai/ha. Furthermore, three trials also included two separate plots that were planted with sweet corn seed that was treated with a tetraniliprole 480 FS formulation at a rate of 49–63 g ai/ha. One of these seed treated plots was also treated with three foliar applications of tetraniliprole 200 SC at a rate of 48–52 g ai/ha. Trials were carried out in 2015. In some trials adjuvants (NIS or COC) were used.

All sample collection dates were keyed on normal harvest of sweet corn for fresh market, the milk stage. Forage samples were collected at this stage, one (1) day after the last foliar application (DALA). Stover samples were collected one month later (1 DALA + one month), corresponding to about 80 to 85 percent dry matter, except at the NE site stover samples were not collected due to technician error of destroying plants before stover sampling date. Forage samples from the seed treatment only plot were collected on the same day as the other plots. Decline samples of forage were collected at 0, 1 (normal harvest), 3, 7, and 14 DALA. Stover decline samples were collected at 0 DALA + one month, 1 (normal harvest) DALA + 1 month, 3 DALA + 1 month, 7 DALA + 1 month, and 14 DALA + one month. Forage and stover samples were composites of 12 plants. Each stem, with leaves attached, was divided into three (3) equal lengths. Top, middle and bottom portions were randomly selected from each of the three groups of four stems to ensure that parts of all 12 stems were included in the sample. The exception was at the ND site where the entire plant was harvested instead of dividing it into three parts.

Samples were stored frozen for a maximum of 316 days prior to residue analysis. Samples were analysed for residues of tetraniliprole and metabolite tetraniliprole-N-methylquinazolinone using LC-MS/MS method 01414. The LOQ was 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent.

The results on maize forage and stover are presented in Tables 107 to 113.

Almond hulls

Five field trials were conducted in the United States to measure the magnitude of tetraniliprole residues in/on almond, following four foliar applications of a tetraniliprole 200 SC formulation [Greenland, 2016k, M-572123-01-1, Report SARS-15-17]. Applications were made at an actual rate of 44–46 g ai/ha with application intervals of 7 days. Trials were carried out in 2015.

Samples of almond hulls were collected at maturity, 10 days after the final application. Additional decline DALA was collected from 1 site, where samples were taken 0, 5, 10, 15 and 20 days following the final application. Almonds were taken by hand, taking care to avoid the plot boundaries, from several places from upper, middle and lower portions of the trees across the plot. The nutmeats were separated from the hulls. Samples of almond hulls (weighing at least 1 kg) were kept cool until they were placed in freezers

Samples were stored frozen for a maximum of 176 days prior to residue analysis. Samples were analysed for residues of tetraniliprole and metabolite tetraniliprole-N-methylquinazolinone using LC-MS/MS method 01414. The LOQ was 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent. The results of the trials are summarised in Table 114.

FATE OF RESIDUES IN STORAGE AND PROCESSING

In storage

No data.

Nature of residues during processing

The hydrolytic stability of tetraniliprole was investigated in aqueous buffer solutions at 3 pH values and temperatures to simulate representative processing conditions (Bongartz&Schmeling, 2014c, M-475964-01-1, Report EnSa-13-1093). The study was performed at pH 4, 5 and 6 and temperatures of 90 °C, 100 °C and 120 °C, for 20, 60 and 20 minutes, respectively, representing pasteurization, baking/brewing/boiling and sterilization. Temperatures were maintained constant throughout incubation and no significant variation of the pH values was observed in the buffered solutions.

[Pyrazole-carboxamide-^{14}C]-tetraniliprole and [phenyl-carbamoyl-^{14}C]-tetraniliprole were prepared in buffer solution (pH 4, 5 and 6) at a nominal concentration of 1 mg/L. The radioactivity in the samples at start and end of the study was determined by LSC. Material balances ranged from 94 to 107 percent of the applied radioactivity, and at least 97 percent of the radioactivity in the samples was identified by reverse phase HPLC.

A summary of the results are shown in Table 115.

Table 115 Radioactive residues of [pyrazole-carboxamide-^{14}C]-tetraniliprole (py-^{14}C) and of [phenyl-carbamoyl-^{14}C]-tetraniliprole (phe-^{14}C) and hydrolysis products under representative processing conditions.

	Processing conditions					
	pH 4 / 90 °C / 20 min pasteurisation		pH 5 / 100 °C / 60 min baking/brewing/boiling		pH 6 / 120 °C / 20 min sterilisation	
Tetraniliprole , % RA	89.93	94.93	64.61	67.92	1.14	1.46
T-pyrazole-5-N-methyl-amide, % RA	1.04	NA	3.03	NA	1.98	NA

Accountability, % RA	100	100	100	100	100	100

Notes:
RA = Radioactivity; NA = not applicable.

Tetraniliprole was shown to be predominantly stable at pH 4 / 90 °C / 20 min (pasteurisation). However, conversion into degradation compounds increased under conditions with higher pH- and temperature values. Under sterilisation conditions nearly all parent compound was hydrolysed. The main hydrolysis product for both labels was tetraniliprole-N-methyl-quinazolinone. Only low amounts of tetraniliprole-pyrazole-5-N-methyl-amide (specific for the pyrazole-carboxamide label) and tetraniliprole-desamino-methyl-carboxylic acid were detected.

Magnitude of residues during processing

Oranges

Two field trials were conducted, in the United States (Veal&Jerkins, 2016b, M-560734-01-1, Report RAFVN026), to measure the magnitude of tetraniliprole residues in/on orange processed commodities following three foliar applications of tetraniliprole 200 SC at an exaggerated (5×) nominal rate of 300 g ai/ha per application, without the use of an adjuvant. Applications were made to oranges (Valencia) at actual total rates of 900–910 g ai/ha with application intervals of 4–5 days at BBCH 83 to 89. Spray volumes ranged from 465–1414 L/ha. Samples of orange whole fruit were harvested 1-day after the final application at commercial maturity (BBCH 83–89). Single composite samples of orange fruit were harvested from the treated and untreated plots one day after the last application, at BBCH growth stages 83 to 89. Individual sub-samples of control and treated unwashed orange fruit, the raw agricultural commodity (RAC), were removed and frozen for subsequent analysis. Oranges were processed according to simulated commercial procedures into washed whole fruit, peel, washed peel, pulp, juice, raw juice, peel without oil, oil, wet pomace, dry pomace, dried pulp and marmalade. Throughout the study one representative sample of untreated control and two (duplicate) samples of treated processed commodities were taken.

Samples were stored frozen (<-18 °C) for a maximum of 687 days (*ca* 23 months) prior to analysis. All samples were analysed for residues of tetraniliprole and tetraniliprole-N-methyl-quinazolinone using analytical method 01414.

Oranges were weighed after removal from storage or upon receipt. Representative unwashed fruit sample fractions were taken (sample: *raw agricultural commodity*). The remaining fruit was hand inspected for undesirable fruit or field debris, and if observed, it was removed, weighed, and discarded.

Washing and peeling

An aliquot of unwashed fruit (3.9–6.2 kg) was peeled, and the unwashed peel (0.78–1.8 kg) was collected (sample: *unwashed peel)*. The peeled fruit was weighed (2.7–4.4 kg) and discarded. The remaining oranges (195–202 kg) were 'batch tub' washed for 5 minutes. Representative samples of washed fruit fractions were collected (sample: *washed whole fruit)*. An aliquot of washed fruit (4.1–6.1 kg) was peeled, and representative sample (sample: *washed peel)* was taken from the washed peel (1.0/1.8 kg) as well as a sample (sample: *peeled orange (flesh)*) from the peeled fruit (2.9–4.3 kg). The remaining peeled fruit was discarded. The yield factor for peeling unwashed fruit ranged from 0.67 to 0.76. The yield factor for peeling of washed fruit ranged from 0.70 to 0.78.

Marmalade

An aliquot of washed fruit was set aside for producing marmalade (2.0–2.5 kg). The rind of the oranges for marmalade processing was removed with a vegetable peeler/zester (33–117 g). The rind was then chopped in a food processor and cooked for 20 minutes, resulting in 71–172 g (weight gain of -5.3–55 g) and set aside. The remaining rind on the oranges was removed and the seeds discarded (1.1–1.5 kg). The orange flesh was chopped in the Robot Coupe food processor (0.65–1.1 kg) and cooked on the stove for 40 minutes with added water (20 percent of fruit by weight), being 123–210 g. The rind and fruit were then combined with 3 tablespoons of lemon juice per kilogram of fruit, and sugar at 1.5 times the total weight of the fruit mixture. The total mixture was then boiled for 3 minutes, pectin (0.05 kg) was added, and the mixture (1.1–1.8 kg) was boiled for an additional 2 minutes. The finished marmalade (1.6–2.8 kg) was packed into sterilized jars and cooled. Representative jars of marmalade were collected (sample: *marmalade*). Marmalade in excess of needs was discarded. The yield factor from washed fruit to marmalade ranged from 0.71–1.1.

Oil processing

The remaining washed oranges (183–191 kg) were transferred to the modified Hobart Abrasive Peeler for scarifying. Approximately 2.42 kg (average) of oranges per batch were abraded with water for about 90 seconds to scarify the flavedo for oil recovery. The resulting oil–water emulsion was collected. The scarified fruit was weighed (191–213 kg, with weight gain of 8.3–22 kg) and an aliquot retained for juice processing (35–44 kg) and for peeling (4.5–5.1 kg). The remaining scarified fruit was discarded.

The collected oil-water emulsion from the scarification process was transferred to the Sweco Sifter and screened using a 94 TBC screen (-180 jim) to separate any flavedo fragments from the oil-water emulsion. The scarified flavedo (+94 TBC screen) was set aside for later addition to the shredded peel. The oil-water emulsion (-94 TBC screen) was processed through the cream separator and IEC centrifuge to separate the oil and placed in the freezer. The residual emulsion was frozen for a minimum of overnight. After removing the emulsion from the freezer, the sample was thawed, centrifuged, and the oil removed with a volumetric pipette. The entire sample of oil recovered (337–629 gram) was collected (sample: *cold extracted peel oil*). The yield factor from washed fruit to oil ranged from 0.0018–0.0034.

An aliquot of scarified oranges (4.5–5.1 kg) were peeled and representative samples (sample: *peel without oil*) were collected from the recovered peel (1.2–1.6 kg).

Juicing

An aliquot of the scarified oranges (35–44 kg) was transferred to the Hollymatic Juice Extractor to recover juice. The juice (10–15 kg, including a ca. 2 L lost to spillage in one sample) and peel recovered (2.3–3.0 kg) from the juice extraction were weighed and the peel set aside for further processing. The collected juice (10–15 kg) was transferred to the pulper finisher and screened using a -1.19 mm screen to remove vesicular membranes, seeds, segment membranes, and peel fragments from the juice. The recovered, screened juice was weighed and ° Brix taken on the fresh juice (7.5–14 kg (0.49–2.6 kg loss)). The collected rag and seeds (170–350 g) were set aside for later addition to the shredded peel. Representative samples of the fresh juice were taken (sample: *raw juice*). The remaining juice (6.5–13 kg) was pasteurized at 88 – 91 °C for a minimum of 15 seconds, cooled to less than 38 °C, and representative samples (sample: *pasteurized juice*) were taken from the pasteurized juice (6.2–12 kg- loss of 220–530 g). The remaining juice was discarded. The yield of washed fruit to raw juice ranged from 0.28–0.37 and the yield from washed fruit to pasteurized juice 0.27 to 0.35.

Wet pomace

The peel from the Hollymatic Juice Extractor (23–30 kg) was shredded using the Robot Coupe Food Processor. The shredded peel (23–29 kg) was combined with the scarified flavedo (0.17–4.3 kg) from the scarification process and rag and seeds (170–350 g) from the juice finisher process to generate the unpressed wet pomace (24–30 kg).

Wet pomace: A portion (10–14 kg) of the wet pomace was pressed to remove moisture (1.5–4.0 kg) using the Suntech Fruit Press, resulting in 6.6–10 kg pressed wet pomace), and representative samples were taken (sample: *wet pomace*). Calculated weight loss in pressing was 1.0–2.0 kg. The remaining pressed wet pomace (5.6–9.3 kg) was reserved for drying (dry pomace). The yield from RAC (washed oranges) to pressed wet pomace corrected for subsampling ranged from 0.42–0.53.

Limed wet pomace: The remaining unpressed wet pomace (12–16 kg) was used to generate limed wet pomace. Lime (-95 percent CaO) was added to the unpressed wet pomace and mixed on the Hobart mixer for 17 minutes. The limed wet pomace (12–16 kg) was pH tested, pressed using the Suntech Fruit Press resulting in 5.2–8.0 kg limed wet pomace, and the expressed liquid was weighed (6.3–8.6 kg), checked for pH, ° Brix, and discarded. The calculated weight loss during pressing was 0.40–0.77 kg. No sample was taken from the limed wet pomace product.

Dry pomace

Unlimed dry pomace: The unlimed wet pomace (5.6–9.3 kg) was placed on the Laboratory Bin Air Dryer and dried to below 10 percent moisture, resulting in a loss of 4.3–7.3 kg. The remaining dry pomace (1.2–2.0 kg) was milled using the Suntech Fruit Press hammermill resulting in 1.2–2.0 kg, with a loss of 20 g. Representative samples of the dry pomace were taken (sample: *dry pomace*). The remaining dry pomace was discarded. The yield of unlimed wet pomace to unlimed dry pomace ranged from 0.20 to 0.22. The yield from RAC (washed fruit) to unlimed dry pomace ranged from 0.094–0.11.

Limed dry pomace: The pressed, wet, limed pomace (5.2–8.0 kg) was placed on the Laboratory Bin Air Dryer and dried to below 10 percent moisture with a loss of 4.8–6.9 kg. The remaining dried pomace (1.4–2.2 kg) was milled using the Suntech Fruit Press hammermill resulting in 1.3–2.1 kg (loss of 10–30 g). Representative samples of the dry limed pomace were removed (sample: *limed dry pomace*). The remaining limed dry pomace was discarded. The yield of limed wet pomace to limed dry pomace ranged from 0.25 to 027. The yield form RAC (washed fruit) to limed dry pomace ranged from 0.84–0.97.

Figure 7 summarizes the citrus processing procedure.

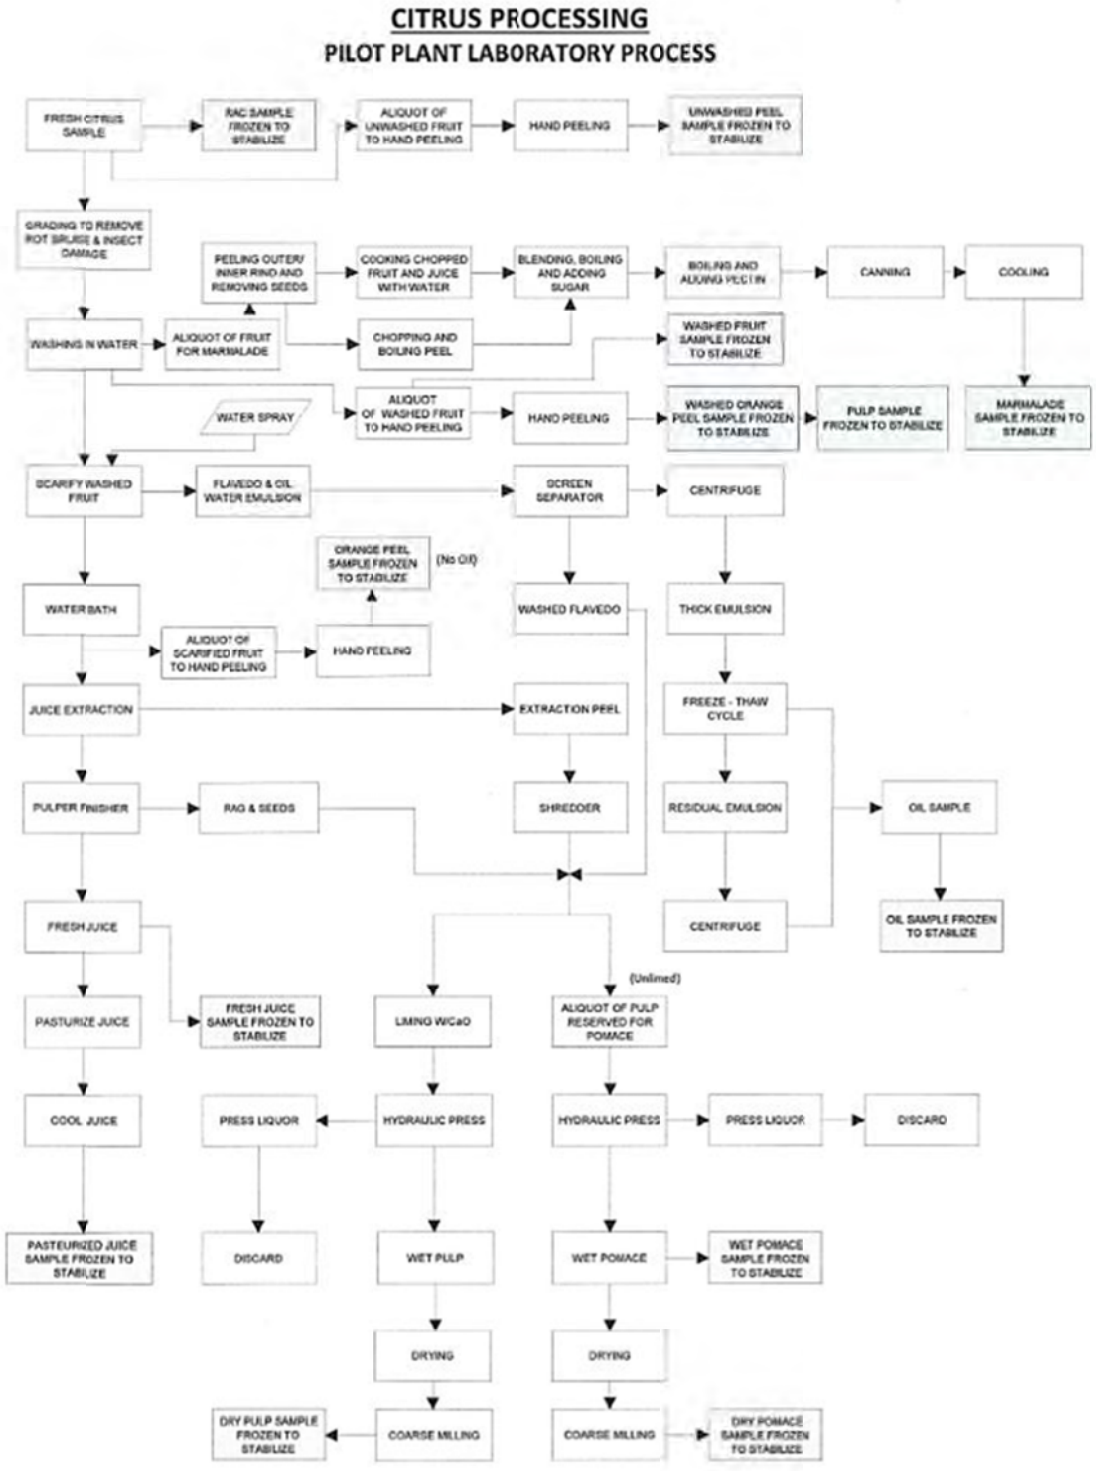

Figure 7 Citrus processing

Processing factors were derived for several orange processed commodities. Trial data, residue levels and processing factors for each type of commodity are summarised Table 116. Note that total residues represent parent + tetraniliprole-N-methyl-quinazolinone, unless levels of the metabolite were <LOQ of 0.01 mg/kg. This generally results in the same PFs, except for cold extracted peel and limed dry pomace in one trial, which is still very similar.

Table 116 Tetraniliprole residues and processing factors in orange whole fruit and processed commodities (Report RAFVN026)

Trial information	Sample	Residues (mg/kg) [a]			PF [b]

Notes:
DALA = Days After Last Application; RAC = Raw Agricultural Commodity; RTI = Retreatment Interval.
[a] Expressed as parent tetraniliprole.
[b] PF: Processing Factor = Residue level in processed commodity (mg/kg) ÷ Residue level in unprocessed commodity (mg/kg). Where the value for parent in the processed commodity is <LOQ, a value of 0.01 mg/kg has been used for calculation of a PF. Where the value for the metabolite tetraniliprole-N-methyl-quinazolinone is <0.01 mg/kg eq, a value of "0" was used.

Apples

Two field trials were conducted, in the United States, to measure the magnitude of tetraniliprole residues in/on apple processed commodities (Dallstream&Jerkins, 2016c, M-560638-01-1, Report RAFVP0640. Three foliar applications of tetraniliprole 200 SC at exaggerated rates (5×) were applied. Applications were made at actual rates of 296–307 g ai/ha, with application intervals of 7 days. Samples of apple whole fruit were collected 7 days after the final application at commercial maturity (BBCH 87–89). Apples were processed according to simulated commercial procedures into wet pomace, juice, washed fruit, peeled fruit, apple sauce, dried fruit, dried pomace, raw juice and peel. Throughout the study one representative sample of untreated control and two (duplicate) samples of treated processed commodities were taken. Figure 8 summarizes the apple processing procedure.

Washing

A batch of 70–93 kg apples was available. An aliquot of unwashed apples (4.9–7.2 kg) was reserved for peeling. Unwashed apples were peeled, resulting in 4.7–6.3 kg peeled apples and 0.84–1.3 kg unwashed peel. Representative samples of unwashed, peeled fruit (sample: *unwashed peeled fruit*) and fruit peel (sample: *unwashed fruit peel*) were taken. The remaining apples (60–83 kg) were washed in a stainless-steel wash cart using a ratio of ~2 kg of cold water to each 1 kg of fruit for 5 minutes. Representative samples were taken (sample: *wash water* and sample: *whole washed fruit*). Aliquots of washed apples were set aside for processing into apple sauce (12–13 kg), dried apple (18 kg), and apple juice (26–43 kg). The apples in excess were discarded.

Juicing

Washed apples for juice processing (26–43 kg) were fed into the Suntech Fruit Press hammermill assembly and reduced to crushed apple pulp (25–42 kg) with a loss to the process of 0.53–0.94 kg. The crushed apple pulp was transferred to the 35 L Swept Surface Steam Jacketed Kettle and heated with low-pressure steam until the temperature of the apple pulp reached 40–50 °C. 1.5 g of pectic enzyme per kg of apple pulp (38–62 g) was then added and mixed for approximately 2 minutes and permitted to react for approximately 2 hours, then pressed using the Suntech Fruit Press.

The collected wet pomace (5.5–10 kg) was analysed for moisture content. A representative wet pomace sample was taken (sample: *wet pomace*). The yield from washed fruit to wet pomace ranged from 0.20 to 0.24. The remaining wet pomace (4.4–9.2 kg) was placed on the Laboratory Bin Air Dryer and dried to below 10 percent moisture, resulting in a weight of dry pomace of 1.0–2.5 kg, with a calculated weight loss of 3.2–6.7 kg. The yield from wet pomace to dry pomace ranged from 0.23 to 0.27. The dry pomace was milled using the Suntech Fruit Press hammermill (1.0–2.4 kg remaining). A representative sample of the dry pomace was taken (sample: *dry pomace*).

The fresh juice recovered from the fruit press (18–29 kg) was filtered over a U.S. #40 screen to remove any coarse solids, resulting in 18–28 kg fresh/raw juice (yield = 0.66–0.70). A representative fresh/raw unpasteurized fresh juice sample taken (sample: *fresh/raw juice*). Part of the fresh raw juice was reserved for pasteurization (11–16 kg). The fresh raw juice in excess was discarded. The calculated loss to the pressing process was 1.6–3.2 kg and to the filtering process 0.04–0.07 kg.

An aliquot of raw fresh juice (11–16 kg) for the pasteurized juice fraction was then heated to approximately 93° C for 15–30 seconds to deactivate the pectic enzymes and then cooled to approximately 30 °C, resulting in a weight of 9.9–15 kg, due to a loss by deactivation process of 0.54–0.74 kg. The unfiltered pasteurized apple juice was placed in refrigerated storage overnight to permit settling of solids. The juice was racked off, resulting in 2.8–9.6 kg juice and settled solids were discarded.

Part of the clear juice (7.54 kg) was discarded (trial FV001 only). Another part of the clear juice (1.3–3.6 kg) was then vacuum filtered using a vacuum pump, vacuum flasks and Büchner vacuum funnels. Diatomaceous earth and filter paper were used as filtering aids. After filtering, the juice (1.1–3.3 kg) was heated again to 93 ± 3 °C for approximately 30 seconds, packed in sterilized cans, and sealed. The cans were inverted for sterilization of the lids and the cans cooled in a cold-water bath. Pasteurized juice weighed 1.0–3.2 kg. The yield of pasteurized juice from washed fruit, corrected for sub-fractionation ranged from 0.18 to 0.41. Samples were taken (sample: *pasteurized juice*). The remaining pasteurized juice was discarded.

Apple sauce

The aliquot of washed apples reserved for apple sauce processing (12–13 kg) were peeled, cored, and sliced. The peel and cores removed were weighed (3.2–5.2 kg) and discarded. The peeled/cored/sliced apples (7.1–9.4 kg) were placed in cold water containing salt to prevent enzymatic browning. The sliced apples were then cooked with water at ~85–95 °C, until completely soft and weighing 8.5–12 kg. The cooked apples were then strained through the pulper finisher and separated into raw apple sauce (6.3–10 kg) and apple fiber (strain rest) weighing 0.58–1.1 kg (loss through the process of 0.70–1.7 kg). The strain rest was weighed and discarded and sugar (0.90–1.6 kg) was added to the apple sauce until a minimum of 18° Brix was achieved. The apple sauce (7.2–12 kg) was then reheated to a minimum of 90 °C and a final Brix taken before pasteurized sauce (6.6–12 kg) is packed in cans and sealed. Loss due to the process of pasteurization and canning is 0.29–0.71 kg. The cans were processed for 10 minutes in boiling water and cooled in cold water. A representative sample of the pasteurized, canned apple sauce was taken (sample: *apple sauce*). The yield of washed apple to pasteurized apple sauce ranged from 0.53 to 0.95.

Drying of apples

The washed aliquot of apples (18 kg) reserved for dried apple processing, were peeled, cored and spiral sliced to ~0.64 cm thickness (11–13 kg). The peel and cores removed were weighed (5.4–7.6 kg) and discarded. A calculated weight loss due to the process of peeling slicing and coring is 0–0.39 kg. The peeled/cored/sliced apples (11–13 kg) were placed in cold water containing salt to prevent enzymatic browning. The sliced apples are then diced using a potato French fry strip culler producing a 0.64 cm square apple piece. The diced apples are then dipped for 5 minutes in a prepared solution of 0.5 percent of potassium meta-bisulfite and 0.2 percent citric acid. The diced apples are evenly divided into three trays and the trays are placed in the tray dryer. The calculated weight loss in dicing and transfer to dryer is 0.0–1.1 kg. The trays are periodically rotated in the dryer and the diced apples stirred and weighed until a target moisture of ~2.5 percent moisture is obtained, resulting 1.0–1.4 kg of dried apple slices, with a calculated weight loss due to drying of 8.6–11.4 kg (corresponding with 88–90 percent). A representative sample of the dried apple was taken (sample: *dried apple*). The yield of washed apple to dried apple slices ranged from 0.055–0.077. Figure 7 shows the processing procedure for apple

Samples were stored frozen (<-18 °C) for a maximum of 259 days prior to analysis. All samples were analysed for residues of tetraniliprole and tetraniliprole-N-methylquinazolinone using analytical method 01414.

Trial data, residue levels and processing factors for each type of commodity are summarised in Table 117. The concentration of residues observed in pomace (wet) and peel suggest that the residue is present on the peel and the PF is due to fractionation. The higher residues in dry pomace correspond with concentration due to the loss on drying.

Note that total residues represent parent + tetraniliprole-N-methyl-quinazolinone, unless levels of the metabolite were <LOQ of 0.01 mg/kg. This generally results in the same PFs, except for the washings in one trial, but still with a similar PF.

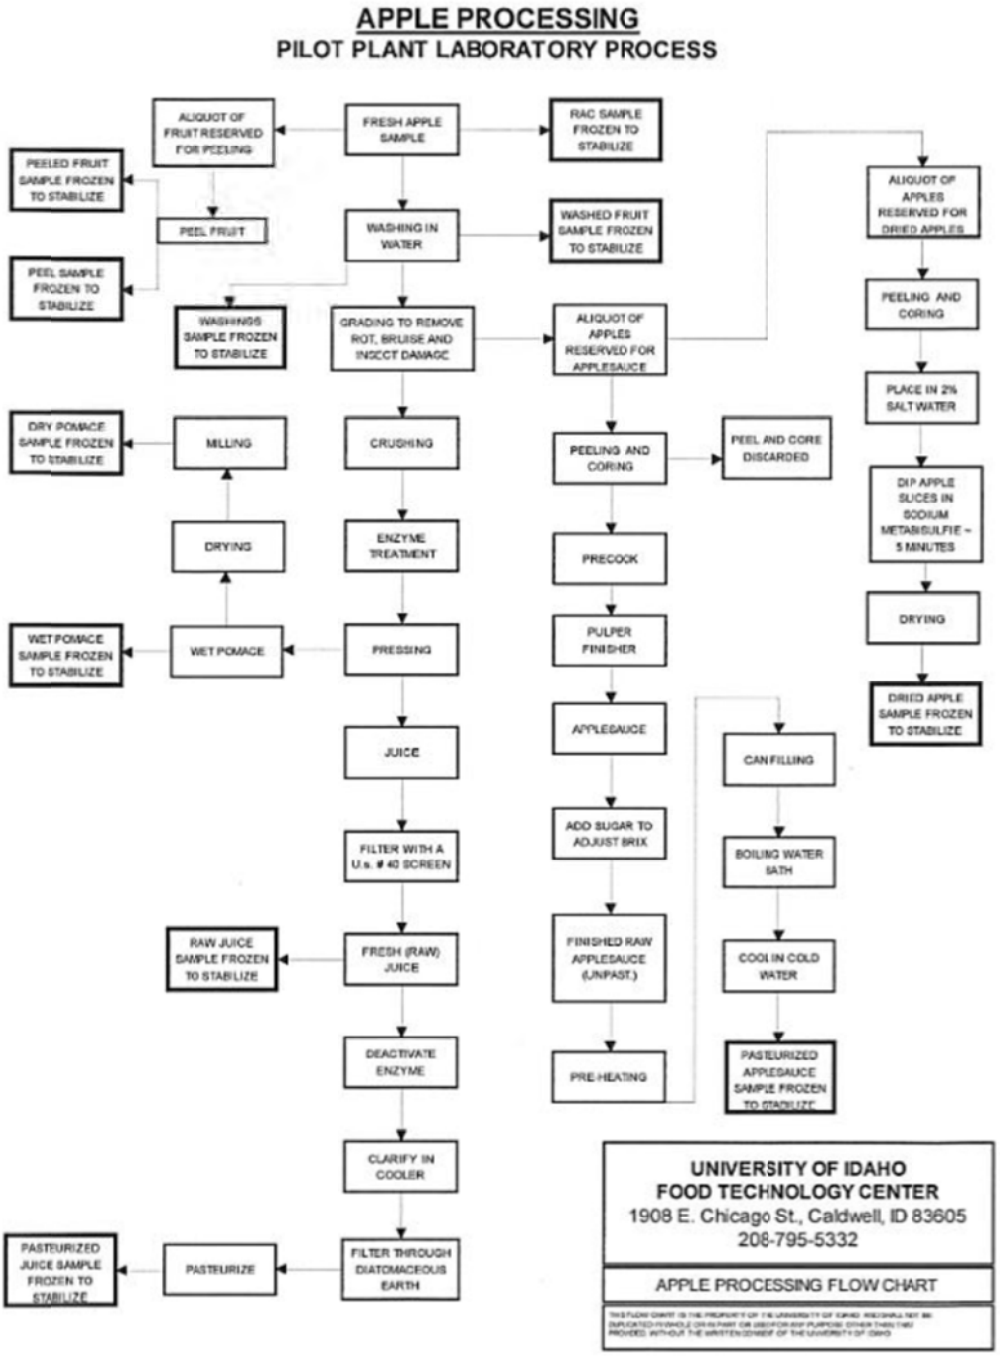

Figure 8 Apple processing

Table 117 Tetraniliprole residues and processing factors in apple whole fruit and processed commodities (Report RAFVP064)

Trial information	Sample	Residues (mean) (mg/kg) [a]			PF [b]

Notes:
DALA = Days After Last Application; RAC = Raw Agricultural Commodity; RTI = Retreatment Interval; T-N-MQZ = tetraniliprole-N-methylquinazolinone.
[a] Expressed as parent tetraniliprole.
[b] PF: Processing Factor = Residue level in processed commodity (mg/kg) ÷ Residue level in unprocessed commodity (mg/kg). Where the value for parent in the processed commodity is <LOQ, a value of 0.01 mg/kg has been used for calculation of a PF. Where the value for the metabolite tetraniliprole-N-methyl-quinazolinone is <0.01 mg/kg eq, a value of "0" was used.

Plums and prunes

Two trials on plums with exaggerated rates (5×) were conducted (Greenland, 2016c, M-572124-01-1 Report SARS-14-01) to provide samples for processing to measure the magnitude of tetraniliprole residues in/on plum and prunes. Three foliar air-blast applications of a tetraniliprole 200 SC formulation were made between growth stage BBCH 74–89 with retreatment intervals of approximately 7 days and samples collected 5 days after the last application. A minimum of 11.8 kg per sample of plums were collected at normal harvest for processing into prunes. The control and treated samples were processed on the day of harvest and the processing procedures were identical for the untreated and treated samples. The fresh plum samples were weighed and arranged on the drying trays of the dehydrator. Plums were dried for one or two days at 54–57 °C. Actual sample weights to establish material balance were not reported. According to the Standing Operating Procedures in the report, the samples had to be dried until they weighed 1/3 of the original weight.

Samples were stored frozen for a maximum of 267 days prior to residue analysis. Samples were analysed for residues of tetraniliprole and metabolite tetraniliprole-N-methylquinazolinone using LC-MS/MS method 01414. The LOQ was 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent.

Trial data, residue levels and processing factors for each type of commodity are summarized Table 118. Processing factors were derived for prunes, where a concentration of residues was observed, consistent with a concentration due to weight loss by drying.

Note that total residues represent parent + tetraniliprole-N-methyl-quinazolinone, unless levels of the metabolite were <LOQ of 0.01 mg/kg. This results either in the same or a similar PF.

Table 118 Residues of tetraniliprole and processing factors in plums/prunes [Report SARS-14-01]

Trial information	Sample	Residues (mean) (mg/kg) [a]			PF [b]	
		Tetraniliprole	T-N-methyl-quinazolinone	total	PF_{parent}	PF_{total}
SARS-14-01-BC-3, Fraser Valley, British Columbia Canada, 2015 (Variety: PRM1 grafter on Moyer) 3 x foliar treatment; 299-308 g ai/ha, RTI = 9 & 5 days; adjuvant (NIS), DALA = 5 days	Plum (RAC)	0.37, 0.45 (0.41)	<0.01, <0.01 (<0.01)	0.37, 0.45 (0.41)	-	-

Notes:
DALA = Days After Last Application; RAC = Raw Agricultural Commodity; RTI = Retreatment Interval.
[a] Expressed as parent tetraniliprole.
[b] PF: Processing Factor = Residue level in processed commodity (mg/kg) ÷ Residue level in unprocessed commodity (mg/kg). Where the value for parent in the processed commodity is <LOQ, a value of 0.01 mg/kg has been used for calculation of a PF. Where the value for the metabolite tetraniliprole-N-methyl-quinazolinone is <0.01 mg/kg eq, a value of "0" was used.

Grapes

Two field trials (one with white grapes and one withe red grapes) were conducted in the United States to provide samples for processing (Greenland, 2016d, M-572121-01-1, Report SARS-14-7). Applications were made at an exaggerated (5×) rate of 225-229 g ai/ha, with one exception of 471 g ai/ha. Applications were made with intervals of 7 days. A minimum of 23 kg per sample of grapes were collected at normal commercial harvest 14 days after the last application for processing into juice or raisins according to simulated commercial procedures. Throughout the study one representative sample of untreated control and two (duplicate) samples of treated processed commodities were taken.

Whole grapes from random bunches were carefully destemmed by hand and packed one layer deep on dehydrator trays which were placed in the dehydrator. Grapes were dehydrated for about 26 hours at 54 to 60 °C to achieve a moisture range between 15–18 percent and samples were collected (sample: *raisin*).

The remaining grapes were passed through a Crusher/Destemmer to remove stems and produce grape mash. The mash was layered into cloth stacks on a hydraulic press and pressed to separate the juice from the wet pomace and samples were collected (sample: *juice, raw*).

According to the protocol for processing small lots of grapes weighing approximately 44 kg are used as starting point, of which 2.3 kg is subtracted before processing. Typically, 6.8–7.7 kg destemmed grapes are used to produce raisins (typically 1.1–1.4 kg), 40-45 percent is raw juice (typically 14–16 kg), 35–40 percent (typically 10–12 kg) is wet pomace, 1–3 percent is grape stem loss and 11–20 percent is

operation loss. Figure 9 shows the processing procedure from grape to juice, wet pomace, raisin and dry pomace.

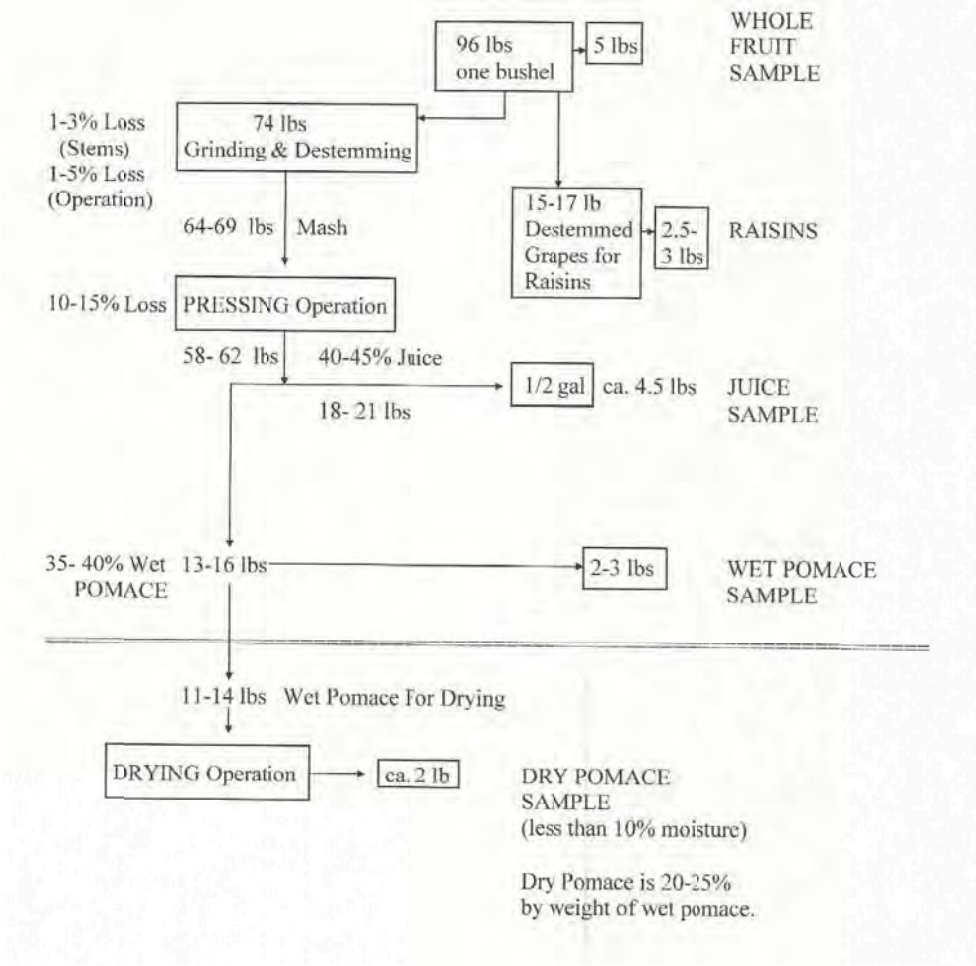

Figure 9 Grape processing flow chart

Samples were stored frozen for a maximum of 212 days prior to residue analysis. Samples were analysed for residues of tetraniliprole and tetraniliprole-N-methylquinazolinone using LC-MS/MS method 01414 with a LOQ of 0.01 mg/kg for both analytes. The concurrent recoveries were within the acceptable range of 70–120 percent.

Trial data, residue levels and processing factors for each type of commodity are summarised Table 119.

Table 119 Residues of tetraniliprole and processing factors in grape and processed commodities (Report SARS-14-7)

Notes:
DALA = Days After Last Application; RAC = Raw Agricultural Commodity; RTI = Retreatment Interval; T-N-MQZ = tetraniliprole-N-methylquinazolinone.
[a] Expressed as parent tetraniliprole.
[b] PF: Processing Factor = Residue level in processed commodity (mg/kg) ÷ Residue level in unprocessed commodity (mg/kg). Where the value in the processed commodity is <LOQ, a value of 0.01 or 0.02 mg/kg has been used for calculation of a PF Where the value for parent in the processed commodity is <LOQ, a value of 0.01 mg/kg has been used for calculation of a PF. Where the value for the metabolite tetraniliprole-N-methyl-quinazolinone is <0.01 mg/kg eq, a value of "0" was used.

In a second study (Freitag & Hoffmeister, 2017, M-577324-01-1, Report 14-03404), four processing trials (two with red grapes and two with white grapes) were conducted throughout Europe to measure the magnitude of tetraniliprole and tetraniliprole-N-methylquinazolinone in grapes and processed grape commodities following one foliar application of tetraniliprole 200 SC. Applications were made at actual rates of 200 g ai/ha at BBCH 85 and samples of grapes were collected approximately 30 days after application (BBCH 89). Grapes were processed according to simulated commercial procedures into juice, pomace and wine.

Juicing of red grapes (trials 14-3404-02 and 14-3404-04)

Deep-frozen bunches of grapes (21–24 kg) were weighed in and destemmed into berries (20–23 kg) and stalks and stems. Unripe, damaged or rot fruits were sorted out, if necessary. The berries were washed (water rate of 2 kg/kg berries), resulting in 20–21 kg and a sample taken (sample: *washed berries*). The remaining sample of washed berries (19–20 kg) was shredded in a cutter into mash. To obtain a good yield of colour in the juice and for enzyming the mash was heated up to approx. 50 °C and then mixed with the pectolytic enzyme product. The residence time took place 2 hours. For trial 02 the enzymed mash was stored overnight at room-temperature and for 04-T the enzyme mash was pressed directly. The enzyme mash (18–19 kg) was pressed in a high-pressure-press into raw juice (15–16 kg) and wet pomace (2.7–3.2 kg) and samples were taken (sample: *raw juice* and sample: *wet pomace*). The yield from RAC to wet pomace corrected for fractionation ranged from 0.12–0.16 and from RAC to raw juice 0.72–0.76. The remaining sample of wet pomace (1.7–2.2 kg) was dried in a convection oven at a temperature of 100 °C for 2.0–3.0 hours until a water content <10 percent (02-T = 6.94 percent; 04-T = 3.15 percent) was reached, resulting in 0.67–0.94 kg dry pomace (yield from wet pomace to dry pomace = 0.40–0.44) and a sample was taken (sample: *dry pomace*). The fining of the remaining raw juice started with the enzymation using a pectolytic-enzyme. First the raw juice (13–15 kg) was heated up to approximately 50 °C and mixed with the enzyme product. The reaction time took place for 1 hour and further left to stand overnight at room temperature for settling down the lees particles. On the next day the enzymed raw juice was decanted, centrifuged and filtered to obtain clear juice and retentate. Clarified juice was pasteurized (77–78 °C) in a plate-heat-exchanger, Brix-values measured, and a sample taken (sample: *juice,*

pasteurized) from the resulting 6.9–10 kg pasteurized juice. After correction for fractionation, the yield from RAC to pasteurized juice ranged from 0.39 to 0.49.

Juicing of white grapes (trials 14-3404-01 and 14-3404-03)

Deep-frozen bunches of grapes were weighed in (20–22 kg) and destemmed into berries (19–22 kg) and stalks and stems. Unripe, damaged or rot fruits were sorted out, if necessary. The berries were washed (water rate of 2 kg/kg berries), resulting in 17–21 kg, and a sample taken (sample: *washed berries*). The remaining sample of the washed berries (16–20 kg) was shredded in a cutter into mash. In contrast to the red grape juice no heating and enzymation took place before pressing. The mash (15–19 kg) was pressed in a high-pressure-press into raw juice (12–15 kg) and wet pomace (2.4–4.1 kg) and samples were taken (sample: *juice, raw* and sample: *wet pomace* (one trial only)). The yield from RAC to wet pomace corrected for fractionation ranged from 0.12–0.19 and from RAC to raw juice 0.63–0.70. The remaining sample of wet pomace (2.2–3.1 kg) was dried in a convection oven at a temperature of 100 °C for 2.5–4.5 hours until a water content <10 percent (01-T = 6.48 percent, 03-T = 3.79 percent) was reached, resulting in 0.83–0.91 kg dry pomace (yield from wet pomace to dry pomace = 0.29-0.38), and a sample was taken (sample: *dry pomace*). The fining of the remaining raw juice started with the enzymation using a pectolytic-enzyme. First the raw juice (11–14 kg) was heated up to approximately 50° and mixed with the enzyme product. The reaction time took place for 1 hour and further left to stand overnight at room temperature for settling down the lees particles. On the next day the enzymed raw juice was decanted, centrifuged and filtered to obtain clear juice and retentate. Clarified juice was pasteurized (~78 °C) in a plate-heat-exchanger, Brix-values measured, resulting in 5.2–8.9 kg pasteurized juice, and a sample was taken (sample: *juice, pasteurized*). After correction for fractionation, the yield from RAC to pasteurized juice ranged from 0.30 to 0.45. The processing procedure is shown in Figure 10.

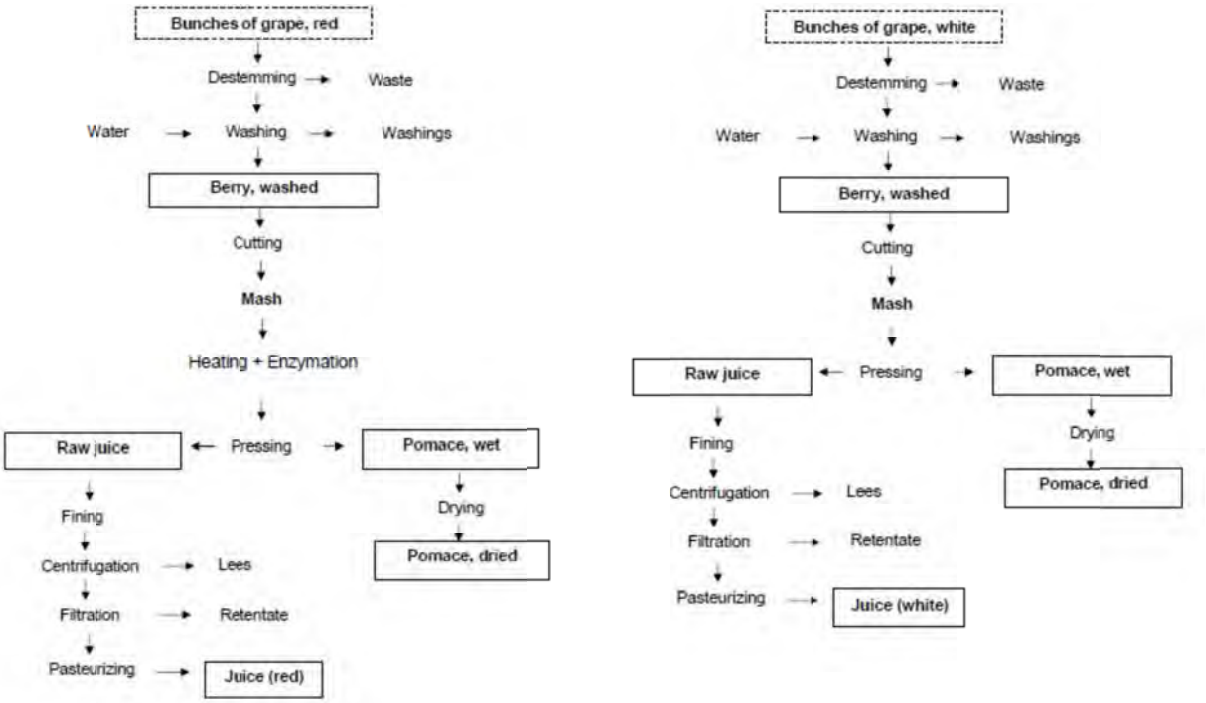

Figure 10 Grape juice production processes

Processing of red grape into must (trials 14-3404-02 and 14-3404-04)

Bunches of frozen grapes were defrosted at ~13 °C for processing into must. The defrosted red grapes (62–63 kg) were destemmed and milled into mash in a screw-extruder. The obtained mash of grapes was filled into the heating machine and heated up to approx. 80 °C for about 2 minutes under constant stirring. Afterwards the mash was cooled down. The mash was pressed in a wine press (vinification plant) to obtain must and pomace (apparatus: Trester). After pressing, it was not necessary to add sugar to the must. To prevent any oxidation processes, the must was treated with potassium disulfide (ratio: 100 mg/L). Furthermore, to prevent any protein diffusion, bentonite was added to the must (ratio: 1 g/L). For the following clarification the must was left to stand for approx. 12–15 hours. After the settling time, the preclarified must was decanted, weighed (43–54 kg), and sampled (sample: *must*).

Processing of grapes into red wine (trials 14-3404-02 and 14-3404-04)

Samples of the preclarified must (22–23 kg) were filled into fermentation vessels and yeast was added (ratio: 20 g/100 L). The following fermentation occurred in absence of air and the disappeared carbon dioxide was measured until the process was finished. For first racking the clear young wine was decanted from the wine lees and was then treated with potassium disulfide (ratio: 30 mg/L). After approximately 2 weeks the second racking followed. The young wine was decanted a second time and treated with potassium disulfide one more time (ratio: 35–40 mg/L) after which the young wine was filtered using a disinfection-filter, weighed (14 kg), and sampled (sample: *first red wine at bottling*). The remaining of the young wine was filled into bottles and stored at approx. 12 °C for approx. 6–7 months. After this maturation time this wine was sampled (sample: red *wine at first taste*). The yield from RAC to young wine is 0.42–0.51. The procedure is shown in Figure 11.

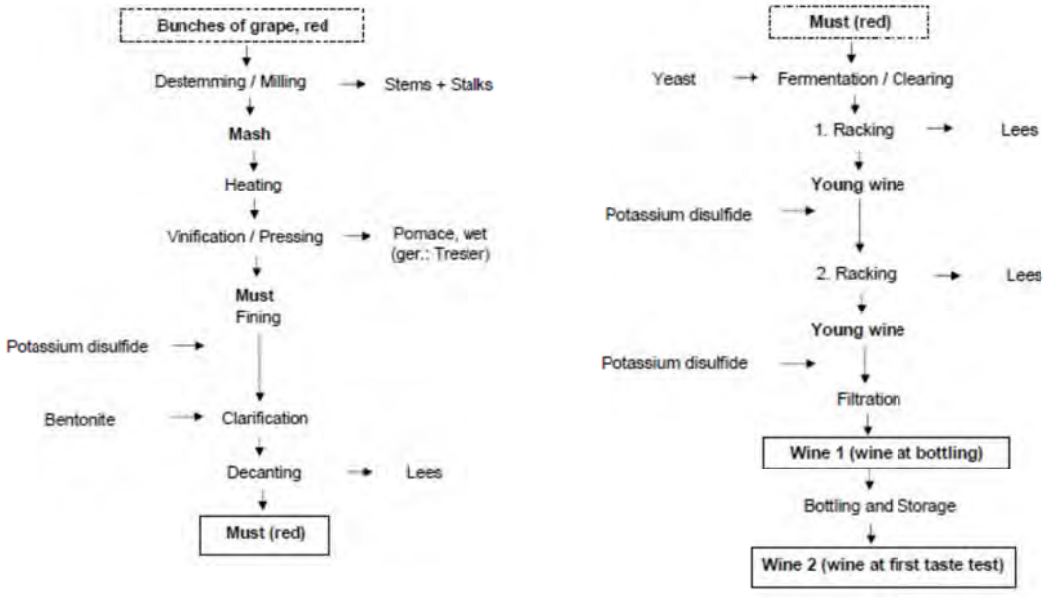

Figure 11 Processing steps in red wine production

Processing of white grape into must (trials 14-3404-01 and 14-3404-03)

Bunches of fresh grapes (14-3404-01) or frozen grapes (14-3404-03) were used for processing into must. The fresh or defrosted white grapes (75.26/72.58 kg) were milled into mash in a screw-extruder without destemming. In contrast to the process with red grapes no heating took place before the vinification. The mash was pressed in a wine press (vinification plant) to obtain must and pomace (apparatus Trester). After pressing the must weight was measured, it was not necessary to add sugar to the must. To prevent any oxidation processes, the must was treated with potassium disulfide (ratio: 100 mg/L). Furthermore, to prevent any protein diffusion, bentonite was added to the must (ratio: 1 g/L). For the following clarification the treated must were left to stand for approx. 12–15 hours. After the settling time, the preclarified must was decanted, weighed (47.94/54.34 kg) and a sample was taken (sample: *must*).

Processing of grapes into white wine (trials 14-3404-01 and 14-3404-03)

An aliquot of the preclarified must (20.0/22.88 kg) was filled into fermentation vessels and yeast was added (ratio: 20 g/100 L). The following fermentation occurred in absence of air and the disappeared carbon dioxide was measured until the process was finished. The fermentation started for 14-3404-01 on 2014-09-25 and was finished on 2014-10-06 (11 days). The fermentation for 14-3404-03 started on 2014-11-28 and was finished on 2014-012-22 (24 days). For first racking the clear young wine was decanted from the wine lees and was then treated with potassium disulfide (ratio: 50 mg/L for 14-3404-01 and 30 mg/L for 14-3404-03). After approx. 2 weeks the second racking followed, though only for trial 14-3404-03. The young wine was decanted a second time and treated with potassium disulfide one more time (ratio: 45 mg/L) after which the young wine was filtered using a disinfection-filter, weighed (15.14/17.40 kg), and sampled (sample: *first white wine at bottling*). The remaining of the young wine was filled into bottles and stored at approx. 12 °C for approx. 6–7 months. After this maturation time this wine was sampled (sample: *white wine at first taste*). The yield from RAC to young red wine is 0.43–0.57.

Samples were stored frozen (< -18 °C) for a maximum of 411 days prior to analysis. This is within the demonstrated storage stability period for tetraniliprole and tetraniliprole-N-methylquinazolinone residues in high acid content commodities (see section on storage stability). All samples were analysed for residues of tetraniliprole and tetraniliprole-N-methylquinazolinone using the validated analytical method 01414.

Processing factors were derived for grape processed commodities. A concentration of residues was observed in pomace (wet and dry), consistent with a concentration due to weight loss by pressing and drying. Residues were diluted in all other commodities. Trial data, residue levels and processing factors for each type of commodity are summarised Table 120.

Note that total residues represent parent + tetraniliprole-N-methyl-quinazolinone, unless levels of the metabolite were <LOQ of 0.01 mg/kg. This generally results in the same or very similar PFs.

Notes:
DALA = Days After Last Application; RAC = Raw Agricultural Commodity; RTI = Re-treatment Interval.
[a] Expressed as parent tetraniliprole.
[b] PF: Processing Factor = Residue level in processed commodity (mg/kg) ÷ Residue level in unprocessed commodity (mg/kg). Where the value in the processed commodity is <LOQ, a value of 0.01 or 0.02 mg/kg has been used for calculation of a PF. Where the value for parent in the processed commodity is <LOQ, a value of 0.01 mg/kg has been used for calculation of a PF. Where the value for the metabolite tetraniliprole-N-methyl-quinazolinone is <0.01 mg/kg eq, a value of "0" was used.

Broccoli

One field trial was conducted to provide samples to determine the effect of washing or washing and cooking on tetraniliprole residues in/on broccoli treated with four applications of a tetraniliprole 200 SC formulation (Netzband&Roberts, 2016, M-565724-02-1, Report RAFVP096-01). Applications were made at actual rates of 45–46 g ai/ha, with application intervals of 4–5 days, without addition of an adjuvant.

Samples of stalks/curd were collected at maturity, nominally 1-day after the final application and consisted of a composite of 12 plants, weighing at least 1 kg. Throughout the study one representative sample of untreated control and two (duplicate) samples of treated processed commodities were taken.

The washing and cooking procedures were performed in a manner similar to normal household practice. For all broccoli samples (RAC, washed, and washed and cooked), the leaves, withered florets, and any woody part of the stem were removed and discarded (sample: *broccoli, head and stem*). The washed subsample was rinsed under lukewarm to cool running tap water for approximately 30 seconds to ensure that all portions of the sample were rinsed. Excessive water was shaken off and the washed subsample was allowed to drain on paper towels for at least 2 minutes (sample: *broccoli, washed*). After draining, the broccoli head with stem was halved lengthwise. The lengthwise cuts were placed in a pan containing a small amount of boiling water and cooked, covered, for 10 minutes. Cooked broccoli was drained and then allowed to cool to room temperature (sample: *broccoli, washed and cooked*). Actual weight data from RAC, washed and cooked broccoli were not reported. Yield factors could not be calculated.

Samples were stored frozen for a maximum of 633 days prior to residue analysis. Samples were analysed for residues of tetraniliprole and metabolite tetraniliprole-N-methylquinazolinone using LC-MS/MS method 01414 (LOQ of 0.01 mg/kg for both analytes in all commodities). The concurrent recoveries were within the acceptable range of 70–120 percent. Trial data, residue levels and processing factors for each type of commodity are summarised Table 121.

Tomato

Two field trials were conducted in the United States to provide samples for processing of tomatoes to paste and puree (Greenland, 2016e, M-572627-01-1, Report SARS-14-19). Applications were made at an exaggerated (5×) rate of 225–229 g ai/ha, with one exception of 471 g ai/ha. Applications were made with intervals of 5 days. A minimum of 23.8 kg per sample of tomatoes were collected at normal commercial harvest for processing into paste or puree. Throughout the study one representative sample of untreated control and two (duplicate) samples of treated processed commodities were taken.

The fresh tomato fruits were washed by placing the fruit in wire baskets and submerging three times in water. The water was changed and this washing process was repeated. The wash water was discarded. The washed tomatoes were quartered and pushed through an electric food strainer/sauce maker to produce raw/fresh puree. One representative sample of untreated control puree and two (duplicate) samples of treated puree were collected, packaged, labelled and frozen (sample: *tomato puree, unpasteurized*). The remaining puree was collected in a kettle and heated between 82 and 93 °C under occasional stirring for 6-10 hours to produce paste. One representative sample of untreated control paste and two (duplicate) samples of treated paste were collected, packaged, labelled and frozen (sample: *tomato paste*). Excess tomato paste was discarded. A bulk of treated tomatoes was received (23.8/24.5 kg). After sampling (2.0 and 2.3/2 × 3.2 kg) a total of 19.5/18.1 kg of treated tomatoes were used to produce 11/7.3 kg of puree and 2.6/1.6 kg of paste. Duplicate samples of puree (1.13/1.02 kg) and of paste (1.24/0.79 kg) were taken. Yield factors from fruit to puree ranged from 0.40–0.56 and from 0.16 to 0.17 for fruit to paste.

Samples were stored frozen for a maximum of 299 days prior to residue analysis. Samples were analysed for residues of tetraniliprole and tetraniliprole-N-methylquinazolinone using LC-MS/MS method 01414, with a LOQ of 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent.

Trial data, residue levels and processing factors for each type of commodity are summarised Table 122. Tetraniliprole residues were found to increase in paste, but less than expected based on weight loss. Overall the data suggest a degradation of the residue due to processing.

Notes:

DALA = Days After Last Applicatin; RAC = Raw Agricultural Commodity; RTI = Retreatment Interval.

[a] Expressed as parent tetraniliprole.

[b] PF: Processing Factor = Residue level in processed commodity (mg/kg) ÷ Residue level in unprocessed commodity (mg/kg). Where the value in the processed commodity is <LOQ, a value of 0.01 or 0.02 mg/kg has been used for calculation of a PF. Where the value for parent in the processed commodity is <LOQ, a value of 0.01 mg/kg has been used for calculation of a PF. Where the value for the metabolite tetraniliprole-N-methyl-quinazolinoneis <0.01 mg/kg eq, a value of "0" was used.

[c] In normal industrial practices, the tomato puree is pasteurized.

Mustard greens

One field trial was conducted to provide samples to determine the effect of washing or washing and cooking on the magnitude of tetraniliprole residues in/on mustard greens treated with four applications of a tetraniliprole 200 SC formulation (Miller & Jerkins, 2016, M-557177-01-1, Report RAFVN036). Applications were made at a rate of 45–46 g ai/ha per application, with application intervals of 4–5 days.

One day after application a bulk sample of 4 kg was collected from plot FV306-14HA for processing purposes. The bulk samples were divided randomly into 24 separate sampling sections. Mustard greens were washed and cooked in a manner similar to normal household practice; All subsamples (RAC, washed, and washed and cooked) had any withered leaves and stems removed and discarded. The washed subsample was placed in a sink filled with water and agitated for 30 seconds so that all leaf surfaces were rinsed. The sink was drained, and the rinsing process was repeated two additional times. The washed subsample was allowed to drain on paper towels for at least 2 minutes. For the cooked subsample, the leaves were washed as described above. After draining, the leaves were placed in boiling water for 9 minutes and then allowed to cool to room temperature. Throughout the study one representative sample of untreated control and two (duplicate) samples of treated processed commodities were taken.

Samples were stored frozen for a maximum of 427 days prior to residue analysis. Samples were analysed for residues of tetraniliprole and metabolite tetraniliprole-N-methylquinazolinone using LC-MS/MS method 01414. The LOQ was 0.01 mg/kg for both analytes in all commodities. The concurrent recoveries were within the acceptable range of 70–120 percent.

Trial data, residue levels and processing factors for each type of commodity are summarised Table 123.

Table 123 Residues of tetraniliprole in mustard greens after processing (Report RAFVN036)

Trial information	Sample	Residues (mg/kg) [a]			PF[b]	
		Tetraniliprole	T-N-methyl-quinazolinone	Total	PF_{parent}	PF_{total}

Soya bean, dry

Two processing trials were conducted in the United States as part of the residue trials to measure the magnitude of tetraniliprole residues in/on dry soya bean processed commodities following four foliar applications of tetraniliprole 200 SC (Greenland, 2016j, M-574330-02-1, Report SARS-15-03). Applications were made at an exaggerated rate of 4 × 250–251 g ai/ha (5×), with application intervals of 3–4 days.

Samples of dry soya bean were collected 14 days after the final application at commercial maturity. Soya beans were processed according to simulated commercial procedures into meal and refined oil. Throughout the study one representative sample of untreated control and two (duplicate) samples of treated processed commodities were taken.

Drying

As the moisture content of the dry soya bean seeds was 13–15 percent, drying prior to processing was not required.

Aspirated grain fraction

To generate aspirated grain fractions (AGF), the seed samples (590 and 529 kg for untreated and treated samples, respectively) of one trial only were placed in a dust generation room containing a holding bin, two bucket conveyors and a screw conveyor. As the samples were moved in the system (120 minutes), aspiration was used to remove grain dust (181 and 136 g, for untreated and treated samples respectively). Light impurities were classified using the following sieves: 2360 micron (8 mesh); 2000 micron (10 mesh); 1180 micron (16 mesh); 850 micron (20 mesh); and 425 micron (40 mesh). After classification of each sample, the material through the 2360 micron sieve was recombined to produce one aspirated grain fraction (AGF), weighing 89 and 104 g for untreated and treated samples respectively. For both samples, the material that passed through the 425 micron screen was greater than half the weight of the total material passing through the 2360 micron screen, so all the material passing through the 2360 micron screen was recombined. A representative sample was removed (sample: aspirated grain fraction (AGF)) and the ash content (17.13 and 50.64 percent for untreated and treated samples, respectively) was determined according to AOCS Method Ba 5a-49. One kg of soya bean yields 0.15–0.2 g AGF.

Cleaning

After generation of aspirated grain fractions, a representative sample of generated soya bean seed (17.5 kg) was cleaned by aspiration; light impurities were removed from the whole soya bean by aspiration in a Kice Industries aspirator. After aspiration, the samples were screened on the Enhanced 2 screen cleaner to separate large and small foreign particles (screenings) from the soya bean seed sample. Resulting in 17.0/28.6 kg cleaned soya bean seeds.

Oil processing

After cleaning, the cleaned soya bean seeds (17/29 kg) were fed into an A.T. Ferrell roller mill to crack the hull and liberate the kernel. After hulling, the material was aspirated and screened to separate hulls (2.59/4.26 kg) and kernel (14.4/24.3 kg) material and samples were taken (sample: hulls). One kg of soya bean seeds yields 0.15 kg hulls.

Kernel moisture content was adjusted to 13.5 percent by water addition and allowed to temper, for at least 12 hours. Then the water adjusted kernels (15.4/25.2 kg) were heated to 71 to 97 °C in a mixer and flaked in a flaking roll. Flakes (15.1/24.7 kg) were extruded in a continuous processer, where they were turned into collets by direct steam injection and compression. The collets were ground in a disc mill and dried in an oven at 66–82 °C for 30–40 minutes and taken to solvent extraction (14.4/23.3 kg). Oil was extracted by solvent (hexane) at 49–60 °C for 30 minutes, repeated again twice for 15 minutes. Extracted collets (2200 g) were toasted in a steam jacketed mixer at temperatures up to 116 °C. After toasting the product (2093/9253 g) was cooled to room temperature, screened (8 mesh screen), and sampled (sample: meal, toasted).

Hexane was removed from the crude oil (3389/4589 g) by aspiration (evaporation), heating (91–96 °C) and filtering. Based on the free fatty acid content, a weighed amount of crude oil (2000/2500 g) was mixed with sodium hydroxide (114/147.5 g), then soapstock (243/316 g) and alkali refined oil (1802/2261 g) were separated using centrifugation. The refined oil was decanted, filtered and activated bleaching earth (1.0 percent by weight of oil) was mixed with the oil (1785/2239 g of the refined oil was used). The solution was stirred and placed under vacuum. The temperature was increased to 85–100 °C and held for 10 to 15 minutes. After the bleaching period, the temperature was reduced to 58–68 °C. Vacuum was broken and a filter aid added. The bleached oil and spent bleaching earth/filter aid separated by vacuum filtration. Resulting fractions were bleached oil (1715/2147 g) and spent bleaching earth/filter aid. Spent bleaching earth/filter aid was discarded. The resulting bleached oil (1703/2028 g was used) was heated and filtered and steam bathed at 220 to 230 °C. Citric acid was added. The resulting fraction was refined-bleached-deodorized oil), weighing 1688/2023 g. This fraction was sampled (sample: refined-bleached-deodorized oil (RBD oil). Corrected for fractionation, 1 kg of soya bean seeds yields 0.14–0.17 kg refined-bleached-deodorized oil.

Samples were stored frozen for a maximum of 130 days prior to analysis. All samples were analysed for residues of tetraniliprole and tetraniliprole-N-methylquinazolinone using analytical method 01414. The results are shown in Table 124.

Table 124 Tetraniliprole residues and processing factors in soya bean and processed commodities (Report SARS-15-03)

Trial information	Sample	Residues (mean) (mg/kg) [a]			PF [b]

Notes:
AGF = Aspirated Grain Fractions; DALT = Days After Last Application; RAC = Raw Agricultural Commodity; RTI = Retreatment Interval; n.c. = not calculated since residues in both RAC and the processed fractions were <LOQ.
[a] Expressed as parent tetraniliprole.
[b] PF: Processing Factor = Residue level in processed commodity (mg/kg) ÷ Residue level in unprocessed commodity (mg/kg). Where the value for parent in the processed commodity is <LOQ, a value of 0.01 mg/kg has been used for calculation of a PF. Where the value for the metabolite tetraniliprole-N-methyl-quinazolinone is <0.01 mg/kg eq, a value of "0" was used.

Potato

Two field trials were conducted, in the United States, to measure the magnitude of tetraniliprole residues in/on potato processed commodities following either a single in-furrow application or four foliar broadcast applications of tetraniliprole 200 SC at exaggerated rates (5×) (Veal, 2016b, M-563221-01-1, Report RAFVP062). Applications were made at an actual rate of 995 g ai/ha for the in-furrow at planting application and 151 g ai/ha for the foliar applications. Samples of potato tubers (80–89 kg) were harvested at commercial maturity and processed according to simulated commercial procedures into washed potato tubers, peeled tubers, peel, crisps, flakes, potato mash, starch and cooked tubers with/without peel. Throughout the study one representative sample of untreated control and two (duplicate) samples of treated processed commodities were taken.

The weight fractions reported represent the in-furrow/foliar application per trial, respectively. The potato samples (76.58/79.74 kg and 84.71/85.35 kg) were batch tub washed for 5 minutes and specific gravity was determined. The washed potatoes (69.59/70.51 kg and 84.23/81.56 kg) were inspected and if necessary, culled potatoes were weighed and disposed (6.83/6.16 kg and 0.0/0.0 kg). Representative samples (sample*: potato washings* and sample: *tuber, washed*) were taken. Aliquots of washed potatoes were removed and either returned to storage for processing potato chips (10.45/10.60 kg and 10.28/10.44 kg) and boiled potatoes (3.38/3.35 kg and 3.21/3.49 kg) at a later time, or sent directly to potato chip processing or cooking. The remaining potatoes (38.12/37.96 kg and 37.89/39.03 kg) were batch steam peeled using the 100 L steam peeler for 45 seconds at 100–120 psi. The potatoes were batch scrubbed for 30 seconds using a peeler. The potato peel was collected from the peeling and scrubbing process. Water from the scrubber was collected for starch processing (45.28/39.10 kg and 46.69/50.04 kg). The peeled potatoes were inspected and hand trimmed to remove additional peel, rot, green or otherwise damaged potatoes. The trim waste (0.62/0.73 kg and 0.41/0.34 kg) was retained. The collected peel (2.77/2.02 kg and 3.38/3.82 kg) was hydraulically pressed. The pressed peel (1.88/0.98 kg and 1.84/2.03 kg) was blended with the cut trim waste (0.62/0.73 kg and 2.25/2.37 kg) collected and a representative sample of the combined wet peel and trimmings was taken (sample: *peel, wet*). Starch water (0.34/0.41 kg and 0.76/0.71 kg) was collected from the hydraulically pressed peel for starch removal.

Potato starch processing

Starch water (0.34/0.41 kg and 0.76/0.71 kg) that was collected from the hydraulically pressed peel was combined with the water from scrubbing for starch removal (45.28/39.10 kg and 46.69/50.04 kg). The total starch water (45.62/39.51 kg and 47.45/50.75 kg) was filtered using a series of sieves to remove pieces of peel and pulp. The filtered starch water was centrifuged to separate the water from the starch until the required amount of starch sample was obtained (1.13/1.13 kg and 1.52/1.18 kg starch recovered). The remaining filtered starch water was disposed. A representative sample was taken (sample: *starch*).

Potato flake processing

After sampling *(sample: tuber, peeled)*, the remaining peeled potatoes (28.53/29.82 kg and 29.12/30.53 kg) were reserved for potato flake processing. The peeled potatoes were cut into slabs using a slicer. The potato slabs were batch spray-washed in cold tap water for 30 seconds to remove free starch using the spray washer. The potato slabs were precooked at about 70–77 ° C while targeting 71–74 °C for 20 minutes in the 150 L kettle. The precooked potato slabs were to less than 32 °C for 20 minutes. An aliquot of precooked and cooled potatoes (21.04/21.05 kg and 24.11/24.12 kg) was removed for further potato flake processing and the excess discarded (7.17/9.43 kg and 4.74/6.40 kg). The cooled potato

slabs were steam-cooked at 94–100 °C for 40 minutes in a cabinet. The cooked potato slabs were mashed using a grinder (18.90/18.86 kg and 22.56/22.21 kg). A representative sample (1.31/1.18 kg and 1.05/1.04 kg) of the potato mash was taken (sample: *tuber, steamed, mashed*). An aliquot of the potato mash (9.07 for all batches) was mixed for 37 seconds in a mixer with an emulsion of pre-weighed food additives specific to the amount of mash for flaking (typically 13.60 kg). Any remaining mash (8.52/8.61 kg and 12.44/12.10 kg) was disposed. The cooked mash was hand fed onto a dryer to dry the cooked mash into a thin sheet and initially broken into large flakes by hand (1.51/1.46 kg and 1.88/1.71 kg). The flakes were then fed into a hammermill for uniform milling of the potato flakes (weight after milling: 1.45/1.44 kg and 1.84/1.70 kg; loss due to milling 0.06/0.02 kg and 0.04/0.01 kg). Moisture analysis was conducted on the potato flakes. All six samples of milled flakes were determined to have < 9 percent moisture and did not require additional drying.

A representative sample was taken (sample: *flakes*). The yield from precooked and cooled potatoes to flakes ranged from 96 to 99 percent. Figure 12 shows the procedure for processing potato to flake

Potato crisps (without peel) processing

An aliquot of washed potatoes previously reserved (10.45/10.60 kg and 10.28/10.44 kg) was removed from storage for the potato crisps process. The washed potatoes were batch peeled for 30 seconds using an abrasive base plate in a restaurant style peeler. The collected peel was weighed (1.07/1.0 kg and 0.82/0.58 kg) and discarded. The peeled potatoes (9.11/9.70 kg and 9.46/9.78 kg) were inspected by hand and trimmed if necessary, to remove rot, green or otherwise damaged potato tissue. Any trim waste collected was weighed and discarded. An aliquot of the remaining peeled potatoes were cut into thin 0.16 cm slices using a restaurant style slicer. Any abrasion peeled potatoes in excess were discarded (6.0/6.67 kg and 5.96/6.73 kg). The potato slices were placed in a tub of hot water to remove free starch. The slices were drained over a screen to remove excess water and were deep fried at 163–191 °C frying oil for approximately 90 seconds. The fried potato crisps were drained, salted and inspected. Undesirable crisps were removed. The weight of the finished potato crisps was 1.05/1.04 kg and 1.15/1.15 kg and taken as sample (sample: *crisps*). Yield from washed potatoes to chips (without peel) ranged from 19–24 percent. Figure 13 shows the potato chip process.

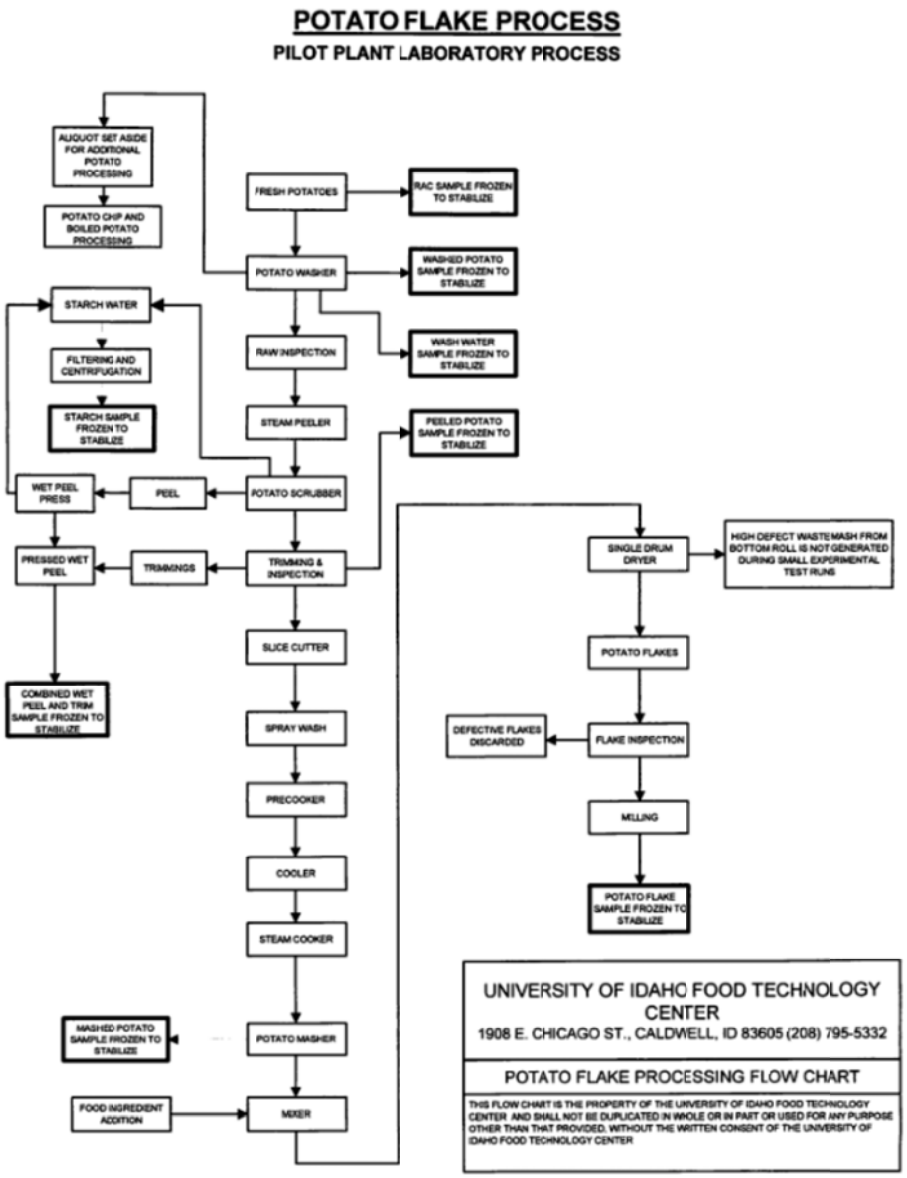

Figure 12 Processing steps in potato flake production

Cooked potato processing

An aliquot of unpeeled washed potatoes (3.38/3.35 kg and 3.21/3.49 kg) was divided into two subsamples for processing into unpeeled boiled potatoes (1.35/1.42 kg and 1.44/1.32 kg) and peeled boiled potatoes (1.67/1.64 kg and 1.76/2.17 kg) and the excess (0.36/0.29 kg and 0/0 kg) was discarded. Potatoes reserved for unpeeled boiled potatoes were cut into quarters using a paring knife. For producing unpeeled boiled potatoes, the quartered potatoes were placed into boiling water and boiled until an internal temperature of 88–92 °C was reached as measured with a probe thermometer. After the desired temperature was reached, the unpeeled boiled potato fraction was removed from the heat and poured through a colander over a bucket to drain the potatoes and capture the cooking water. The weight of the unpeeled boiled potatoes was 1.25/1.31 kg and 1.39/1.20 kg. A representative sample of both the cooking water and unpeeled boiled potato was taken (sample: *tuber with peel, cooked* and sample: *cooking water*). The yield from washed potatoes to boiled unpeeled potatoes was 100 percent.

Figure 13 Potato chip processing process

Potatoes reserved for peeled boiled potatoes (1.67/1.64 kg and 1.76/2.17 kg) were hand peeled with a vegetable peeler (weighed of peeled potatoes: 1.41/1.36 kg and 1.56/1.89 kg) and then cut into quarters using a paring knife. For producing peeled boiled potatoes, the quartered potatoes were placed into boiling water and boiled until an internal temperature of 88–92 °C was reached as measured with a probe thermometer. After the desired temperature was reached, the peeled boiled potato fraction was removed from the heat and drained through a colander. The weight of the boiled peeled potatoes was 1.29/1.19 kg and 1.34/1.60 kg and a representative sample was taken (sample: *tuber, peeled and cooked*). The yield from washed potatoes to boiled unpeeled potatoes ranged from 73-77 percent.

Samples were stored frozen for a maximum of 278 days prior to analysis. All samples were analysed for residues of tetraniliprole and tetraniliprole-N-methylquinazoline using analytical method 01414. Trial data, residue levels and processing factors for each type of commodity are summarised in

Table 125. Residues of tetraniliprole and its metabolite were seen to dilute upon processing with PF's <1 in most cases. Concentration of residues was only seen in washed tubers and wet peel.

Notes:

DALA = Days After Last Application; RAC = Raw Agricultural Commodity; RTI = Retreatment Interval; n.c. = not calculated since residues in both RAC and the processed fractions were below LOQ; T-N-MQZ = tetraniliprole-N-methylquinazolinone.

[a] Expressed as parent tetraniliprole.

[b] PF: Processing Factor = Residue level in processed commodity (mg/kg) ÷ Residue level in unprocessed commodity (mg/kg). Where the value for parent in the processed commodity is <LOQ, a value of 0.01 mg/kg has been used for calculation of a PF. Where the value for the metabolite tetraniliprole-N-methyl-quinazolinone is <0.01 mg/kg eq, a value of "0" was used.

Rice

Two processing trials were conducted in the United States to measure the magnitude of tetraniliprole and metabolite tetraniliprole-N-methylquinazolinone residues in/on paddy rice processed commodities following three foliar applications of tetraniliprole 200 SC (Brungardt, 2018, M-638211-01-1, Report RAFV0032). Applications were made at rates ranging from 91–92 g ai/ha each, with application intervals of 13–16 days between BBCH growth stages 26 and 58. No adjuvant was used. Samples of rice were collected 30 days after the last application at commercial maturity. At the processing facility, triplicate subsamples of rice grain, the raw agricultural commodity (RAC), were removed and frozen for subsequent analysis. The remaining rice grain was used to generate the processed commodities of polished rice (grain, polished), hulls, and bran. Samples were frozen for subsequent analysis.

Drying and cleaning

After removal from the freezer, representative rough rice (RAC) fractions were collected and placed into frozen storage. Samples were weighed (40/40.5 kg) and the moisture content determined with an electronic moisture analyser. If the moisture was greater than 14 percent, samples were dried in an oven at 43–60 °C to a moisture content of 11–14 percent. All samples required drying. The yield from RAC to dried rice was 78–91 percent. Following drying, samples (31.6/37 kg) were cleaned by aspiration (1.63/0.50 kg) and screening (2.18/7.80 kg). Samples were aspirated in an aspirator to remove light impurities from the rough rice. Following aspiration, samples were screened in a cleaner to separate large and small foreign particles (screening) from the rough rice, resulting in 27.9/28.6 kg cleaned rice. The yield from RAC to cleaned rice was *ca* 70 percent.

Milling–Dehulling and Bran Removal

Cleaned rough rice samples of 15.9/13.6 kg were dehulled and milled in a Satake rice mill. During the dehulling process, samples entered the hulling section of the mill where hull was removed by rubber rolls rotating in opposite directions at different speeds. Hull material (2.99/2.27 kg) was separated from the brown rice (12.6/11.1 kg) by aspiration. During this sequence, the brown rice passed through the milling section and exited the machine. No milling (bran removal) was performed during this pass. For production of bran and white milled rice (polished rice), brown rice (12.6/11.1 kg) entered the hulling portion where additional hull material was removed. During this pass through the milling chamber, brown rice was held in the milling chamber where it was milled into white milled rice and bran by friction. Bran

(1.81/1.09 kg) was separated from the white milled rice (7.08/8.57 kg) by air injected into the milling chamber (slotted screen). Bran percentage can be increased by adding weights to the exit door of the milling chamber. After exiting the chamber, bran was sieved with a Great Western sifter equipped with a 24 mesh screen to remove broken pieces of brown and white milled rice and small amounts of hull material from bran. Samples of hull material, white milled rice and bran were collected (sample: *hulls*; sample: *polished white rice*; sample: *bran*). The preferred hull percentage to starting rough rice of 18–24 percent was achieved. During the milling process, the goal is to obtain a bran percentage of 8.5 to 14.5 percent (based on a calculated amount of white milled rice and bran). The yield from rice grain (prior to drying and cleaning) to white milled rice is 31–45 percent.

Samples were stored frozen for up to a maximum of 183 days prior to analysis. All samples were analysed for residues of tetraniliprole and tetraniliprole-N-methylquinazolinone using the analytical method 01414.

Trial data, residue levels and processing factors for each type of commodity are summarised in Table 126.

Notes:
DALA = Days After Last Application; RAC = Raw Agricultural Commodity; RTI = Retreatment Interval.
[a] Expressed as parent tetraniliprole.
[b] PF: Processing Factor = Residue level in processed commodity (mg/kg) ÷ Residue level in unprocessed commodity (mg/kg). Where the value for parent in the processed commodity is <LOQ, a value of 0.01 mg/kg has been used for calculation of a PF. Where the value for the metabolite tetraniliprole-N-methyl-quinazolinone is <0.01 mg/kg eq, a value of "0" was used.

Maize

Two processing trials were conducted in the United States as part of the residues trials to measure the magnitude of tetraniliprole residues in/on maize processed commodities (Stewart&Greenland, 2016, M-574645-01-2, Report SARS-15-06). Four foliar applications of tetraniliprole 200 SC at an exaggerated nominal rate of 250 g ai/ha, with application intervals of 7 days. Samples of maize grain were collected 14 days after the final application at commercial maturity. Grain was processed according to simulated commercial procedures into grits, meal, flour, starch and oil (wet and dry milled). Throughout the study

one representative sample of untreated control and two (duplicate) samples of treated processed commodities were taken.

Drying

Maize grain samples for aspirated grain fraction generation and processing were removed from freezer storage. Samples were weighed and the moisture content determined with an electronic moisture analyser. Since the moisture content of samples for aspirated grain fraction generation from trial SARS-15-06-NY were above 13.0 percent, drying was required. Samples were dried in a Steelman Industries oven at 110-135°F until the moisture content was 10.0–13.0 percent. All samples for processing only (sample SARS-15-06-NY-012 and both samples from trial SARS-15-06-MN2) were dried in the oven at 54–71 °C until the moisture content was 10.0 -15.0 percent.

Generation of Aspirated Grain Fraction (AGF)

To generate aspirated grain fractions, each maize grain sample (286 kg) was dried and the dried maize (239 kg) was placed in a dust generation room containing a holding bin, two bucket conveyors, and a screw conveyor. As the samples were moved in the system (120 minutes), aspiration was used to remove light impurities (grain dust) weighing 0.77 kg. Light impurities (784 gram) were classified using different sieves and the material through the 2360 micron sieve was recombined to produce one aspirated grain fraction (AGF). A representative sample was removed and the ash content (1.42 percent) was determined according to AOCS Method Ba 5a-49.

Production of processed fractions

Following AGF generation for sample SARS-15-06-NY-010 and drying for both samples from SARS-15-06-MN2, samples were cleaned by aspiration and screening. Light impurities were removed using a Kice aspirator. After aspiration, samples were screened in an Enhance 2 screen cleaner to separate large and small foreign particles (screenings) from the cleaned grain.

Dry milling process

After drying, samples for production of processed fractions (185/230 kg) were cleaned resulting in batches of cleaned maize grain weighing 167/207 kg. For the dry milling process, maize grain (91.7/102 kg) was moisture conditioned to 21.0 percent and tempered for approximately two hours (steeping with 9.5/10.2 kg water added). The samples were fed into a C. S. Bell disc mill to crack the kernels. Corn stock from the mill was dried and screened to separate germ (13.8/13.7 kg) from meal (11.5/10.3 kg), grits (12.5/11.0 kg), large grits (52.8/69.0 kg), flour (4.2/2.72 kg) and bran (2.59/1.95 kg) and samples were taken (sample: *meal*; sample: *grits*; sample: *flour*). Dried germ material (13.8/13.5 kg) was heated, flaked and submerged in solvent (hexane) to extract the crude oil (739/1184 g) and leaving 1.16/12.3 kg solvent extracted germ flakes. Hexane was removed from the crude oil by aspiration, heating and filtering. Crude oil (719/1079 g) was mixed with Braumé sodium hydroxide (30.9/47.5 g), then soapstock (128/127 g) and alkali refined oil (602/975 g) were separated using centrifugation. The refined oil (588/961 g) was decanted, filtered and an activated bleaching earth was mixed with the oil. Of the resulting bleached oil (571/931 g), 565/921 gram was heated and filtered and steam bathed at 220–230 °C. Citric acid was added. The resulting fraction (560/919 g) was refined-bleached-deodorized oil (RBD oil) and samples were taken (sample: *refined bleached deodorized oil, wet milled*). The yield of cleaned corn to refined, bleached, deodorized oil via dry milling process ranged from 6–9 percent.

Wet Milling Process

For the wet milling process, whole grain (75.1/79.4 kg) was steeped in 49–54 °C water containing sulfur dioxide for 22–48 hours. The steeped whole corn (118/127 kg) was passed through a C. S. Bell disc mill and germ and hull were separated from the cornstock and dried. Germ and hull were then separated. Cornstock was ground in the disc mill and screened, separating out the starch (53.4/53.6 kg), which was dried and sampled (sample: *starch*). Also fibre (8.62/9.12 kg), gluten (4.35/4.63 kg) and germ (5.62/5.94 kg) were separated in the process. The germ samples were moisture conditioned, flaked and pressed in an expeller to liberate part of the crude oil (453/451 gram). The rest of the crude oil (906/1236 g) was extracted from the presscake (3.63/5.72 kg) using hexane, leaving 2.54/4.45 kg solvent extract germ. Combined crude oil samples (1249/1607 g) from the wet milling process were alkali refined (55/66 g NaOH added) to 1154/1417 g refined oil and 133/147 g soapstock. A batch of 1140/1400 g refined oil was bleached (1100/1369 g) and 1092/1356 g of this was deodorized (1240/1353 g), similar as for the dry milling process, and samples were taken (sample: *refined bleached deodorized oil, dry milled*). The yield of cleaned corn to refined, bleached, deodorized oil via the wet milling process was *ca* 17 percent.

Samples were stored frozen (<-4 °C) for a maximum of 108 days prior to analysis. All samples were analysed for residues of tetraniliprole and tetraniliprole-N-methylquinazolinone using the analytical method 01414.

Processing factors were derived for field corn/maize grain processed commodities. A concentration of residues was observed in aspirated grain fractions, flour and meal, residues were diluted in all other commodities. Trial data, residues and processing factors for each type of commodity are summarised in Table 127

Where the value for the metabolite tetraniliprole-N-methyl-quinazolinone is <0.01 mg/kg eq, a value of "0" was used.

RESIDUES IN ANIMAL COMMODITIES

Farm animal feeding studies

Dairy feeding study in lactating cows

A residue feeding study in dairy cattle was conducted in the United States in 2015/2016 (Williams, 2016d, M-569181-01-1, Report RAFVP037) to measure the residues of tetraniliprole found in milk and tissues. Encapsulated tetraniliprole was fed to 18 (3–5 year old) lactating Holstein (*Bos taurus*) dairy cows (three-six cows/dose group) for 29 consecutive days. Experimental conditions are indicated in Table 74. The animals received actual dose levels of tetraniliprole of 0, 0.94, 9.3, 28, and 94 ppm diet (dry weight), corresponding with a calculated mean dose of 0.03, 0.35, 0.99 and 3.09 mg/kg bw/day. Three animals were maintained in the high dose group for up to 2 weeks after cessation of the treatment in order to provide data on the decline of any incurred residues. Animals were observed several times daily for any clinical signs of toxicity or ill health. Bodyweights were determined at intervals and concentrate food/hay consumption was monitored daily.

The cows weighed on average 461–603 kg during the experiment and had an average daily milk production of 145 kg/week (21.3 percent RSD, n=72) during the experiment. The milk production was not adversely affected. The experimental condictions are shown in Table 128.

Table 128 Experimental conditions of the cow feeding study dosed for 29 days

Cow number	no. of depuration days	Mean group bodyweight at start and end of the feeding period (kg)	Mean daily dry feed intake (kg feed/animal) (wk -2-4)	Actual mean dose (ppm tetraniliprole in feed (DM basis))	Actual mean dose (mg/kg bw/day)
12, 19, 13	7, 14, 21	593-603	18	0 (empty capsule)	0 (empty capsule)
15, 1, 14	-	500-521	18.2	0.94	0.03
10, 9, 11	-	461-496	18.2	9.32	0.35
16, 5, 2	-	478-501	18.1	28	0.99
17, 7, 3 & 8, 4, 20	7, 14, 21	520-537	18.0	94	3.09

Doses were administered after the morning milking and milk samples were collected twice daily (morning and evening) on study days 0, 2, 4, 7, 10, 14, 17, 21, 25, and 28. A composite milk sample was collected containing the evening milk and the following morning milk prior to daily administration. A

portion of the day 25 milk sample from a single control and three cows from the 94 dose group were separated into skim milk and cream. On day 29 (3 to 8 hours after the final dose), two of the control cows, all of the low and mid dose groups and 3 of the highest dose group cows were sacrificed. Perirenal, omental, and subcutaneous fat, and composite kidney, liver, and muscle samples were collected from each cow for analysis. The remaining cows (one control and three from the highest dose level) entered the depuration phase of the study. The depuration cows were sacrificed 7, 14, and 21 days post-dosing (days 36, 43, and 50). The remaining control cow was sacrificed on day 50.

Additional milk samples were collected from the remaining control cow and the highest dose depuration cows on days 31, 35, 38, 42, and 49. Milk and tissues from the cows sacrificed at each interval were analysed to monitor the decline of tetraniliprole residues.

Samples of approximately 0.5 kg each of liver, kidney, composite muscle, and fat (mesenterial, subcutaneous, and perirenal) were collected from all animals. One additional sample of each fat was collected for fat) determination. After collection and processing tissue and milk samples were stored frozen at -6 °C to -28.5 °C, with an average storage temperature of ≤-18 °C during the storage period. All samples were extracted within 30 days of sample origination and analysed within seven days of extraction. Therefore, no additional storage stability data are required for these analytes.

Samples were analysed for tetraniliprole and metabolites tetraniliprole-N-methylquinazolinone and tetraniliprole-benzyl alcohol using LC-MS/MS method FV-002-A16-01-1 with an LOQ of 0.01 mg/kg for each of the separate compounds. Average concurrent fresh recoveries in liver, kidney, muscle, fat, milk, cream and skim milk were within the range of 70–110 pecent for tetraniliprole and its metabolites at 0.01–1.0 mg/kg in tissues and milk. Control samples had residues below 0.2LOQ.

Analytical results in tissue samples are shown in Table 129.

Table 129 Tetraniliprole related residues (mg/kg) in cow tissues for dose groups

Notes:

T-N-MetQuin = tetraniliprole-N-methyl-quinazolinone;T-BenzOH= tetraniliprole-benzylalcohol.

[a] Total residues is the sum of tetraniliprole, tetraniliprole-N-methylquinazolinone, and tetraniliprole-benzyl alcohol expressed as tetraniliprole. For calculation of total residues in parent equivalents no correction was made for molecular weight, since these deviate ~only 3 percent (MW parent = 545 g/mol, MW tetraniliprole-N-methyl-quinazolinone = 527 g/mol, MW tetraniliprole-benzylalcohol = 561 g/mol).

In the low dose group only parent tetraniliprole was observed in the liver. Metabolite tetraniliprole-N-methylquinazolinone was observed in the low dose groups in fat tissues. Both parent and metabolite tetraniliprole-N-methylquinazolinone were observed in all other tissues at the higher feeding levels. The benzylalcohol metabolite was only observed in liver in the mid and high dose groups and in kidney in the high dose group.

Tetraniliprole residues were not found in any of the milk samples of cows dosed at 0.94 ppm. Tetraniliprole residues in milk above the LOQ were found in all milk samples of the two mid and the high dosed animals. Parent tetraniliprole ranged from 0.040 to 0.056 mg/kg at 9.3 ppm, to 0.058–0.11 mg/kg at 28 ppm and 0.17–0.19 mg/kg at the 94 ppm feeding level. Similar patterns were found for both metabolites, though at lower concentrations compared to parent (factor 1.5–2 parent to metabolite tetraniliprole-N-methylquinazolinone and factor 2–2.5 parent to tetraniliprole-benzylalcohol). Concentrations ranged from 0.015–0.038 mg/kg at the 9.3 ppm feeding group to 0.052–0.12 in the high dose group for tetraniliprole-N-methylquinazolinone and from 0.019–0.028 at the 9.4 ppm feeding group to 0.061–0.071 mg/kg at the high dose group for tetraniliprole-benzylalcohol. The residue concentrations are summarized in Table 130.

Levels of parent compound in skim milk (0.12 mg) and cream (0.36 mg/kg) measured on day 25 (highest feeding level only) indicate that parent compound has a tendency to concentrate in fat. Metabolite tetraniliprole-N-methylquinazolinone has an even greater tendency to concentrate in fat (<0.01 mg/kg in skim milk to 0.43 mg/kg in cream), whereas the benzylalcohol metabolite seems to distribute evenly (0.056 mg/kg in skim milk and 0.060 mg/kg in cream). The ratio of the concentration of parent in muscle to fat was 1:1.3–2.1 and the ratio of tetraniliprole-N-methylquinazolinone in muscle to fat was 1: 1.1–9 in the three different fats at the three highest feeding levels, also showing the tendency of the residue to concentrate in fat. The results were similar across the three different types of fat.

Apart from one finding in kidney (0.012 mg/kg on depuration day 7 (day 36 after start of dosing), the depuration data show that only metabolite tetraniliprole-N-methylquinazolinone was still observed in

concentrations up to 0.26 mg/kg after 7 days and up to 0.015 mg/kg after 21 days after end of dosing in fat only.

Table 130 Residues in the milk of cows (means of 3 cows/dose group) dosed with tetraniliprole for 29 days at 0.94, 9.3, 28 and 94 mg/kg tetraniliprole in the diet

Notes:

T-N-MetQuin = tetraniliprole-N-methyl-quinazolinone;T-BenzOH= tetraniliprole-benzylalcohol.

[a] Expressed as tetraniliprole.

[b] Total residues is the sum of tetraniliprole, tetraniliprole-N-methylquinazolinone, and tetraniliprole-benzylalcohol, expressed as tetraniliprole. For calculation of total residues in parent equivalents no correction was made for molecular weight, since these deviate ~only 3% (MW parent = 545 g/mol, MW tetraniliprole-N-methyl-quinazolinone = 527 g/mol, MW tetraniliprole-benzylalcohol = 561 g/mol).

[c] Mean average values of 3 cows.

[d] Mean average of 6 cows, except for the depuration group, which lasted 3 cows.

Plateau levels was reached within 7–10 days after start of the study (Figure 14)

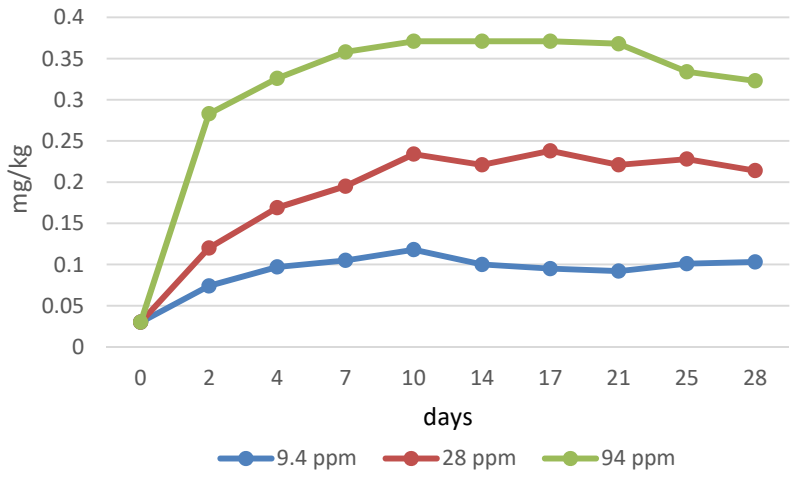

Figure 14 Residues in milk during 28 days dosing at the three feeding levels

Poultry feeding study

No poultry feeding study was submitted. A waiver in support of this was submitted (Ducas, 2016, M-574911-01-1, Report RAFVP036). Three studies on the metabolism of tetraniliprole in laying hens were conducted with the test compound radiolabelled with in the [pyrazole-carboxamide]-, the [pyridinyl-2]- or the [tetrazolyl]-position. Hens were dosed for 14 consecutive days and were fed a dose of 1 mg ai/kg bw/day which was equivalent to 18–19 mg ai/kg feed/day for the three labels, with an average dose of 18.41 mg ai/kg feed/day.

For purposes of this waiver, as a worst case assumption, the total radioactive residues (TRRs) were used to calculate transfer factors for eggs and tissues (Table 131).

Table 131 Tetraniliprole poultry egg and tissue to feed transfer factors (TRR/dose)

Label	Pyrazole Carboxamide		Pyridinyl		Tetrazolyl		Max. Transfer factor
Dose	18.64 ppm		17.94 ppm		18.66 ppm		
Matrix	TRR (mg eq/kg)	Transfer factor	TRR (mg eq/kg)	Transfer factor	TRR (mg eq/kg)	Transfer factor	
Eggs	0.084	0.00451	0.084	0.00468	0.086	0.00461	0.00468
Muscle	0.017	0.00091	0.025	0.00139	0.031	0.00166	0.00166
Fat	0.046	0.00247	0.028	0.00156	0.095	0.00509	0.00509
Liver	0.485	0.02602	0.734	0.04091	0.766	0.04105	0.04105

There are several primary and rotational crops that may be included as potential poultry feed items that have finite residues of tetraniliprole: soybean seed, cotton seed, corn grain and milled by-products, and alfalfa meal. The authors used the median values from the residue trials for seed, grains and other blended commodities (soybean, seed, cotton seed and corn grain) and the highest average field trials residues was used for alfalfa meal to construct an assumed maximum reasonably dietary burden of 0.0159 ppm. Using this dietary burden and the maximum tissue to feed transfer ratio (Max Tfm), the anticipated secondary residues in poultry tissues and eggs were calculated at 1× and 10× the dietary burden (Table 132).

Table 132 Estimation of residues in poultry tissues from use of tetraniliprole

Commodity	Max. transfer factor (Tfm)	Dietary burden (ppm)	1× Expected residue (mg/kg) [a]	10× Expected residue (mg/kg) [a]
Eggs	0.00468	0.0159	0.0000742	0.000742
Muscle	0.00166	0.0159	0.0000263	0.000263
Fat	0.00509	0.0159	0.0000807	0.000807
Liver	0.04105	0.0159	0.0006506	0.006506

Note:

[a] Expected residue = Tf_m × Dietary burden (ppm).

From the calculations presented above, it is expected that measurable, finite residues greater than 0.01 mg/kg will not be observed in poultry tissues or eggs even when the diet contains up to ten times the anticipated total tetraniliprole-derived dietary burden. Based on these data, the metabolism studies already conducted are sufficient to describe the magnitude of the residue in poultry tissues and eggs and a conventional poultry feeding study will not be required.

APPRAISAL

Tetraniliprole (ISO name) is a new broad spectrum fast acting insecticide. The IUPAC name for tetraniliprole is 1-(3-chloropyridin-2-yl)-*N*-[4-cyano-2-methyl-6-(methylcarbamoyl) phenyl]-3-{[5-(trifluoromethyl)-2*H*-tetrazol-2-yl]methyl}-1*H*-pyrazole-5-carboxamide. Tetraniliprole belongs to the anthranilic diamide chemical class. The mode of action of anthranilic diamides involves activating ryanodine receptors (RyRs), which play a critical role in muscle function.

Tetraniliprole was scheduled at the Fifty-first Session of the CCPR (2019) for evaluation as a new compound by the 2020 JMPR, which was postponed to the 2021 JMPR for toxicology and to the 2022 JMPR for residues. The 2021 JMPR estimated an ADI of 0–2 mg/kg bw and concluded that an ARfD was not necessary.

The Meeting received information on identity, physical chemical properties, plant and animal metabolism, aerobic soil degradation, residue analysis, storage stability, use patterns, residues resulting from supervised trials on citrus fruits, pome fruits, stone fruits, grapes, head and stem brassica vegetables, fruiting vegetables, leafy vegetables, soya beans, root and tuber vegetables, cereal grains, tree nuts, and rice, fate of residues during processing, and livestock feeding studies.

Table 133 The structure of tetraniliprole and of the major metabolites are shown below

Name	Abbreviation	Structure
Tetraniliprole	Tetraniliprole	Tetraniliprole-N-methyl-quinazolinone	T-N-methyl-quinazolinone T-N-Met-quinazolinone	Tetraniliprole-benzylalcohol	T-benzyl-alcohol	Tetraniliprole-hydroxy-N-methyl	T-hydroxy-N-methyl T-OH-N-Met	Tetraniliprole-pyrazole-5-amide	T-pyrazole-5-amide	
Name	Abbreviation	Structure

Physical and chemical properties

Tetraniliprole is not volatile (3.2 × 10-6 mPa at 20 °C), relatively insoluble in water (1.0 mg/L pH4 and 7), but appears to be more soluble in organic solvents (up to 21.8 g/L in acetone). It is hydrolytically stable at environmental conditions (pH4 and 20 °C), but not at higher temperatures and higher pH. Aqueous photolysis is a significant route of degradation. The octanol/water partition coefficient log P_{ow} of 2.6 suggests a slight potential to partition into fat.

Plant metabolism

The Meeting received plant metabolism studies for tetraniliprole after different types of application on apples (foliar application), tomatoes (soil drench application), potatoes (foliar applications or seed treatment in furrow), lettuce (foliar application), paddy rice (foliar application or granular in planting hole treatment) and maize (seed treatment) using [pyrazole-carboxamide-^{14}C]- and/or [phenyl-carbamoyl-^{14}C]-labelled tetraniliprole, as shown below. The results for both labels are presented as pyrazole-carboxamide/phenyl-carbamoyl, unless indicated otherwise.

Pyrazole-carboxamide label	Phenyl-carbamoyl label
	[pyrazole-carboxamide-^{14}C]-tetraniliprole	[phenyl-carbamoyl-^{14}C]-tetraniliprole

Seed treatments and soil treatments (soil drench, in-furrow, granular)

Tomato–soil drench application (indoor)

Pyrazole-carboxamide or phenyl-carbamoyl labelled tetraniliprole was applied to greenhouse grown tomato plants, as a single soil drench application at BBCH stage 15–16. The application rate was equivalent to 156/153 g ai/ha (based on 20,000 plants/ha; 7.65–7.81 mg ai/plant). Soil characteristics were not reported.

In fruits and leaves collected at 83–99 days after treatment (DAT), total radioactive residue (TRR) were < 0.001 mg eq/kg (both labels) in fruits and 0.005/0.006 mg eq/kg in leaves indicating limited uptake from soil. Despite the limited amount of residue, the extraction efficiency with acetonitrile/water/formic acid seems to be high (> 90/> 86 percent TRR) for both fruit and leaf samples, with the main portion on partitioning detected in the organic phase 68/56 percent TRR in fruit and 76/78 percent TRR in leaves. The unextracted radioactivity was 9.3/13.5 percent TRR in fruits and 6.1/5.6 percent TRR in leaves (all < 0.001 mg eq/kg).

A total of 33/54 percent TRR and 58/64 percent TRR was identified in tomato fruit and leaves, respectively. The predominant radioactive residues in fruits and leaves were parent tetraniliprole accounting for 22/34 percent TRR in fruit and 24/27 percent TRR in leaves and tetraniliprole-N-methyl-quinazolinone at 11/20 percent TRR in fruits and 34/37 percent TRR in leaves. Apart from two unknown metabolites (15 percent TRR each) in fruit, the radioactivity was not further characterised (pyrazole-carboxamide label only). In leaves, six unknown metabolites were characterised, all less than 4.5 percent TRR and < 0.001 mg eq/kg (total 17.5/13.5 percent TRR and < 0.001 mg eq/kg).

Potato – seed treatment in furrow (outdoor)

Pyrazole-carboxamide labelled tetraniliprole was applied to potato tubers in the furrow at planting before covering the seeds with sandy loam soil. The actual application rate corresponded to 200 g ai/ha and potatoes were grown outdoors. Tubers were collected at 151 DAT (BBCH 99).

TRR amounted to 0.001 mg eq/kg indicating limited uptake from soil. No further investigation of the residues was performed.

Paddy rice–granular soil application (indoor)

Rice seedlings (BBCH 13–14, three to four leaves unfolded) were transplanted into containers filled with sandy loam soil treated with granular pyrazole-carboxamide or phenyl-carbamoyl labelled tetraniliprole at

205/211 g ai/ha. Rice forage (BBCH 34–35, 64 DAT), grain (husked rice), husks and straw (BBCH 89–92, 150 DAT) were collected for analysis.

Radioactive residues were low in husked rice, forage, husks and straw, totaling 0.003/0.004, 0.011/0.08, 0.026/0.018, 0.098/0.069 mg eq/kg, in each matrix respectively. The extraction efficiency with acetonitrile/water/formic acid ranged from 76/49 percent TRR in husked rice, to 91/91 percent TRR in straw. The unextracted radioactivity was highest in husked rice with 24/51 percent TRR (0.001/0.002 mg eq/kg) and ranged from 9.0 to 15 percent TRR (0.001–0.004 mg eq/kg) in straw, forage, and husks.

A total of 58/28 percent TRR (0.001/0.001 mg eq/kg) was identified in husked rice and ≥ 78 percent TRR (both labels) in the other matrices. The majority of the identified radioactivity was parent tetraniliprole (48/22 percent TRR, 0.001/0.001 mg eq/kg) in husked rice, accounting for ≥ 77 percent TRR (0.007–0.075 mg eq/kg) with both labels in the other matrices. A minor part of the radioactivity could be attributed to tetraniliprole-N-methyl-quinazolinone (3.9–14 percent TRR, < 0.001–0.014 mg eq/kg across all matrices). With the exception of one unknown in husked rice (17/21 percent TRR, 0.001/0.001 mg eq/kg), all other unknown metabolites were ≤ 4.6 percent TRR and ≤0.001 mg eq/kg.

Maize – seed treatment (outdoor)

Pyrazole-carboxamide labelled tetraniliprole was used as a seed treatment to maize grown outdoors in a sandy loam soil. Two different application rates were tested, corresponding to 63 or 150 g ai/ha. Maize forage was harvested at 98 DAT (BBCH 79–83) and mature plants at 145 DAT (BBCH 89).

Radioactive residues after both treatments were low in kernels (< 0.001 mg eq/kg) and forage (< 0.006 mg eq/kg) and amounted to 0.004 mg eq/kg (63 g ai/ha treatment) to 0.008 mg eq/kg (150 g ai/ha treatment) in fodder. Only the higher treatment fodder was subjected to extraction with acetonitrile/water/formic acid, with 76 percent TRR (0.006 mg eq/kg) extracted. The unextracted radioactivity was 24 percent TRR (0.002 mg eq/kg).

The extracted residues in fodder were identified as parent tetraniliprole and tetraniliprole-N-methyl-quinazolinone, representing 26 percent TRR (0.002 mg eq/kg) and 17 percent TRR (0.001 mg eq/kg), respectively. All other metabolites represented ≤0.001 mg eq/kg.

Apple–foliar application (indoor)

Pyrazole-carboxamide or phenyl-carbamoyl labelled tetraniliprole was applied to greenhouse grown apples trees, with two foliar spray applications at fruit development (BBCH stage 71 and 73) at a rate of 85–88 g ai/ha per application.

At 64 (fruit) and 66 (leaves) days after application, TRR were 0.18/0.52 mg eq/kg in apple fruits and 99 mg eq/kg in apple leaves. A fruit surface wash with dichloromethane released 92/97 percent TRR, indicating that tetraniliprole residues remained mainly on the surface of the apple fruits. The surface wash with dichloromethane and extraction with acetonitrile/water/formic acid released most of the radioactivity (> 99.5 percent TRR) for both labels in fruit and leaf samples.

Greater than 99 percent TRR could be identified in apple fruit and leaves with both labels. The only identified radioactive residue in fruits and leaves was parent tetraniliprole, accounting for 99.2/99.3 percent TRR in fruit and 98.6 percent TRR in leaves. Two to six minor metabolites were found in fruit and leaves, but none exceeded 0.3 percent TRR (< 0.001 mg eq/kg in fruits and 0.051–0.32 mg eq/kg in leaves).

Lettuce–foliar application (indoor)

Pyrazole-carboxamide or phenyl-carbamoyl labelled tetraniliprole was applied to greenhouse grown lettuce plants, with two foliar spray applications at BBCH stage 44/45. The application rate was 2 × 59–60 g ai/ha, with a retreatment interval of 7 days.

Lettuce was collected at BBCH 49, 7 days after the last application. Total radioactive residues were 4.1 mg eq/kg in lettuce with both labels. Extraction with acetonitrile/water/formic acid released a high level of radioactivity (> 99 percent TRR) with both labels.

A total of 99.5/99.1 percent TRR was identified as parent tetraniliprole. No metabolites were found.

Potato–foliar application (indoor)

Pyrazole-carboxamide or phenyl-carbamoyl labelled tetraniliprole was applied to greenhouse grown potato plants, with two applications at BBCH 38 and 97–99and rates ranging from 101–105 g ai/ha, with a retreatment interval of 49 days. TRR were low at 0.001 mg eq/kg in potato tubers collected at 14 DAT. Extracted radioactivity of potato tubers with acetonitrile/water was high (79/75 percent TRR), and unextracted radioactivity was 21/25 percent TRR (equivalent with < 0.001 mg eq/kg).

A total of 38/55 percent TRR (both labels) could be identified (< 0.001 mg eq/kg). Tetraniliprole was the major component (29/42 percent TRR), followed by tetraniliprole-N-methyl-quinazolinone (9.0/13 percent TRR). All other metabolites represented < 0.001 mg eq/kg and, apart from one unknown (11.8 percent TRR), all were ≤ 5.3 percent TRR.

Paddy rice–foliar application (indoor)

Pyrazole-carboxamide or phenyl-carbamoyl labelled tetraniliprole was applied to greenhouse grown paddy rice, with two foliar spray applications of 50–52 g ai/ha each with an interval of 42 days, at BBCH 14 and BBCH 73–77 (early to late milk stage). Rice forage was harvested at 13 DAT (BBCH 34–35) and mature rice plants at 56 DAT (BBCH 89–92).

TRRs in rice kernels, forage, husks and straw amounted 0.040/0.024, 1.3/2.6, 2.5/2.1, 4.3/4.6 mg eq/kg, respectively. Extraction with acetonitrile/water/formic acid released high levels of radioactivity (≥ 93 percent TRR) for all matrices and with both labels. The unextracted radioactivity ranged from 0.4–1.7 percent TRR (equivalent with 0.015–0.022 mg eq/kg) in forage, husks and straw and was 6.3/7.3 percent TRR (equivalent with 0.002 mg eq/kg) in kernels.

A total of ≥ 92.7 percent TRR (both labels) was identified. The majority of the identified radioactivity was parent tetraniliprole (≥ 91 percent TRR with both labels in all matrices). A minor contribution to the total radioactivity was attributed to tetraniliprole-N-methyl-quinazolinone (0.7–3.7 percent TRR, < 0.001–0.151 mg eq/kg). All other metabolites represented ≤ 0.8 percent TRR and ≤ 0.027 mg eq/kg.

Summary of plant metabolism

Tetraniliprole is only marginally taken up from the soil and translocated to other parts of the plants after seed treatment or soil applications (drench or granular). In foliar applications, the majority of the residue remains on the surface, and very limited metabolism in apples or lettuce (indoor foliar applications) was observed. The metabolic pathway involves cyclisation in the parent molecule leading to tetraniliprole-N-methyl-quinazolinone, with highest levels in tomato fruits (up to 20 percent TRR but < 0.001 mg eq/kg)

and tomato leaves (37 percent TRR, 0.002 mg eq//kg). This metabolite was also found in rat studies. Parent tetraniliprole was the major residue found in all crops.

Apart from one outdoor study in maize and another in potatoes (seed treatment in furrow), all studies were conducted indoor. The Meeting concluded that the indoor studies sufficiently cover outdoor uses (see photochemical degradation section).

Environmental fate

The Meeting received information on hydrolytic stability, photochemical degradation in water and soil, and aerobic soil metabolism studies for tetraniliprole. Soil degradation field studies were also provided.

Aqueous hydrolysis

Radiolabelled (pyrazole-carboxamide) tetraniliprole was incubated in the dark in sterile aqueous buffered solutions at pH 4, 7, and 9 for 30 days at 20, 25 and 50 °C. The results show that the DT_{50} of tetraniliprole depends both on the pH and temperature. Where tetraniliprole slowly degrades at 20 and 25 °C and pH 4 (265–287 days), the DT_{50} decreases with high pH to 58/39 days at pH 7 and 1.27 and 0.75 days at pH 9 at normal temperatures (20 and 25 °C). At higher temperatures the DT_{50} decreases to 10.9 days at pH4 and to 3.74 and 0.04 days at pH 7 and 9, respectively.

One degradation product was identified as tetraniliprole-N-methyl-quinazolinone with a maximum amount of 99.6 percent of applied radioactivity (AR) (at DAT-30; pH 9, 20 °C). The Meeting concluded that hydrolysis is likely to be a minor path of degradation for tetraniliprole under environmental conditions.

Photochemical degradation

The photolysis in sterile water of pyrazole-carboxamide labelled tetraniliprole was studied under simulated sunlight in sterile aqueous acetate buffer (pH 4, 25 °C) with a DT_{50} of 3.4 days, equivalent to 10.5 summer days in Arizona (approximately 34° latitude). Tetraniliprole was stable under dark conditions (DT_{50} of 188.5 days). The major degradation product was tetraniliprole-deschloro-oxazine.

In two other studies, pyrazole-carboxamide or phenyl-carbamoyl labelled tetraniliprole was incubated in sterile natural waters (pH 8.0–8.5) at 25 °C under dark or simulated sunlight for 10–11 days. Tetraniliprole was readily degraded, with an estimated DT_{50} of 0.7–0.8 days, similar to the non-irradiated (dark) samples (DT_{50} of 0.3–0.8 days). Degradation product tetraniliprole-N-methyl-quinazolinone was the only compound observed in the dark samples (up to 92–99 percent after 10–11 days), whereas it reached levels up to max 39 percent AR (after 1 day) in the irradiated samples. In the irradiated samples other degradation products were also observed; tetraniliprole-deschloro-pyrazine (up to 37–39 percent AR at day 2), tetraniliprole -despyridyl-N-methyl-quinazolinone (up to 7 percent AR), tetraniliprole-deschloro-pyrazine (up to 27 percent AR at day 2) and tetraniliprole-pyrazole-5-carboxylic acid up to 18 percent AR at day 10).

The Meeting concluded that aqueous photolysis is a significant route of degradation, which was similar for dark and irradiated samples but the metabolic profile differed significantly.

In a soil photodegradation study, [pyrazole-carboxamide-^{14}C]-tetraniliprole was applied to a thin layer of silt loam soil (at a rate equivalent to about 200 g ai/ha). Tetraniliprole was slightly photolysed, decreasing from 93 percent AR (day 1) to 77 percent AR (day 11). Tetraniliprole-N-methyl-quinazolinone was the degradation product observed. The estimated photolysis DT_{50} was 27 days, equivalent to 82 summer days in Arizona. The Meeting concluded that photodegradation is, at the most, only a minor path of degradation in soil.

In summary, aqueous photolysis and hydrolysis at higher pHs are significant routes of degradation, although it was not possible to distinguish between the effects caused by pH or by photolysis. Residue decline trials performed outdoor in apples (at 0–14 DAT) and rice straw (at 38–53 DAT) show that tetraniliprole is stable over > 14 days. The Meeting concluded that photolysis does not play an important role in degradation of the tetraniliprole on outdoor crops, including seed treatments and foliar treatments (sprayed on the leaves) in paddy rice.

Aerobic soil metabolism

The biotransformation of [pyrazole-carboxamide-^{14}C]-tetraniliprole was investigated in four German soils and in six United States soils under laboratory conditions. The equivalent of 200 g tetraniliprole/ha was mixed with soil and incubated under aerobic conditions in the dark at 20 °C for 119–120 days.

The two main degradation products were tetraniliprole-carboxylic acid (up to 48 percent AR) and tetraniliprole-N-methyl-quinazolinone (up to 33 percent AR). Additionally, tetraniliprole-quinazolinone-carboxylic acid (up to 6.5 percent AR), tetraniliprole-amide (up to 6.96 percent AR), tetraniliprole-desmethyl-amide-carboxylic acid (up to 12 percent AR), and tetraniliprole-N-methyl-quinazolinone-carboxylic acid (up to 11 percent AR) were found, but each not exceeding 12 percent AR at any sampling interval. The estimated DT_{50} for tetraniliprole ranged from 18 to 183 days.

The biotransformation of [pyrazole-carboxamide-^{14}C]-tetraniliprole was investigated in an Italian paddy soil under laboratory conditions. The equivalent of 200 g tetraniliprole/ha was mixed with soil and water and incubated under anaerobic/aerobic conditions in the dark at 25 °C for 181 days.

Tetraniliprole-N-methyl-quinazolinone was the only identified degradation product (maximum 48 percent AR at DAT-140). Other unidentified residues amounted to a total maximum of 6.3 percent AR, with no single component exceeding 3.6 percent AR at any sampling interval. The estimated DT_{50} for tetraniliprole was 4.4 days in water and 84 days in the entire soil/water system.

The Meeting concluded that, under laboratory conditions, tetraniliprole is moderately persistent to persistent in soil and soil/water systems.

Rotational crop metabolism

The Meeting received information on the metabolism of tetraniliprole in wheat, turnip and Swiss chard grown as confined rotational crops and in a range of representative field crops grown in tetraniliprole treated soil.

Confined rotational crop studies

In two confined rotational crop studies, soil was treated with either [phenyl-carbamoyl-^{14}C]- or pyrazole-carboxamide label at 213/209 g ai/ha, and planted with wheat, turnip, and Swiss chard at plant-back intervals (PBI) of 30, 168, and 286 days. The TRR in the different RACs were generally low and decreased significantly from the 1st to the 3rd PBI. Residues in wheat matrices were generally higher, with exception of grain (no detected residues). Residues declined from 0.060/0.057 to 0.007/0.014 mg eq/kg in forage, from 0.16/0.21 to 0.028/0.064 mg eq/kg in hay and from 0.12/0.26 mg eq/kg to 0.035/0.110 mg eq/kg in straw. Residues in mature Swiss chard declined from 0.047/0.052 mg eq/kg at PBI of 30 days to 0.008/0.016 mg eq/kg at of PBI 286 days. In turnip leaves and turnip roots residue levels were even lower, ranging from 0.001 to 0.008 mg eq/kg, regardless of PBI.

Samples were extracted with acetonitrile/water/formic acid, with extraction efficiency ranging from 77 to 99 percent TRR with both labels. Post-extraction solids (PES) of wheat hay from the 1st and 2nd rotation and straw from the 1st rotation were exhaustively extracted using microwave assistance

with a mixture of acetonitrile/water and formic acid and, in case of wheat hay of the 2nd rotation, subsequently with 0.1 mol/L hydrochloric acid. The residues in the acetonitrile/water mixture were further characterised by partitioning against ethyl acetate. The radioactive residues in the organic and aqueous phases amounted to ≤ 0.010/≤ 0.016 mg eq/kg with the respective labels (6.4–15 percent TRR with both labels).

The predominant residue in all matrices at all PBIs was parent tetraniliprole, ranging from 40–88 percent TRR (0.003–0.15 mg eq/kg) at PBI of 30 days to 8.8–52 percent TRR (0.001–0.017 mg eq/kg) at PBI of 286.

In food commodities, tetraniliprole-carboxylic acid contributes significantly to the total residue (up to 28 percent TRR, 0.004 mg eq/kg) at 168 days PBI in Swiss chard and to 18 percent TRR (< 0.001 mg eq/kg) in turnip roots at 30 days PBI. The same applies for tetraniliprole-dihydroxy (up to 30 percent TRR, 0.005 mg eq/kg) in mature Swiss chard at 286 days PBI, but the metabolite was not found in roots. Tetraniliprole-desmethyl-amide-carboxylic-acid was found at 31 percent TRR in Swiss chard at 286 days PBI and at 18 percent TRR (< 0.001 mg eq/kg) in turnip roots at 30 days PBI. Tetraniliprole-N-methyl-quinazolinone contributed up to 14 percent TRR (0.002 mg eq/kg) in immature Swiss chard, 9.0 percent TRR (0.001 mg eq/kg) in mature Swiss chard and up to 16 percent TRR (0.001 mg eq/kg) in turnip roots (30 days PBI). Finally, tetraniliprole-despyridyl-N-methyl-quinazolinone-pyrazole-3-carboxylic acid was observed in Swiss chard at 2.9–16 percent TRR (< 0.001–0.008 mg eq /kg), but was not found in turnip roots

In feed matrices (wheat forage, hay, straw, and turnip leaves) metabolite tetraniliprole-N-methyl-quinazolinone accounted for 0.001 to 0.028 mg eq/kg (1.8–22 percent TRR), tetraniliprole-dihydroxy for 0.001 to 0.024 mg eq/kg (1.6–22 percent TRR), tetraniliprole-desmethyl-amide-carboxylic acid for 0.002–0.021 mg eq/kg (2.4–24 percent TRR), tetraniliprole-carboxylic acid for 0.001 to 0.011 mg eq/kg (2.7 to 17 percent TRR), and tetraniliprole-amide for 0.001 to 0.011 mg eq/kg (2.7–7.1 percent TRR).

In summary, residues in confined rotational crops were lower in grains and roots than in foliage and decreased slowly over time. The residues consisted mainly of parent tetraniliprole. Metabolites tetraniliprole-N-methyl-quinazolinone, tetraniliprole-dihydroxy, tetraniliprole-desmethyl-amide-carboxylic acid, tetraniliprole-carboxylic acid, and tetraniliprole-amide may also occur in significant proportions when considering percent TRR, but at very low absolute concentrations (< 0.001–0.008 mg eq/kg in food commodities and 0.001–0.021 mg eq/kg in feed commodities).

Field rotational crop studies

In a series of field rotational crop studies conducted in the United States, tetraniliprole was applied as one broadcast application to bare soil at a rate of 170–220 g ai/ha, which is similar to the most critical total maximum seasonal GAP rate of 200 g ai/ha for primary crops. Onions (11 trials), peas with pods (seven trials), beans with pods (nine trials), peas without pods (eight trials), beans without pods (eight trials), dried peas (seven trials), dried beans (nine trials), melons (10 trials), summer squash (nine trials), cucumber (eight trials), wheat (12 trials), barley (nine trials), sorghum (seven trials), alfalfa (11 trials), rapeseed (seven trials), and sunflowers (six trials) were planted at PBI of 25–31 days. Longer PBIs were not included for the food commodity plants, since no quantified residues were observed in food commodities and the confined rotational crop studies indicated that residues declined over time.

In one study, wheat (three trials) and soya bean (three trials) were planted after one application either to a target crop (potatoes) or to bare soil at PBI of 22–29 days, 108–119 days and 334–365 days. In the trials that made applications to potatoes, the potatoes were grown to maturity or until the time of rotational crop planting. For the 4-month and 12-month PBI plots, potatoes were harvested after

approximately 4 months DAT or at maturity, respectively; for the 1-month PBI plots, potato plants were disked or tilled into the plot. Samples of mature commodities were analysed for tetraniliprole and tetraniliprole-N-methyl-quinazolinone.

Considering all twelve field rotational crop studies, the residues in food commodities of the rotational crops with a 30 days PBI were all below the LOQ of < 0.01 mg/kg. Quantified residues were observed in feed commodities at PBIs up to 365 days. Median and highest residues of tetraniliprole and tetraniliprole-N-methyl-quinazolinone and total residues at any PBI (but mostly up to 3 months) are summarised below. Note that the total residues only includes the metabolite if the residue level was ≥ 0.01 mg/kg.

Table 142 Median and highest residues of tetraniliprole and tetraniliprole-N-methyl-quinazolinone and total residues at any PBI

Matrix	N	Tetraniliprole		Tetraniliprole-N-methyl-quinazolinone		Total [a]	
		max (mg/kg)	median (mg/kg)	max (mg eq/kg)	median (mg eq/kg)	max (mg/kg)	median (mg/kg)
Pulses forage [c]	25	0.056 [b]	< 0.01	< 0.01	< 0.01	0.056	< 0.01
Pulses hay [c]	25	0.19 [b]	< 0.01	0.026	< 0.01	0.22 [b]	< 0.01
Wheat forage [d]	21	0.030 [b]	< 0.01	< 0.01	< 0.01	0.030	< 0.01
Sorghum forage [e]	7	< 0.01	< 0.01	< 0.01	< 0.01	< 0.01	< 0.01
Wheat/barley hay [f]	30	0.035 [b]	< 0.01	< 0.01	< 0.01	0.035 [b]	< 0.01
Sorghum hay/fodder dry [e]	7	< 0.01	< 0.01	< 0.01	< 0.01	< 0.01	< 0.01
Wheat/barley straw [f]	30	0.097 [b]	< 0.01	0.038 [b]	< 0.01	0.14 [b]	< 0.01
Alfalfa forage (3 cuttings) [g]	33	0.013	< 0.01	< 0.01	< 0.01	0.013	< 0.01
Alfalfa hay (3 cuttings)	33	0.051 [b]	< 0.01	0.015 [b]	< 0.01	0.066 [b]	< 0.01

Notes:

[a] Total residue expressed as tetraniliprole.

[b] Single highest value.

[c] Based on beans, peas and soya bean data also representative for trefoil, vetch, clover, and lespedeza; forage also representative for silage and vines.

[d] Based on wheat data and also representative for barley, oat, rye, triticale; forage is also representative for silage.

[e] Based on sorghum data, also representative for millet; forage also representative for silage.

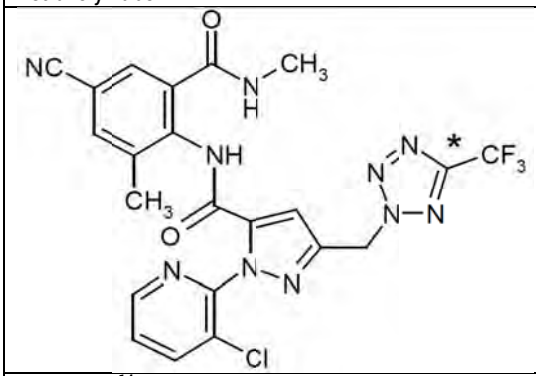
[f] Based on wheat and barley data, also representative for oat, rye and triticale.

[g] Forage is also representative for alfalfa silage.

The Meeting concluded that maximum residue levels should be estimated for crops that might be planted in rotation, for which no primary uses are in place (see section on residues from rotational crops to consider for animal feeds).

Animal metabolism

The Meeting received animal metabolism studies on rats, lactating goats and laying hens, where animals were dosed with tetraniliprole radiolabelled at the pyrazole-carboxamide site, the pyridinyl-ring, or the tetrazolyl-ring.

Pyrazole-carboxamide label	Pyridinyl label
	[pyrazole-carboxamide-^{14}C]-tetraniliprole	[pyridinyl-2-^{14}C]-tetraniliprole
Tetrazolyl label	
	


[tetrazolyl-^{14}C]-tetraniliprole	

Rats

The metabolism of tetraniliprole in rats was reviewed in the framework of the toxicological evaluation by the WHO Core Assessment Group of the 2020 JMPR.

Lactating goats

In a series of three separate studies, lactating goats (one per study) were dosed orally by capsule once each morning for 5 consecutive days after milking with [pyrazole-carboxamide-^{14}C]-tetraniliprole, [pyridinyl-2-^{14}C]-tetraniliprole, or [tetrazolyl-^{14}C]-tetraniliprole at dose of a ca 1 mg/kg bw/day, corresponding to a rate of 27, 21 or 38 ppm dry feed for each label, respectively. The goats were sacrificed 5.5 to 6 hours after the last dose. The quantitative results of the three studies are reported without correction for the differences in dose levels.

Most of the radioactivity was excreted in the faeces (61–69 percent of total applied radioactivity, TAR) and urine (20–3.3 percent TAR), 1.1–1.3 percent TAR (0.24–0.42 mg eq/kg) in milk and 1.8–2.4 percent TAR in tissues, with approximately 26–32 percent TAR likely to be still present in the gastro-intestinal tract.

The highest levels of radioactivity were found in liver (0.42–0.57 percent TAR, 0.88–1.2 mg eq/kg) and fat (0.89–1.4 percent TAR, 0.39–0.60 mg eq/kg), followed by kidney (0.020–0.10 percent TAR, 0.24–0.33 mg eq/kg) and muscle (0.49–0.72 percent TAR, 0.086–0.12 mg eq/kg). The milk samples contained higher residues and reached a plateau (0.28–0.43 mg eq/kg) at approximately 60–96 hours after the first dose.

Using acetonitrile/water mixture, residues were efficiently extracted from milk and tissues (89–100 percent TRR). For liver, an additional 8.8–11 percent TRR was released using microwave assisted extraction. Low amounts of radioactivity (≤ 0.7–1.0 percent TRR) remained in the PES of all commodities.

Parent tetraniliprole was the predominant residue in milk (64–70 percent TRR, 0.16–0.27 mg/kg), muscle (65–66 percent TRR, 0.057–0.064 mg/kg), liver (55–62 percent TRR, 0.54–0.55 mg/kg), and kidney (69–71 percent TRR, 0.17–0.18 mg/kg) and was a major component in fat (24–28 percent TRR, 0.094–0.16 mg /kg). Tetraniliprole-N-methyl-quinazolinone was the main metabolite in fat (67–72 percent TRR, 0.28–0.40 mg eq/kg) and muscle (28 percent TRR, 0.024–0.028 mg eq/kg). It was also a found in milk (11–13 percent TRR, < 0.026–0.056 mg eq/kg) and kidney (13–14 percent TRR, 0.033–0.044 mg eq/kg), and to a minor extent in liver (2.2–5.6 percent TRR, < 0.036–0.067 mg eq/kg) when using the pyridinyl or tetrazolyl-label.

Another prominent metabolite was tetraniliprole-benzylalcohol, with 9.0–11 percent TRR (0.022–0.045 mg eq/kg) in milk, 6.9–8.9 percent TRR (0.060–0.11 mg eq/kg) in liver and 3.6–6.2 percent TRR (0.009–0.020 mg eq/kg) in kidney. Metabolite tetraniliprole-hydroxy-N-methyl was found in milk (3.5–5.0 percent TRR, 0.008–0.019 mg eq/kg), liver (6.4–8.9 percent TRR, 0.061–0.088 mg eq/kg) and kidney (3.0–3.7 percent TRR, 0.007–0.009 mg eq/kg). Tetraniliprole-desmethyl-amide was only found in the liver of the goats treated with the pyridinyl or tetrazolyl-label (4.5–7.7 percent TRR, 0.055–0.067 mg eq/kg).

Several metabolites were identified, each accounting for ≤ 3.9 percent TRR, but some with absolute levels above 0.01 mg eq/kg; metabolites tetraniliprole-N-methyl-quinazolinone-pyrazole-3-carboxylic acid, tetraniliprole-pyridinyl-pyrazole-5-carboxylic acid (once 0.012 mg eq/kg in kidney with one label), tetraniliprole-N-methyl quinazolinone-benzylalcohol, tetraniliprole-desmethyl-amide (0.021 and 0.046 mg eq/kg in liver with two labels and 0.013 mg eq/kg in milk and kidney and 0.045 mg eq/kg in liver with one label) and tetraniliprole-quinazolinone (0.013 amd 0.026 mg eq/kg in milk and liver with one label).

Pyrazole-carboxamide label specific metabolites were tetraniliprole-pyrazole-5-amide, tetraniliprole-pyrazole-5-N-methyl-amide and tetraniliprole-5-carboxylic acid and were detected only in milk and liver (≤ 1.8 percent TRR). Tetrazolyl-specific metabolites were not identified.

Laying hens

In a series of three separate studies, six laying hens in each study were dosed orally once each morning for 14 consecutive days with [pyrazole-carboxamide-^{14}C]-tetraniliprole, [pyridinyl-2-^{14}C]-tetraniliprole, or [tetrazolyl-^{14}C]-tetraniliprole at rate of 18–19 ppm dry feed (approx. 1 mg/kg bw/day) and were sacrificed about 6 hours after the last dose.

Most of the radioactivity was excreted (91–92 percent TAR), with approximately 7–8 percent TAR likely to be still present in the gastro-intestinal tract. An average amount of *ca* 0.2 percent TAR was found in eggs and 0.2–0.4 percent TAR in tissues. TRR were 0.48–0.77 mg eq/kg in liver, 0.033–0.098 mg eq/kg in kidney, 0.028–0.095 mg eq/kg in subcutaneous fat, 0.035–0.078 mg eq/kg in skin and 0.017–0.031 mg eq/kg in skeletal muscle. In eggs, it ranged from 0.005 to 0.011 mg eq/kg at day one to 0.091–0.10 mg eq/kg at sacrifice. A residue plateau-level of 0.084–0.089 mg eq/kg was reached approximately seven to nine days after the first dose and decreased rapidly after cessation of the treatment.

Using acetonitrile/water, or methanol in case of fat, residues were efficiently extracted from fat (86 percent TRR), but less efficiently from eggs (54 percent TRR), muscle (44 percent TRR), and liver (34 percent TRR). Eggs, liver, and muscle (pyridinyl-label) were further extracted using microwave, releasing another 12–46 percent TRR from eggs, 41–66 percent TRR from liver, and 56 percent TRR from muscle. Final PES for the pyridinyl label were 9.7 percent TRR (0.008 mg eq/kg) in eggs (tetrazolyl-label only),

5.9–11.4 percent TRR (0.002 mg eq/kg) in muscle and 0.3 percent TRR (< 0.001 mg eq/kg) in fat for both other labels, and were not further characterized.

In the pyridinyl-label study, parent tetraniliprole was the predominant residue in fat (55 percent TRR, 0.015 mg eq/kg), and was also found in egg (14 percent TRR, 0.012 mg eq/kg), but less in liver and muscle (1.6 and 3.7 percent TRR, 0.12 and 0.001 mg eq/kg). Tetraniliprole-dihydroxy was the only metabolite observed at levels > 10 percent TRR (15 percentTRR, 0.004 mg eq/kg), but only in hen fat. All other metabolites were below 6.5 percent TRR.

In the pyrazole-carboxamide label study, parent tetraniliprole accounted for 10–26 percentTRR in fat (up to 0.012 mg/kg), for 10 percentTRR in muscle and egg (0.002 and 0.008 mg/kg) and for 4.8 percent TRR (0.023 mg/kg) in liver. Metabolite tetraniliprole-despyridyl-N-methyl-quinazolinone was the major compound in eggs (36 percent TRR, 0.030 mg eq/kg) and fat (63 percent TRR, 0.029 mg eq/kg) and was found in liver (12 percent TRR, 0.065 mg eq/kg) and muscle (8.6 percent TRR, 0.001 mg eq/kg). In muscle, tetraniliprole-pyrazole-5-N-methyl-amide contributed to 40 percent TRR (0.007 mg eq/kg), but accounted for 5.5 percent TRR or less in other tissues. Tetraniliprole-pyrazole-5-amide accounted for 13 percent TRR (0.002 mg eq/kg) in muscle, but for less than 3 percent TRR (up to 0.005 mg eq/kg) in other tissues.

In the tetrazolyl-label study, parent tetraniliprole accounted for 10 percent TRR or more only in fat (26 percentTRR, 0.025 mg eq/kg) with levels of 4.2, 4.2 and 9.4 percent TRR in eggs, liver, and muscle, respectively. Tetraniliprole-despyridyl-N-methyl-quinazolinone was the major compound in eggs (27 percent TRR, 0.023 mg eq/kg) and fat (62 percent TRR, 0,059 mg eq/kg) and was found in liver (8.4 percent TRR, 0.065 mg eq/kg) and muscle (6.8 percent TRR, 0.002 mg eq/kg). In muscle, the metabolite tetraniliprole-pyrazole-5-N-methyl-amide contributed to 17.6 percent TRR (0.005 mg eq/kg), but to 5.8 percent TRR or less in other tissues. Tetraniliprole-pyrazole-5-amide also accounted for 9.7 percent TRR (0.003 mg eq/kg) in muscle, but for less than 3.5 percent TRR (0.027 mg eq/kg) in other tissues.

Other metabolites that were identified with the different labels accounted for < 10 percent TRR. Tetraniliprole-benzylalcohol-Gluc was found in eggs and liver (1.3–6.5 percent TRR, 0.001–0.047 mg eq/kg), and tetraniliprole-dihydroxy (1.1–15 percent TRR, < 0.001–0.009 mg eq/kg), tetraniliprole-benzylalcohol (0.5–8.1 percentTRR, < 0.001–0.062 mg eq/kg), tetraniliprole-hydroxy-N-methyl (1.3–3.9 percent TRR, < 0.001–0.030 mg eq/kg), and tetraniliprole-N-methyl-quinazolinone (3.1–7.4 percent TRR, < 0.01 mg eq/kg) in eggs only.

The pyrazole-carboxamide and the tetrazolyl-label specific metabolites < 10 percent TRR were tetraniliprole-pyrazole-5-N-methyl-amide-hydroxy (0.5–3.2 percent TRR, 0.001–0.016 mg eq/kg) in all matrices, except fat, tetraniliprole-pyrazole-5-carboxylic acid (5.0–7.6 percent TRR, 0.037–0.039 mg eq/kg) in liver only, tetraniliprole-despyridyl (1.9–9.7 percent TRR, 0.001–0.074 mg eq/kg) in all matrices, tetraniliprole-despyridyl-N-methyl-quinazolinone-hydroxy and tetraniliprole-despyridyl-hydroxy (1.1–9.3 percent TRR, < 0.001–0.069 mg eq/kg (mixture of both metabolites)) in eggs, liver and fat (pyrazole-carboxamide label only), and tetraniliprole-despyridyl-quinazolinone (1.0–7.0 percent TRR, < 0.001–0.044 mg eq/kg) in eggs, fat and liver.

The pyridinyl-specific metabolite deschloro-desmethyl-amide accounted for 1.7–4.5 percent TRR (< 0.001–0.022 mg eq/kg). A large portion of unknown pyridinyl-labelled metabolites was found in the polar HPLC region of eggs and liver. There were no metabolites detected by HPLC analysis in the microwave assisted extract of muscle (0.014 mg eq/kg, 56.1 percent TRR), due to the low radioactivity in the sample and the high number of metabolites, as demonstrated in liver.

The tetrazolyl-label specific metabolite tetraniliprole-tetrazole and its conjugates was found in eggs, muscle, fat and liver with levels ranging from (0.8–15 percent TRR). The sum of tetraniliprole-

tetrazole and its conjugates was highest in eggs and muscle (23–29 percent, 0.009–0.019 mg eq/kg), but also observed in fat and liver (3.3–5.5 percent TRR, 0.005–0.025 mg eq/kg).

Summary of animal metabolism

The principal metabolic reactions of tetraniliprole in the lactating goat are:

- intra-molecular condensation (cyclisation) of parent compound leading to quinazolinone compounds;
- hydroxylation in the methyl group of the phenyl moiety leading to tetraniliprole-benzylalcohol and the N-methyl moiety leading to tetraniliprole hydroxy-N-methyl;
- demethylation of the N-methyl group to form tetraniliprole-quinazolinone and tetraniliprole-desmethyl-amide;
- cleavage of the pyridine ring leading to tetraniliprole-pyrazole-5-amide (PC- and tetra-label) followed by further oxidation to a tetraniliprole-pyrazole-5-carboxylic acid or by methylation leading to tetraniliprole-N-methyl-amide;
- cleavage of the phenyl ring to form tetraniliprole-pyridinyl-pyrazole-5-carboxylic acid;
- cleavage of the tetrazole ring followed by oxidation leading to tetraniliprole-N-methyl-quinazolinone-3-carboxylic acid.

The principal metabolic reactions of tetraniliprole in the laying hens are:

- cleavage of the pyridine ring, leading to despyridyl compounds;
- intra-molecular condensation of despyridyl compounds and parent compound leading to the quinazolinone compounds;
- cleavage of the tetrazole ring, followed by conjugation (tetra-label only);
- hydroxylations, leading to mono- and/or dihydroxy compounds such as tetraniliprole-dihydroxy, tetraniliprole-despyridyl-hydroxy, tetraniliprole-despyridyl-N-methyl-quinazolinone-hydroxy, and tetraniliprole-pyrazole-5-N-methyl-amide-hydroxy;
- conjugation with glucuronic acid after hydroxylation to tetraniliprole-benzylalcohol;
- cleavage of the phenyl moiety, leading to tetraniliprole-5-amide followed by methylation into tetraniliprole-pyrazole-5-N-methyl-amide followed by hydroxylation (tetraniliprole-pyrazole-5-N-methyl-amide-hydroxy);
- demethylation of the N-methyl group after intra-molecular condensation (cyclisation) of tetraniliprole-despyridyl to form tetraniliprole-despyridyl-quinazolinone.

The Meeting concluded that the total administered radioactivity was readily absorbed and extensively metabolised in goats and hens. Considering the very low levels of (other) metabolites observed in hen, the Meeting concluded that a single residue definition for animal commodities can be proposed.

Tetraniliprole (parent) is a major component in all goat tissues (24–71 percent TRR), in poultry fat (26–55 percent TRR) and in eggs (4.2–14 percent TRR), but contributes to the overall residue to a minor extent in poultry muscle (3.7–10 percent TRR) and poultry liver (1.6–4.2 percent TRR).

Tetraniliprole-N-methyl-quinazolinone is a major metabolite in goat tissues (11–67 percent TRR) except liver (2.2–5.6 percent TRR) and was observed in poultry studies in eggs only (3.1–7.4 percent TRR).

Tetraniliprole-benzylalcohol is a major metabolite in goat milk (9–11 percent TRR). Several other minor metabolites are observed in goat tissues, but all accounting for less than 10 percent TRR, though a number of them represent > 0.01 mg eq/kg.

Tetraniliprole despyridyl-N-methyl-quinazolinone contributes significantly to the total residue in eggs (27–36 percent TRR), poultry fat (63 percent TRR) and poultry liver (8.5–12 percent TRR), and contributes less to the total residue in poultry muscle (6.8–8.6 percent TRR). Tetraniliprole-pyrazole-5-N-methyl-amide is a major component in poultry muscle (18–40 percent TRR) and contributes less to the total residue in poultry liver, fat, and eggs (4.6–6 percent TRR).Tetrazole conjugates contributed significantly to the total residue in eggs (23 percent TRR) and poultry muscle (29 percent TRR), but less in poultry fat (5.5 percent TR) and poultry liver (3.3 percent TRR).

Methods of analysis

The Meeting received information on analytical methods for tetraniliprole residues in plant and animal matrices.

For plant matrices, analytical methods for measuring residues of tetraniliprole and tetraniliprole-N-methyl-quinazolinone generally involved extraction with water and acetonitrile, followed by quantification with LC-MS/MS. The method has been succesfully validated for commodities with high water, high acid, high oil, high starch/dry and high protein content with a LOQ of 0.01 mg/kg each.

For animal matrices, analytical methods for measuring residues of tetraniliprole, tetraniliprole-N-methyl-quinazolinone and tetraniliprole-benzylalcohol involve two extractions with acetonitrile/water, followed by drying and reconstitution in 0.1 percent aqueous formic acid. Residues were determined by LC-MS/MS. The method has been fully validated for animal tissues, eggs and milk, with an LOQ of 0.01 mg/kg for all analytes in all matrices.

The Meeting concluded that the presented methods were sufficiently validated and are suitable to measure tetraniliprole, tetraniliprole-*N*-methyl-quinazolinone in plant and animal commodities and tetraniliprole-benzylalcohol in animal commodities.

The Meeting noted that a modified version of QuEChERS multiresidue (MRM) enforcement method 01463 for determination of tetraniliprole and tetraniliprole-N-methyl-quinazolinone in plant commodities is confirmed as being a suitable enforcement method, with acceptable recovery rates at relevant fortification levels. The method was validated in tomato, grapes, wheat grain, dry bean seed and rapeseed seed, with an LOQ of 0.01 mg/kg each for both parent and metabolite.

Stability of pesticide residues in stored analytical samples

The Meeting received information on storage stability of tetraniliprole and tetraniliprole-N-methyl-quinazolinone in raw and processed plant commodities. No freezer storage stability data were submitted on animal matrices, but samples from the animal feeding studies were processed and analysed within 30 days and the samples from the radiolabelled metabolism studies were processed within 5 months of sampling.

The storage stability studies showed that tetraniliprole and tetraniliprole-N-methyl-quinazolinone (at 0.2 mg/kg) were stable when stored frozen for at least 24 months in crop commodities representative of the high water (tomato), high acid (grape), high starch (wheat grain), high protein (dry bean) and high oil (rape seed seed) commodity groups.

The Meeting agreed that the demonstrated storage stability on various representative plant commodities covered the residue sample storage intervals used in the field trials considered by the current Meeting.

Definition of the residue

Plant commodities

In the plant metabolism studies involving foliar applications (apples, potato, lettuce, paddy rice), soil drench application (tomato), granular in planting hole applications (rice) and seed treatments (potato and maize), in confined rotational crop metabolism studies and in processing studies, tetraniliprole was the major component (apple, tomato, lettuce, tomato, potato) of the radioactive residue.

Tetraniliprole is found in all primary crop commodities and is considered suitable as a marker compound. The Meeting noted that suitable analytical methods exist to measure tetraniliprole in plant commodities. The Meeting decided to define the residue for compliance with the MRL as tetraniliprole.

In deciding which additional compounds should be included in the residue definition for dietary risk assessment, tetraniliprole-N-methyl-quinazolinone is the only compound identified in relevant amounts in plant matrices. This metabolite was found at up to 20 percent TRR in tomato, rice grain and potatoes, but generally at levels ≤ 0.01 mg eq/kg in food commodities, which was confirmed in the supervised field trials, in which it was only found occasionally above the LOQ of 0.01 mg/kg, with tetraniliprole being present at levels about an order of magnitude higher.

A high temperature hydrolysis study shows that, though stable during pasteurization, tetraniliprole is not stable under baking/brewing/boiling (BBB) (pH 5, 100 °C, 60 minutes) and sterilization (pH 6, 120 °C, 20 minutes) conditions. Under these conditions 65–68 percent and 1.1–1.5 percent AR was recovered as parent and 27–30 percent AR and 94 percent AR as tetraniliprole-N-methyl-quinazolinone, respectively. Processing under heating indicated conversion of parent tetraniliprole into tetraniliprole-N-methyl-quinazolinone, e.g., mustard greens (up to 20 percent TRR), broccoli (up to 29 percent TRR), tomato paste (23–48 percent TRR), and soya bean meal (up to 81 percent TRR).

Tetraniliprole-N-methyl-quinazolinone was found in the rat and is covered by the health based guidance value of parent tetraniliprole.

The Meeting concluded that tetraniliprole-N-methyl-quinazolinone may occur in primary and rotational crops and that the metabolite contributes significantly to the residue in processed commodities. Hence the Meeting agreed to define a residue definition for dietary risk assessment for plant commodities is tetraniliprole and tetraniliprole-N-methyl-quinazolinone, expressed as tetraniliprole.

Animal commodities

Tetraniliprole is a major component in all goat tissues (24–71 percent TRR), poultry fat (26–55 percent TRR) and eggs (4.2–14 percent TRR), but it contributes little to the overall residue in poultry muscle (3.7–10 percent TRR) and liver (1.6–4.2 percent TRR). Parent tetraniliprole is also the major component in all cattle tissues and milk.

The Meeting noted that suitable analytical methods exist to measure tetraniliprole in animal commodities and decided to define the residue for compliance with the MRL as tetraniliprole.

Tetraniliprole has a Log Kow of 2.6, indicating a low to moderate potential to sequester into fatty matrices. The ratios of concentrations of muscle to fat (1:1.3–2.1) and skim milk to cream (1:3) indicate only a very slight tendency to concentrate in fat.

The Meeting considered the residue not to be fat soluble.

In deciding which compound should be included in the residue definition for dietary risk assessment, the Meeting noted that the tetraniliprole was metabolized into numerous components, of which 17 were accounted for > 10 percent TRR and/or > 0.01 mg eq/kg. The metabolites were considered in three categories, either covered by the toxicity of the parent, suitable for assessment by the TTC approach following Cramer Class III or by the TTC approach for genotoxic compounds.

The 2021 and 2022 JMPR Meeting concluded that the following metabolites are covered by the health based guidance values for tetraniliprole and should be considered for inclusion in the residue definition:

Tetraniliprole-N-methyl-quinazolinone contributes significantly to the total residue in goat tissues (11–72 percent TRR), except liver (2.2–5.6 percent TRR) and was observed in poultry studies in eggs only (3.1–7.4 percent TRR). The Meeting agreed that the metabolite should be included in the residue definition for dietary risk assessment.

Tetraniliprole-benzylalcohol contributed significantly to the total residue in goat milk (9–11 percent TRR, 0.022–0.045 mg eq/kg), and to a lesser extent in other goat and poultry matrices (1.3–8.1 percent TRR, 0.001–0.062 mg eq/kg). This metabolite also contributes to the total residue in dairy feeding studies in milk (36–66 percent of parent), liver (6.6–8.8 percent of parent), kidney (5.0–6.3 percent of parent). The Meeting agreed that the metabolite tetraniliprole-benzylalcohol should be included in the residue definition for dietary risk assessment.

Tetraniliprole-hydroxy-N-methyl was found in all goat (3.0–8.9 percent TRR, 0.007–0.088 mg eq/kg) and poultry matrices (1.3–3.9 percent TRR, < 0.001–0.030 mg eq/kg), except fats. However, since this analyte would contribute only little to the total residues (tetraniliprole + tetraniliprole-N-methyl-quinazolinone + tetraniliprole-benzylalcohol), the Meeting agreed that the metabolite does not need to be included in the residue definition for dietary risk assessment.

Tetraniliprole-desmethyl-amide was found in all goat matrices at levels ranging from 0.2 to 7.7 percent TRR (0.001–0.067 mg eq/kg). However, since it would contribute only little to the total residues (tetraniliprole + tetraniliprole-N-methyl-quinazolinone + tetraniliprole-benzylalcohol), the Meeting agreed that the metabolite does not need to be included in the residue definition for dietary risk assessment.

The 2021 and 2022 JMPR Meetings concluded that the TTC Cramer Class III could be applied (no indication for genotoxicity) for the following metabolites: tetraniliprole-pyrazole-5-carboxylic acid, tetraniliprole-N-methyl-quinazolinone-benzylalcohol, tetraniliprole-despyridyl-N-methyl-quinazolinone, tetraniliprole-pyrazole-5-amide, tetraniliprole-N-methyl-quinazolinone-pyrazole-3-carboxylic acid (2021 JMPR), tetraniliprole-desmethyl-amide, tetraniliprole-quinazolinone, tetraniliprole-pyridinyl-pyrazole-5-carboxylic acid, and T-pyrazole-5-N-methyl-amide (2022 JMPR)

In the absence of toxicological data for a number of (poultry specific) metabolites, the 2022 JMPR concluded that the remaining should be assessed under the TTC approach for genotoxic compounds; tetraniliprole-despyridy, tetrazole-conjugates, tetraniliprole-despyridyl-N-methyl-quinazolinone-hydroxy and tetraniliprole-despyridyl-hydroxy (mixture of both metabolites), tetraniliprole-despyridyl-quinazolinone, tetraniliprole-pyrazole-5-N-methyl-amide-hydroxy, tetraniliprole-deschloro-desmethyl-amide.

The Meeting concluded that for dietary risk assessment in animal commodities, the residue definition should be the sum of tetraniliprole, tetraniliprole-N-methyl-quinazolinone and tetraniliprole-benzylalcohol, expressed as tetraniliprole.

The Meeting agreed that:

The residue definition for tetraniliprole for compliance with the MRL in plant and animal commodities is: *Tetraniliprole*

The definition of the residue for dietary risk assessment for plant commodities: *Tetraniliprole + tetraniliprole-N-methyl-quinazolinone, expressed as tetraniliprole.*

Definition of the residue for dietary risk assessment for animal commodities: *Tetraniliprole + tetraniliprole-N-methyl-quinazolinone + tetraniliprole-benzylalcohol, expressed as tetraniliprole*.

Results of supervised residue trials on crops

Supervised trials were available for the use of tetraniliprole on citrus fruit (orange, mandarin, lemon, and grapefruit), pome fruit (apple and pear), stone fruit (cherry, peach plum), grapes, flowerhead brassicas (broccoli and cauliflower) and head brassicas (head cabbage), fruiting vegetables (tomato, peppers), leafy vegetables (lettuce head, lettuce leaf, spinach, mustard greens), pulses (dry soya beans), tuberous and corm vegetables (potato), cereal grains (rice, maize, sweet corn), tree nuts (almonds and pecans).

GAP information was available from Canada and the United States (foliar treatment of pome fruit, stone fruit, small fruit vine climbing, brassica vegetables, except leafy vegetables, fruiting vegetables other than cucurbits, leafy vegetables, soya bean, tuberous and corm vegetables, maize cereals, sweet corn, tree nuts), Korea (foliar treatment on apple, pear, and sweet persimmon), India (foliar treatment on soya bean and rice) and Japan (seed treatment on rice).

In this appraisal the term 'total residues' refers to the sum of tetraniliprole and tetraniliprole-N-methyl-quinazolinone, and was used to estimate STMR, HR, median and higest residues. Since residues in the evaluation were expressed as parent equivalents, no conversion factor is needed. Parent constitutes the majority of the tetraniliprole residues in most RACs, with low metabolite levels, except for feed and processed commodities subjected to heating.

To estimate the total residues, where residues tetraniliprole-N-methyl-quinazolinone are < LOQ it was assumed to be zero, except when both parent and metabolite were < LOQ and in that case the total was taken as < LOQ. The method for calculating the total residue for various situations is illustrated below.

Tetraniliprole	Tetraniliprole-N-methyl-quinazolinone	Tetraniliprole + Tetraniliprole-N-methyl-quinazolinone
0.29	0.02	0.31
0.039	< 0.01	0.039
< 0.01	< 0.01	< 0.01

Citrus fruit

GAP for tetraniliprole in the United States for citrus fruit includes three different uses, a single soil or single drip chemigation application at 120 g ai/ha, a single soil or drip chemigation application at 120 g ai/ha followed by single foliar application at 60 g ai/ha, and three foliar applications at 60 g ai/ha each. Trials were submitted in support of the combined soil and foliar applications and the triple foliar applications. Based on the results of these field trials the Meeting decided that the critical GAP in the United States for citrus fruit is three foliar applications at 60 g ai/ha, with a re-treatment interval of 5 days and a PHI of 1 day.

Grapefruit

A total of six independent supervised residue trials on grapefruits matching the critical United States GAP were conducted in the United States. Residues of tetraniliprole both for MRL and risk assessment in ranked order were (n=6): 0.039, 0.071, 0.081, 0.11, 0.19 and 0.49 mg/kg in whole fruit.

Noting that grapefruit is a representative crop for the subgroup of pummelo and grapefruits the Meeting estimated a maximum residue level of 0.9 mg/kg and an STMR of 0.091 mg/kg for tetraniliprole in the Subgroup of Pummelo and Grapefruits (including Shaddock-like hybrids, among other Grapefruit).

Lemon

Independent supervised residue trials on lemons matching the United States GAP were conducted in the United States. Residues of tetraniliprole both for MRL and risk assessment in ranked order were (n=5): 0.062, 0.13, 0.19, 0.20 and 0.77 mg/kg in whole fruit.

Noting that lemons is a representative crop for the subgroup of lemons and limes the Meeting estimated a maximum residue level of 1.5 mg/kg and an STMR of 0.19 mg/kg for tetraniliprole in the Subgroup of Lemons and Limes (including Citron).

Mandarin

Independent supervised residue trials on mandarin matching the United States GAP were conducted in United States. Residues of tetraniliprole both for MRL and risk assessment in ranked order were (n=4): 0.17, 0.18, 0.19 and 0.54 mg/kg in whole fruit.

Noting that mandarin is a representative crop for the subgroup of mandarins the Meeting estimated a maximum residue level of 1.0 mg/kg and an STMR of 0.185 mg/kg for tetraniliprole in the Subgroup of Mandarins (including Mandarin-like hybrids).

Oranges

A total of eight independent supervised residue trials on oranges matching the United States GAP were conducted in United States. Residues of tetraniliprole both for MRL and risk assessment in ranked order were (n=8): 0.044, 0.066, 0.13, 0.14, 0.14, 0.15, 0.16, and 0.29 mg/kg in whole fruit.

Noting that orange is a representative crop for the subgroup of oranges, sweet, sour the Meeting estimated a maximum residue level of 0.5 mg/kg. Using the processing factor for peeling of 0.11 (see section on processing) the Meeting estimated an STMR of 0.015 mg/kg in orange flesh for tetraniliprole in the Subgroup of Oranges, Sweet, Sour (including Orange-like hybrids).

Pome fruit

The critical GAP for pome fruit is in Canada and the United States allowing three foliar applications at 60 g ai/ha, with a re-treatment interval of 7 days and a PHI of 7 days. Trials conducted in Australia did not match this critical GAP.

In trials conducted in apples in Canada and the United States approximating the critical GAP, tetraniliprole residues both for MRL and risk assessment were (n=12): 0.064, 0.092, 0.10, 0.11, 0.11, 0.13, 0.15, 0.15, 0.16, 0.17, 0.17 and 0.20 mg/kg.

In trials conducted in pears in Canada and the United States approximating the critical GAP, tetraniliprole residues were (n=8): 0.044, 0.048, 0.080, 0.081, 0.13, 0.14, 0.16 and 0.24 mg/kg.

Noting that the median residues of tetraniliprole, for apples and pears from the United States/Canadian trials are within a 5-fold range, and that there is no evidence of a difference in the residue populations across the pome fruit types by Mann-Whitney test, the Meeting decided to make a recommendation for the Group of Pome fruit based on the combined data.

The combined apple and pear data for tetraniliprole residues, both for MRL and risk assessment, in ranked order, were (n=20): 0.044, 0.048, 0.064, 0.080, 0.081, 0.092, 0.10, 0.11, 0.11, 0.13, 0.13, 0.14, 0.15, 0.15, 0.16, 0.16, 0.17, 0.17, 0.20 and 0.24 mg/kg.

Noting that the United States GAP is for the group of pome fruits, which does not include Japanese persimmon, the Meeting estimated a maximum residue level of 0.4 mg/kg and an STMR of 0.13 mg/kg for tetraniliprole in the Group of Pome Fruits, excluding Japanese persimmon.

Stone fruit

The critical GAP for stone fruit in Canada and the United States allows three foliar applications at 60 g ai/ha, with a retreatment interval of 7 days and a PHI of 5 days.

Field trials were available on cherries, peaches and plums, and the fruit was analysed without stone. At the 2017 JMPR Meeting, it was concluded that the contribution of the pit to the weight of the whole fruit of cherries, plums and peaches is approximately 10 percent. Correcting the residue levels for tetraniliprole using this weight/weight ratio would lead to the same rounded residue levels, so no adjustment was made on the residues.

Cherries

In trials conducted in Canada and the United States matching GAP, tetraniliprole residues both for MRL and risk assessment were (n=11): 0.085, 0.12, 0.24, 0.27, 0.28, 0.29, 0.38, 0.44, 0.49, 0.56, and 0.66 mg/kg.

The Meeting estimated a maximum residue level of 1.5 mg/kg and an STMR of 0.29 mg/kg in the Subgroup of Cherries.

Peaches

In trials conducted in Canada and the United States matching the GAP, tetraniliprole residues both for MRL and risk assessment were (n=15): 0.030, 0.041, 0.056, 0.064, 0.070, 0.080, 0.086, 0.089, 0.091, 0.095, 0.15, 0.15, 0.21, 0.38, and 0.44 mg/kg.

The Meeting estimated a maximum residue level of 0.7 mg/kg and an STMR of 0.089 mg/kg for tetraniliprole in the Subgroup of Peaches (including Nectarines and Apricots).

Plums

In trials conducted in Canada and the United States matching the GAP, tetraniliprole residues both for MRL and risk assessment were (n=8): < 0.01, 0.012, 0.016, 0.026, 0.039, 0.081, 0.11, and 0.13 mg/kg.

The Meeting estimated a maximum residue level of 0.3 mg/kg and an STMR of 0.033 mg/kg for tetraniliprole in the Subgroup of Plums.

Small fruit vine climbing

The critical GAP for small fruit vine climbing in Canada and the United States allows four foliar applications at 45 g ai/ha, with a retreatment interval of 7 days and a PHI of 14 days.

In trials conducted on grapes in Canada and the United States matching the GAP, tetraniliprole residues both for MRL and risk assessment were (n=10): 0.20, 0.25, 0.26, 0.27, 0.27, 0.28, 0.29, 0.39, 0.82 and 0.92 mg/kg.

Noting that grapes is a representative commodity for the subgroup, the Meeting estimated a maximum residue level of 1.5 mg/kg and an STMR of 0.275 mg/kg for tetraniliprole in the Subgroup of Small fruit vine climbing.

Brassica vegetables, except brassica leafy vegetables

The critical GAP for Brassica vegetables, except brassica leafy vegetables in Canada and the United States allows four foliar applications at 45 g ai/ha, with a retreatment interval of 5 days and a PHI of 1 day.

Flowerhead brassicas

Residue trials performed in the United States on broccoli and cauliflower matching the GAP, tetraniliprole residues both for MRL and risk assessment were:

Broccoli (n=5): 0.11, 0.14, 0.15, 0.18, and 0.24 mg/kg;

Cauliflower (n=5): 0.036, 0.066, 0.11, 0.16, and 0.19 mg/kg.

Noting that broccoli and cauliflower are representative commodities for flowerhead brassicas, that median residues are within a 5-fold range and the residue populations are similar according to the Mann-Whitney test, the Meeting decided to combine the data as (n=10): 0.036, 0.066, 0.11, 0.11, 0.14, 0.15, 0.16, 0.18, 0.19, and 0.24 mg/kg.

The Meeting estimated a maximum residue level of 0.5 mg/kg and an STMR of 0.145 in the Subgroup of Flowerhead Brassicas.

Head Brassicas

In trials conducted in the United States matching the GAP, tetraniliprole residues in head cabbages with wrapper leaves, both for MRL and dietary burden calculation, in ranked order, were (n=10): 0.046, 0.073, 0.087, 0.096, 0.12, 0.15, 0.31, 0.35, 0.48, and 1.1 mg/kg (1.2 highest individual value).

Residues of tetraniliprole in head cabbages without wrapper leaves for STMR estimation in ranked order, were (n=10): < 0.01 (3), 0.010, 0.011, 0.013, 0.020, 0.020, 0.024, and 0.026 m/kg.

The Meeting estimated a maximum residue level of 2.0 mg/kg and an STMR of 0.012 for tetraniliprole in Cabbages, head.

The Meeting also estimated a median and highest residue level of 0.135 mg/kg and 1.2 mg/kg, respecetively, for Cabbages, Head with wrapper leaves.

Fruiting vegetables, other than cucurbits

The critical GAP for fruiting vegetables in Canada and the United States allows four foliar applications at 45 g ai/ha, with a retreatment interval of 5 days and a PHI of 1 day.

Data were available from supervised residue trials in tomato (including a variety of fruit sizes, ranging from 28–450 g, including trials with cherry tomatoes) in the United States.

In trials matching the GAP tetraniliprole residues, both for MRL and risk assessment, were (n=16): 0.030, 0.034, 0.042, 0.042, 0.053, 0.053, 0.057, 0.064, 0.066, 0.075, 0.079, 0.080, 0.12, 0.22, 0.23 and 0.32 mg/kg (highest individual value 0.35 mg/kg).

In trials conducted in peppers, including trials with chili peppers in United States matching the GAP, tetraniliprole residues, both for MRL and risk assessment, were (n=12): 0.011, 0.024, 0.041, 0.048, 0.075, 0.077, 0.079, 0.087, 0.093, 0.11, 0.15 and 0.20 mg/kg.

Noting that residue data on small and large varieties of tomatoes and sweet and chili peppers are available, that the median residues of tetraniliprole, for tomatoes and peppers are within a 5-fold range, and that there is no evidence of a difference in the residue populations across the fruiting vegetable types by Mann-Whitney test, the Meeting decided to make a recommendation for the Group of Fruiting vegetables, other than cucurbits based on the combined data.

The combined data for tetraniliprole, in ranked order, were (n=28): 0.011, 0.024, 0.030, 0.034, 0.041, 0.042 (2), 0.048, 0.053 (2), 0.057, 0.064, 0.066, 0.075 (2), 0.077, 0.079 (2), 0.080, 0.087, 0.093, 0.11, 0.12, 0.15, 0.20, 0.22, 0.23, and 0.32 mg/kg.

The Meeting estimated a maximum residue level of 0.4 mg/kg and an STMR of 0.075 mg/kg for tetraniliprole in the Group of Fruiting vegetables, other than cucurbits, excluding okra, martynia and roselle.

Chili peppers, dried

Based on the estimated maximum residue level of 0.4 mg/kg for the Group of Fruiting vegetables and applying a default processing factor of 10, the Meeting estimated a maximum residue level of 4 mg/kg for peppers, chili, dried, together with a STMR of 0.75 mg/kg.

Leafy vegetables (including Brassica leafy vegetables)

The critical GAP for Brassica vegetables, except brassica leafy vegetables in Canada and the United States allows four foliar applications at 45 g ai/ha, with a re-treatment interval of 5 days and a PHI of 1 day. The Meeting received data on head lettuce, leaf lettuce, spinach and mustard greens.

Leafy greens

Data were available from supervised residue trials in head lettuce, leaf lettuce and spinach in the United States. The trials did not match the Canadian or United States GAP, because the RTIs ranged from 2–4 days. Decline data indicate a slow decline, indicating that the duration of the retreatment intervals has an impact on the final residue level.

The Meeting was unable to make a recommendation for the Subgroup of Leafy greens.

Brassica leafy vegetables

In trials conducted in United States matching the GAP, tetraniliprole residues, both for MRL and risk assessment, in mustard greens were (n=5): 3.2, 3.6, 4.0, 4.2, and 7.3 mg/kg.

Noting that mustard greens is representative for brassica leafy vegetables, the Meeting estimated a maximum residue level of 15 mg/kg, an STMR and a median residue level of 4.0 mg/kg and a highest residue of 7.3 mg/kg for tetraniliprole in the Subgroup of Leaves of Brassicaceae.

Soya beans, dry

The United States GAP for soya beans includes either a single in-furrow soil application at 200 g ai/ha (PHI not applicable), 4 foliar applications at 50 g ai/ha, with a retreatment interval of 3 days, and PHI of 14 days, or a combination of both, with a maximum of 200 g ai/ha per season. The Meeting concluded that

the critical United States GAP for soya beans is 4 foliar applications at 50 g ai/ha, with a retreatment interval of 3 days and a PHI of 14 days.

Trials conducted in Canada and the United States matching the critical GAP, tetraniliprole residues, both for MRL and risk assessment, in dry soya bean seeds were (n=20): < 0.01 (3), 0.012, 0.012, 0.016, 0.018, 0.018, 0.025, 0.026, 0.026, 0.030, 0.033, 0.037, 0.038, 0.048, 0.053, 0.092, 0.13, and 0.14 mg/kg.

The Meeting estimated a maximum residue level of 0.2 mg/kg and an STMR of 0.026 mg/kg for tetraniliprole in Soya bean (dry).

Tuberous and corm vegetables

The critical United States GAP for tuberous and corm vegetables is a single in-furrow application at 200 g ai/ha (PHI not applicable).

Potato

In trials conducted in Canada and the United States matching the GAP, tetraniliprole residues, both for MRL and risk assessment, in ranked order were (n=18): < 0.01 (16), 0.012 and 0.015 mg/kg (highest individual level 0.017 mg/kg).

Noting that potato is a representative crop for tuberous and corm vegetables, the Meeting estimated a maximum residue level of 0.02 mg/kg and an STMR of 0.01 mg/kg for tetraniliprole in the Subgroup of Tuberous and corm vegetables.

Rice

The critical GAP for rice is from India, which allows 2 foliar applications at 60 g ai/ha, with a RTI of 11 days and a PHI of 43 days, but trials conducted in Brazil, India, Thailand and Vietnan did not match this GAP. Applying proportionality to trials showing residues (>0.01 mgkg) with 2 foliar applications at 40 g ai/ha with identical RTI (11 days) and would still result in a too limited data set (n=2) for estimation of a maximum residue level.

The Japanese GAP for rice consists of a single seed treatment at 264 g ai/ha. Trials performed in India, Thailand and Vietnam, approximating this GAP, were available.

Tetraniliprole, residues, both for MRL and risk assessment, in rice grain were (n=12): < 0.01 (11) and 0.013 mg/kg.

Tetraniliprole, residues, both for MRL and risk assessment, in husked rice were (n=12): < 0.01 (12) mg/kg.

The Meeting estimated a maximum residue level of 0.02 mg/kg and an STMR of 0.01 mg/kg for tetraniliprole in Subgroup of Rice cereals.

The Meeting estimated a maximum residue level of 0.01(*) mg/kg and an STMR of 0.01 mg/kg for tetraniliprole in Rice, husked.

Noting that residue levels in polished rice are usually lower than residue levels in husked rice, which was confirmed in the processing study submitted to the current Meeting, the Meeting decided to extrapolate the MRL of 0.01(*) mg/kg and STMR of 0.01 mg/kg for Rice, husked to Rice, polished.

Maize cereals

The critical GAP in the United States for maize (field corn, popcorn) is 4 foliar applications at 50 g ai/ha with a retreatment interval of 7 days and a PHI of 14 days.

In residue trials in maize/field corn from Canada and the United States matching this GAP, tetraniliprole residues, both for MRL and risk assessment, were (n=15): < 0.01 (14) and 0.011 (0.012 highest individual value) mg/kg.

The Meeting estimated a maximum residue level of 0.015 mg/kg and an STMR of 0.01 mg/kg for tetraniliprole in the Subgroup of Maize cereals.

Sweet Corn (corn-on-the-cob)

The critical GAP for sweet corn in United States is 4 foliar applications at 50 g ai/ha with a retreatment interval of 7 days and a PHI of 1 day.

In residue trials conducted in sweet corn according to GAP in Canada and the United States, tetraniliprole residues, both for MRL and risk assessment, were (n=14): < 0.01 (14) mg/kg.

The Meeting estimated a maximum residue level of 0.01(*) mg/kg and an STMR of 0.01 mg/kg for tetraniliprole for Sweet Corn (corn-on-the-cob) (kernels plus cob with husk removed).

Tree nuts

The critical GAP for tree nuts in Canada and the United States allows for 4 foliar applications at 45 g ai/ha, with an RTI of 7 days and a PHI of 10 days. Data were available from supervised residue trials in almond and pecan in Canada and the United States matching the GAP.

Residues of tetraniliprole, both for MRL and risk assessment, in almonds were (n=3): < 0.01 (1), 0.010, and 0.015 mg/kg.

Residues of tetraniliprole, both for MRL and risk assessment, in pecans were (n=6): < 0.01 (6) mg/kg.

Noting that the median residues of tetraniliprole, in almonds and pecans are within a 5-fold range and that there is no evidence of a difference in the residue populations by Mann-Whitney test, the Meeting decided to combine the results as (n=9): < 0.01 (7), 0.010, and 0.015 mg/kg.

Considering that a high number of residue levels below the LOQ of 0.01 mg/kg results in a higher statistical uncertainty, the Meeting decided to estimate the maximum residue level based on 2 × HR, leading to a higher value than would be calculated with the OECD calculator.

Noting that almond and pecan are two representative crops for the Tree nut group, the Meeting estimated a maximum residue level of 0.03 mg/kg and an STMR of 0.01 mg/kg for tetraniliprole in the Group of Tree Nuts.

Residues in animal feeds

Soya bean forage (56 percent dry matter) and hay (85 percent dry matter)

The Canadian and United States labels have a feeding restriction for soya bean forage and hay after foliar use, but not after in-furrow soil treatment or seed treatment. The critical GAP in the United States for soya beans as relates to soya bean forage and hay is in-furrow-treatment at 200 g ai/ha.

In three trials on soya bean forage conducted according to this GAP, tetraniliprole residue levels, both for MRL and dietary burden estimations, were (n=3): < 0.01 (2) and 0.031 mg/kg.

The Meeting concluded that three trials are insufficient to estimate a median and highest residue level for tetraniliprole in soya bean forage and hay.

Since residue levels were observed in soya bean forage and hay when planted in crop rotation, maximum residue levels estimated in that section are applicable for soya bean forage and hay in the absence of sufficient data after primary use.

Rice straw (90 percent dry matter)

The critical GAP for rice in India allows for 2 foliar applications at 60 g ai/ha, with an RTI of 11 days and a PHI of 43 day. Supervised residue trials conducted in rice in Brazil, India, Thailand and Vietnam used a lower application rate (2 × 40 g ai/ha) or a higher number of applications (3 × 60 g ai/ha). The Meeting agreed to use the trials with the lower application rates by applying proportionality.

Unscaled tetraniliprole residue levels in rice straw from supervised residue trials conducted at 2 × 40 g ai/ha (RTI 10–12 days and harvested at 43 DALA) were (n=6): 0.24, 0.26, 1.6, 1.9, 3.5, and 5.0 mg/kg (highest individual value of 5.1 m/kg). Scaled tetraniliprole residues for MRL estimation were (n=6): 0.36, 0.39, 2.4, 2.8, 5.2, and 7.5 (highest individual value 7.6 mg/kg) on an as received basis.

Unscaled total tetraniliprole residue levels were (n=6): 0.26, 0.29, 1.7, 2.0, 3.6, and 5.4 mg/kg (highest individual value of 5.5 mg/kg). Scaled total tetraniliprole residues for median and highest residue estimation in ranked order were (n=6): 0.39, 0.44, 2.6, 3.0, 5.4 and 8.1 mg/kg (highest individual value 8.2 mg/kg) on as received basis.

Assuming a default of 90 percent dry matter, the Meeting estimated a maximum residue level of 20 (dw) mg/kg for tetraniliprole in rice straw.

Based on the total tetraniliprole residues, the Meeting estimated a median and highest residue level of 2.8 mg/kg and 8.2 mg/kg for tetraniliprole in rice straw on an as received basis for dietary burden calculations.

The Meeting noted that residues may occur in rice planted in rotation. However, the residues from prior uses will not contribute significantly to the total residue and were not included in the calculation.

Rice whole crop silage (40 percent dry matter)

The critical GAP for rice in India allows for 2 foliar applications at 60 g ai/ha, with a RTI of 11 days and a PHI of 43. Data were available from supervised residue trials in rice in Brazil, India, Thailand and Vietnam but trials were conducted at 2 × 40 g ai/ha. The Meeting agreed to apply the proportionality approach using the data at PHI is 0 days for crop silage.

Unscaled tetraniliprole residue and unscaled total residue levels were the same in supervised residue with application rates of 2 × 40 g ai/ha (RTI 10-12 days and harvested at 0 DALA) and were (n=5): 1.2, 1.7, 1.8, 1.9, and 3.1 mg/kg (highest individual value of 3.5 mg/kg). Both scaled tetraniliprole residues and scaled total residues were the same and were (n=5): 1.8, 2.6, 2.7, 2.8, and 4.6 mg/kg (highest individual value of 5.2 mg/kg).

The Meeting estimated a median and highest residue level of 2.7 mg/kg and 5.2 mg/kg, respectively for tetraniliprole in rice whole crop silage on an as received basis for dietary burden calculations, both for subsequent maximum residue level and STMR estimations in animal commodities.

The Meeting noted that residues may occur in rice planted in rotation. However, the residues from prior uses will not contribute significantly to the total residue and were not included in the calculation.

Maize/ field corn forage (40 percent dry matter) or sweet corn forage (48 percent dry matter)

The critical GAP in the United States for maize (field corn, sweet corn, popcorn) is 4 foliar applications at 50 gai/ha with a retreatment interval of 7 days and a PHI of 14 days (field corn, popcorn) and 1 day PHI for sweet corn, with a restriction not to feed forage or stover within PHI 14 days.

Tetraniliprole residue levels in maize/field corn forage (PHI=14 days) from trials conducted according to GAP in Canada and the United States were (n=19): < 0.01, 0.040, 0.11, 0.19, 0.24, 0.44, 0.44, 0.48, 0.49, 0.53, 0.55, 0.68, 0.96, 1.1, 1.3, 1.3, 1.4, 2.2, 3.1 mg/kg (highest individual value of 3.6 mg/kg).

Tetraniliprole residue levels in sweet corn forage conducted according to GAP (PHI=14 days) were (n=2): 2.1 and 2.2 mg/kg.

Total tetraniliprole residue levels in maize/field corn forage (PHI=14 days) were (n=19): < 0.01, 0.040, 0.11, 0.19, 0.24, 0.44, 0.44, 0.49, 0.50, 0.53, 0.55, 0.68, 0.97, 1.1, 1.3, 1.3, 1.4, 2.2, 3.1 (highest individual value 3.6 mg/kg).

Total tetraniliprole residue levels in sweet corn forage (PHI=14 days) were (n=2): 2.1 and 2.2 mg/kg.

Noting that the residue levels in sweet corn forage fall within the range of field corn forage the Meeting decided to combine the data. The combined total tetraniliprole residues for median and highest residue estimation, in ranked order, were (n=21): < 0.01, 0.040, 0.11, 0.19, 0.24, 0.44, 0.44, 0.49, 0.50, 0.53, 0.55, 0.68, 0.97, 1.1, 1.3, 1.3, 1.4, 2.1, 2.2, 2.2, 3.1 (highest individual value 3.6 mg/kg).

The Meeting estimated a median residue of 0.55 mg/kg and a highest residue of 3.6 mg/kg for tetraniliprole in maize forage on an as received basis.

The Meeting noted that residues may occur in maize/field corn or sweet corn planted in rotation. However, the residues from prior uses will not contribute significantly to the total residue and were not included in the calculation.

Maize/field corn or sweet corn stover (83 percent dry matter)

The critical GAP in the United States for maize (field corn, sweet corn, popcorn) is 4 foliar applications at 50 g ai/ha with a retreatment interval of 7 days and a PHI of 14 days (field corn, popcorn, and corn grown for seed) and 1 day for sweet corn, with a withholding period of 14 days.

Tetraniliprole residue levels in maize/field corn stover (PHI=14-21 days) from trials conducted according to GAP were (n=21): < 0.01, 0.20, 0.28, 0.37, 0.80, 1.1, 2.3, 2.4, 2.5, 2.6, 2.9, 2.9, 2.9, 3.1, 3.2, 4.3, 4.4, 5.9, 7.9, 9.1, and 10 mg/kg.

Tetraniliprole residue levels in sweet corn stover (PHI=14-36 days) from trials conducted according to GAP were (n=14): < 0.01, 0.014, 0.13, 0.54, 0.72, 0.80, 1.2, 1.4, 1.4, 2.2, 2.5, 5.4, 7.9, and 16 mg/kg (17 mg/kg highest individual value).

Recognizing that normally the dataset with highest levels would be used for median and highest residue estimation the Meeting decided to combine the datasets as that results in the highest median residue.

The combined tetraniliprole residues in field corn and sweet corn stover are (n=35): < 0.01 (2), 0.014, 0.13, 0.20, 0.28, 0.37, 0.54, 0.72, 0.80, 0.80, 1.1, 1.2, 1.4, 1.4, 2.2, 2.3, 2.4, 2.5, 2.5, 2.6, 2.9, 2.9, 2.9, 3.1, 3.2, 4.3, 4.4, 5.4, 5.9, 7.9, 7.9, 9.1, 10, and 16 mg/kg (highest individual value 17 mg/kg).

Total tetraniliprole residues for median and highest residue estimation, in ranked order, are (n=35): < 0.01 (2), 0.014, 0.16, 0.21, 0.28, 0.39, 0.56, 0.80, 0.82, 0.87, 1.1, 1.3, 1.4, 1.5, 2.3 (2), 2.5, 2.5, 2.6 (2), 2.9, 3.0, 3.0, 3.2, 3.3, 4.3, 4.4, 5.5, 6.1, 8.0, 8.0, 9.1, 10, and 16 mg/kg (highest individual value 17 mg/kg).

The Meeting estimated a maximum residue level of 30 mg/kg (dw), based on a dry matter content of 83 percent for maize corn stover.

The Meeting estimated a median residue of 2.5 mg/kg and a highest residue of 17 mg/kg for tetraniliprole in maize stover and sweet corn stover on an as received basis for dietary burden calculations.

The Meeting noted that residues may occur in maize/field corn or sweet corn planted in rotation. However, the residues from prior uses will not contribute significantly to the total residue and were not included in the calculation.

Almond hulls

The critical GAP in Canada and the United States for tree nuts is 4 foliar applications at 45 g ai/ha with a retreatment interval of 7 days and a PHI of 10 days. In trials matching the GAP, tetraniliprole residues, both for maximum residue and median residue level estimation, in almond hulls are (n=5): 0.22, 0.77, 0.80, 1.1, and 1.8 mg/kg.

Based on a dry matter content of 90 percent the Meeting estimated a maximum residue level of 4 mg/kg (dw). The Meeting estimated a median residue level of 0.80 for tetraniliprole in almond hulls on an as received basis for the dietary burden calculations.

Residues from rotational crops to consider for animal feeds

Rotational crop studies indicate that residue can be expected in feed commodities grown in crop rotation. Residues were found in forage and hay from legume vegetables (beans, peas, soya bean and alfalfa) and in forage, hay and straw from cereals (wheat, barley and sorghum). The findings were combined in the two major crop groups to estimate a maximum residue level and median and highest residue levels.

Table 134 Maximum and mean residues found in feed commodities from rotational crops

Matrix	N	Tetraniliprole		Tetraniliprole-N-methyl-quinazolinone		Total [a]	
		max (mg/kg)	median (mg/kg)	max (mg/kg)	median (mg/kg)	max (mg/kg)	median (mg/kg)
Legume feeds with high water content (forage and silage) [b]	58	0.056	< 0.01	< 0.01	< 0.01	0.066 [d]	< 0.01
Legume feeds with low water content (hay) [b]	58	0.19	< 0.01	0.026	< 0.01	0.22	< 0.01
Cereal grains (including pseudocereals) feed products with high water (≥20 percent) content (forage and silage) [c]	28	0.030	< 0.01	< 0.01	< 0.01	0.030	< 0.01
Cereal grains (including pseudocereals) feed products with low water (<20 percent) content (hay, straw)	67	0.097	< 0.01	0.038	< 0.01	0.14	< 0.01

Notes:

[a] Total residue expressed as tetraniliprole.

[b] Based on data in alfalfa, beans, peas and soya bean data.

[c] Based on wheat, barley and sorghum data.

[d] In alfalfa one value of 0.051 mg/kg tetraniliprole + 0.015 mg/kg tetraniliprole N-methyl-quinazolinone also added to 0.066 mg/kg.

The Meeting estimated a median and highest residue level of 0.01 and 0.066 mg/kg (parent + tetraniliprole-N-methyl-quinazolinone), respectively, for the Subgroup of Products of legume feeds with high water (≥ 20 percent) content (forage and silage).

The Meeting estimated a maximum residue level (parent only) of 0.3 mg/kg for the Subgroup of Products of legume feeds with low (< 20 percent) water content (hay), and a median and highest residue level of 0.01 and 0.21 mg/kg (parent + tetraniliprole-N-methyl-quinazolinone), respectively.

The Meeting estimated a median and highest residue level of 0.01 and 0.030 mg/kg (parent + tetraniliprole-N-methyl-quinazolinone), respectively, for the Subgroup of Cereal grains (including pseudocereals) feed products, excluding maize, corn and rice, with high water (≥ 20 percent) content (forage and silage).

The Meeting estimated a maximum residue level of 0.2 mg/kg for the Subgroup of Cereal grains (including pseudocereals) feed products, excluding maize, corn and rice with low water (< 20 percent) content (hay, straw), and a median and highest residue level of 0.01 and 0.14 mg/kg (parent + tetraniliprole-N-methyl-quinazolinone), respectively.

Fate of residues during processing

The Meeting received information on the hydrolysis of tetraniliprole as well as information on the fate of tetraniliprole residues during processing in oranges, apples, plums, grapes, broccoli, tomatoes, mustard greens, soya bean, potato, field corn, and rice.

High temperature hydrolysis

The hydrolysis of [pyrazole-carboxamide-^{14}C]-Tetraniliprole and [phenyl-carbamoyl-^{14}C]-tetraniliprole was studied in sterile buffered aqueous solutions under conditions simulating pasteurization, baking/brewing/boiling, and sterilization.

Tetraniliprole was shown to be stable under the condition representing pasteurization (pH 4, 90 °C, 20 minutes) with 90–95 percent AR recovered. Under baking/brewing/boiling (BBB) (pH 5, 100 °C, 60 minutes) and sterilization (pH 6, 120 °C, 20 minutes) conditions, 65–68 percent and 1.1–1.5 percent AR was recovered as parent at the end of incubation, respectively. Tetraniliprole-N-methyl-quinazolinone was the major degradation product, accounting for 27 to 30 percent AR under BBB conditions and 94 percent AR under sterilization conditions. Two other metabolites, pyrazole-5-N-methyl-amide and desamino-methyl-carboxylic acid, were also found, but these were present in lower amounts (maximum 3 percent AR)

Processing

Estimated processing factors based on total residues (parent plus tetraniliprole-N-methyl-quinazolinone) for the commodities considered at this Meeting are summarised below, together with STMR-P values. Since two dietary burdens will be estimated, one for maximum residue level estimations (parent only=P) in animal commodities and one for STMR estimations (T: total residues, including parent and

tetraniliprole-N-methyl-quinazolinone), sometimes two median values for processed feed commodities were estimated, when processing factors differed (Table 1).

Table 135 Calculated STMRs based on parent plus tetraniliprole-N-methyl-quinazolinone for processed food and feed commodities and for parent only (P) in feed commodities, where different PF were derived

Raw commodity [STMR]	Processed commodity	Individual processing factors	Mean or best estimate	STMR-P = $STMR_{RAC}$ × PF (mg/kg)

Notes:

[a] Highest value selected from limed dry pomace, wet pomace and dry pomace .

[b] Highest value of either pasteurized or raw juice.

[c] Results in highest residue in dietary burden calculation.

[f] Foliar application.

[if] In-furrow application.

Using the estimated maximum residue level of 0.5 mg/kg for oranges and applying the processing factor of 9.1 (based on parent only), the Meeting estimated a maximum residue level of 5 mg/kg for tetraniliprole in orange oil, edible.

Using the estimated maximum residue level of 0.3 mg/kg for plums and applying the processing factor of 4.1 (based on parent only), the Meeting estimated a maximum residue level of 1.5 mg/kg for tetraniliprole in prune, dried.

Using the estimated maximum residue level of 1.5 mg/kg for grapes and applying the processing factor of 1.3 (based on parent only), the Meeting estimated a maximum residue level of 2 mg/kg for tetraniliprole in dried grapes.

Using the estimated maximum residue level of 0.4 mg/kg for tomatoes and applying the processing factor of 3.5 (based on parent only), the Meeting estimated a maximum residue level of 1.5 mg/kg for tetraniliprole in tomato paste.

Residues in animal commodities

Farm animal feeding studies

The Meeting received one feeding study involving tetraniliprole in lactating cows. No poultry feeding study was submitted.

In the dairy cow feeding study, four groups of lactating Holstein cows (3 cows/group) were dosed orally once daily via capsule corresponding with a feeding rate of 0.94, 9.3, 28, or 94 ppm tetraniliprole in feed/day (dry weight) for 29 consecutive days. Milk was collected twice daily and pooled samples were taken at intervals throughout the study period. The animals were sacrificed within 3 to 8 hours after the last dose and samples of liver, kidney, muscle and fat (mesenterial, subcutaneous, and perirenal) were collected for analysis. Samples were stored frozen for up to 20 days before extraction and were analysed within 7 days for tetraniliprole, tetraniliprole-N-methyl-quinazolinone or tetraniliprole-benzylalcohol.

Tetraniliprole residues in milk above the LOQ were found in the milk samples of the animals in the three highest dose groups. Residues of parent tetraniliprole reached a plateau after approximately 7–10 days, with mean (day 7–28) levels of 0.047, 0.10 and 0.18 mg/kg at 9.3 ppm, 28 ppm and 94 ppm feeding levels, respectively.

Similar patterns were found for both metabolites, though at lower concentrations compared to parent. The mean (day 7–28) concentrations for tetraniliprole-N-methyl-quinazolinone were 0.031, 0.073, and 0.10 mg/kg, for the three highest dose groups respectively. And for tetraniliprole-benzylalcohol the mean concentrations found were 0.025, 0.048, and 0.069 mg/kg, respectively. Mean (day 7–28) total residue levels in milk were 0.10, 0.22 and 0.36 mg/kg, respectively.

At 0.94 ppm, parent tetraniliprole was only observed in the liver (0.025–0.037 mg/kg, mean 0.031 mg/kg) and tetraniliprole-N-methyl-quinazolinone was observed in fat tissues only (< 0.01–0.033 mg/kg).

Both parent and metabolite tetraniliprole-N-methyl-quinazolinone were observed in all other tissues at the three higher feeding levels (9.3, 28, and 94 ppm), whereas the benzylalcohol metabolite was only observed in liver in the mid and high dose groups (28 and 94 ppm) and kidney in the high dose group (94 ppm). The total residues below represents the sum of parent tetraniliprole + tetraniliprole-N-methyl-quinazolinone + tetraniliprole benzylalcohol.

At 9.3 ppm, the highest concentration of parent was 0.37 mg/kg in liver, 0.067 mg/kg in kidney, 0.023 mg/kg in muscle, and 0.063 mg/kg in fats. Total highest residues were 0.41 (mean 0.37) mg/kg in liver, 0.10 (mean 0.085) mg/kg in kidney, 0.043 (mean 0.041) mg/kg in muscle, 0.26 (highest mean 0.20) mg/kg in three fats. The results across the three different fat types were similar for both parent and total residues.

At 28 ppm, the highest concentration of parent was 0.87 mg/kg in liver, 0.19 mg/kg in kidney, 0.060 mg/kg in muscle, and 0.12 mg/kg in fats. Total highest residues were 0.97 (mean 0.70) mg/kg in liver, 0.27 (mean 0.19) mg/kg in kidney, 0.094 (mean 0.075) mg/kg in muscle, and 0.83 (highest mean 0.54) mg/kg in three fats.

At 94 ppm, the highest concentration of parent was 1.5 mg/kg in liver, 0.28 mg/kg in kidney, 0.090 mg/kg in muscle, and 0.22 mg/kg in fats. Total highest residues were 1.7 (mean 1.4) mg/kg in liver, 0.34 (mean 0.31) mg/kg in kidney, 0.16 (mean 0.14) mg/kg in muscle, 1.2 (highest mean 0.77) mg/kg in fats.

Farm animal dietary burden

The dietary burden was based on the intake of tetraniliprole for maximum residue estimation. An additional dietary burden calculation based on the intake of tetraniliprole + tetraniliprole-N-methyl-quinazolinone was calculated for STMR and HR estimation. Residues found in feed commodities in both supervised residue trials and field rotational crops studies and processing studies were used for dietary burden calculations (see the various tables at the appropriate sections throughout the appraisal).

Dietary burdens were calculated for beef cattle, dairy cattle, broilers and laying poultry based on feed items evaluated by the JMPR in 2022. The dietary burdens, estimated using the OECD diets listed in Appendix IX of the 2016 edition of the FAO manual, are presented in Annex 6 and summarised below.

Table 136 Estimated maximum and mean dietary burdens of farm animals

	Animal dietary burden: tetraniliprole, ppm of dry matter diet							
	United States-Canada		European Union		Australia		Japan	
	max	mean	Max	mean	max	mean	max	mean
Beef cattle	3.21	0.55	19.8	6.8	13.6	3.2	4.9	1.8
Dairy cattle	6.05	1.091	17.6	6.6	29.46❶❷	12.7	11.2	3.73
Poultry – broiler	0.015	0.015	0.026	0.026	0.014	0.014	0.012	0.012
Poultry – layer	0.015	0.015	0.47❸❹	0.077	0.014	0.014	0.013	0.013

Notes:

❶ Highest maximum beef or dairy cattle dietary burden suitable for MRL estimates for mammalian tissues.

❷ Highest maximum dairy cattle dietary burden suitable for MRL estimates for mammalian milk.

❸ Highest maximum poultry dietary burden suitable for MRL estimates for poultry tissues.

❹ Highest maximum poultry dietary burden suitable for MRL estimates for poultry eggs.

Table 137 Estimated maximum and mean dietary burdens of farm animals for STMR calculation

	Animal dietary burden: tetraniliprole + tetraniliprole-N-methyl-quinazolinone, ppm of dry matter diet							
	United States-Canada		European Union		Australia		Japan	
	max	mean	Max	mean	max	mean	max	mean
Beef cattle	3.22	0.57	19.8	6.85	13.61	3.34	5.25	1.91
Dairy cattle	6.07	1.08	17.56	6.617	29.46	12.76	11.2	3.73
Poultry – broiler	0.015	0.015	0.026	0.026	0.014	0.014	0.012	0.012
Poultry – layer	0.015	0.015	0.47	0.077	0.014	0.014	0.013	0.017

Notes:

❶ Highest mean beef or dairy cattle dietary burden suitable for STMR estimates for mammalian tissues.

❷ Highest mean dairy cattle dietary burden suitable for STMR estimates for mammalian milk.

❸ Highest mean poultry dietary burden suitable for STMR estimates for poultry tissues.

❹ Highest mean poultry burden suitable for STMR estimates for poultry eggs.

Animal commodity maximum residue levels

Cattle

For beef and dairy cattle, a maximum and mean dietary burden of 33.7 and 12 ppm were estimated. For a maximum residue level estimation, the highest residues in the tissues and the mean residues in milk (day 7–28) were calculated by taking the maximum dietary burden (33.7 ppm) and interpolation of the highest

(tissues) and mean (milk, day 7–28) residue levels (parent only) found in the individual animals in the feeding study at 28 and 94 ppm.

The STMR values for the tissues and milk were calculated from the mean dietary burden level of 12 ppm by interpolation of the mean total residue levels (parent, tetraniliprole-N-methyl-quinazolinone, and tetraniliprole-benzylalcohol) found in milk and tissues of animals dosed at 9.4 and 28 ppm.

Table 138 Residues in milk and tissues from cattle dosed with tetraniliprole in the diet

Tetraniliprole feeding study	Feed level (ppm) for milk residues	Residues (mg/kg) in milk	Feed level (ppm) for tissue residues	Residues (mg/kg)			
				Muscle	Liver	Kidney	Fat
MRL (beef or dairy cattle); parent only							
Feeding study	28	0.10	28	0.060	0.87	0.19	0.12
	94	0.18	94	0.090	1.50	0.28	0.22
Dietary burden and high residue	29.46	0.10	29.46	0.061	0.88	0.19	0.12
STMR Determination (beef or dairy cattle); parent + tetraniliprole-N-methyl-quinazolinone + tetraniliprole-benzylalcohol, expressed as tetraniliprole							
Feeding study	9.3	0.10	9.3	0.041	0.37	0.085	0.20
	28	0.22	28	0.075	0.70	0.19	0.54
Dietary burden and residue estimate	12.76	0.12	12.76	0.047	0.43	0.10	0.26

The Meeting concluded that residues > 0.01 mg/kg are expected in milk, muscle, liver, kidney and fat and estimated maximum residue levels of 0.15 mg/kg for milk, 0.1 mg/kg for meat (0.8 × 0.061 + 0.2 × 0.12= 0.728 mg/kg), 1.0 mg/kg for edible offal (based on liver), and 0.15 mg/kg for fat.

For estimating dietary exposure to total residues, calculated STMRs are: 0.12 mg/kg for milk, 0.047 mg/kg for muscle, 0.43 mg/kg for liver, 0.10 mg/kg for kidney, and 0.26 mg/kg for fat.

Poultry

For poultry a maximum (parent only) and mean (parent + tetraniliprole-N-methyl-quinazolinone) dietary burden of 0.47 and 0.077 ppm, respectively were estimated, respectively. However, no feeding study in laying hens was provided.

The laying hen metabolism studies involved administration of approximately 18 ppm tetraniliprole in the diet, which is about 36 times overdosed compared to the expected maximum dietary burden (maximum of 0.5 ppm). Scaling of the highest residue (parent+tetraniliprole-N-methyl-quinazolinone + tetraniliprole-benzylalcohol (+conjugates)) found in poultry tissues and eggs (0.12 mg eq/kg) to the maximum dietary burden would result in residues at up to a maximum of 0.0033 mg eq/kg.

Acknowledging that there might be some exposure and a feeding study is preferred, the Meeting concluded that no residues > 0.01 mg/kg are expected in eggs and poultry tissues and estimated maximum residue levels of 0.01(*) mg/kg or poultry meat, eggs, fat and edible offal as well as STMRs values of 0.01 mg/kg.

RECOMMENDATIONS

On the basis of the data obtained from supervised trials, the Meeting concluded that the residue levels listed in Annex 1 are suitable for establishing maximum residue limits and for IEDI, IESTI and GECDE assessments.

Definition of the residue for compliance with the MRL for plant commodities: *tetraniliprole*.

Definition of the residue for dietary risk assessment for plant commodities: *tetraniliprole + tetraniliprole-N-methyl-quinazolinone, expressed as tetraniliprole.*

Definition of the residue for compliance with the MRL for animal commodities: *tetraniliprole*.

Definition of the residue for dietary risk assessment for animal commodities: *tetraniliprole + tetraniliprole-N-methyl-quinazolinone + tetraniliprole-benzylalcohol, expressed as tetraniliprole.*

The residue is not fat-soluble.

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The ADI for tetraniliprole is 0–2 mg/kg bw. The International Estimated Daily Intakes (IEDIs) for tetraniliprole were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the JMPR. The results are shown in Annex 3 of the 2022 JMPR Report.

The IEDIs ranged from 0–0 percent of the maximum ADI. The Meeting concluded that long-term dietary exposure to residues of tetraniliprole from uses considered by the JMPR is unlikely to present a public health concern.

Acute dietary exposure

The 2021 JMPR decided that an ARfD for tetraniliprole was unnecessary. The Meeting therefore concluded that the acute dietary exposure to residues of tetraniliprole from the uses considered is unlikely to present a public health concern.

Threshold of toxicological concern (TTC) consideration for metabolites

At the JMPR 2021 Meeting the WHO concluded that for the metabolites T-pyrazole-5-carboxylic acid, T-N-methyl-quinazolinone-benzylalcohol, T-despyridyl-N-methyl-quinazolinone, T-pyrazole-5-amide, and T-N-methyl-quinazolinone-pyrazole-3-carboxyilic acid the TTC Cramer Class III could be applied (no indication for genotoxicity).

For the current Meeting additional information was provided to the WHO. For three metabolites T-quinazolinone, T-pyridinyl-pyrazole-5-carboxylic acid, and T-pyrazole-5-N-methyl-amide the 2022 WHO concluded that the TTC Cramer Class III could be applied (no indication for genotoxicity) for these metabolites.

The exposure based on the residue levels found in animal commodities from the goat and laying hen metabolism studies, resulted in the following maximum long-term exposures (T= tetraniliprole). It is noted that the exposure levels were not corrected for the dose levels used in the goat study (slightly under dosed) but were corrected for the dose levels used in the laying hen study (36 times over dosed):

TTC III (< µg/kg bw)

T-quinazolinone (goat)	0.11 µg/kg bw
T-pyrazole-5-carboxylic acid (goat and poultry)	0.07 µg/kg bw
T-N-methyl-quinazolinone-benzylalcohol (goat)	0.033 µg/kg bw
T-pyridinyl-pyrazole-5-carboxylic acid (goat)	0.03 µg/kg bw
T-despyridyl-N-methyl-quinazolinone (poultry)	0.03 µg/kg bw
T-pyrazole-5-N-methyl-amide (goat and poultry)	0.02 µg/kg bw
T-pyrazole-5-amide (poultry and goat liver only)	0.01 µg/kg bw
T-N-methyl-quinazolinone-pyrazole-3-carboxylic acid (goat)	0.0023 µg/kg bw

The Meeting concluded that the exposures to these metabolites are below the TTC for Cramer Class 3 compounds of 1.5 µg/kg bw/day and were unlikely to present a health concern from the uses evaluated by the current Meeting.

In addition, for a number of poultry specific metabolites no toxicity data was available. The Meeting decided these should be assessed using the TTC approach for genotoxic compounds (below the threshold of 0.0025 µg/kg bw/day).

TTC for genotoxic compounds (< 0.0025 µg/kg bw – corrected for dietary burden)

T-despyridyl (poultry)	0.00034 µg/kg bw
Tetrazole-conjugates (poultry)	0.00063 µg/kg bw
T-despyridyl-N-methyl-quinazolinone-hydroxy/ T-despyridyl-hydroxy (poultry)	0.00019 µg/kg bw
T-deschloro-desmethyl-amide (poultry)	0.00015 µg/kg bw
T-despyridyl-quinazolinone (poultry)	0.00014 µg/kg bw
T-pyrazole-5-N-methyl-amide-hydroxy (poultry)	0.000094 µg/kg bw
T--deschloro-desmethyl-amide	0.00015 µg/kg bw

The Meeting concluded that these poultry metabolites are below the TTC for genotoxic compound and were unlikely to present a health concern from the uses evaluated by the current Meeting.

Should further uses be considered in the future, these conclusions may need to be re-evaluated.

TRIFLUMURON (317)

First draft prepared by Dr H Kobayashi, Ministry of Agriculture, Forestry and Fisheries, Japan

APPRAISAL

Triflumuron is a benzoylurea insecticide. The mode of action is insect growth regulation by inhibiting the synthesis of chitin in insect larvae that are about to moult and interfering with the moulting hormone system. The IUPAC name for triflumuron is 1-(2-chlorobenzoyl)-3-[4-trifluoromethoxyphenyl]urea.

The 2019 JMPR evaluated triflumuron as a new compound and concluded that the definition of the residue compliance with the MRL for animal and plant commodities was: *triflumuron.*

The residue is fat soluble.

However, the Meeting was unable to conclude on residue definitions for dietary exposure assessment for plant and animal commodities due to concerns over potential genotoxicity of two metabolites: M01 and M04.

The current Meeting received toxicological data for M01 and M04 and concluded that these compounds could be assessed using the threshold of the Cramer Class III of 1.5 ug/kg bw/day.

Definition of the residue

Plant commodities

The 2019 JMPR considered the plant metabolism studies on apple, tomato, soya bean and potato.

In deciding which compounds should be included in the residue definition for dietary risk assessment, the Meeting noted that no metabolites exceeded 10 percent TRR or 0.01 mg eq/kg in the metabolism studies on apples and tomatoes. In the metabolism study on soya bean, M02 and M07 exceeded 10 percent TRR and 0.01 mg eq/kg after acid hydrolysis of the unextracted residue. In the plant metabolism study on potatoes, M02 exceeded 10 percent TRR and 0.01 mg/kg after acid hydrolysis of the unextracted residue.

For M02, similar toxicity to parent triflumuron was assumed and the ADI for triflumuron (0–0.008 mg/kg bw) should apply. The 2019 JMPR concluded that M02 (free and conjugated) should be included in the residue definition.

For M07, the Meeting established a separate ADI of 0–0.02 mg/kg bw and ARfD of 0.02 mg/kg bw to be applicable. The Meeting concluded that M07 (free and conjugate) should be included in the residue definition. The 2019 JMPR also noted that increase of M07 and M08 during processing was not necessary to be considered.

In conclusion, the residue definition for plant commodities for dietary risk assessment should be sum of triflumuron and M02 (expressed as triflumuron), and M07 (assessed separately).

Animal commodities

The 2019 JMPR considered the animal metabolism studies on lactating goat and laying hen.

In deciding which compounds should be included in the residue definition for risk assessment, the Meeting noted that among the animal commodities tested, the residues that exceeded 10 percent TRR and 0.01 mg eq/kg were: in lactating goat, M03 and M04 (free and conjugated) in kidneys, and in laying hens, M02 in kidneys.

The 2019 JMPR concluded that it was not necessary to include M02 and M03 in the residue definition for animal products for dietary risk assessment. The current Meeting concluded that M04 could be assessed using the threshold of the Cramer Class III of 1.5 ug/kg bw/day. Therefore, the residue definition for animal commodities for dietary risk assessment should be triflumuron.

Conclusion

The Meeting concluded that residue definition for triflumuron should be as follows:

Definition of the residue for compliance with MRL for plant and animal commodities: *triflumuron*

Definition of the residue for dietary risk assessment for plant commodities: *sum of triflumuron and M02 (expressed as triflumuron), and M07* (assessed separately).

Definition of the residue for dietary risk assessment for animal commodities: *triflumuron*

Results of supervised residue trials on crops

The 2019 Meeting noted that M02 (free and conjugated) and M07 (free and conjugated) were not analysed in the supervised trials and decided to estimate these concentrations using the following conversion factors derived from metabolism study:

- Concentration of M02 (free and conjugate) in soya bean: 2.1 times (0.064 mg eq/kg/ 0.030 mg eq/kg) higher than parent triflumuron (expressed as triflumuron);
- Concentration of M07 (free and conjugated) in soya bean: 2.5 times (0.10 mg eq/kg/ 0.040 mg eq/kg) higher than parent (expressed as triflumuron). Considering the ratio of molecular weight (191.2/358.7), the concentration of M07 expressed as the compound should be calculated as ×1.4 of triflumuron.

Soya bean

The critical GAP for triflumuron on soya bean in Colombia is two applications at 0.077 kg ai/ha with a minimum interval between sprays of 15 days and a PHI of 21 days. In trials matching the Colombian GAP, residues of triflumuron in soya beans were (n=9): < 0.01 (3), 0.011, 0.014 (2), 0.048, 0.051 and 0.055 mg/kg.

The Meeting estimated a maximum residue level of 0.1 mg/kg.

The Meeting estimated STMR for triflumuron+M02 of 0.043 mg/kg ((1+2.1) × 0.014) and for M07 of 0.020 mg/kg (1.4 × 0.014).

Residues in animal commodities

Animal commodity maximum residue levels

Cattle

The 2019 Meeting noted that no residues were detected in milk at 2× the dietary burden for dairy cattle or in tissues at the approximate dietary burden for beef cattle. The Meeting estimated maximum residue levels of 0.01(*) mg/kg for milks, 0.05(*) mg/kg for mammalian offal, 0.1(*)(fat) for meat, mammalian and 0.1(*) mg/kg for mammalian fat.

The current Meeting estimated STMRs of 0 mg/kg for milks, 0.05 mg/kg for mammalian offal, 0.1 mg/kg for meat, mammalian and 0.1 mg/kg for mammalian fat.

Poultry

Table 1 Maximum residue levels of triflumuron in poultry commodities

	Feed Level (ppm) for eggs residues	Triflumuron (mg /kg) in eggs	Feed Level (ppm) for tissue residues	Triflumuron (mg /kg)			
				Muscle	Liver	Kidney	Fat
HR Determination (broiler or laying hen)							
Metabolism Study	100	0.57	100	0.73	6.2	1.8	26
Dietary burden and estimate of highest residue	1.5	0.0085	1.5	0.011	0.093	0.027	0.39
Dietary burden and estimate of STMR residue	1.5	0.0085	1.5	0.011	0.093	0.027	0.39

The Meeting noted that no feeding study for laying hen was available. The Meeting considered the metabolism study where hens were administered triflumuron for 5 days at rates 67× the estimated dietary burdens. Noting the magnitude of the estimated residues and the large difference in the feeding level used in the metabolism study compared to the dietary burden, the Meeting decided that the metabolism study could not be used to estimate maximum residue levels with confidence.

RECOMMENDATIONS

On the basis of the data from supervised trials the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessment.

Definition of the residue for compliance with MRL for plant and animal commodities: *triflumuron.*

Definition of the residue for dietary risk assessment for plant commodities: *sum of triflumuron and 2-chlorobenzoic acid (M02), expressed as triflumuron and 4-trifluoromethoxyaniline (M07)* assessed separately.

Definition of the residue for dietary risk assessment for animal commodities: *triflumuron.*

The residue is fat-soluble.

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The ADIs for triflumuron (triflumuron+M02) and M07 are 0–0.008 and 0–0.02 mg/kg bw, respectively. The International Estimated Daily Intakes (IEDIs) were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the current and earlier JMPR. The results are shown in Annex 3 of the 2022 JMPR Report.

The IEDIs ranged from 0–4 percent of the maximum ADI for sum of triflumuron and 2-chlorobenzoic acid (M02), and was 0 percent of the maximum ADI for 4-trifluoromethoxyaniline (M07).

The Meeting concluded that long-term dietary exposure to residues of triflumuron from uses considered by the JMPR is unlikely to present a public health concern.

Acute dietary exposure

The ARfD for triflumuron and 2-chlorobenzoic acid (M02) is not necessary.

The ARfD for 4-trifluoromethoxyaniline (M07) is 0.02 mg/kg bw. The International Estimated Short Term Intake (IESTI) for M07 was calculated. The results are shown in Annex 4 to the Report.

The IESTIs for M07 from the intake of the residue evaluated by the Meeting were 0–1 percent for general population and children of the ARfD (0.02 mg/kg bw).

The Meeting concluded that acute dietary exposure from the residues of triflumuron, from uses that have been considered by the JMPR, is unlikely to present a public health concern.

Threshold of toxicological concern (TTC) consideration for metabolites

The Meeting agreed metabolites 2-chlorobenzamide (M01) and 1-(2-chloro-3-hydroxybenzoyl)-3-[4-trifluoromethoxyphenyl]urea (M04) could be assessed using the TTC approach (Cramer Class III threshold

of 1.5 µg/kg bw/d). The 2019 Meeting estimated maximum long-term exposures of 0.046 and 0.0041 µg/kg bw/d for M01 and M04, respectively. Both of the estimated exposures are below the threshold of toxicological concern for Cramer Class III compounds. The Meeting concluded that M01 and M04 were unlikely to present a dietary exposure concern from the uses.

The annual Joint Meeting of the Food and Agriculture Organization of the United Nations (FAO) Panel of Experts on Pesticide Residues in Food and the Environment and the World Health Organization (WHO) Core Assessment Group on Pesticide Residues (JMPR) was held in Rome, Italy, from 13 to 22 September. The FAO panel of experts had met in preparatory sessions from 8 to 12 September. The meeting was held in pursuance of recommendations made by previous meetings and accepted by the governing bodies of FAO and WHO that studies should be undertaken jointly by experts to evaluate possible hazards to humans arising from the occurrence of pesticide residues in foods. During the meeting the FAO Panel of Experts was responsible for reviewing pesticide use patterns (use of good agricultural practices), data on the chemistry and composition of the pesticides and methods of analysis for pesticide residues and for estimating the maximum residue levels that might occur as a result of the use of the pesticides according to good agricultural use practices. The WHO Core Assessment Group was responsible for reviewing toxicological and related data and for estimating, where possible and appropriate, acceptable daily intakes (ADIs) and acute reference doses (ARfDs) of the pesticides for humans. This report contains information on ADIs, ARfDs, maximum residue levels, and general principles for the evaluation of pesticides. The recommendations of the Joint Meeting, including further research and information, are proposed for use by Member governments of the respective agencies and other interested parties.
