Plant metabolism

Fluazaindolizine is a nematicide that is typically incorporated into the soil at planting, with additional applications to the soil shortly thereafter. Primary plant metabolism studies were conducted with [^{14}C]-fluazaindolizine in tomato, carrot, potato, soya bean, and sugar cane and provided examples of metabolism in several crop groups including fruit/fruiting vegetables, root/tuber, oil seed and grass crops.

	[phenyl-^{14}C(U)]fluazaindolizine or [Ph-^{14}C]-fluazaindolizine)	[imidazo[1,2-a]pyridine-5,8a-^{14}C]fluazaindolizine or [IP-5,8a-^{14}C]-fluazaindolizine)

The protocol for analysis of samples was similar across the plant metabolism studies using phenyl and/or imidazo ^{14}C-labelled fluazaindolizine.Samples were homogenised (milled) with dry ice, and total radioactive residues (TRR) determined. Portions of milled samples were extracted with methanol:water (7:3) and the extracts concentrated under a stream of nitrogen or using a rotary evaporator. For carrot and potato extracts, volatile metabolites evaporated during the concentration step were trapped by passing sequentially through an acetone/dry ice cold trap and a methanol:water (7:3) trap. The unextracted radioactivity in the post-extracted solids (PES) was determined by combustion analysis. Extracts containing ≥0.010 mg eq/kg) were analysed by liquid chromatography.

Endogenous materials in the concentrated methanol extracts were removed from the samples by solid phase extraction (SPE). The concentrated extracts were loaded onto a Varian Bond Elut C18 extraction cartridge preconditioned with acetonitrile followed by 10 mM ammonium acetate. Sample was then eluted with acetonitrile:10 mM ammonium acetate (7:3). The elutes were then concentrated to 100 percent aqueous prior to loading onto Waters Oasis HLB cartridges, washed with 10 mM ammonium acetate, before being eluted with acetonitrile:10 mM ammonium acetate (9:1) followed by 100 percent acetonitrile.

Conjugates in selected extracts were hydrolysed using 1M HCl at 80°C overnight to determine the core fluazaindolizne-related structure of various conjugates (exocon). Selected extracts from tomato fruit from plants grown in soil treated with [IP-5,8a-^{14}C]fluazaindolizine were also incubated in a β-glucosidase solution in pH 5 acetate buffer for *ca* 48 hrs at *ca.* 37 ºC.

PES from selected soya bean and carrot samples were dried under ambient conditions, rehydrated and with water prior to extraction with acetonitrile:water (1:1) at 40 °C/ultrasonication, followed by sequential treatment with Driselase (cell degrading enzyme mix containing cellulase, laminarinase, xylanase) in acetate buffer (37 °C, pH 4.6, 24 hours), 0.1 M HCl (50–60 °C, 6 hours), 1.3 M HCl (80 °C, 20 hours) and 0.1 M NaOH (80 °C, 4 hours). PES from selected sugarcane samples were further extracted with acetonitrile:water (1:1), water, Driselase and 0.1 M HCl.

Identification of the principal ^{14}C-residues was accomplished by HPLC and LC-MS with reference to authenticated putative metabolite standards where available. Fluazaindolizine and IN-F4106, IN-UGA20, IN-TUT81, IN-UNS90 (IN-TQD54), IN-R3Z85, IN-RUS03, IN-REG72, IN-QEK31, IN-RYC33, IN-R2W56, IN-UDH13, IN-A5760 and IN-QZY47 were confirmed by comparison of their retention times and where concentrations permitted, accurate mass determination, chlorine isotopic pattern and mass spectral fragments (MS/MS) to authentic synthesised standards. Chiral analysis was carried out on a number of metabolites (IN-RSU03, IN-QZY47, IN-UNS90).

Tomato

Hobbs et al. (2017; DuPont-34946) investigated the metabolic fate of [Ph-^{14}C(U)]-fluazaindolizine and [IP-5,8a-^{14}C]-fluazaindolizine in glasshouse grown tomatoes (cv Red Alert). Tomato plants were transplanted into sandy loam soil (pH 6.0, percent OM 5.1, 67 percent sand, 17 percent silt, 16 percent clay, CEC 15 meq/100g) approximately 2 hours after a soil drench application with an SC formulation of [Ph-^{14}C]- or [IP-5,8a-14C]fluazaindolizine, at a nominal application rate of 1.5 kg ai/ha. A further application at a nominal application rate of 0.5 kg ai/ha was made 30 days after the initial application. The total achieved treatment rates were 1.93 kg ai/ha and 1.92 kg ai/ha for the [Ph-^{14}C] and [IP-5,8a-^{14}C] labels, respectively.

Red Alert is an indeterminate tomato variety, therefore, red ripe fruit were available for sampling at various times during the growing period between 71 days (41 days after application 2 41DAA2, BBCH 82) and 92 days (62DAA2, BBCH 89) after transplanting of the seedlings. Foliage was taken for analysis 60 days after transplant (30DAA2). Fruit and foliage were taken for analysis 71, 80 and 92 days after transplanting and corresponded to an early ripe sample (41DAA2), a medium ripe sample (50DAA2) and a full ripe sample (62DAA2). Samples were kept under frozen storage (*ca.* -20 °C) until analysis. Plant samples were generally extracted within 42 days (fruit) or 195 days (foliage) of harvest and the extracts were stored for no more than 38 days before initial chromatography. A selected sample from the [Ph-^{14}C]-fluazaindolizine experiment (62DAA2 fruit and foliage), as well as a selected sample from the [IP-5,8a-^{14}C]-fluazaindolizine experiment (62DAA2 fruit and foliage) were re-extracted and profiled to demonstrate stability of the residue in the stored samples. The profile remained the same for at least 53 months for fruit and 39 months for foliage for both radiolabels.

TRR in tomato fruit from the [Ph-^{14}C]-fluazaindolizine experiment fluctuated from 0.070 mg eq/kg at 41DAA2 to 0.079 and 0.066 mg eq/kg at the 50DAA2 and 62DAA2 sampling intervals, respectively while TRR in foliage increased from 2.344 mg eq/kg at the 30DAA2 to 5.743 mg eq/kg at 50DAA2 sampling before declining to 1.857 mg eq/kg at 62DAA2 (Table 1).

TRR in tomato fruit from the [IP-5,8a-^{14}C]-fluazaindolizine experiment increased from 0.029 mg eq/kg at 41DAA2 and 50DAA2 sampling intervals to 0.037 at 62DAA2, while the foliage fluctuated from 0.596, 0.577, 0.919 and 0.438 mg eq/kg respectively at the same intervals (Table 1).

The extractability of ^{14}C with methanol:water was good (80–98 percent TRR).

Table 1 TRR (mg eq/kg) in tomato plant matrices following two applications of [^{14}C]-fluazaindolizine

Days after planting	Sample	[Ph-^{14}C]-fluazaindolizine		[IP-5,8a-^{14}C]-fluazaindolizine	
		Fruit	Foliage	Fruit	Foliage
60	30DAA2	NA	2.344	NA	0.596
71	41DAA2	0.070	4.232	0.029	0.577
80	50DAA2	0.079	5.743	0.029	0.919
92	62DAA2	0.066	1.857	0.037	0.438

Identification and characterisation of radioactive residues [Ph-^{14}C]fluazaindolizine

Tomato fruit

Parent fluazaindolizine was detected only in the 62DAA2 tomato fruit sample, at 0.4 percent TRR (<0.001 mg/kg) (Table 2). The principal residue extracted from the fruit samples was the glucose conjugate of IN-A5760 (IN-R3Z85), which constituted 45.0 percent TRR (0.032 mg eq/kg) in the 41DAA2 fruit sample, rising to 48.6 percent TRR (0.038 mg eq/kg) in the 50DAA2 fruit, and decreasing to 24.4 percent TRR (0.016 mg eq/kg) in the 62DAA2 fruit sample with a corresponding increase in unconjugated IN-A5760, 13.0 percent TRR (0.009 mg eq/kg).

The glucose conjugate of IN-RSU03 was the second most abundant metabolite present within [Ph-^{14}C]-treated tomato fruit, constituting 20.3 and 19.7 percent TRR (0.014 and 0.016 mg eq/kg) in the 41DAA2 and 50DAA2 fruit samples respectively, and to 22.6 percent TRR (0.015 mg eq/kg) in the 62DAA2 fruit.

Two glucose conjugates of IN-UNS90, were present mostly in the 41DAA2 to 50DAA2 tomato fruit samples (up to 12.7 percent TRR, 0.010 mg eq/kg), with lesser amounts found in the 62DAA2 sample (<1 percent TRR, <0.001 mg eq/kg). In the fruit, the major glucose conjugate of IN-UNS90 was proposed to be conjugated *via* the 2-hydroxy propanoic acid moiety. IN-F4106 was present between 2.6 and 7.9 percent TRR (0.002–0.005 mg eq/kg) in the various fruit samples.

Other identified metabolites in the fruit included IN-RSU03, IN-REG72 and IN-UNS90 (each ≤ 2.0 percent TRR, ≤ 0.002 mg eq/kg). Up to 16 minor unknown metabolites were found in the mature fruit, representing an aggregate total of 22.5 percent TRR and 0.013 mg eq/kg. No individual unknown metabolite was greater than 2.6 percent TRR or 0.002 mg eq/kg.

Analysis of acid-hydrolysed tomato fruit extracts from the 62DAA2 [Ph-^{14}C]-experiment demonstrated hydrolysis of IN-R3Z85 and the glucose conjugates of IN-UNS90 and IN-RSU03, primarily to IN-A5760, IN-RSU03, and IN-UNS90.

- Not detected in this sample.

Tomato foliage

The majority of residues were extracted from the [Ph-^{14}C] tomato foliage by initial methanol:water extractions, 92.6–94 percent TRR (Table 3). Unextracted residues accounted for 6.0–7.4 percent TRR.

Fluazaindolizine was detected in the 41DAA2 foliage (0.5 percent TRR) but not at later harvest points. More than 10 metabolites were found in the foliage and their proportion of ^{14}C remained relatively constant. The principal metabolite was the glucose conjugate of IN-RSU03 (46.7 percent–53.9 percent TRR). Other metabolites included IN-QZY47 (5.7–7.4 percent TRR), IN-A5760 (6.0–6.4 percent TRR) and its glucose conjugate IN-R3Z85 (4.5–6.0 percent TRR), the malonic acid conjugate of IN-QZY47 (IN-TUT81, 2.7–3.1 percent TRR), IN-RSU03 (3.2–5.0 percent TRR) and IN-F4106 (3.9–4.9 percent TRR) together with IN-UNS90 (1.8–2.1 percent TRR) and two glucose conjugates of IN-UNS90, one proposed to be conjugated *via* the phenol (3.2 to 4.0 percent) and the other conjugated *via* the 2-hydroxy propanoic acid moiety (2.9–3.0 percent TRR).

Acid hydrolysis of tomato foliage extracts from the 50DAA2 [Ph-^{14}C]-experiment resulted in hydrolysis of the glucose conjugates of IN-UNS90, IN-RSU03 and IN-R3Z85 with the resulting chromatogram showing enhancement of unconjugated metabolites, free IN-A5760, IN-RSU03, and IN-UNS90 (Table 3).

The observation of the methyl ester of IN-RSU03 (8.4 percent TRR) observed in the acid hydrolysed foliage extract is proposed to be due to the incomplete removal of methanol prior to the hydrolysis step resulting in the esterification of IN-RSU03 and is therefore an artifact of the analysis protocol.

Identification and characterisation of radioactive residues [IP-5,8a-^{14}C]fluazaindolizine

Tomato fruit

Extractability of ^{14}C in fruit using methanol:water was good (92.8–95.6 percent TRR). Fluazaindolizine was detected in small amounts in both the 41DAA2 and 50DAA2 tomato fruit samples, at 0.8 and 0.9 percent TRR (<0.001 mg/kg), respectively (Table 4). The principal residue was the glucose conjugate of IN-QEK31 (identified as IN-UGA20), which constituted 39.9–51.4 percent TRR. Free IN-QEK31 became increasingly conjugated over time as it decreased as a proportion of the ^{14}C from 14.3 percent TRR in the 41DAA2 fruit sample to 4.5 percent and 7.1 percent TRR in the tomato fruit sampled 50DAA2 and 62DAA2, respectively. Other identified metabolites included inositol conjugate of IN-QEK31 (IN-UHD13), methyl ester of IN-QEK31 (IN–R2W56), IN-RYC33, and IN-REG72 (all ≤ 2.3 percent TRR) (Table 4).

Acid hydrolysis of 50DAA2 tomato fruit extracts resulted in conversion/hydrolysis of fluazaindolizine, IN-REG72, IN-UHD13, and IN-UGA20, IN-RYC33 and methyl ester of IN-QEK31 (IN-R2W56) to IN-QEK31 (Table 4). Treatment of a sample of the 50DAA2 tomato fruit extract with β-glucosidase resulted in hydrolysis of IN-UHD13 and IN-UGA20 with resulting increase in IN-QEK31.

Notes:

[A] Unidentified consisting of five components. None >9.1 percent TRR, 0.003 mg eq/kg.

[B] Unidentified consisting of seven components. None >8.4 percent TRR, 0.002 mg eq/kg.

[C] Unidentified consisting of seven components. None >3.9 percent TRR, 0.004 mg eq/kg.

- Not detected in this sample.

Tomato foliage

The majority of residues were extracted from the [IP-5,8a-^{14}C] tomato foliage by initial extractions, 80.2-83.9 percent TRR (0.366–0.770 mg eq/kg: Table 15). The remaining unextracted residues determined by oxidative combustion accounted for 16.1–19.8 percent TRR (0.071–0.148 mg equiv/kg).

Fluazaindolizine was detected in all sample timepoints, at 2.7–3.7 percent TRR (Table 5). The principal residues were IN-QEK31 (9.9–15.8 percent TRR) and its glucose conjugate IN-UGA20, (13.6–14.0 percent TRR). Other identified metabolites in foliage included inositol conjugate of IN-QEK31 (IN-UHD13), methyl ester of IN-QEK31 (IN-R2W56), IN-RYC33, and IN-REG72 (all ≤ 5.7 percent TRR, ≤ 0.049 mg eq/kg).

Analysis of acid hydrolysed 50DAA2 tomato foliage extracts from the [IP-5,8a-^{14}C]-labelled experiment demonstrated hydrolysis of fluazaindolizine, IN-UGA20 (and the various rearranged glucose conjugates of IN-QEK31) and nearly all of the various unidentified metabolites to IN-QEK31. Nearly all unidentified metabolites were conjugated through the ester linkage (Table 5). Chiral HPLC determined IN-RSU03 was present as the *R*-enantiomer (IN-TMQ01). A proposed metabolic pathway of fluazaindolizine in tomato is shown in Figure 1.

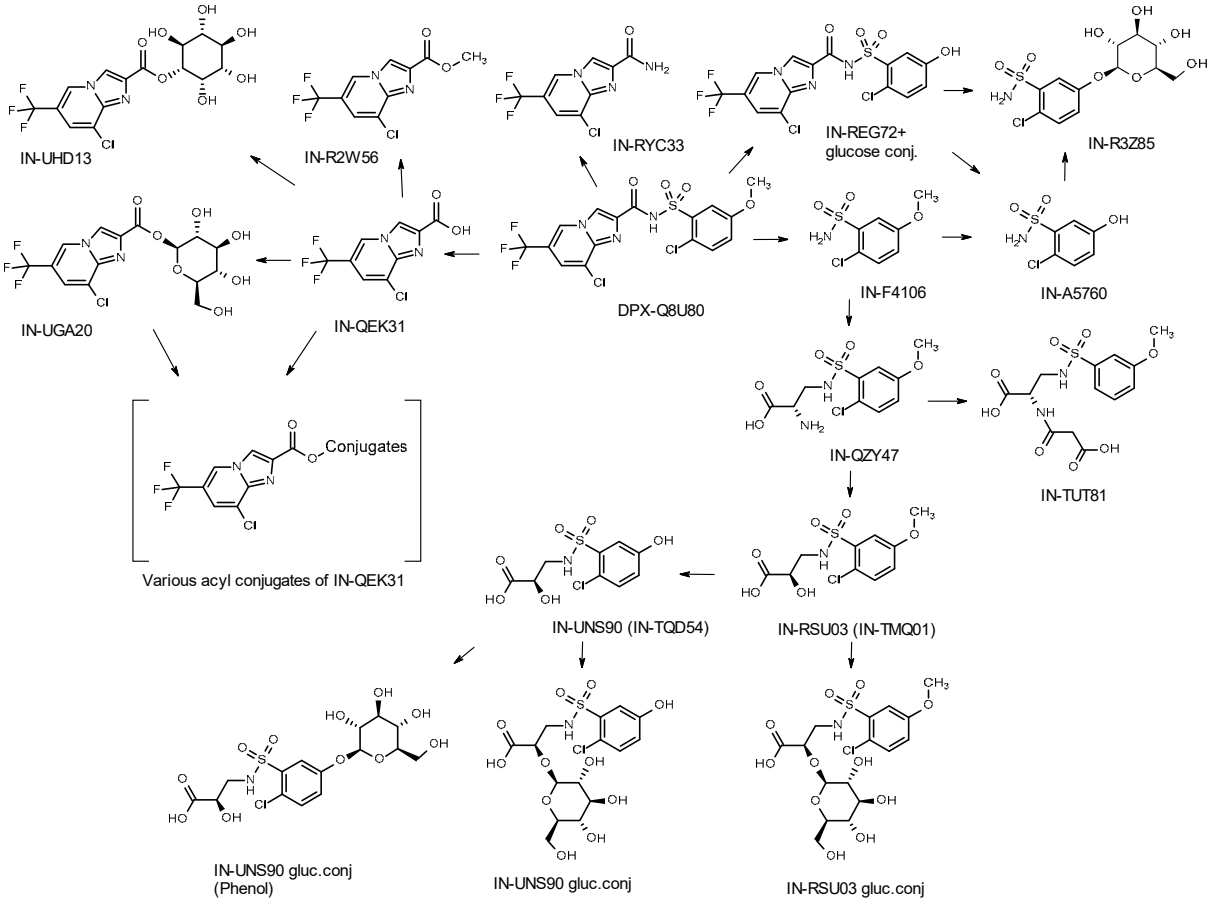

Figure 1 Proposed metabolic pathway of fluazaindolizine in tomato plant

In summary, fluazaindolizine is taken up by tomato plants and found in fruit and foliage. Fluazaindolizine is *O*-demethylated to form IN-REG72. Fluazaindolizine and IN-REG72 are hydrolysed at the amide bond resulting in IN-F4106 (and/or IN-A5760 and its glucose conjugate), and IN-QEK31. IN-F4106 is conjugated with endogenous serine to form IN-QZY47. The free amino moiety of IN-QZY47 is conjugated with malonic acid to form IN-TUT81which is found only in foliage. IN-QZY47 is mostly deaminated to the lactic acid derivative IN-RSU03, which was found only as the *R*-enantiomer, IN-TMQ01.

IN-RSU03 can undergo *O*-demethylation to form IN-UNS90 (*R*-enantiomer designated as IN-TQD54) which appears to be mostly found in the conjugated form.

IN-QEK31 is conjugated to glucose *via* an ester bond to form IN-UGA20. Some degree of acyl-migration of the glucose ester is observed. A glycerol glucuronide conjugate of IN-QEK31 was also identified as well. More complex carbohydrate esters of IN-QEK31 are proposed to form as numerous radioactive peaks are found with retention characteristics consistent with glucose or inositol (IN-UHD13) esters. The methyl ester of IN-QEK31 (IN-R2W56) was formed to a small extent (≤ 3.1 percent TRR) and could be an artefact of the extraction methodology (using methanol in the procedure).

IN-RYC33, is found in fruit and foliage, is formed either by hydrolysis of fluazaindolizine at the sulfonamide bond in the plant or taken up directly as a metabolite from the soil. All of the metabolites containing the imidazo-pyridine rings are readily hydrolysed to IN-QEK31 under acidic conditions.

Soya beans

The metabolic fate of [Ph-^{14}C(U)]-fluazaindolizine and [IP -5,8a-^{14}C]-fluazaindolizine in soya beans was studied by Begley and Hobbs (2016 DuPont-34948).

Soya bean seeds (cv Elena) were sown into treated sandy loam soil (pH 7.3, percentOM 2.4, 65 percent sand, 20 percent silt, 15 percent clay, CEC 10 meq/100g) *ca.* 1 hour after a soil drench application of an SC formulation of [Ph-^{14}C]-fluazaindolizine or [IP-5,8a-^{14}C]-fluazaindolizine, at a nominal application rate of 1000 g ai/ha. The achieved treatment rates were 1.00 kg ai/ha for both the [Ph-^{14}C] and [IP-5,8a-^{14}C]-experiments.

Plants were taken for analysis 48, 75 and 112 days after planting and corresponded to a forage (48DAA, BBCH63), hay samples (75DAA, BBCH69) and seed (112DAA, BBCH99) at crop maturity. Samples were stored frozen until analysis and extracted, and analysed within 1 month of harvest.

Extractability of ^{14}C with methanol:water was good (78–91 percent TRR). Further sequential extraction using water, acetonitrile:water, and treatment with driselase (a cell wall degrading enzyme), 0.1M HCl, 1.3M HCl and 0.1M NaOH released a further 7.1–22.3 percent TRR.

TRR in soya bean plants from the [Ph-^{14}C]-fluazaindolizine experiment were 0.435–0.660 mg eq/kg while TRR in soya bean plants from the [IP-5,8a-^{14}C]-fluazaindolizine experiment ranged from 0.763 to 2.018 mg eq/kg (Table 6).

Table 6 TRR (mg eq/kg) in soya bean plant matrices following one application at plant of [^{14}C]fluazaindolizine

Days after planting	Sample type	[Ph-^{14}C]fluazaindolizine	[IP-5,8a-^{14}C]fluazaindolizine
48	Forage (BBCH 61)	0.435	0.763
75	Hay (BBCH 75)	0.660	1.042
112	Seed (maturity, BBCH 99)	0.271	2.018

Soya bean forage

Extractability of ^{14}C with methanol:water in the [Ph-^{14}C] experiment soya bean forage was good (90.1 percent TRR; Table 7). Further ^{14}C was released following additional treatments (7.2 percent TRR).

Fluazaindolizine accounted for 7.2 percent TRR in extracts (7.0 percent TRR in methanol:water; 0.2 percent TRR further treatments). The principal component of the ^{14}C in the extracts in [Ph-^{14}C] experiment was a malonyl conjugate of IN-QZY47 (IN-TUT81) at 56.5 percent TRR. Other identified metabolites included IN-QZY47 and IN-F4106 (both ≤4.9 percent TRR) with IN-REG72 and IN-RSU03 (IN-

TMQ01) as low level metabolites accounting for ≤1 percent TRR. A polar metabolite accounting for 4.2 percent TRR was tentatively assigned as a conjugate of IN-UJV12. Multiple unidentified metabolites were also detected accounting for an aggregate total of 17.6 percent TRR but each individually ≤ 2.6 percent TRR, ≤ 0.011 mg eq/kg.

Following hydrolysis of the methanol:water forage extract, the malonyl conjugate (IN-TUT81) was hydrolysed to IN-QZY47 (Table 7). An increase in IN-F4106 and IN-A5760 was also observed after hydrolysis. While some formation of IN-F4106 can be attributed to the hydrolysis of fluazaindolizine and IN-REG72, it is apparent that several other minor unidentified metabolites or conjugates are also cleaved under these conditions and released as IN-F4106 and IN-A5760. Small amounts of IN-RSU03 (IN-TMQ01) and IN-UJV12 are also released by acid hydrolysis.

Soya bean hay

Extractability of ^{14}C in hay with methanol:water was good in the [Ph-^{14}C] experiment (90.6 percent TRR Table 7). A further 7.0 percent TRR was released with additional treatments.

Fluazaindolizine accounted for 6.1 percent TRR and was found only in the hay methanol:water extracts. The principal extracted residue in the [Ph-^{14}C] experiment was a malonyl conjugate of IN-QZY47 (IN-TUT81) accounting for 56.4 percent TRR. Other identified metabolites included IN-QZY47 and IN-F4106 (both ≤ 5.3 percent TRR, ≤ 0.034 mg eq/kg) and IN-REG72 and IN-RSU03 (IN-TMQ01) both at less than 1.2 percent TRR. A polar metabolite was observed accounting for 2.4 percent TRR and was tentatively assigned as a conjugate of IN-UJV12. Multiple unidentified metabolites were also detected; all ≤ 3.4 percent TRR, ≤ 0.022 mg eq/kg.

Following hydrolysis of the hay extract the malonyl conjugate (IN-TUT81) was hydrolysed to IN-QZY47. An increase in IN-F4106 and IN-A5760 was also observed after hydrolysis. While some formation of IN-F4106 and IN-A5760 could be attributed to the hydrolysis of fluazaindolizine and IN-REG72, it was apparent that minor other unidentified metabolites or conjugates were also cleaved under these conditions and liberated mostly as IN-F4106 (17.8 percent TRR) with small amounts of IN-A5760 (3.5 percent TRR). A polar metabolite with retention time of approximately 8.5 minutes was mostly hydrolysed to IN-UJV12.

Soya bean seed

Extractability of ^{14}C in seed with methanol:water in the [Ph-^{14}C] experiment was good with 80.6 percent TRR recovered (Table 7). A further 17.4 percent TRR was released using additional treatments.

The principal extracted residue identified in seed in the [Ph-^{14}C]fluazaindolizine experiment was parent fluazaindolizine (46.2 percent TRR of which 45.0 percent TRR in the methanol:water extract). A malonyl conjugate of IN-QZY47 (IN-TUT81) was the only other residue exceeding 10 percent TRR (15.3 percent TRR). Other metabolites were IN-REG72 (9.0 percent TRR) and IN-F4106 (1.9 percent TRR). Multiple unidentified metabolites were detected; none >1.3 percent TRR.

Following hydrolysis of the seed methanol water extract, mostly IN-F4106 was formed which was mostly attributed to the hydrolysis of fluazaindolizine (Table 7). The malonyl conjugate (IN-TUT81) was hydrolysed to IN-QZY47. Other hydrolysis products including IN-A5760 (6.0 percent TRR, originating from IN-REG72) as well as small amounts of IN-UJV12 from hydrolysis of more complex conjugates were observed. As the increase in IN-F4106 was slightly more than what was expected from fluazaindolizine, it is apparent that minor other unidentified metabolites or conjugates were also cleaved under HCl hydrolysis conditions and released as IN-F4106.

Table 7 Identification of TRR (% TRR) in various soya bean extracts and fractions after application of [Ph-^{14}C]-fluazaindolizine

Identification and characterisation of radioactive residues [IP-5,8a-^{14}C]fluazaindolizine

Soya bean forage

Extractability of ^{14}C in forage from the [IP-5,8a-^{14}C] experiment using methanol:water was good (89.5 percent TRR; Table 8). Further treatments released an additional 8.0 percent TRR.

Fluazaindolizine was exclusively extracted from the forage into the methanol:water extract, accounting for 6.9 percent TRR (0.053 mg/kg). The principal extracted residue identified was IN-QEK31 accounting for 40.5 percent TRR (0.309 mg/kg) in the methanol water extract, with a small amount (1.4 percent TRR) in the acetonitrile extract for a total of 41.9 percent TRR (0.320 mg/kg). A glycerol glucuronide conjugate of IN-QEK31 accounting for 9.5 percent TRR (0.072 mg/kg) was identified as a major metabolite by LC-MS. IN-UGA20 and acyl migrated glucose ester isomers accounted for 11.8 percent TRR (0.092 mg eq/kg), and were found as several closely eluting peaks in the radiochromatogram. IN-UHD13, an inositol conjugate of IN-QEK31, was tentatively identified as a minor metabolite (1.5 percent TRR, 0.012 mg eq/kg) based on similar retention time to the reference standard. Other identified metabolites include, IN-RYC33 (5.7 percent TRR, 0.043 mg eq/kg) and minor metabolites IN-REG72, and methyl ester of IN-QEK31 (IN-R2W56) (both ≤ 1.7 percent TRR, ≤ 0.013 mg eq/kg). Multiple unidentified metabolites were also detected; all ≤ 2.0 percent TRR, ≤ 0.015 mg eq/kg. A minor volatile metabolite was trapped during the concentration of forage extracts and accounted for 0.6 percent TRR, 0.004 mg eq/kg. This component was thought to be IN-VM862, based on its chromatographic behaviour, and analysis of a volatile metabolite formed in the crop rotation study (DuPont-34945, Revision No. 1).

Acid hydrolysis of forage samples showed that the various conjugates of IN-QEK31, as well as IN-REG72, IN-RYC33, methyl ester of IN-QEK31 (IN-R2W56) and fluazaindolizine, readily hydrolysed to IN-QEK31 using 1N HCl (Table 8). The majority of the other minor unidentified metabolites were also hydrolysed to IN-QEK31 using 1N HCl.

Soya bean hay

Extractability of ^{14}C in hay with methanol:water in the [IP-5,8a-^{14}C] experiment was good with 86.6 percent TRR recovered (Table 8). Further treatments released an additional 10.3 percent TRR with 3.1 percent TRR remaining in the solids.

Fluazaindolizine was exclusively extracted in [IP-5,8a-^{14}C] hay methanol:water extracts at low concentrations (4.8 percent TRR). The principle extractable residue identified was IN-QEK31 accounting for 39.0 percent TRR with the majority extracted into methanol:water (36.2 percent TRR). A glycerol glucuronide conjugate of IN-QEK31 was identified accounting for 7.5 percent TRR. IN-UHD13 an inositol conjugate of IN-QEK31 was tentatively assigned to 1.7 percent TRR. The multiplex of peaks associated with IN-UGA20 (the glucose conjugate of IN-QEK31) accounted for 14.8 percent TRR. IN-UHD13, IN-REG72, IN-RYC33 and methyl ester of IN-QEK31 (IN-R2W56) were also identified at low levels (≤ 3.2 percent TRR, ≤ 0.033 mg eq/kg).

Multiple unidentified metabolites were also detected in the hay, (≤ 2.3 percent TRR, ≤ 0.024 mg eq/kg). The majority of the minor unidentified metabolites as well as glycerol glucuronide conjugate of IN-QEK31, IN-UGA20 and IN-UHD13 were hydrolysed to IN-QEK31 using 1M HCl (Table 8).

Soya bean seed

Extractability of ^{14}C in seed with methanol:water in the [IP-5,8a-^{14}C] experiment was good with 77.7 percent TRR recovered (Table 8). A further 22.3 percent TRR was released using additional treatments.

Parent molecule fluazaindolizine was found primarily in the methanol water fraction with a trace amount in the further extracts and accounted for a total of 8.3 percent TRR (0.167 mg/kg). The principle extractable residue identified was IN-QEK31 accounting for 65.8 percent TRR in the methanol water extract and 20.2 percent TRR in the further extracts for a total of 86.0 percent TRR (1.736 mg/kg). IN-UGA20, IN-REG72 and IN-R2W56 (≤ 1.7 percent TRR, ≤ 0.034 mg/kg), were also identified by comparison

of retention time with known reference standards. No radioactive residues were found at the HPLC retention times of IN-RYC33 in seed samples.

Sample residues were further characterised by acid hydrolysis and the major residues confirmed and identified by LC-MS analysis. Acid hydrolysis demonstrated that fluazaindolizine and nearly all of the minor components were hydrolysed to IN-QEK31, an indication that they were conjugates of this metabolite (Table 8).

Table 8 Identification of TRR (% TRR)in various soya bean extracts and fractions after application of [IP-5,8a-^{14}C]fluazaindolizine

Notes:

[A] Total unidentified metabolites consist of multiple components – none greater than 2.3 percent TRR, 0.024 mg eq/kg: most minor unknown metabolites are hydrolysed with 1M HCl to IN-QEK31

[B] Consisting of 27 components, none greater than 1.3 percent TRR (0.010 mg eq/kg).

[C] Consisting of 16 components, none greater than 4.3 percent TRR (0.045 mg eq/kg).

[D] Consisting of a single component.

[E] Data obtained from measurements that were <LOQ.

[F] Insufficient volume of tissue remained following the further extracts to analyse remaining unextractable residues. All initially identified residues from the PES were observed in the further extracts.

Chiral analysis of metabolites

Chiral HPLC determined the S-enantiomeric configuration of IN-QZY47, consistent with naturally occurring L-serine. The metabolic pathway for fluazaindolizine in soya bean plants following soil application is presented in Figure 2 and is proposed based on the metabolites identified in forage, hay, and soya bean seed. Metabolites in the figure are depicted in their free acid or free base forms.

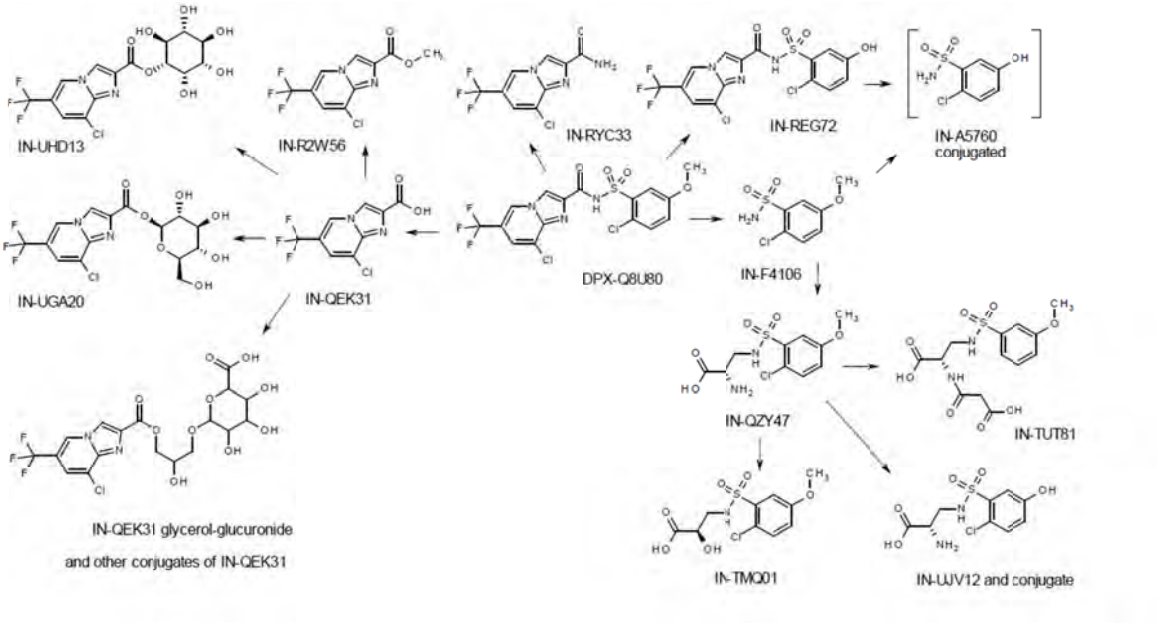

Figure 2 Proposed metabolic pathway of fluazaindolizine in soya bean plant

Carrots

The metabolic fate of [phenyl-^{14}C(U)]fluazaindolizine and [imidazo[1,2-a]pyridine-5,8a-^{14}C]fluazaindolizine in glasshouse grown carrot plants (cv. F1 Bangor) was studied by Hobbs et al. (2016 DuPont-34947).

Carrot seeds were sown into treated sandy loam soil (pH 6, percentOM 5.1, 67 percent sand, 17 percent silt, 16 percent clay, CEC 15 meq/100 g) *ca.* one hour after a soil drench application with an SC formulation of [Ph-^{14}C]fluazaindolizine or [IP-5,8a-^{14}C]fluazaindolizine, at a nominal application rate of 1500 g ai/ha. Seeds were sown in four rows approximately 10 cm apart at a depth of *ca.* 13 mm. A further application was made to the same plots 30 days after the initial application at a nominal application rate of 0.5 kg ai/ha. The total achieved treatment rates were 2.00 kg ai/ha and 1.96 kg ai/ha for the [Ph-^{14}C] and [IP-5,8a-^{14}C] labels, respectively.

Plants were taken for analysis 30, 73 and 93 days after planting and corresponded to a foliage only sample (30 days after application 1, 30DAA1; BBCH 42), an immature root and foliage sample

(43DAA2, BBCH 45) and root and foliage sample at crop maturity (63DAA2, BBCH 49). Samples were kept under frozen storage (*ca.* -20°C) until analysis.

Plant samples were generally extracted within 50 days of harvest and the extracts were stored for no more than 52 days before initial chromatography. A mature foliage sample from the [Ph-^{14}C]fluazaindolizine experiment and an immature foliage sample from the [IP-5,8a-^{14}C]fluazaindolizine experiment were re-extracted and profiled. The profiles remained qualitatively the same after 3 years storage. The results are shown in Table 9.

Table 9 TRR (mg eq/kg) in carrot plant matrices following one or two applications of [^{14}C]fluazaindolizine

Days after planting	Sample type	[Ph-^{14}C]-fluazaindolizine		[IP-5,8a-^{14}C]-fluazaindolizine	
		Foliage	Root	Foliage	Root
30	30DAA1	4.434	NS	3.169	NS
73	Immature 43DAA2	0.659	0.135	0.278	0.073
93	Mature 63DAA2	1.174	0.104	0.382	0.068

Notes:

NS = No sample available

Carrot foliage

Extractability of ^{14}C in foliage with methanol:water in the [Ph-^{14}C] experiment was good with 82.6–87.2 percent TRR recovered (Table 10). Unextracted residues in the 63DAA2 sample was subjected to further treatments released an additional 9.4 percent TRR with 4.7 percent TRR remaining in the solids.

Fluazaindolizine, found primarily in the methanol:water extracts, was identified in the early foliage (20.9 percent TRR, 0.926 mg/kg) decreasing in later samples. The principal extracted residue was IN-RSU03 increasing from 23.4 percent TRR at 30DAA1 to 51.1 percent TRR at crop maturity. Additional residues of IN-RSU03 and fluazaindolizine were released in the rehydrated: acetonitrile extracts of the mature foliage; 2.4 percent TRR and 0.2 percent TRR for IN-RSU03 and fluazaindolizine, respectively (Table 10).

Other identified metabolites were the malonyl conjugate of IN-QZY47 (IN-TUT81), glucose conjugate of IN-A5760 (IN-R3Z85), IN-QZY47, IN-F4106, IN-REG72 and IN-UNS90 (all ≤15.6 percent TRR, ≤ 0.691 mg eq/kg) as well as a malonyl conjugate of IN-RSU03 (15.5 percent TRR, 0.182 mg eq/kg), and glucose conjugates of IN-UNS90, IN-RSU03 and IN-REG72 (≤ 2.6 percent TRR, ≤ 0.042 mg eq/kg).

Multiple unidentified metabolites were also detected and accounted for an aggregate total of 2.7-5.2 percent TRR in each sample but each individually was ≤ 1.7 percent TRR (≤ 0.076 mg eq/kg).

Carrot roots

Extractability of ^{14}C in roots from the [Ph-^{14}C] experiment using methanol:water was good (92.8–92.9 percent TRR Table 10). Unextracted residues accounted for 7.1–7.2 percent TRR.

The fluazaindolizine accounted for 8.4 percent TRR in immature carrot roots decreasing to 1.7 percent TRR in mature carrot roots. The principal extracted residues were the malonyl conjugate of IN-RSU03 (35.5–40.0 percent TRR) in addition to unconjugated IN-RSU03 metabolite (15.3–21.8 percent TRR). Other identified metabolites were the malonyl conjugate of IN-QZY47 (IN-TUT81), IN-QZY47, IN-UNS90, the glucose conjugate of IN-RSU03 and a glucose conjugate of IN-UNS90 (all ≤ 25.7 percent TRR, ≤ 0.035 mg eq/kg). Multiple unidentified metabolites were also detected accounting for an aggregate total of 2.4–4.9 percent TRR in each sample but each individually was ≤ 2.6 percent TRR (≤ 0.003 mg eq/kg).

Following hydrolysis of the mature carrot root aqueous methanol extract, the malonyl conjugate and glucose conjugate of IN-RSU03 were hydrolysed to IN-RSU03 (Table 10). The malonyl conjugate of IN-QZY47 (IN-TUT81) was mostly hydrolysed to IN-QZY47, and the glucose conjugate of IN-UNS90 was hydrolysed to IN-UNS90. An increase in IN-F4106 was also observed after hydrolysis, while some formation of IN-F4106 can be attributed to the hydrolysis of fluazaindolizine, it is apparent that other minor unidentified metabolites or conjugates found in the HPLC chromatogram were also cleaved under these conditions and released as IN-F4106 (Table 10).

Notes:

DAA = days after one or two soil applications.

[A] Only found as the *R*-enantiomer IN-TMQ01.

[B] Total unidentified metabolites consist of multiple components – none greater than 2.6 percent TRR: in the roots and 1.7 percent TRR, in the foliage, several of which appear to be hydrolysed with 1M HCl to IN-F4106.

Identification and characterisation of radioactive residues [IP-5,8a-^{14}C]fluazaindolizine

Carrot foliage

Extractability of ^{14}C in foliage from the [IP-5,8a-^{14}C] experiment using methanol:water was good (67–81 percent TRR Table 11). Unextracted residues accounted for 19.9-32.9 percent TRR. Further treatment of unextracted residues from mature foliage (63DAA2) released an additional 17.7 percent TRR with 15.1 percent TRR remaining in the solids.

Fluazaindolizine in methanol:water extracts from the [IP-5,8a-^{14}C] experiment carrot foliage decreased from 40.6 percent TRR at 30DAA1 foliage to 13.4 percent TRR in the mature foliage. The major metabolite was IN-QEK31 (8.9-21.1 percent TRR), although in later samples IN-QEK31 was increasingly present in the conjugated forms (*i.e.,* the glycerol glucuronide, IN-UGA20, inositol conjugate of IN-QEK31 (IN-UHD13) plus the methylated form IN-R2W56). Other identified metabolites were the glucose conjugate of IN-REG72, IN-RYC33, and IN-VM862 (all ≤ 10.3 percent TRR, ≤ 0.328 mg eq/kg).

Additional residues of IN-QEK31 (0.9 percent TRR) and fluazaindolizine (0.5 percent TRR) were released in the acetonitrile extracts of the mature foliage.

A volatile metabolite was also detected in the immature and mature carrot foliage extracts during the concentration process, accounting for 12.7 percent and 2.4 percent TRR, respectively. This component is thought to be IN-VM862, based on its chromatographic behaviour, and analysis of a volatile metabolite formed during the growth of crops under rotational crops study (DuPont-34954).

Multiple unidentified metabolites were also detected accounting for an aggregate total of 3.5–17.5 percent TRR in each sample but each individually was ≤ 2.7 percent TRR (≤ 0.043 mg eq/kg).

Following hydrolysis of the mature carrot foliage aqueous methanol extract, fluazaindolizine, the glycerol glucuronide of IN-QEK31, the glucose conjugate of IN-REG72, glucose conjugate of IN-QEK31 (IN-UGA20), methyl ester of IN-QEK31 (IN-R2W56) and IN-RYC33 were hydrolysed to IN-QEK31. It was apparent that minor other unidentified metabolites or conjugates were also cleaved under these conditions and released as IN-QEK31 or minor unknown metabolites (Table 11).

Carrot roots

Extractability of ^{14}C in roots from the [IP-5,8a-^{14}C] experiment using methanol:water was good (86.3–89.1 percent TRR Table 11). Unextracted residues accounted for 10.9–13.7 percent TRR.

The principal extracted residue in the [IP-5,8a-^{14}C] experiment carrot roots was IN-QEK31 (53.7–66.0 percent TRR). Fluazaindolizine accounted for 11.9–12.6 percent TRR. Other identified metabolites were the glycerol glucuronide of IN-QEK31, methyl ester of IN-QEK31 (IN-R2W56), glucose conjugate of IN-QEK31 (IN-UGA20) and IN-RYC33 (≤ 3.3 percent TRR, 0.002 mg/kg). A volatile metabolite was also detected in the mature carrot root extracts during the concentration process and accounted for 3.8 percent TRR. Multiple unidentified metabolites were also detected accounting for an aggregate total of 1.4–6.1 percent TRR in each sample but each individually was ≤ 3.4 percent TRR (≤ 0.002 mg eq/kg).

Chiral analysis of metabolites

Chiral HPLC was conducted on IN-RSU03 and it was determined that only the R-enantiomer designated as IN-TMQ01 was present. As O-demethylation would not alter the chiral carbon, by analogy, only the R-enantiomer IN-TQD54 is expected in those metabolites as determined by the racemic standard IN-UNS90.

Proposed metabolic pathway of fluazaindolizine in carrots

The metabolic pathway for fluazaindolizine in carrot following soil application is presented in Figure 3 and is proposed based on the metabolites identified in foliage and roots. Metabolites in the figure are depicted as their free acid or free base forms and not as the various salt forms.

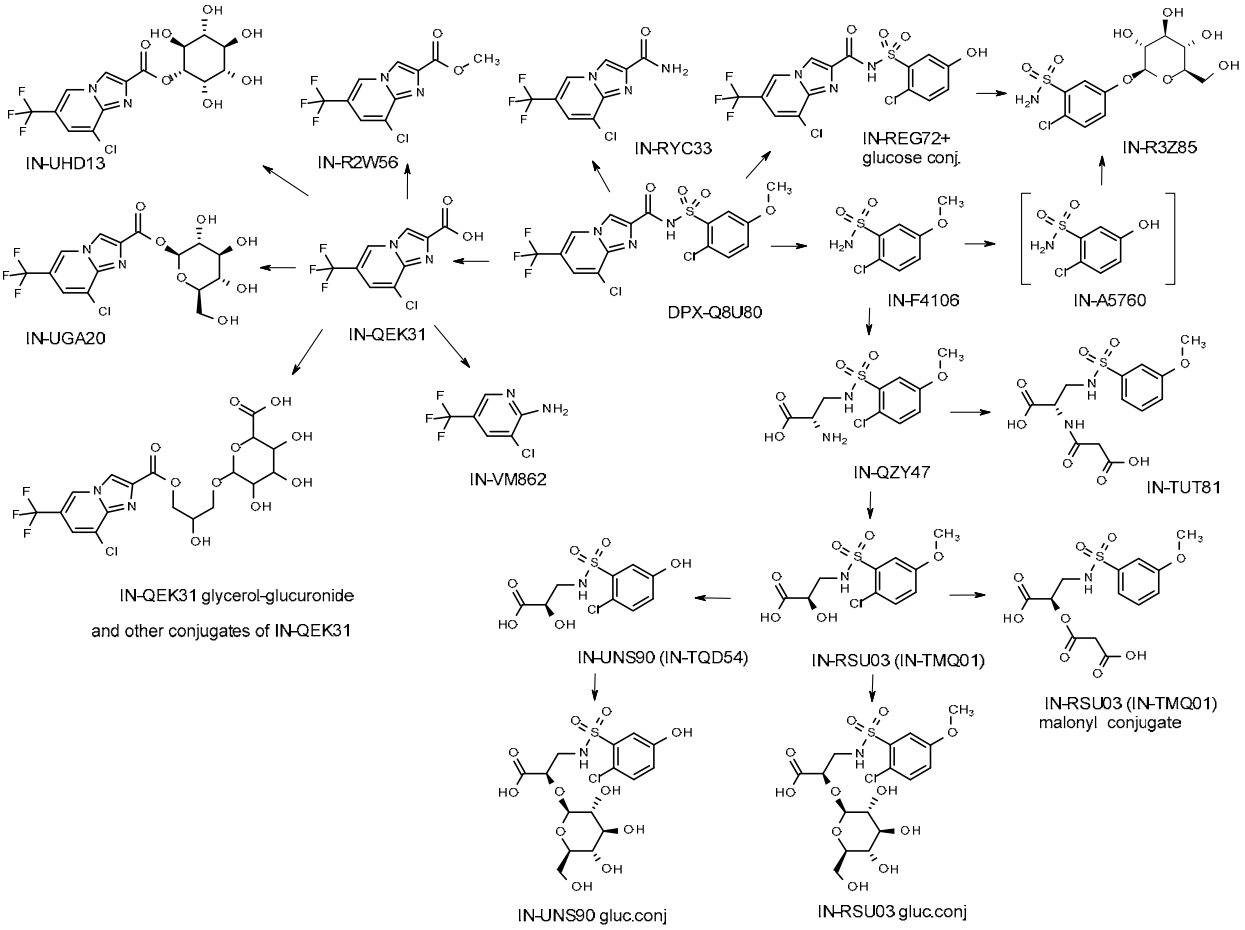

Figure 3 Proposed metabolic pathway of fluazaindolizine in carrots

Potato

The metabolism of [Ph-^{14}C(U)]-fluazaindolizine and [IP -5,8a-^{14}C]-fluazaindolizine in potatoes (cv. Maris Bard) was studied by Hobbs (2017 DuPont-43220). Seed potatoes were sown into treated sandy loam soil (pH 7.3, percent OM 2.4, 65 percent sand, 20 percent silt, 15 percent clay, CEC 10 meq/100 g) ca. 2 hours prior to a soil drench application with an SC formulation of [Ph-^{14}C]- or [IP-5,8a-^{14}C]-fluazaindolizine, at a nominal application rate of 1000 g ai/ha and maintained in a glasshouse. A further application at a nominal rate of 1.00 kg ai/ha was made to the same plots 30 days after the initial application. The total achieved treatment rates were 2.01 kg ai/ha and 2.00 kg ai/ha for the [Ph-^{14}C]- and [IP-5,8a-^{14}C]-fluazaindolizine experiments, respectively.

Foliage was taken for analysis 45 days after planting (15DAA2) for total radioactivity analysis only, tuber and foliage were taken for analysis at 65 and 100 days after planting and corresponded to an immature sample (35DAA2) and a mature sample (70DAA2). Samples were kept under frozen storage (*ca.* -20 °C) until analysis. Tuber samples were extracted within 14 days of harvest and the extracts were stored for no more than 39 days before initial chromatography. Overall, the time between the harvest and initial HPLC analysis was ≤ 53 days. Foliage samples were stored in a freezer set to maintain *ca.* -20 °C

from harvest until extraction. Overall, the time between the harvest and initial HPLC analysis of the foliage samples was ≤ 146 days. The results are shown in Table 12)

Table 12 TRR (mg eq/kg) in potato plant matrices following two applications of [^{14}C]-fluazaindolizine

Days after planting	Sample type	[Ph-^{14}C]-fluazaindolizine		[IP-5,8a-^{14}C]-fluazaindolizine	
		Tuber	Foliage	Tuber	Foliage

Identification and characterisation of radioactive residues [Ph-^{14}C]-fluazaindolizine

Potato tuber

Extractability of ^{14}C in tubers from the [Ph-^{14}C] experiment using methanol:water was good (76.6–80.4 percent TRR Table 13). Unextracted residues accounted for 19.6–23.4 percent TRR. The unextracted residues from mature tubers (70DAA2) were subject to further treatments which released an additional 15.1 percent TRR with 4.5 percent TRR remaining with the solids.

Fluazaindolizine was identified in the early tubers (6.8 percent TRR, 0.006 mg/kg) decreasing in later samples to where it was not detected. The principal extracted residue identified in [Ph-^{14}C]fluazaindolizine potato tubers was IN-QZY47 (15.3–15.4 percent TRR). IN-TUT81 (the malonyl conjugate of IN-QZY47) was present at 6.1–6.7 percent TRR) in immature and mature samples.

Other identified metabolites were IN-F4106, IN-A5760, IN-UNS90, IN-RSU03, glucose conjugate of IN-A5760 (IN-R3Z85), IN-REG72 and IN-UJV12 (all ≤6.6 percent TRR, ≤ 0.005 mg eq/kg). A number of metabolites were subsequently identified by LC-MS analysis including a glucose conjugate of IN-UNS90 (≤11.3 percent TRR, ≤ 0.014 mg eq/kg), and glucose conjugates of IN-RSU03 (≤10.1 percent TRR, ≤ 0.013 mg eq/kg).

Multiple unidentified metabolites were also detected in tuber samples accounting for aggregate totals of 16.4-24.2 percent TRR (0.013-0.031 mg eq/kg); each component ≤5.6 percent TRR (≤ 0.007 mg eq/kg). The majority of these multiple unidentified metabolites appeared to be more complex conjugates of IN-F4106 and/or IN-A5760, as determined after acid hydrolysis.

Following hydrolysis of the mature potato tuber aqueous methanol extract, the glucose conjugate of IN-RSU03 was hydrolysed to IN-RSU03. The malonyl conjugate of IN-QZY47 (IN-TUT81) was hydrolysed to IN-QZY47, and the glucose conjugate of IN-UNS90 was hydrolysed to IN-UNS90 (Table xx). An increase in IN-F4106, IN-UJV12 and IN-A5760 were also observed after hydrolysis. Other minor unidentified metabolites or conjugates found were also cleaved under these conditions releasing IN-F4106, IN-UJV12 and IN-A5760.

Potato foliage

Extractability of ^{14}C in foliage from the [Ph-^{14}C] experiment using methanol:water was good (76.0 percent TRR Table 13). Unextracted residues accounted for 23.9 percent TRR and were not examined further.

Fluazaindolizine was identified in low quantities in the potato foliage sample (0.2 percent TRR; 0.010 mg/kg). The principle extracted residues identified were metabolites associated with IN-RSU03 (including the malonyl and glucose conjugates) accounting in total for 12.0 percent TRR (0.606 mg eq/kg) and metabolites associated with IN-QZY47 (including the malonyl conjugate, IN-TUT81 and the acetyl conjugate) accounting in total for 14.9 percent TRR (0.750 mg eq/kg).

Other identified metabolites were IN-F4106, IN-A5760, IN-UNS90, glucose conjugate of IN-A5760 (IN-R3Z85) and IN-UJV12 (all ≤8.3 percent TRR, ≤ 0.422 mg eq/kg). A number of metabolites were subsequently identified by LC-MS analysis including a glucose conjugate of IN-UNS90 (5.6 percent TRR, 0.283 mg eq/kg) and malonyl and glucose conjugates of IN-RSU03 (≤8.1 percent TRR, ≤ 0.410 mg eq/kg).

Multiple unidentified metabolites were also detected accounting for an aggregate total of 21.2 percent TRR (1.076 mg eq/kg) in each foliage sample but each individually was ≤ 1.8 percent TRR (≤ 0.092 mg eq/kg). The majority of these multiple unidentified metabolites appeared to be more complex conjugates of IN-QZY47, IN-F4106 and/or IN-A5760, as determined after acid hydrolysis. As expected, following hydrolysis of the mature potato foliage aqueous methanol extract, the glucose and malonyl conjugates of IN-RSU03 were hydrolysed to IN-RSU03. The malonyl conjugate of IN-QZY47 (IN-TUT81) and acetyl conjugate of IN-QZY47 were hydrolysed to IN-QZY47, and the glucose conjugate of IN-UNS90 was hydrolysed to IN-UNS90 (Table 13). An increase in IN-F4106, IN-UJV12 and IN-A5760 were also observed after hydrolysis; it was apparent that other minor unidentified metabolites or conjugates were also cleaved under these conditions and released as IN-F4106, IN-UJV12 and IN-A5760 (Table 13).

Identification and characterisation of radioactive residues [IP-5,8a-^{14}C]fluazaindolizine

Potato tuber

Extractability of ^{14}C in tubers from the [IP-5,8a-^{14}C] experiment using methanol:water was good (80.8-84.1 percent TRR Table 14). Unextracted residues accounted for 15.9-19.2 percent TRR. The unextracted residues from mature tubers (70DAA2) were subject to further treatments which released an additional 10.8 percent TRR with 8.4 percent TRR remaining with the solids.

Fluazaindolizine was identified in the early tubers (9.3 percent TRR, 0.004 mg/kg) with non-detectable residues found in the mature tubers. The principal extracted residue was IN-QEK31 (59.3-65.0 percent TRR). Other identified metabolites were glucose conjugate of IN-QEK31 (IN-UGA20), inositol conjugate of IN-QEK31 (IN-UHD13) and methyl ester of IN-QEK31 (IN-R2W56), (all ≤ 3.5 percent TRR, ≤ 0.002 mg eq/kg). Multiple unidentified metabolites were also detected accounting for an aggregate total of 3.6-8.2 percent TRR in each sample but each individually was ≤ 1.7 percent TRR (≤ 0.001 mg eq/kg). A volatile component was trapped only in the mature potato extract (2.7 percent TRR; 0.002 mg eq/kg) but was not characterised further due to its low level.

Following hydrolysis of the mature potato tubers aqueous methanol extract the fluazaindolizine and IN-R2W56 were hydrolysed to IN-QEK31 (Table 14).

Potato foliage

Extractability of ^{14}C in foliage from the [IP-5,8a-^{14}C] experiment using methanol:water was good (73.8 percent TRR Table 14). Unextracted residues accounted for 26.2 percent TRR.

Fluazaindolizine was identified in small quantities in the foliage (1.9 percent TRR, 0.015 mg/kg). The principle extractable residue identified was IN-QEK31 accounting for 18.5 percent TRR (0.143 mg eq/kg). Other identified metabolites were IN-REG72, glucose conjugate of IN-QEK31 (IN-UGA20), IN-RYC33 and methyl ester of IN-QEK31 (IN-R2W56), (all ≤6.3 percent TRR, ≤ 0.049 mg eq/kg). Multiple unidentified metabolites were also detected accounting for an aggregate total of 37.7 percent TRR but each individually was ≤ 3.5 percent TRR (≤ 0.027 mg eq/kg).

Following hydrolysis of the mature potato foliage aqueous methanol extract the following metabolites were hydrolysed to IN-QEK31: fluazaindolizine, IN-REG72, IN-UGA20, IN-R2W56 and IN-RYC33 (Table 14). It was apparent that other minor unidentified metabolites or conjugates also cleaved under these conditions releasing IN-QEK31 or minor unknown metabolites.

Table 14 Identification of TRR (% TRR) in various potato tuber and foliage extracts and fractions after application of [IP-5,8a-^{14}C]fluazaindolizine

	Immature Tuber 35DAA2	Mature Tuber 70DAA2	Mature Foliage 70DAA2	Mature Foliage (70DAA2)

Amylase		5.6		
remaining		8.4		

Notes:

[A] Total unidentified metabolites consist of multiple components – none greater than 1.7 percent TRR, 0.001 mg eq/kg in the tubers and 3.5 percent TRR, 0.027 mg eq/kg in the foliage, several of which appear to be hydrolysed with 1M HCl to IN-QEK31.

[B] Post-hydrolysis: Unidentified consisting of 11 components. None >5.2 percent TRR (0.041 mg eq/kg).

Chiral analysis of metabolites

Chiral HPLC was conducted on isolates from [Ph-^{14}C]-fluazaindolizine experiment foliage containing components corresponding to the racemic compounds IN-RSU03, IN-UTG08 and IN-UNS90. Only the R-enantiomer of IN-RSU03, designated as IN-TMQ01, was present. IN-UNS90 was also identified as only the R-enantiomer, IN-TQD54, consistent with IN-TMQ01 as O-demethylation would not alter the chiral carbon. Residues measured as IN-QZY47 were confirmed to be in the S configuration, consistent with naturally occurring L-serine.

The metabolic pathway for fluazaindolizine in potato plants following soil application is presented in Figure 4 and was proposed based on the metabolites identified in tubers and foliage. Metabolites in the figure are depicted in their free acid or free base forms.

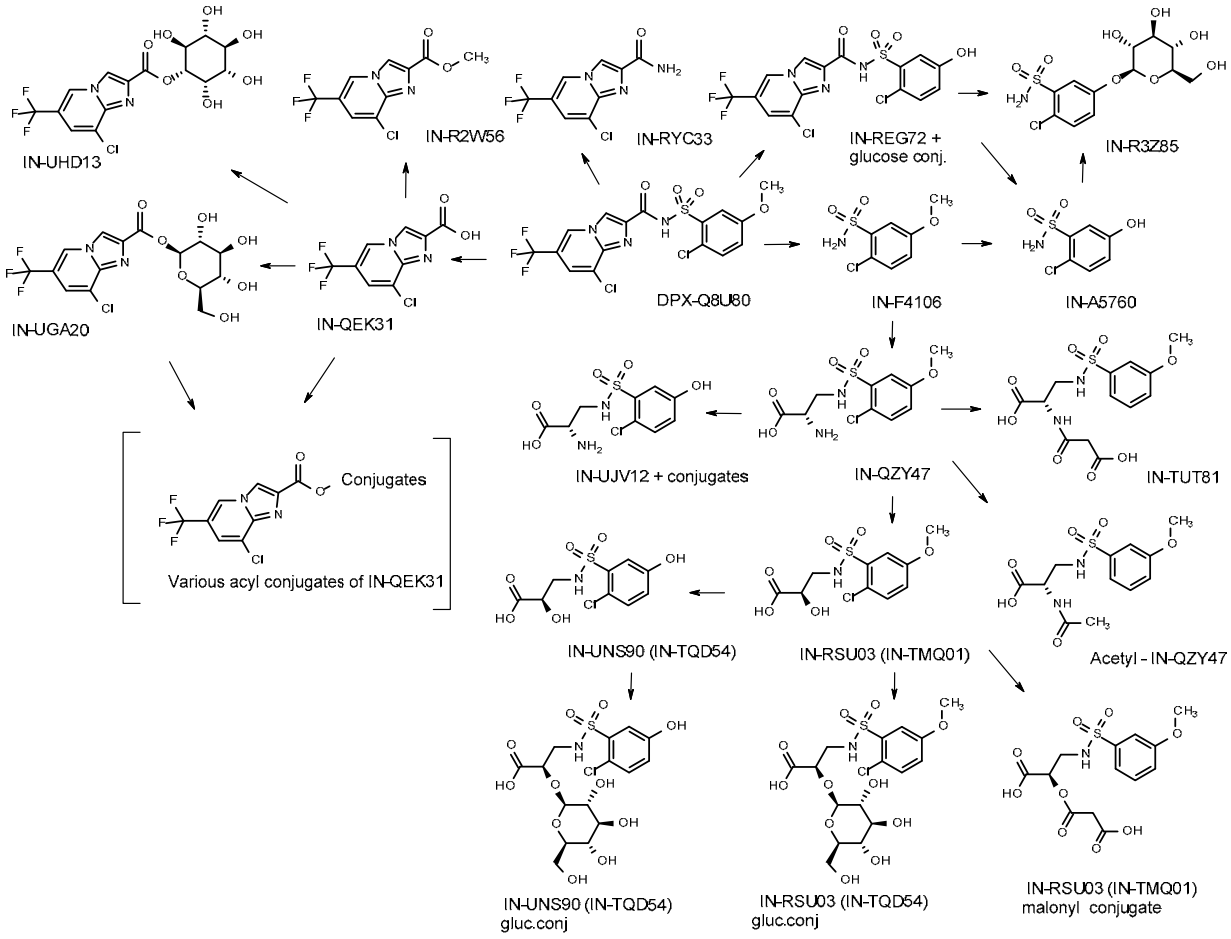

Figure 4 Proposed metabolic pathway of fluazaindolizine in potato plant

Sugar cane

Begley and Lloyd (2017 DuPont-41849) studied the metabolic fate of [phenyl-^{14}C(U)]fluazaindolizine and [imidazo[1,2-a]pyridine-5,8a-^{14}C]fluazaindolizine in sugar cane plants.

Mature sugar cane sets (cv. NC0310) were propagated in a sand/loam mixture until reaching 2–3 leaf stage (BBCH 12) at which time they were transplanted into crates filled with a sandy loam soil (pH 7.3, 2.4 percentOM, 64 percent sand, 21 percent silt, 15 percent clay, CEC 10 meq/100g). [Ph-^{14}C]fluazaindolizine or [IP-5,8a-^{14}C]fluazaindolizine was applied as an SC formulation at a nominal rate of 1.0 kg ai/ha, as a soil drench application within 2 hours of transplant. The achieved application rates were 1.00 kg ai/ha and 1.01 kg ai/ha for [Ph-^{14}C]-fluazaindolizine and [IP-5,8a-^{14}C]-fluazaindolizine, respectively.

Whole plant samples, consisting of mostly foliage, were taken at 51 days after application at BBCH 32 and whole plants above soil level at maturity (BBCH 39) which was 231 days after application. At maturity, the sample was separated into foliage and mature cane.

Samples were stored at *ca.* -20 °C prior to analysis. Plant samples were extracted within 17 days of harvest and the extracts were stored for no more than 10 days before initial chromatography. Overall, the time between the harvest and initial HPLC analysis was 23 days. Sample extracts were also reconstituted in more aqueous solvent and the HPLC analysis repeated, and in these cases, the time between harvest and this HPLC analysis was no greater than 71 days.

Table 15 TRR (mg eq/kg) in sugar cane plant matrices following one application of [^{14}C]-fluazaindolizine

Days after application	Sample type	[Ph-^{14}C]-fluazaindolizine	[IP-5,8a-^{14}C]-fluazaindolizine
51	Foliage	0.162	0.087
231	Foliage	0.069	0.121
231	Cane	0.020	0.052

Identification and characterisation of radioactive residues in sugar cane plants grown in [Ph-^{14}C]fluazaindolizine treated soil

Extractability of ^{14}C in foliage using methanol:water was good (82.9-91.5 percent TRR Table 16) and in mature cane 80.8 percent TRR. Foliage from 51DAA were subject to further solvent (acetonitrile/water), enzyme and acid treatment which increased the ^{14}C recovered to >89 percent TRR with 4.0-10.8 percent TRR remaining in the solids.

Sugar Cane Foliage

The principal extracted residue identified in [Ph-^{14}C] experiment sugar cane foliage was IN-RSU03 (IN-TMQ01) and its glucose and malonyl conjugates. The IN-RSU03 glucose conjugate was the principal conjugate detected accounting for 37.6–40.6 percent TRR (Table 16). The malonyl conjugate was detected at lower levels accounting for 1.6–6.7 percent TRR and IN-RSU03 was also identified at 2.0–9.6 percent TRR. IN-UNS90 was detected at 7.1–12.4 percent TRR and its glucose conjugate at 14.3–15.4 percent TRR (Table 16).

Multiple unidentified metabolites were also detected accounting for an aggregate total of 6.6–7.1 percent TRR in each sample but individually none >2.3 percent TRR (0.004 mg eq/kg).

Acid hydrolysis experiments demonstrated the residues were converted to the expected hydrolysis products. The conjugates of IN-RSU03 being converted to IN-RSU03, the glucose conjugates of IN-UNS90 being converted to IN-UNS90 and glucose conjugate of IN-A5760 (IN-R3Z85) being converted to IN-A5760 (Table 16).

Mature Sugar Cane

The principal extracted residue identified in [Ph-^{14}C] experiment mature sugar cane was IN-RSU03 glucose conjugate (19.4 percent TRR, 0.004 mg/kg, Table 16). Lower levels of the malonyl conjugate of IN-RSU03 were also detected accounting for 2.2 percent TRR. IN-R3Z85 (the glucose conjugate of IN-A5760) was the second highest residue detected (15.8 percent TRR). IN-UNS90 was detected at 4.0 percent TRR and its glucose conjugate at 4.9 percent TRR. The IN-RSU03 conjugates and IN-UNS90 and its conjugates were identified by comparison of retention time with the residues identified by LC-MS in the 51 DAA foliage. The identification of IN-R3Z85 by co-chromatography, in one system, with the provided reference standards, was supported by the acid hydrolysis experiments and the analysis of the 51 DAA foliage by LC-MS through the detection of the in-source fragment, IN-A5760.

IN-QZY47, IN-A5760, IN-TUT81 and IN-UJV12 were also identified by co-chromatography, in one system, with the provided reference standards (all ≤4.9 percent TRR, ≤ 0.001 mg eq/kg).

Multiple unidentified metabolites were also detected accounting for an aggregate total of 19.0 percent TRR (<0.005 mg eq/kg) but individually none >7.0 percent TRR (0.001 mg eq/kg).

Acid hydrolysis experiments showed the residues were converted to the expected hydrolysis products. The glucose conjugate of IN-RSU03 was converted to IN-RSU03, the glucose conjugate of IN-

UNS90 converted to IN-UNS90 and IN-R3Z85 converted to IN-A5760. Acid hydrolysis converted a significant portion of the unidentified metabolites to IN-UJV12 (Table 16).

Table 16 Identification of TRR (% TRR) in various sugar cane extracts and fractions after application of [Ph-^{14}C]fluazaindolizine

Identification and characterisation of radioactive residues in sugar cane plants grown in [IP-5,8a-^{14}C]fluazaindolizine treated soil

Extractability of ^{14}C in foliage using methanol:water was good (69.0–76.1 percent TRR Table 17) and in mature cane 82.0 percent TRR. Foliage and mature cane from 51DAA were subject to further solvent (acetonitrile/water), enzyme and acid treatment which increased the ^{14}C recovered to >92 percent TRR with 7.3–9.5 percent TRR remaining in the solids.

Sugar Cane Foliage

The principal extracted residue IN-QEK31 accounted for 27.9 percent TRR in the 51 DAA foliage and decreased to 5.1 percent TRR in the 231 DAA foliage (Table 17). IN-QEK31 was also detected as the glucose conjugate, IN-UGA20, accounting for 15.3 percent TRR in 51 DAA foliage and 8.5 percent TRR in 231 DAA foliage and the methyl ester, IN-R2W56 accounting for 1.3 percent TRR in 51 DAA foliage and 12.4 percent TRR in 231 DAA foliage. The identity of IN-QEK31 and its conjugates IN-UGA20 and IN-R2W56 were confirmed by LC-MS.

IN-RYC33, IN-REG72 and its glucose conjugate were also detected at low levels (≤4.6 percent TRR, ≤ 0.004 mg eq/kg). The glucose conjugate of IN-REG72 was tentatively identified by LC-MS. Multiple unidentified metabolites were also detected accounting for an aggregate total of 25.5-36.7 percent TRR in each sample but individually none >6.2 percent TRR (0.007 mg eq/kg). Acid hydrolysis experiments demonstrated that most of these low-level metabolites were hydrolysed to IN-QEK31 with the post-hydrolysis extract. The IN-QEK31 associated metabolites accounted for 64.5 percent TRR (0.056 mg eq/kg) in 51 DAA foliage and 35.1 percent TRR (0.042 mg eq/kg) in 231 DAA foliage (Table 17).

Mature Sugar Cane

The principal extracted residue identified in sugar cane was IN-QEK31 and associated metabolites. IN-QEK31 accounted for 13.5 percent TRR, the glucose conjugate of IN-QEK31 (IN-UGA20) accounted for 31.7 percent TRR and the methyl ester of IN-QEK31 (IN-R2W56), accounted for 3.9 percent TRR. The identity of IN-QEK31 and its conjugates, IN-UGA20 and IN-R2W56, were confirmed by LC-MS in the [IP-5,8a-^{14}C]-fluazaindolizine 51 DAA foliage extract.

The acid hydrolysis experiments supported the identifications showing that IN-QEK31 and associated metabolites accounted for 65.4 percent TRR (Table 17).

The glucose conjugate of IN-REG72 was also detected at low levels (3.9 percent TRR) and was tentatively identified by retention time match with the metabolite identification in [IP-5,8a-^{14}C]fluazaindolizine 51 DAA foliage extract by LC-MS.

Multiple unidentified metabolites were also detected accounting for an aggregate total of 19.5 percent TRR but individually none >3.1 percent TRR (0.002 mg eq/kg).

Notes:

[A] Total unidentified metabolites consist of multiple components – none greater than 3.1 percent TRR, 0.002 mg eq/kg in the cane and 6.2 percent TRR, 0.007 mg eq/kg in the foliage.

Proposed metabolic pathway of fluazaindolizine in sugar cane

The metabolic pathway for fluazaindolizine in sugar cane is presented in Figure 5 and is proposed based on the metabolites identified in sugar cane and sugar cane foliage. Metabolites in the figure are depicted in their free acid or base forms.

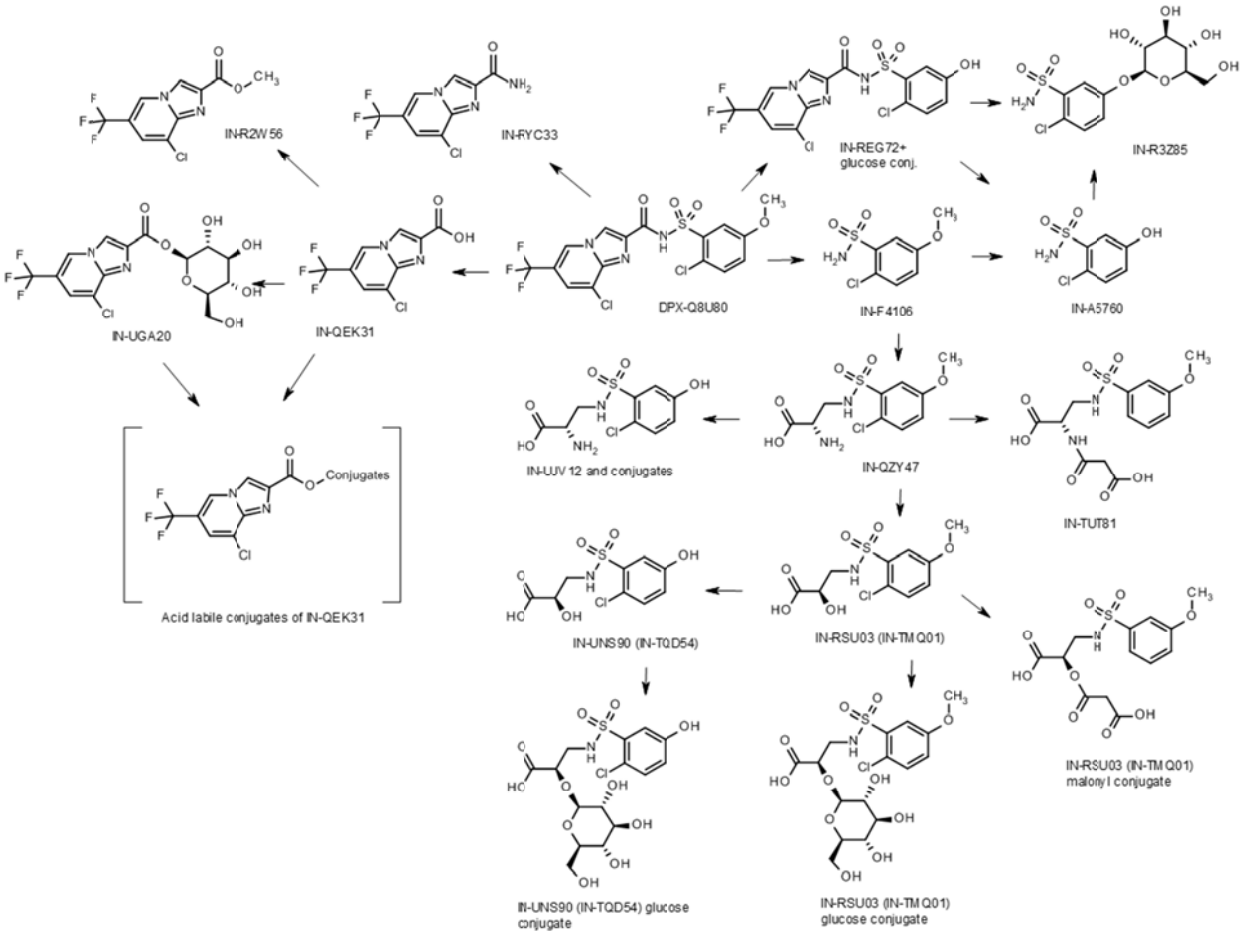

Figure 5 Proposed metabolic pathway of fluazaindolizine in sugar cane

Metabolism in rotational crops

Hobbs (2019 DuPont-34945, Revision No. 1) studied the metabolic fate of [Ph-^{14}C]fluazaindolizine and [IP-5,8a-^{14}C]fluazaindolizine in succeeding and rotated crops of spring wheat, spinach, and radish.

Single spray applications of SC formulations of [Ph-^{14}C]fluazaindolizine or [IP-5,8a-^{14}C]fluazaindolizine, at a nominal application rate of 2.0 kg ai/ha were made to bare sandy loam soil (pH 6.0, 5.1 percentOM, 64 percent sand, 19 percent silt, 17 percent clay, CEC 15 meq/100 g). The total achieved treatment rates were 1.95 and 1.94 kg ai/ha for the [Ph-^{14}C] and [IP-5,8a-^{14}C] labels, respectively.

Soil aging and crop maintenance were performed in a glasshouse. Seeds of wheat (cv Paragon), spinach (cv Renegade F1) and radish (cv Helox F1) were subsequently sown into the soil at 30, 120, and 300 days after application (DAA) and grown to maturity. Wheat forage, hay, straw and grain, spinach foliage, radish foliage (immature and mature foliage for both spinach and radish), and radish roots were sampled. Soil samples were collected following application, at each sowing point and at crop maturity.

Following harvest, samples were stored in a freezer set to maintain -20 °C within 2 hours, maintained under these conditions until processed, and returned to storage in the freezer once processing was complete. Plant samples were generally extracted within 3 months of harvest and the extracts were generally stored for no more than 3 months before initial chromatography; however, some samples were extracted beyond 6 months of harvest and extracts stored for longer than 6 months prior to chromatographic analysis due to additional HPLC method development needed to resolve various metabolites. Some extracts were also reanalysed at later time points using these HPLC methods and enabled efficient isolation of peaks of interest for LC-MS identification.

Soil extraction and analysis

Subsamples (ca. 50 g) of selected soil cores, 0, 71 (30DAA mature radish harvest), 120, and 300DAA, were extracted with acetonitrile:0.2 percent formic acid (aq) 9:1 followed by acetonitrile:0.2 percent formic acid (aq) 4:1 and two further extractions with acetonitrile:0.2 percent formic acid (aq) 1:1 . The unextracted radioactivity (bound radioactivity in the soil) was determined by combustion analysis. Extracted residues were analysed by HPLC. Concentration of the extracts from the [IP-5,8a-^{14}C]fluazaindolizine treated soil were concentrated in conjunction with trapping devises to capture any volatile metabolites as observed in previous soil metabolism studies. Identification of ^{14}C -residues was accomplished by either HPLC, or LC-MS with reference to authenticated analytical standards.

Portions of each homogenised crop sample were then extracted three times using methanol:water (7:3). Where necessary samples were further extracted with acetonitrile:water (1:1, 50 °C, 30 min), subjected to enzymatic digestion with driselase (an enzymatic mixture containing cellulase, laminarinase, and xylanase at 37 °C, 24 h; twice) and extracted with 0.1 M HCl (50 or 60 °C, 6 hrs), 0.1 M NaOH (80 °C, 4 hrs), and 1 M HCl (80 °C, 20 hrs). The results are shown in Table 18.

Table 18 TRR (mg eq/kg) found in soil

Radiolabel	Day 0 Application	Day 30 Sowing	Day 71 Mature Radish	Day 120 Sowing	Day 300 Sowing
[Ph-^{14}C]-fluazaindolizine	3.074	1.746	1.556	0.795	0.491
[IP-5,8a-^{14}C]-fluazaindolizine	4.655	3.628	0.456	0.662	1.307

Fluazaindolizine, IN-F4106, and IN-QEK31 were the major residues extracted from soil which were available for uptake by plants. IN-F4106, and IN-QEK31 exceeded 50 percent of the residue in the 120-300DAA samples, while IN-RYC33, IN-REG72, and IN-A5760 were found between 2.3 and 11.7 percent TRR at various sampling intervals. IN-VM862 was only presnt at low levels (<4 percent TRR determined *via* capture of volatile residues). The major metabolic route in the soil was the hydrolysis of fluazaindolizine at the amide bond, resulting in IN-F4106 and IN-QEK31. Fluazaindolizine was also *O*-demethylated to form IN-REG72, which also was hydrolysed to IN-A5760 and IN-QEK31. Less prominent pathways were hydrolysis of fluazaindolizine at the sulfonamide bond, resulting in IN-RYC33 and the further degradation of IN-QEK31 to IN-VM862.

TRR values expressed as mg/kg equivalents of the parent fluazaindolizine in the various commodities at the 30, 120, and 300DAA plant-back intervals are shown in Table 19.

Table 19 TRR (mg eq/kg) in the various commodities at the 30, 120, and 300 plant-back intervals

		Wheat				Spinach		Radish		
		Forage	Hay	Straw	Grain	Immature	Mature	Immature Foliage	Mature Foliage	Mature Roots
[Ph]	30DAA	1.165	1.433	6.873	0.086	0.254	0.647	0.342	0.328	0.388

		Wheat				Spinach		Radish		
		Forage	Hay	Straw	Grain	Immature	Mature	Immature Foliage	Mature Foliage	Mature Roots
Label	120DAA	0.422	0.334	2.559	0.055	0.052	0.095	0.062	0.054	0.131
	300DAA	0.396	0.531	2.741	0.026	0.087	0.147	0.056	0.103	0.054
[IP-5,8a Label	30DAA	0.411	1.143	3.547	1.517	0.116	0.520	0.329	0.537	0.277
	120DAA	0.198	0.377	1.357	0.521	0.018	0.043	0.049	0.064	0.037
	300DAA	0.609	0.969	4.073	1.296	0.167	0.233	0.092	0.200	0.051

In general, residues were lower with longer PBIs apart from wheat commodities from the [IP-5,8a-^{14}C]fluazaindolizine soil application, where TRRs in the various commodities at the 30 and 300 day PBIs were comparable.

Most residues were readily extracted across all commodities using a methanol:water mixture (70:30). In cases where residues were more extensively incorporated into the crop matrix such as wheat straw or grain samples, additional enzymatic and acid treatments allowed for recovery of >90 percent TRR. Extracted residues containing significant radioactivity (≥0.01 mg equiv/kg) were analysed by HPLC. Identification of ^{14}C-residues was accomplished by either HPLC, or LC-MS with reference to authenticated analytical standards.

Uptake and metabolism of fluazaindolizine in rotated crops

Metabolic pathways of fluazaindolizine and its soil metabolites were similar among all the rotational crops and rotational intervals. Differences observed in the various crops were mainly in the degree and type of more complex conjugation with endogenous constituents.

Spinach

TRR for spinach commodities for the various plant-back intervals are presented in Table 20. The highest concentrations of total radioactivity were found in the mature samples.

Table 20 TRR (mg eq/kg) in spinach 30, 120, and 300 days after a soil drench application of [^{14}C]fluazaindolizine

Days after application	[Ph-^{14}C]-fluazaindolizine		[IP-5,8a-^{14}C]-fluazaindolizine	
	Immature	Mature	Immature	Mature
30	0.254	0.647	0.166	0.520
120	0.052	0.095	0.18	0.043
300	0.087	0.147	0.167	0.233

Identification and characterization of radioactive residues [Ph-^{14}C]-fluazaindolizine in spinach

Extractability of ^{14}C in [Ph-^{14}C] spinach using methanol:water was good (85.2-95.2 percent TRR Table 21). The unextracted residues in the 30DAA sample was subject to further investigations; these further treatments released almost all the ^{14}C unextracted by methanol:water (Table 21).

Fluazaindolizine was found at all plant-back intervals (0.4-14.1 percent TRR, ≤ 0.091 mg/kg) decreasing in later samples. The principal extracted residue was IN-TUT81 (43.9-68.8 percent TRR) which is derived from *N*-malonyl conjugation of IN-QZY47. An acetylated derivative of IN-QZY47 identified by LC-MS accounted for 1.7-8.0 percent TRR (0.001-0.028 mg eq/kg) and IN-QZY47 for 0.9-2.4 percent TRR (0.001-0.010 mg eq/kg). The total of IN-QZY47 derived metabolites (IN-TUT81, acetylated IN-QZY47, and

IN-QZY47) accounted for most of the spinach residues comprising of 49.7-75.7 percent TRR (0.035-0.322 mg eq/kg: Table 22).

Other identified metabolites were the IN-REG72, IN-RSU03, IN-UNS90, IN-A5760, IN-UJV12, glucose conjugate of IN-A5760 (IN-R3Z85), and IN-F4106, (all ≤5.1 percent TRR, ≤ 0.033 mg eq/kg) as well as glucose conjugates of IN-REG72 and IN-RSU03 (≤ 3.3 percent TRR, ≤ 0.021 mg eq/kg; Table 22).

Multiple unidentified metabolites were also detected accounting for an aggregate total of 6.6-14.2 percent TRR in each sample but each individually was ≤ 2.8 percent TRR (≤ 0.013 mg eq/kg). Most of these metabolites were hydrolysed to IN-F4106, IN-RSU03, IN-QZY47, or IN-UNS90 among other known metabolites (Table 22).

Identification and characterization of radioactive residues [IP-5,8a-^{14}C]fluazaindolizine in spinach

Extractability of ^{14}C in [IP-5,8a-^{14}C] spinach using methanol:water was good (81.2–93.2 percent TRR Table 23). The unextracted residues in the 300DAA immature and mature samples were subject to further investigations; these further treatments released 7.1–7.5 percent TRR with ≤ 3.3 percent TRR remaining in the solids (Table 23).

Fluazaindolizine was identified in all samples (2.9–29.0 percent TRR, ≤ 0.114 mg/kg) decreasing in concentration in later samples. The principal extracted residue was IN-QEK31 accounting for 19.2–52.5 percent TRR (0.010–0.115 mg eq/kg) apart from immature spinach at the 30DAA plant-back interval where fluazaindolizine was the principal residue at 29.0 percent TRR (0.034 mg eq/kg; Table 24).

Other identified metabolites were the IN-REG72, inositol conjugate of IN-QEK31 (IN-UHD13), glucose conjugate of IN-QEK31 (IN-UGA20), methyl ester of IN-QEK31 (IN-R2W56), IN-RYC33, and malic acid conjugate IN-QEK31 (IN-UJU44), (all ≤9.4 percent TRR, ≤ 0.045 mg eq/kg) as well as a glucose conjugate of IN-REG72 (≤9.3 percent TRR, ≤ 0.048 mg eq/kg) and a glycerol glucuronide conjugate of IN-QEK31 (≤11.1 percent TRR, ≤ 0.022 mg eq/kg; Table 24).

Multiple unidentified metabolites were also detected accounting for an aggregate total of 10.7-29.4 percent TRR in each sample but each individually was ≤5.3 percent TRR (≤ 0.011 mg eq/kg). Acid hydrolysis cleaved many of these components to IN-QEK31 (Table 24).

Identification and characterization of radioactive residues [Ph-^{14}C]-fluazaindolizine in radish

Foliage

Extractability of ^{14}C in [Ph-^{14}C] radish foliage using methanol:water was good (88.8-92.9 percent TRR Table 26). The unextracted residues in the 300DAA sample were subject to further investigations; these further treatments released 7.5 percent TRR with ≤ 3.8 percent TRR remaining in the solids (Table 26).

Fluazaindolizine was identified at all plant-back intervals (0.2-11.8 percent TRR, ≤ 0.039 mg/kg) decreasing in later samples. The principal extracted residue was IN-QZY47 (25.8-32.6 percent TRR) which in conjunction with other IN-QZY47 derived metabolites (IN-TUT81 and acetylated IN-QZY47 identified by LC-MS analysis) accounted for 31.3-37.3 percent TRR (0.018–0.112 mg eq/kg; Table 27).

Other identified metabolites were IN-RSU03, IN-UJV12, IN-UNS90, IN-A5760, glucose conjugate of IN-A5760 (IN-R3Z85), and IN-F4106, (all ≤5.8 percent TRR, ≤ 0.018 mg eq/kg) as well as glucose conjugates of IN-REG72, IN-UNS90, and IN-RSU03 (≤34.7 percent TRR, ≤ 0.080 mg eq/kg) and an acetyl conjugate of IN-QZY47 (≤ 2.0 percent TRR, ≤ 0.007 mg eq/kg; Table 27).

Multiple unidentified metabolites, including unretained components which may contain multiple metabolites, were also detected accounting for an aggregate total of 2.7–5.9 percent TRR in each sample but each individually was ≤ 2.9 percent TRR (≤ 0.010 mg eq/kg). Most of these metabolites were hydrolysed to known metabolites such as IN-F4106, IN-RSU03, IN-QZY47 and IN-UNS90 (Table 27).

Roots

Extractability of ^{14}C in [Ph-^{14}C] radish roots using methanol:water was good (94.3–95.1 percent TRR Table 28).

Fluazaindolizine was identified at all plant-back intervals (1.7-12.2 percent TRR, ≤ 0.047 mg/kg) decreasing in later samples. The principal extracted residue identified was IN-QZY47 (18.0-26.6 percent TRR) which in conjunction with the malonyl and acetylated derivatives of IN-QZY47 (IN-TUT81 and acetylated IN-QZY47) accounted for 36.7-40.3 percent TRR (0.021-0.143 mg eq/kg; Table 29).

Other identified metabolites were IN-RSU03, IN-REG72, IN-UNS90, IN-A5760, glucose conjugate of IN-A5760 (IN-R3Z85), and IN-F4106, (all ≤ 3.3 percent TRR, ≤ 0.013 mg eq/kg) as well as glucose conjugates of IN-REG72, IN-USN90, and IN-RSU03 (≤36.5 percent TRR, ≤ 0.073 mg eq/kg; Table 29).

Multiple unidentified metabolites, including unretained components which may contain multiple metabolites, were also detected accounting for an aggregate total of 7.7-8.8 percent TRR in each sample but each individually was ≤ 3.4 percent TRR (≤ 0.005 mg eq/kg). Most of these metabolites were hydrolysed to known metabolites such as IN-F4106, IN-RSU03, IN-QZY47 and IN-UNS90 (Table 29).

Identification and characterization of radioactive residues [IP-5,8a-^{14}C]fluazaindolizine in radish

Foliage

Extractability of ^{14}C in [IP-5,8a-^{14}C] radish foliage using methanol:water was good (84.7–91.3 percent TRR Table 30). The unextracted residues in the 30DAA and 300DAA samples were subject to further investigations; these further treatments released 9.9–12.0 percent TRR (Table 30).

Fluazaindolizine was found in all samples (1.0-6.8 percent TRR, ≤ 0.036 mg/kg) decreasing in concentrations at later plant-back intervals. The principal extractable residue identified was IN-UJU44, a malic acid conjugate of IN-QEK31 accounting for 32.6-43.9 percent TRR (0.016-0.236 mg eq/kg; Table 31). The next most abundant metabolite was IN-QEK31 accounting for 10.2-23.9 percent TRR (0.010-0.059 mg eq/kg).

Other identified metabolites were the inositol conjugate of IN-QEK31 (IN-UHD13), glucose conjugate of IN-QEK31 (IN-UGA20), glutamic acid conjugate of IN-QEK31 (IN-WUK12), methyl ester of IN-QEK31 (IN-R2W56), and IN-RYC33 (all ≤7.9 percent TRR, ≤ 0.026 mg eq/kg) together with a glucose conjugate of IN-REG72 (≤ 2.2 percent TRR, ≤ 0.012 mg eq/kg; Table 31).

Multiple unidentified metabolites, including unretained components which may contain multiple metabolites, were also detected accounting for an aggregate total of 7.2-12.2 percent TRR in each sample but each individually was ≤5.7 percent TRR (≤ 0.023 mg eq/kg).

Roots

Extractability of ^{14}C in [IP-5,8a-^{14}C] radish roots using methanol:water was good (86.4-93.7 percent TRR, Table 32).

Fluazaindolizine was found in all samples (6.3–17.3 percent TRR, ≤ 0.048 mg/kg) decreasing in concentration in later samples. The principal extracted residue identified was the malic acid conjugate IN-QEK31 (IN-UJU44) accounting for 13.2–28.8 percent TRR (0.005–0.073 mg eq/kg) with the next most abundant metabolite IN-QEK31 accounting for 4.8–14.0 percent TRR (0.002–0.026 mg eq/kg), and its glucose conjugate IN-UGA20, accounting for 9.9–13.9 percent TRR (0.004–0.039 mg eq/kg; Table 33).

Other identified metabolites were IN-REG72, inositol conjugate of IN-QEK31 (IN-UHD13), glutamic acid conjugate of IN-QEK31 (IN-WUK12), methyl ester of IN-QEK31 (IN-R2W56), and IN-RYC33 (all ≤4.2 percent TRR, ≤ 0.010 mg eq/kg) and a glucose conjugate of IN-REG72 (≤9.3 percent TRR, ≤ 0.026 mg eq/kg; Table 33).

Multiple unidentified metabolites, including unretained components which may contain multiple metabolites, were also detected accounting for an aggregate total of 10.2-25.7 percent TRR in each sample but each individually was ≤8.2 percent TRR (≤ 0.017 mg eq/kg). These metabolites would appear to be mostly conjugates of IN-QEK31 based upon their hydrolysis behaviour (Table 33).

[D] Unidentified consisting of a single unretained component.

Wheat

The TRR for spring wheat commodities for the various plant-back intervals are presented in Table 34. The highest levels of total radioactivity were found in straw from wheat grown in the [Ph-^{14}C]-fluazaindolizine treated soil. Radioactive residues in grain were considerably higher in wheat grown in soil treated with [IP-5,8a-^{14}C]-fluazaindolizine as compared to the [Ph-^{14}C] label, indicating cleavage of fluazaindolizine molecule.

Table 34 TRR (mg eq/kg) in wheat sown 30, 120, and 300 days after a soil drench application of [^{14}C]-fluazaindolizine

Days after application	[Ph-^{14}C]-fluazaindolizine				[IP-5,8a-^{14}C]-fluazaindolizine

Identification and characterization of radioactive residues [Ph-^{14}C]fluazaindolizine in wheat forage, hay, and grain

Forage

Extractability of ^{14}C in [Ph-^{14}C] forage using methanol:water was good (94.5–96.9 percent TRR, Table 35).

Table 35 Extraction of residues in wheat forage from crops sown 30, 120, and 300 days after application of [Ph–^{14}C]-fluazaindolizine

Fraction	30DAA		120DAA		300DAA	
	% TRR	mg eq/kg	% TRR	mg eq/kg	% TRR	mg eq/kg
Extracted (MeOH/water)	96.1	1.120	94.5	0.399	96.9	0.383

Total	100	1.165	100	0.422	100	0.396

Fluazaindolizine was only identified in small quantities at the 30DAA plant-back interval (0.7 percent TRR, 0.009 mg/kg); it was not found in later plant-back intervals (Table 36). The principal extracted residue identified in [Ph-^{14}C] forage was the glucose conjugate of IN-UNS90 (38.2–41.4 percent TRR). An additional glucose conjugate of IN-UNS90 proposed to be conjugated to the phenolic position accounted for 2.8–3.0 percent TRR. Free IN-UNS90 and its two glucose conjugates accounted for greater than half the residue (53.3–64.0 percent TRR; Table 36).

Other identified metabolites were IN-REG72, IN-RSU03, IN-QZY47, malonic acid conjugate of IN-QZY47 (IN-TUT81), IN-A5760, glucose conjugate of IN-A5760 (IN-R3Z85), and IN-F4106 (all ≤ 3.4 percent TRR). A number of metabolites in the [Ph-^{14}C] experiment forage were observed including the glucose conjugate of IN-RSU03 (≤12.2 percent TRR), a malonyl glucose conjugate on IN-RSU03 (≤ 2.3 percent TRR) and a glucose conjugate of IN-REG72 (≤ 1.7 percent TRR).

Unidentified metabolites, including unretained components which may contain multiple metabolites, were also detected, accounting for an aggregate total of 11.6–14.8 percent TRR in each sample, were comprised of 10-17 individual metabolites but each individually was ≤4.8 percent TRR (≤ 0.027 mg eq/kg). A significant portion of the unknown metabolites in the initial methanol water extracts were shown to hydrolyse with 1M HCl to IN-F4106, IN-A5760, IN-RSU03, and other known metabolites (Table 36).

[A] Unidentified, including unretained components, consisting of 17 components, none >2.3 percent TRR, 0.027 mg eq/kg.

[B] Unidentified, including unretained components, consisting of 10 components, none >4.8 percent TRR, 0.020 mg eq/kg.

[C] Unidentified, including unretained components, consisting of 11 components, none >2.7 percent TRR, 0.011 mg eq/kg.

[D] Unidentified, including unretained components, consisting of 17 components, none >2.3 percent TRR, 0.027 mg eq/kg.

[E] Unidentified consisting of 3 components, none >2.2 percent TRR, 0.026 mg eq/kg.

Hay

Extractability of ^{14}C in [Ph-^{14}C] hay using methanol:water was good (91.6–92.8 percent TRR Table 37). The unextracted residues from 30DAA and 300DAA samples were subject to further investigations; these further treatments released an additional 5.1–7.1 percent TRR from the bound residues with terminal unextracted residues accounting for 0.8–2.0 percent TRR (Table 37).

Fluazaindolizine was only identified in small quantities at the 30DAA plant-back interval (0.5 percent TRR, 0.008 mg/kg) and not in later samples. The principal extracted residue was the glucose conjugate of IN-UNS90 (32.7–37.0 percent TRR) which in conjunction with IN-UNS90 and the phenol glucose conjugate of IN-UNS90 accounted for 46.1–51.2 percent TRR (Table 38). Chiral HPLC analysis was conducted on the isolated IN-UNS90 and it was demonstrated that only the *R*-enantiomer, IN-TQD54, was present.

Other identified metabolites were IN-RSU03, IN-QZY47, malonic acid conjugate of IN-QZY47 (IN-TUT81), IN-A5760, glucose conjugate of IN-A5760 (IN-R3Z85), and IN-F4106 (all ≤ 3.9 percent TRR). Chiral HPLC analysis was conducted on the isolated IN-RSU03 and it was demonstrated that only the *R*-enantiomer, IN-TMQ01, was present.

Other metabolites identified included a glucose conjugate of IN-RSU03 (13.7 percent TRR) and a malonyl glucose conjugate on IN-RSU03 (≤ 1.7 percent TRR).

Multiple unidentified metabolites, including unretained components which may contain multiple metabolites, were also detected accounting for an aggregate total of 16.5-19.1 percent TRR in each sample but each individually was ≤5.2 percent TRR. A significant portion of the unknown metabolites were shown to hydrolyse with 1M HCl to IN-F4106, IN-A5760, IN-RSU03, and other known metabolites in the forage and straw (Table 38).

Straw

Extractability of ^{14}C in [Ph-^{14}C] straw using methanol:water was good (72.3–86.0 percent TRR Table 39). The unextracted residues were subject to further investigations; these further treatments released an additional 7.6–26.1 percent TRR with terminal residues remaining in solids accounting for 1.7–6.4 percent TRR (Table 39).

Fluazaindolizine was only identified in small quantities at the 30DAA plant-back interval (0.7 percent TRR, 0.041 mg/kg) and was not found in later plant-back intervals (Table 40). The principal extracted residue identified in [Ph-^{14}C] straw was IN-UNS90 (17.5–27.6 percent TRR). In conjunction with its glucose conjugates these metabolites accounted for 36.8–42.9 percent TRR (Table 40).

Other identified metabolites were IN-REG72, IN-RSU03, IN-QZY47, malonic acid conjugate of IN-QZY47 (IN-TUT81), IN-A5760, glucose conjugate of IN-A5760 (IN-R3Z85), IN-F4106, and IN-UJV12 (all ≤ 5.6 percent TRR, ≤ 0.228 mg eq/kg), together with a glucose conjugate of IN-RSU03 (≤ 12.2 percent TRR) and a malonyl glucose conjugate of IN-RSU03 (≤ 2.8 percent TRR) and a glucose conjugate of IN-REG72 (≤ 2.4 percent TRR).

Multiple unidentified metabolites, including unretained components which may contain multiple metabolites, were also detected accounting for an aggregate total of 21.4–27.6 percent TRR in each sample but each individually was ≤ 7.2 percent TRR (≤ 0.198 mg eq/kg). A significant portion of the unknown metabolites were shown to hydrolyse with 1M HCl to IN-F4106, IN-A5760, IN-RSU03, and other known metabolites (Table 40).

[E] Unidentified consisting of 6 components. None >6.2 percent TRR, 0.426 mg eq/kg.

Grain

Extractability of ^{14}C in [Ph-^{14}C] grain using methanol:water was poor (16.0–34.3 percent TRR, Table 41). The unextracted residues were subject to further investigations; these further treatments released an additional 62.9–84.0 percent TRR with terminal residues remaining in solids accounting for 2.8 percent TRR in case of the 300DAA grain sample (Table 41).

It was not possible to obtain accurate profiles from the 120 and 300DAA samples due to the large quantity of endogenous materials and large volumes of sample extract required to release the residue. The profiles obtained demonstrated that the residue was comprised of multiple metabolites although it was not possible to accurately determine their identity. Most of the residues were released by enzyme and/or acidic extractions which may alter the nature of the residue in the extraction process. The tentatively identified metabolites in these samples are presented in Table 42.

Fluazaindolizine was found in small quantities at the 30DAA plant-back interval (3.3 percent TRR, 0.003 mg/kg). The principal extracted residue identified in [Ph-^{14}C] grain was IN-A5760 (3.5–6.1 percent TRR, 0.002–0.005 mg eq/kg).

Other identified metabolites were IN-UNS90 and IN-F4106 (all ≤ 3.3 percent TRR, ≤ 0.003 mg eq/kg). IN-RSU03, IN-QZY47, and IN-REG72 were tentatively observed in the 300DAA grain although due to the low residues these regions could not be positively assigned. The glucose conjugate of IN-RSU03 (0.9 percent TRR, 0.001 mg eq/kg) and glucose conjugates on IN-UNS90 (≤ 2.4 percent TRR, ≤ 0.002 mg eq/kg) were also identified.

Multiple unidentified metabolites, including unretained components which may contain multiple metabolites, were also detected accounting for an aggregate total of 18.0-96.6 percent TRR in each sample but generally each individually was ≤ 15.7 percent TRR (≤ 0.012 mg eq/kg). An unretained region accounted for 52.1 percent TRR and 0.029 mg eq/kg in the 120DAA grain following enzyme digestion and extraction which may consist of multiple components, as observed in other grain fractions where this radioactive region is partially resolved into numerous polar metabolites. As fluazaindolizine and its major phenyl metabolites (IN-F4106 and IN-A5760) are known to mineralise in soil to $^{14}CO_2$ at significant levels, these polar components may result from the reincorporation of the radiolabel into endogenous plant materials.

Identification and characterization of radioactive residues [IP-5,8a-^{14}C]fluazaindolizine in wheat forage, hay, straw, and grain

Forage

Extractability of ^{14}C in [IP-5,8a-^{14}C] forage using methanol:water was good (83.2–89.9 percent TRR Table 43). The unextracted residues were subject to further investigations; these further treatments released an additional 8.4–11.4 percent TRR with terminal residues remaining in solids accounting for ≤ 5.5 percent TRR (Table 43).

Fluazaindolizine was identified in all plant-back intervals (0.6–3.9 percent TRR, ≤ 0.016 mg/kg) decreasing in later samples (Table 44). The principal extracted residue identified in forage was IN-QEK31 accounting for 25.9–40.8 percent TRR (0.051-0.248 mg eq/kg).

Other identified metabolites were the glucose conjugate of IN-QEK31 (IN-UGA20), IN-RYC33, and malic acid conjugate of IN-QEK31 (IN-UJU44), (all ≤ 7.8 percent TRR, ≤ 0.032 mg eq/kg) together with a glucose conjugate of IN-REG72 (≤ 2.8 percent TRR) and multiple conjugates of IN-QEK31 (≤ 2.6 percent TRR).

Multiple unidentified metabolites, including unretained components which may contain multiple metabolites, were also detected accounting for an aggregate total of 28.2–37.2 percent TRR in each sample but each individually was ≤ 6.7 percent TRR (≤ 0.039 mg eq/kg). A significant portion of the unknown metabolites were shown to hydrolyse to IN-QEK31 (Table 44).

[G] Unidentified, including unretained components, consisting of 3 components none >3.9 percent TRR, 0.016 mg eq/kg.

Hay

Extractability of ^{14}C in [IP-5,8a-^{14}C] hay using methanol:water was good (76.4–84.7 percent TRR Table 45). The unextracted residues were subject to further investigations; these further treatments released an

additional 10.5–16.1 percent TRR with terminal residues remaining in solids accounting for ≤ 7.5 percent TRR (Table 45).

Fluazaindolizine was identified only in the 30 and 120DAA samples at low concentrations (0.7–1.4 percent TRR, ≤ 0.016 mg/kg; Table 46). The principal extracted residue identified were IN-QEK31 accounting for 17.4–26.5 percent TRR (0.066-0.303 mg eq/kg) and glucose conjugate of IN-QEK31 (IN-UGA20 5.8–16.9 percent TRR, 0.022-0.192 mg eq/kg).

Other identified metabolites were IN-RYC33 (≤ 5.8 percent TRR, ≤ 0.066 mg eq/kg), the inositol conjugate of IN-QEK31 (IN-UHD13) and methyl ester of IN-QEK31 (IN-R2W56), (both ≤ 4.8 percent TRR, ≤ 0.055 mg eq/kg) as well as a glucose conjugate of IN-REG72 (≤8.0 percent TRR, ≤ 0.091 mg/kg) and multiple conjugates of IN-QEK31 (≤ 4.0 percent TRR, ≤ 0.046 mg eq/kg).

Multiple unidentified metabolites, including unretained components which may contain multiple metabolites, were also detected accounting for an aggregate total of 12.5-48.9 percent TRR in each sample but each individually was ≤9.1 percent TRR (≤ 0.088 mg eq/kg). A significant portion of the unknown metabolites were shown to hydrolyse to IN-QEK31 (Table 46).

Several small acidic metabolites are also postulated in [IP-5,8a-^{14}C]fluazaindolizine wheat samples occurring in the polar region of the chromatogram were further divided into distinct multiple metabolites.

Notes:

[1] the numbers in parentheses are results, where different, of repeat analysis just prior to acid hydrolysis

[A] Glucose-polyol and other conjugates of IN-QEK31 as determined by LC-MS.

[B] Values indicate the total residue of multiple unidentified polar metabolites in the 0-5 min region of the chromatogram, which were further analysed in the IP-5,8a straw extracts and demonstrated to incorporate multiple components.

[C] Unidentified, including unretained components, consisting of 7 components none >4.2 percent TRR, 0.048 mg eq/kg. The unretained residue was demonstrated to incorporate multiple components in the IP-5,8a straw extracts.

[D] Unidentified, including unretained components, consisting of 21 components none >8.7 percent TRR, 0.033 mg eq/kg. The unretained residue was demonstrated to incorporate multiple components in the IP-5,8a straw extracts.

[E] Unidentified components, consisting of 29 components none >4.3 percent TRR, 0.042 mg eq/kg plus an unretained component of 9.1 percent TRR, 0.088 mg equiv/kg. The unretained residue was demonstrated to be composed of at least 3 components in the IP-5,8a straw extracts.

[F] Unidentified, including unretained components, consisting of 6 components none >4.2 percent TRR, 0.048 mg eq/kg.

[G] Unidentified, including unretained components consisting of 3 components none >4.0 percent TRR, 0.045 mg eq/kg.

Straw

Extractability of ^{14}C in [IP-5,8a-^{14}C] straw using methanol:water was poor (52.8–64.4 percent TRR Table 47). The unextracted residues were subject to further investigations; these further treatments released an additional 27.7-38.9 percent TRR with terminal residues remaining in solids accounting for ≤ 8.3 percent TRR (Table 47).

Fluazaindolizine was found only in the 30 and 120DAA samples (1.4-4.3 percent TRR, ≤ 0.153 mg/kg). The principal extracted residue was IN-QEK31 accounting for 12.3-24.9 percent TRR (0.217-1.018 mg eq/kg: Table 48).

Other identified metabolites were IN-REG72, the inositol acid conjugate IN-QEK31 (IN-UHD13), glucose conjugate of IN-QEK31 (IN-UGA20), methyl ester of IN-QEK31 (IN-R2W56), IN-RYC33, and malic acid conjugate IN-QEK31 (IN-UJU44), (all ≤ 6.0 percent TRR, ≤ 0.246 mg eq/kg) together with a glucose conjugate of IN-REG72 (≤6.3 percent TRR, ≤ 0.224 mg eq/kg) and several more complex conjugates of IN-QEK31 (≤ 3.5 percent TRR, ≤ 0.123 mg eq/kg).

Multiple unidentified metabolites were also detected accounting for an aggregate total of 49.4–61.0 percent TRR in each sample but each individually was ≤ 7.6 percent TRR (≤ 0.228 mg eq/kg). A significant portion of these unknown metabolites were shown to hydrolyse to IN-QEK31 (Table 48). In addition, an unretained region was observed accounting for 7.1–14.0 percent TRR (≤ 0.568 mg eq/kg). Additional chromatography of the polar region of the chromatogram demonstrated that this region was comprised of several components, none greater than 4.3 percent of the TRR.

Grain

Extractability of ^{14}C in [IP-5,8a-^{14}C] grain using methanol:water was poor (53.8-62.8 percent TRR Table 49). The unextracted residues were subject to further investigations; these further treatments released an additional 36.5-46.2 percent TRR with terminal residues remaining in solids accounting for 0.7 percent TRR (Table 49).

Fluazaindolizine was not found in the grain samples. The principal extractable residue identified in grain was IN-QEK31 accounting for a total of 58.7–64.6 percent TRR (0.337–0.889 mg eq/kg) although

these values incorporate the residues identified following further extracts, which may have become deconjugated during the extraction procedure (Table 50).

Other identified metabolites were the inositol conjugate of IN-QEK31 (IN-UHD13), glucose conjugate of IN-QEK31 (IN-UGA20), IN-RYC33, and methyl ester of IN-QEK31 (IN-R2W56) (all ≤ 2.9 percent TRR, ≤ 0.023 mg eq/kg; Table 50). Radioactivity in the chromatograms with a similar retention time to IN-VM862 was found only in the 30DAA grain sample and accounted for 1.1 percent TRR (0.016 mg eq/kg) but could not be confirmed due to its low concentration. Additional metabolites included a glucose conjugate of IN-REG72 (≤ 2.6 percent TRR, ≤ 0.040 mg eq/kg) and multiple conjugates of IN-QEK31 (≤ 1.9 percent TRR, ≤ 0.025 mg eq/kg).

Multiple unidentified metabolites, including unretained components, were also detected accounting for an aggregate total of 15.3–26.7 percent TRR in each sample but each individually was ≤ 7.8 percent TRR (≤ 0.041 mg eq/kg). Most of these components appeared to be conjugates of IN–QEK31 based on their formation of IN-QEK31 after hydrolysis (Table 50).

Characterisation of residues in soil

The total radioactive residues for soil sampled at various points, determined after extraction and analysis of unextracted residues are shown in Table 51 and Table 52.

The majority of the ^{14}C in the [Ph-^{14}C] soil was released by initial extractions, 77.3–99.5 percent TRR. Fluazaindolizine was identified in all samples. Other metabolites identified included IN-REG72, IN-F4106, IN-A5760, IN-QEK31, and IN-RYC33.

Similarly, in the [IP-5,8a-^{14}C] experiment soil the initial extractions released 77.1–99.6 percent TRR. Fluazaindolizine was identified in all samples. Other metabolites identified included IN-REG72, IN-QEK31, and IN-RYC33. A volatile metabolite was captured during the concentration of the [IP-5,8a-^{14}C] labelled soil extracts. A volatile metabolite, trapped using the same methods, was identified as IN-VM862 in other studies with fluazaindolizine. Due to the low levels of the volatile metabolite observed in this study (<4 percent TRR), no further characterization or confirmation was attempted.

Notes:

[A] Samples were extracted sequentially; once with acetonitrile:0.2 percent formic acid (aq) (9:1), once with acetonitrile:0.2 percent formic acid (aq) (4:1) and twice with acetonitrile:0.2 percent formic acid (aq) (1:1). The percent TRR values and mg/kg values have been calculated from the total TRR. The limit of detection was determined by the Currie method.

[B] During concentration process, a PU plug was placed in the flask to trap any volatile metabolites, this was rinsed with methanol and quantified by LSC.

[C] Unknown metabolite.

Uptake and metabolism of fluazaindolizine in rotational crops

The metabolic pathway for fluazaindolizine in rotational crops following soil application is presented in Figures 6 to 8 and is proposed based on the metabolites identified in wheat, spinach, and radish.

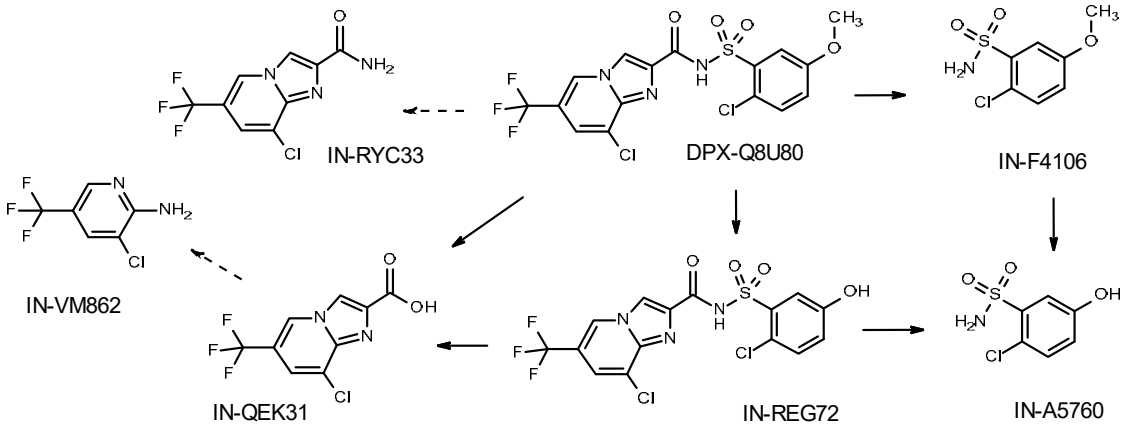

Figure 6 Proposed metabolic pathway of fluazaindolizine in soil from rotational crops

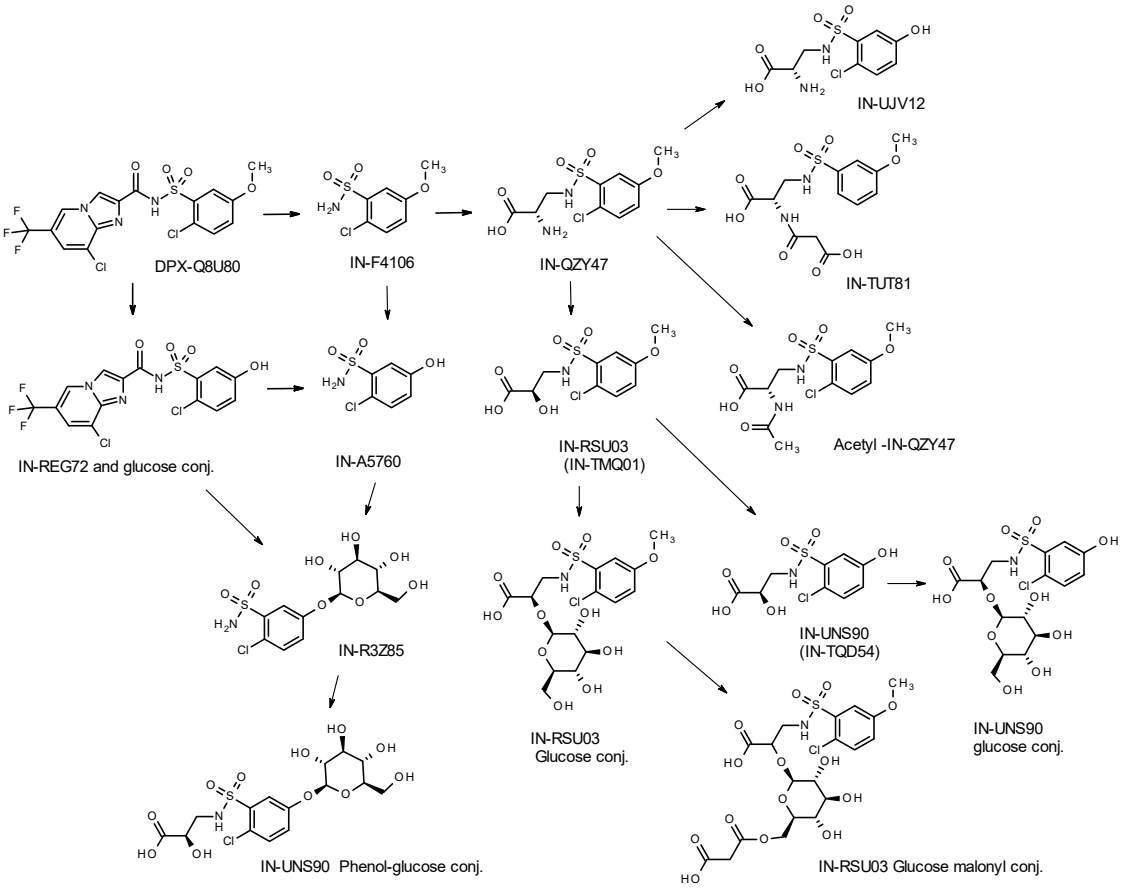

Figure 7 Proposed metabolic pathway of fluazaindolizine in rotational crops (metabolites containing [Ph-^{14}C] radiolabel

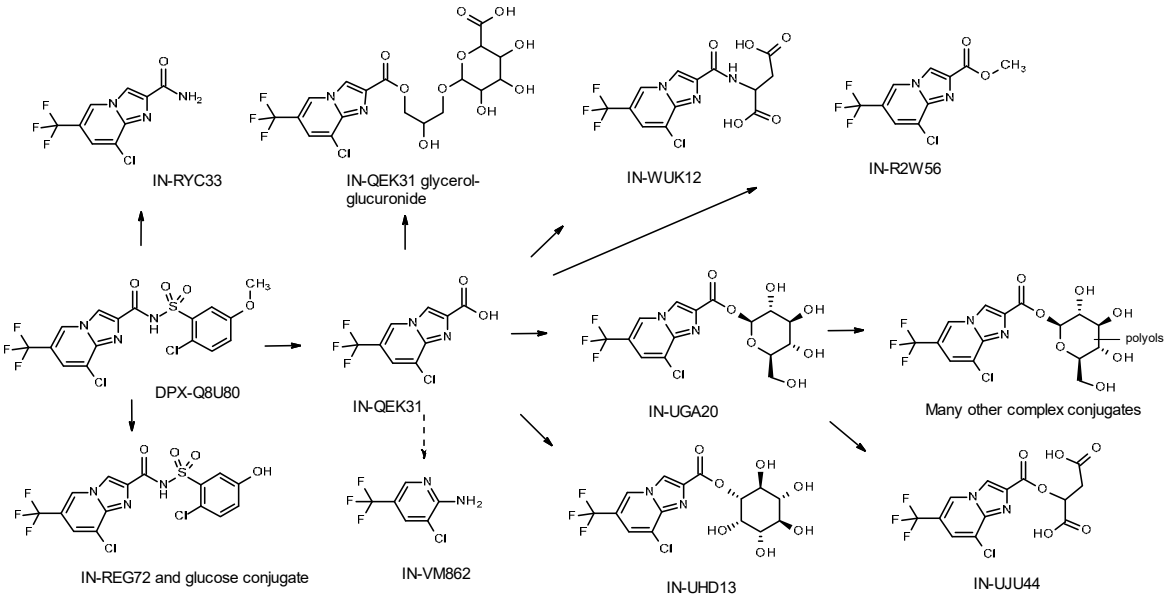

Figure 8 Proposed metabolic pathway of fluazaindolizine in rotational crops (metabolites containing [IP-5,8a-^{14}C] radiolabel)

Metabolic pathways of fluazaindolizine and its soil metabolites were similar across all the rotational crops and rotational intervals. Differences observed in the various crops were mainly in the degree and type of more complex conjugation with endogenous constituents that occurred.

Fluazaindolizine, IN-F4106, and IN-QEK31 were the major residues found in the soil which were available for uptake by plants. IN-F4106 and IN-QEK31 exceeded 50 percent of the residue by the 120-300 day plant-back intervals, while IN-RYC33, IN-REG72, and IN-A5760 were found between 2.3 and 11.7 percent TRR at various sampling intervals. IN-VM862, a soil metabolite containing only the pyridinyl ring was not observed in significant amounts in the soil (<4 percent TRR determined *via* capture of volatile residues). The major metabolic route in the soil was the hydrolysis of fluazaindolizine at the amide bond, resulting in IN-F4106 and IN-QEK31. Fluazaindolizine was also *O*-demethylated to form IN-REG72, which also was hydrolysed to IN-A5760 and IN-QEK31. A less prominent pathway was hydrolysis of fluazaindolizine at the sulfonamide bond, resulting in IN-RYC33 or the further degradation of IN-QEK31 to IN-VM862.

Fluazaindolizine was taken up and metabolised in the various rotational crops primarily by hydrolysis of the amide bond to IN-F4106 (observed in the [Ph–^{14}C]fluazaindolizine experiment) and to IN-QEK31 (observed in the [IP-5,8a-^{14}C]fluazaindolizine experiment). IN-F4106 and IN-QEK31 were the major metabolites found in soil at the various plant-backs and were likely taken up from soil directly. Hydrolysis of fluazaindolizine at the sulfonamide bond occurred to a lesser extent and resulted in forming IN-RYC33 from the [IP-5,8a-^{14}C]fluazaindolizine which could also be taken up directly from the soil into the various crops. Fluazaindolizine was metabolised to IN-REG72 *via O*-demethylation and found mostly in crops as its glucose conjugate. IN-F4106 and IN-QEK31 residues, whether formed in the plant or taken up from the soil were metabolised and conjugated to a significant degree. IN-F4106 was conjugated to serine to form IN-QZY47. The free amino moiety of IN-QZY47 was conjugated with malonic acid to form IN-TUT81 or acetylated, as found in spinach. The amino moiety of IN-QZY47 was also oxidatively deaminated to the lactic acid derivative, IN-RSU03, which was found only as the *R*-enantiomer, IN-TMQ01. IN-RSU03 (as IN-TMQ01) was conjugated to glucose and subsequently to malonic acid. IN-RSU03 underwent *O*-demethylation to form IN-UNS90 (as *R*-enantiomer IN-TQD54) and was found mostly conjugated to glucose at the 2-hydroxy propionic and/or phenolic positions, which were the major metabolites in wheat commodities. IN-REG72 and its glucose conjugate were metabolised to IN-A5760 and to IN-R3Z85 (IN-A5760 glucose conjugate). IN-UJV12 was formed from the *O*-demethylation of IN-QZY47 and was further conjugated. Several more complex conjugates originating from the [Ph Proposed metabolic pathway of fluazaindolizine in rotational crops (metabolites containing [Ph-^{14}C] radiolabel–^{14}C]fluazaindolizine were hydrolysed with 1N HCl to IN-F4106, IN-A5760, IN-QZY47, IN-RSU03, IN-UNS90, and IN-UJV12.

IN-QEK31 unconjugated and/or conjugated with various endogenous constituents, were the predominant metabolites identified from the [IP-5,8a-^{14}C]fluazaindolizine. IN-QEK31 was the major metabolite in wheat forage, hay, grain, and spinach. Glucose conjugation of IN-QEK31 through the acyl moiety to form IN-UGA20 appeared to be the initial conjugation reaction, while conjugation to inositol sugar derivative (IN-UHD13) occurred at lower levels in the various crops. The simple glucose conjugates of IN-QEK31 underwent acyl migration forming multiple isomers. In wheat, more complex glucose-polyols derivatives were also proposed to be formed based on mass spectral analysis. The glucose conjugate of IN-QEK31 in radish was largely displaced with malic acid, to form IN-UJU44. Other IN-QEK31 conjugates identified included a glycerol glucuronide found primarily in spinach, and a glutamic acid conjugate (IN-WUK12) found in radish. IN-RYC33, IN-REG72 and/or its glucose conjugate were also found in all rotated crops. The methyl ester of IN-QEK31 (IN-R2W56) was formed to a small extent and could be an artefact of the extraction methodology or a metabolite. Most residues found in rotated crops from the [IP-5,8a-^{14}C]fluazaindolizine were hydrolysed to IN-QEK31 with 1N HCl. Certain highly polar residues composed of multiple components were present in various wheat straw extracts and accounted for a sum of 15.3 percent TRR. These polar components were resistant to HCl hydrolysis and, where analysed, no chromatographically separated polar metabolites from this polar region exceeded 4.3 percent TRR upon further HPLC separation. These components may be formed from the further degradation of IN-QEK31 or

may be the result of $^{14}CO_2$ incorporation into endogenous constituents. The soil metabolite IN-VM862 was found as a minor component in wheat straw < 1 percent TRR and may account for 1.1 percent TRR in wheat grain, based on the radioactive region co-eluting at its HPLC retention time, but appeared to be insignificant in other crop matrices (<LOD).

Identified residues found at greater than 10 percent TRR in any crop commodity at any PBI (30, 120, or 300DAA) are presented as sum total of metabolites and their corresponding conjugates (e.g., IN-UNS90 and glucose conjugates expressed as IN-UNS90, IN-QZY47 and its malonyl conjugate IN-TUT81 expressed as IN-QZY47, etc.). Those residues for wheat are IN-UNS90 (IN-TQD54), IN-RSU03 (IN-TMQ01), and IN-QEK31, but in spinach are fluazaindolizine, IN-REG72, IN-QZY47, IN-QEK31, and on acid hydrolysis IN-F4106 (identified residues in rotated crops >10 percent TRR). In radish the residues are fluazaindolizine, IN-RSU03, IN-QZY47, IN-UNS90, IN-QEK31, and on acid hydrolysis IN-F4106 (identified residues in rotated crops >10 percent TRR). This also includes any degradates greater than 10 percent TRR released by hydrolysis.

Animal metabolism

Metabolism studies with livestock were carried out with [Ph-^{14}C (U)]-fluazaindolizine or [imidazo-(1,2-α)-pyridine-2-^{14}C]-fluazaindolizine.

	[phenyl-^{14}C (U)]fluazaindolizine	[imidazo[1,2-a]pyridine-2-^{14}C]fluazaindolizine

Livestock (goat) studies

Wicksted (2014 DuPont-33573, Revision No. 1) investigated the metabolism of fluazaindolizine in lactating goats administered either as [Ph-^{14}C]fluazaindolizine or [IP-2-^{14}C]fluazaindolizine.

Two goats (Saanen/Toggenburg cross breed, 2-4 years, 42-44 kg bw) were dosed orally *via* capsules, once a day for seven consecutive days, with [Ph-^{14}C]-fluazaindolizine or [IP-2-^{14}C]-fluazaindolizine, at doses equivalent to 12.2 and 11.8 ppm of fluazaindolizine in the diet. The average feed consumption of 1.393-1.819 kg/day during the dosing period. These doses were equivalent to an average dose of 0.420 and 0.479 mg fluazaindolizine/kg bw, respectively. Milk production was 2.2 kg/day. Milk samples were collected twice a day while urine and faeces samples were collected daily. Goats were sacrificed 6 hours after the final dose, samples of whole liver, both kidneys, muscle (composite of loin, hind, and fore quarter muscle in approximately equal proportions) and fat (individual omental, renal, and subcutaneous fat samples) were collected from each goat. Composite milk (Day 4-6), urine and faeces (Day 1-7) samples were prepared for analysis for both dose groups. Milk, tissues, and excreta were extracted and analysed within 189 days (6 months) of sampling.

Analytical procedures

Tissue and fat samples were homogenised in dry ice. Equal amounts of milk from Days 4–6 were pooled by dose group. Aliquots of the composited whole milk samples were also centrifuged (3000 rpm; 10 min) to determine the radioactive distribution in the cream and skimmed milk fractions prior to storage at ca. -

20 °C and assayed by LSC. Subsamples of tissues and milk were extracted with acetonitrile:0.1 M ammonium formate, pH 7 (9:1). The resulting extracts were combined by matrix, concentrated, and analysed by LSC and HPLC. The liver PES from both goats were further treated with protease (37 °C; 72 hours) to release unextracted residues. All extracts were stored at -20 °C prior to HPLC.

The total recovery was 96.7-108 percent of the administered dose for both goats. For both [^{14}C]-labels, 79.9 and 89.7 percent of the dose was recovered from the urine, faeces, bile, and cage wash with a further 15.9 and 17.4 percent found in the gastrointestinal tract (Table 53). About 0.9 percent of the dose was recovered in edible tissues and another 0.1 percent of the dose was recovered in the milk. Radioactivity plateaued in milk within 3 days at 0.05–0.06 mg eq/kg for the [Ph-^{14}C]fluazaindolizine and 0.04-0.05 mg eq/kg for the [IP-2-^{14}C]fluazaindolizine (Table 53). TRR in the composite milk (Day 4–6) from goats dosed with [Ph-^{14}C]fluazaindolizine partitioned equally in cream (0.050 mg eq/kg) in skim milk (0.054 mg eq/kg). TRR in the composite milk from goats dosed with [IP-2-^{14}C]fluazaindolizine partitioned slightly higher in cream (0.063 mg eq/kg) *vs.* skim milk (0.046 mg eq/kg), however, overall, this data indicated no selective partitioning as residues (less than 2-fold) in the milk fractions from goats dose with either radiolabel.

TRR levels in edible tissues were 0.223 mg eq/kg in liver, 0.358 in kidney, 0.011 in muscle, 0.015 in omental fat, 0.028 in renal fat and 0.024 mg eq/kg in subcutaneous fat from the [Ph-^{14}C]fluazaindolizine dosed goat, and 0.275 mg eq/kg in liver, 0.357 in kidney, 0.010 in muscle, 0.008 in omental fat, 0.014 in renal fat and 0.013 mg eq/kg in subcutaneous fat from the [IP-2-^{14}C]fluazaindolizine dosed goat. There was not a selective partitioning into skim milk or cream or into the various fat types (Tables 53 and 54). The residues in whole milk from day 1 to 6 os shown in Figure 9.

Extractability from tissues with acetonitrile:0.1 M ammonium formate, pH 7 (9:1) was good for liver, kidney, muscle, and fat (>85 percent TRR) and Day 4-6 milk (>96.9 percent TRR). Digestion of liver PES with protease released ^{14}C, overall ≥96 percent TRR. Extracted [^{14}C]-residues were analysed and quantified by reverse phase HPLC, and metabolite identities were confirmed by co-chromatography with reference standards and by LC-MS.

Table 53 Percent administered dose recovered in milk, tissues and excreta from lactating goats following seven consecutive daily oral doses of [Ph-^{14}C]fluazaindolizine or [IP-2-^{14}C]fluazaindolizine

Sample	[Ph-^{14}C]fluazaindolizine	[IP-2-^{14}C]fluazaindolizine
Tissues	0.8	0.9
Liver	0.3	0.4

Identification and characterisation of radioactive residues

The majority of radioactive residues (73.3–92.3 percent TRR) was identified and/or characterised in tissues from the [Ph-^{14}C]fluazaindolizine dosed goat (Table 55). Fluazaindolizine accounted for 17.5-84.6 percent TRR in tissues and milk. The phenyl-derived metabolites included IN-A5760 (maximum 4.1 percent TRR), IN-F4106 (maximum 38.4 percent TRR) and IN-REG72 (maximum 7.0 percent TRR). Several minor unidentified metabolites were also detected, none of which individually were greater than 7.3 percent TRR, which combined accounted for 5.5–12.8 percent TRR in milk and tissues.

The majority of radioactive residues (83.1-100 percent TRR) was identified and/or characterised in tissues from the [IP-2-^{14}C]fluazaindolizine dosed goat (Table 56). Fluazaindolizine (parent) accounted for 25.0-83.2 percent TRR in tissues and milk. The imidazopyridine-derived metabolites included IN-QEK31 (maximum 42.8 percent TRR), IN-REG72 (maximum 11.6 percent TRR) and methyl ester of IN-QEK31 (IN-R2W56) (maximum 0.6 percent TRR). Several minor unidentified metabolites were also

detected, none of which individually were greater than 4.0 percent TRR, which combined accounted for 4.0–8.3 percent TRR in milk and tissues.

Identification/characterisation of urine, faeces, and bile metabolites

In Day 1-7 urine composite from a goat dosed with [Ph-^{14}C]-fluazaindolizine, unchanged fluazaindolizine accounted for 25.2 percent of the total administered dose. The metabolites IN-A5760 (4.1 percent dose), IN-F4106 (0.2 percent dose) and IN-REG72 (1.0 percent dose) were identified. Several minor unknown components were detected none of which individually accounted for >1.0 percent dose.

In Day 1–7 faeces composite from a goat dosed with [Ph-^{14}C]-fluazaindolizine, unchanged fluazaindolizine accounted for 30.8 percent of the total administered dose. The metabolite IN-REG72 (7.9 percent dose) was identified. Several minor unknown components were detected, however, none of which individually accounted for >0.9 percent dose.

Bile from a goat dosed with [Ph-^{14}C]fluazaindolizine contained metabolites IN-A5760 (<0.1 percent dose), IN-F4106 (0.1 percent dose) and IN-REG72 (2.7 percent dose). Two minor unknown components were detected, neither of which individually accounted for >1.0 percent dose.

In Day 1-7 urine composite from a goat dosed with [IP-2-^{14}C]fluazaindolizine, unchanged fluazaindolizine accounted for 19.0 percent of the total administered dose. The metabolites IN-QEK31 (1.5 percent dose) and IN-REG72 (0.7 percent dose) were identified. Two minor unknown components were detected, neither of which individually accounted for >0.1 percent dose.

For Day 1-7 faeces composite from a goat dosed with [IP-2-^{14}C]fluazaindolizine, unchanged fluazaindolizine accounted for 27.7 percent of the total administered dose. The metabolites, IN-QEK31 (0.8 percent dose), IN-REG72 (6.5 percent dose) and IN-RYC33 (0.1 percent dose) were identified. Several minor unknown components were also detected, none of which individually accounted for >3.9 percent dose.

Bile from a goat dosed with [IP-2-^{14}C]fluazaindolizine contained unchanged fluazaindolizine which accounted for <0.1 percent of the total administered dose. The metabolites IN-QEK31 (<0.5 percent dose), IN-REG72 (3.9 percent dose) and IN-R2W56 (0.1 percent dose) were identified. Two minor unknown components were detected, neither of which individually accounted for >0.3 percent dose.

Proposed metabolic pathway of fluazaindolizine in the goat

The proposed metabolic pathway of [^{14}C]fluazaindolizine was shown in Figure 10. The metabolism of fluazaindolizine was complex and was based on metabolites identified in the tissues and in the excreta. The following metabolic pathway was proposed: biotransformation of fluazaindolizine in the goat occurred primarily through O-demethylation and hydrolysis of the amide bond to form the cleaved metabolites IN-QEK31 and IN-A5760 via IN-REG72. Direct hydrolysis of fluazaindolizine gave metabolites IN-F4106 and IN-QEK31. IN-RYC33 was formed from the hydrolysis of the sulphonamide bond of fluazaindolizine. The metabolite IN-R2W56 was formed via methylation of the carboxylic acid group on IN-QEK31.

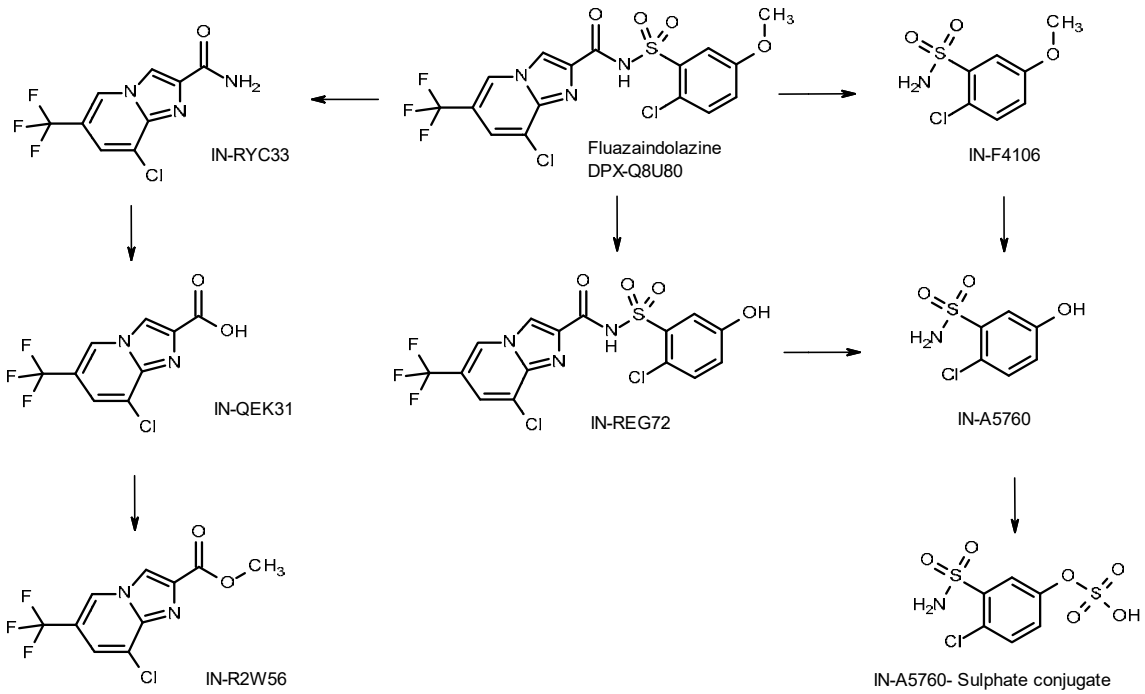

Figure 10 Proposed metabolic pathway of fluazaindolizine in lactating goats

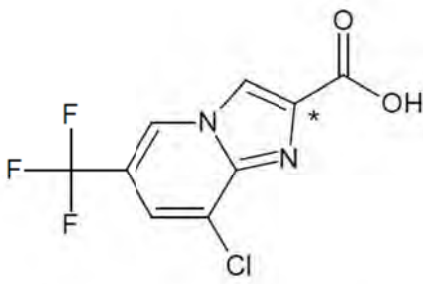
Metabolism of [^{14}C]IN-QEK31 in lactating goats

Cochrane (2017a DuPont-41870) studied the metabolism of [^{14}C]-IN-QEK31 in the lactating goat.



* – Denctes position of radiolabel

[IP-2-^{14}C]-IN-QEK31 was administered *via* capsules to a lactating goat (Saanen/Alpine cross, 4 years old, 44–45 kg bw) as a single daily oral dose for five consecutive days. The average daily dose administered to the goat was 12.469 ppm [IP-two-^{14}C]-IN-QEK31 in the diet (dw equivalent). The dose level was equivalent to an average dose of 0.348 mg IN-QEK31/kg bw/day. Milk production was 2.2 kg/day. Feed consumption was 1.26 kg/day.

Faeces and urine were collected once daily and milk collected twice daily. The goat was sacrificed approximately 6 h after the last dose and liver, kidney, muscle, omental fat, renal fat, subcutaneous fat, bile, gastrointestinal tract, and contents were collected.

All samples were stored at *ca.* -20 °C until taken for analysis. All samples were extracted within 13 days and extracts initially analysed within 52 days following the extraction procedure. The longest storage interval (between sample collection and analysis of sample extracts) recorded for any individual sample (liver, kidney, and renal fat) was 63 days (*ca.* 2 months).

Analytical procedures

Tissue samples were homogenised with the aid of dry ice. Composite samples (Days 1-5) of milk, faeces, and urine were prepared by combining equal amounts of each daily sample by matrix. Subsamples of tissues, milk (Days 1-5 composite) and faeces (Days 1-5 composite) were prepared for metabolite extraction and analysis. Samples were extracted with acetonitrile:0.1 M ammonium formate, pH 7 (9:1). The liver PES from the goat were further treated with dilute acid (acetonitrile:0.1M hydrochloric acid (1:4)) to release unextracted residues. All extracts were stored at -20°C prior to HPLC.

The total recovery was 87.1 percent of the administered dose, of which 73.1 percent of the dose was recovered from the urine, faeces, and cage wash with a further 11.8 percent found in the gastrointestinal tract (Table 57), 2.1 percent of the dose was recovered in the milk. Radioactivity in milk reached plateau within 3 days post first dose *ca.* 0.169 mg eq/kg (Table 58). TRR in the composite milk (Day 1-5) were separated into cream (0.105 mg eq/kg) and skim milk (0.170 mg eq/kg) fractions by LSC analysis following physical separation (centrifugation). This data indicated no selective partitioning as residues (less than 2-fold) in the milk fractions from goats dosed with IN-QEK31. Negligible amounts of radioactivity were recovered in the edible tissues (< 0.1 percent of the administered total dose).

TRR in edible tissues were 0.035 mg eq/kg in liver, 0.282 in kidney, <0.001 in muscle, 0.005 in omental fat, 0.046 in renal fat and 0.002 mg eq/kg in subcutaneous fat (Table 57). Residues in milk from day 1 to 4 is shown in Figure 11.

5[A]	104[B]	0.209	0.342

Notes:

[A] Partial day milk sample (0-6 hr) after last dose.

[B] 104 h refers to the sample ID only, the goat was milked directly before sacrifice which was *ca.* 102 hour (6 hour after last dose).

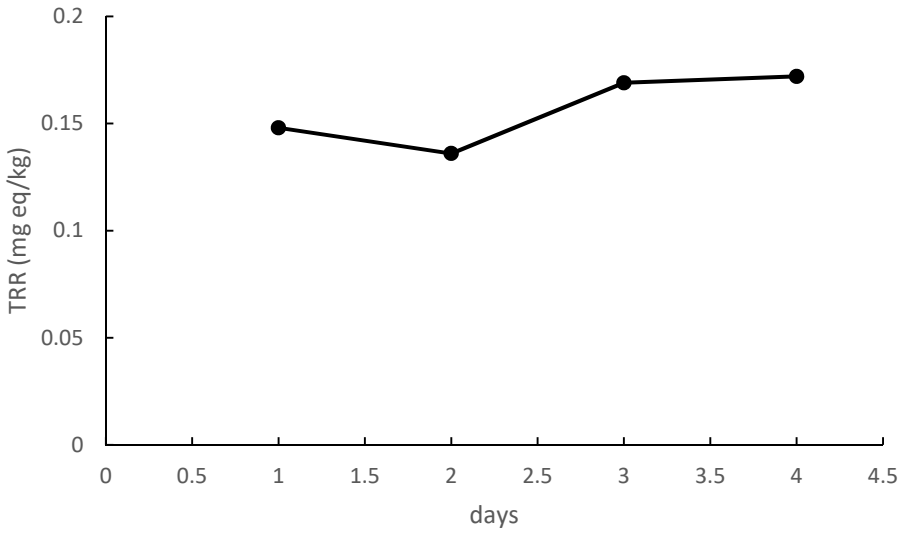

Figure 11 Residues in milk following dosing with ^{14}C-IN-QEK31 (note last milk sample not plotted as does not represent a 24-hour sample, i.e. residues in milk are higher in the first milking collected after dosing).

Identification and characterization of radioactive residues

Extractability of milk and tissues with acetonitrile:(100 mM ammonium formate) (9:1) was good with > 90 percent TRR released, the exception being liver for which 79.7 percent TRR was released. Extraction of the bound liver residues with more polar and acidic extraction methods did not release any further radioactivity; however, the levels of bound residue were low 0.007 mg eq/kg.

Identification/characterization of tissue residues

The majority of radioactive residues (74.1–95.5 percent TRR) was identified and/or characterised in tissues. Unchanged IN-QEK31 accounted for 74.3–95.4 percent TRR in tissues and milk. A single metabolite was present at greater than 10 percent TRR which was identified as IN-R2W56 and detected only in renal fat (Table 59). Several minor unidentified metabolites were also detected, none of which individually were greater than 5.0 percent TRR, which combined accounted for 6.2 percent TRR in milk and tissues.

Table 59 Identification of radioactivity in milk and tissues from [IP-2-^{14}C]-IN-QEK31 dosed lactating goat (% TRR)

	Milk, TRR= 0.168 mg eq/kg	Liver, TRR= 0.035 mg eq/kg	Kidney, TRR= 0.282 mg eq/kg	Renal fat. TRR= 0.046 mg eq/kg

	Milk, TRR= 0.168 mg eq/kg	Liver, TRR= 0.035 mg eq/kg	Kidney, TRR= 0.282 mg eq/kg	Renal fat. TRR= 0.046 mg eq/kg

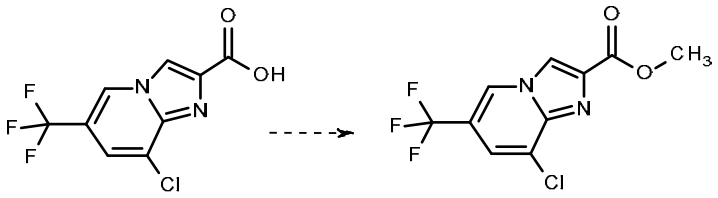
ND = Not detected.
[A] Sum of all unidentified radioactivity in chromatograms, no single metabolite greater than 5.0 percent TRR or 0.004 mg eq/kg

Unchanged IN-QEK31 was identified in urine (57.1 percent dose) and faeces (11.8 percent dose).

IN-QEK31 was eliminated from the goat and remained unchanged in milk, tissues, urine, and faeces with no significant metabolism observed. IN-R2W56 was formed via methylation of the carboxylic acid group on IN-QEK31 and was present as a metabolite only in renal fat at 16.6 percent TRR but at a low concentration of 0.008 mg/kg (Figure 12).

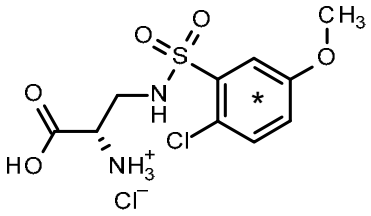


IN-QEK31 IN-R2W56 (renal fat only)

Figure 12 Proposed metabolic pathway for IN-QEK31 in lactating goat

Metabolism of [^{14}C]-IN-QZY47 in lactating goats

Cochrane (2017b DuPont-44398) also studied the metabolism of [^{14}C]-IN-QZY47 in the lactating goat (Saanen/Toggenburg breed, 5 years old, 59 kg bw). [Phenyl-^{14}C (U)]-IN-QZY47 was administered via capsules to a lactating goat as a single daily oral dose containing on average 20 mg [^{14}C]-IN-QZY47 for five consecutive days. The average daily dose administered to the goat was 10.06 ppm [^{14}C]-IN-QZY47 in the diet (dry weight equivalent). Feed consumption was 1.999 kg/day. The dose level was equivalent to an average dose of 0.351 mg IN-QZY47/kg bw/day. Milk production was 2.3 kg/day.



Faeces and urine were collected once daily, and milk collected twice daily. The goat was sacrificed approximately 6 hours after the last dose and liver, kidney, muscle, omental fat, renal fat, subcutaneous fat, bile, gastrointestinal tract, and contents were collected.

Analytical procedures

Tissue samples were homogenised with the aid of dry ice. Composite samples (Days 1–5) of milk, faeces and urine were prepared by combining equal amounts of each daily sample by matrix. Subsamples of tissues and milk (Days 1–5 composite) were prepared for metabolite extraction and analysis. Samples were extracted with acetonitrile:0.1 M ammonium formate, pH 7 (9:1). The extraction mixtures were homogenised followed by centrifugation and the resulting supernatants analysed by LSC. The liver and kidney PES were further treated with protease enzyme to release unextracted residues. To confirm the presence of certain conjugates, a urine extract was also incubated with β-glucuronidase from Helix pomatia, in sodium acetate buffer for ca. 18 hours at ca. 37 ºC. The reaction was stopped by addition of acetonitrile and the radioactive content was determined by LSC analysis of triplicate aliquots prior to HPLC analysis. All extracts were stored at -20 °C prior to analysis.

The total recovery was 86.4 percent of the administered dose, of which 83.7 percent of the dose was recovered from the urine, faeces, and cage wash with a further 2.5 percent found in the gastrointestinal tract (Table 60). Negligible amounts of radioactivity were recovered in the edible tissues and milk (*ca.* 0.2 percent of the administered total dose). Radioactivity reached plateau in milk after 1 day at *ca.* 0.016 mg eq/kg (Table 61 and Figure 13). A Day 1-5 composite milk sample (0.018 mg eq/kg) was prepared and separated into cream (0.021 mg eq/kg) and skimmed milk (0.018 mg eq/kg). This data indicated no selective partitioning of residues (less than 2-fold) in the milk fractions from goats dosed with IN-QZY47.

TRR in edible tissues were 0.344 mg eq/kg in liver, 0.824 mg eq/kg in kidney, 0.057 mg eq/kg in muscle, 0.034 mg eq/kg in omental fat, 0.044 mg eq/kg in renal fat and 0.050 mg eq/kg in subcutaneous fat (Table 60).

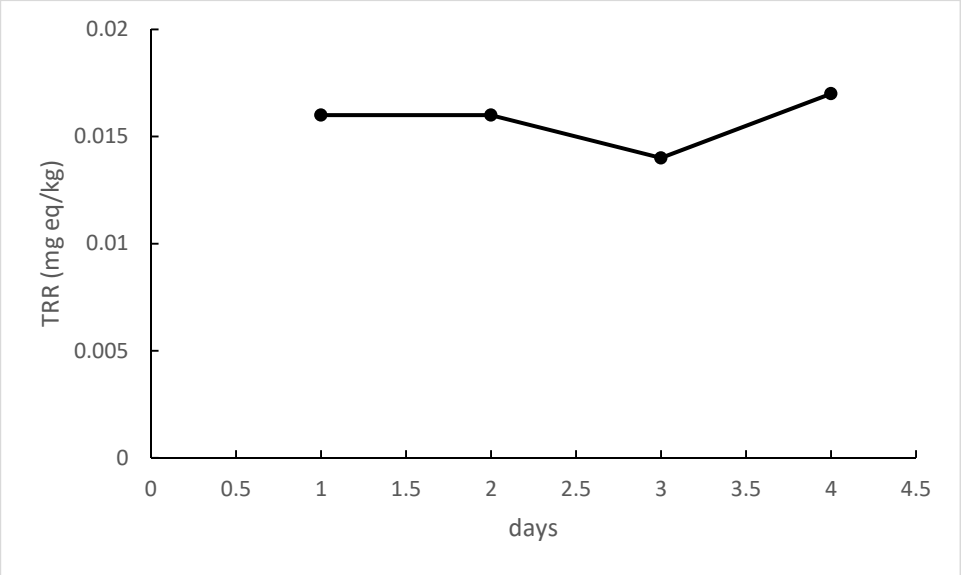

Figure 13 Residues in milk following dosing with ^{14}C-IN-QZY47 (note last milk sample not plotted as does not represent a 24-hour sample, i.e. residues in milk are higher in the first milking collected after dosing).

Extractability of milk and tissues with acetonitrile:(100 mM ammonium formate) (9:1) was good with > 83 percent TRR released.

The majority of radioactive residues (74.6–98.6 percent TRR) were identified and/or characterised in various tissues from the [^{14}C]-IN-QZY47 dosed goat. In milk and tissues, metabolites included IN-F4106 (maximum 81.4 percent TRR), IN-A5760 (maximum 11.4 percent TRR) and IN-A5760 conjugates (maximum 41.0 percent TRR). Several minor unidentified metabolites were also detected, none of which individually were greater than 8.3 percent TRR or 0.017 mg eq/kg (Table 62).

Notes:

NA=Not applicable.

ND=Not detected (detection limit typically 0.001 mg/kg).

[A] Sum of all other unidentified radioactivity in chromatograms, no single metabolite greater than 3.2 percent TRR (0.011 mg eq/kg).

[B] Sum of two components identified as IN-A5760 glucuronide.

[C] Sum of all other unidentified radioactivity in chromatograms, no single metabolite greater than 5.0 percent TRR (0.017 mg eq/kg).

[D] Sum of all other unidentified radioactivity in chromatograms, no single metabolite greater than 5.0 percent TRR (0.017 mg eq/kg).

[E] Sum of all other unidentified radioactivity in chromatograms, no single metabolite greater than 5.0 percent TRR (0.003 mg eq/kg).

HPLC analysis of composite urine identified IN-A5760 (14.4 percent dose) and IN-F4106 (0.8 percent dose) and to unknown components tentatively identified as glucuronide and sulfate conjugates of IN-A5760 accounting for 53.6 and 5.6 percent of the total administered dose, respectively. Qualitative analysis of urine incubated in a β-glucuronidase solution supported the presence of IN-A5760 conjugates. Faeces contained IN-A5760 (6.0 percent dose) and IN-F4106 (0.8 percent dose), a sulfate conjugate of IN A5760 (0.1 percent dose).

Proposed metabolic pathway of IN-QZY47 in the lactating goat

The proposed metabolic pathway of [^{14}C]-IN-QZY47 is shown in Figure 14. The primary biotransformation pathway of IN-QZY47 involved hydrolysis of the amide bond to form the cleaved metabolite IN-F4106. The metabolite IN-A5760 formed via O-demethylation of IN-F4106. Glucuronide and sulphate conjugates of IN-A5760 were formed and eliminated in the excreta. A glutathione conjugate of IN-A5760 was found only in liver extracts.

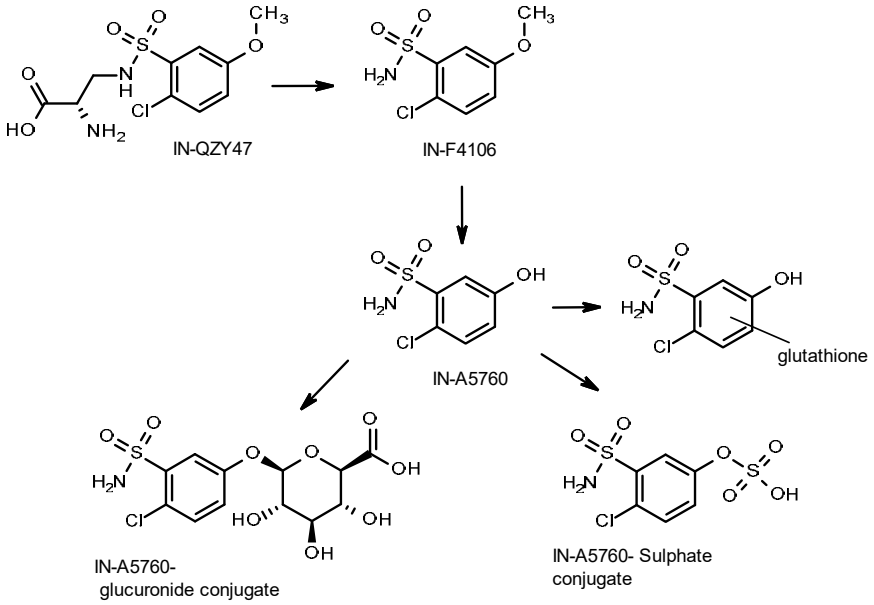

Figure 14 Proposed metabolic pathway for IN-QZY47 in the lactating goat

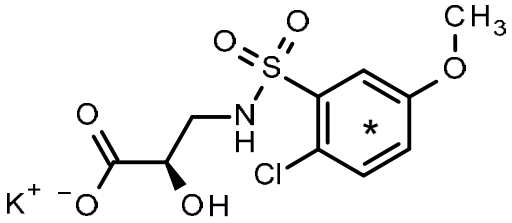
Note: All structures are depicted in their free acid or base forms.

Metabolism of [^{14}C]-IN-TMQ01 in lactating goats

Cochrane (2017c DuPont-42614) also investigated the metabolism of [^{14}C]-IN-TMQ01 in the lactating goat.



[Phenyl-^{14}C(U)]IN-TMQ01 was administered *via* capsules to a lactating goat (Saanen/Toggenburg breed, 4 years old, 57.5 kg bw) as a single daily oral dose for five consecutive days. The average daily dose administered to the goat was 10.86 ppm [^{14}C]-IN-TMQ01 diet (dry weight equivalent). The dose level was equivalent to an average dose of 0.278 mg IN-TMQO1 mg/kg bw/day. Milk production was 2.0 kg/day. Feed consumption was 1.478 kg/day.

Faeces and urine were collected once daily, and milk collected twice daily. The goat was sacrificed approximately 6 hours after the last dose and liver, kidney, muscle, omental fat, renal fat, subcutaneous fat, bile, gastrointestinal tract, and contents were collected.

All samples were stored at *ca.* -20 °C until taken for analysis. All samples were extracted within 47 days frozen storage and extracts initially analysed within 96 days from collection with the exception of analysis of subcutaneous fat, which occurred within 222 days (7 months).

Tissue samples were homogenised with the aid of dry ice. Composite samples (Days 1-5) of milk, faeces and urine were prepared by combining equal amounts of each daily sample by matrix. Subsamples of tissues, milk (Days 1-5 composite) and faeces (Days 1-5 composite) were prepared for metabolite extraction and analysis. Samples were extracted with acetonitrile:0.1 M ammonium formate, pH 7 (9:1).

Fat samples were first extracted with dichloromethane which removed negligible amount of radioactivity. The extraction mixtures were homogenised followed by centrifugation and the resulting supernatants analysed by LSC. Extracts warranting analysis were combined by matrix (where applicable), concentrated, and analysed by LSC and HPLC. The liver PES was further treated with protease enzyme to release unextracted residues, and the resulting extract analysed by LSC. All extracts were stored at -20 °C prior to HPLC.

The total recovery was 98.3 percent of the administered dose, of which 80.4 percent of the dose was recovered from the urine, faeces, and cage wash with a further 17.9 percent found in the gastrointestinal tract (Table 63). Negligible amounts of radioactivity were recovered in the edible tissues and milk (<0.1 percent of the administered total dose). Radioactivity reached plateau in milk within 3 days at 0.008 mg eq/kg (Table 64, Figure 15).

TRR in edible tissues were 0.021 mg eq/kg in liver, 0.220 in kidney, 0.002 in muscle, 0.001 in omental fat, 0.003 in renal fat and 0.003 mg eq/kg in subcutaneous fat (Table 63).

Table 63 Percent administered dose recovered in milk, tissues and excreta from a lactating goat following five consecutive daily oral doses of [^{14}C]-IN-TMQ01

Sample	% dose [A]
Tissues	<0.1
Liver	<0.1
Kidney	<0.1
Muscle	<0.1
Omental Fat	<0.1
Renal Fat	<0.1
Subcutaneous Fat	<0.1
Milk[A,B]	<0.1
Faeces	43.7
Urine	34.5
Cage Wash	2.2
GI Tract Contents	17.9
Total	98.3

Notes:

[A] TRR values correspond to the concentration determined for the Day 1-5 composite samples.

[B] Total radioactive residues in the composite milk (Day 1-5) were separated into cream (0.006 mg equiv/kg) and skim milk (0.007 mg equiv/kg) fractions and measured by LSC analysis following physical separation (centrifugation).

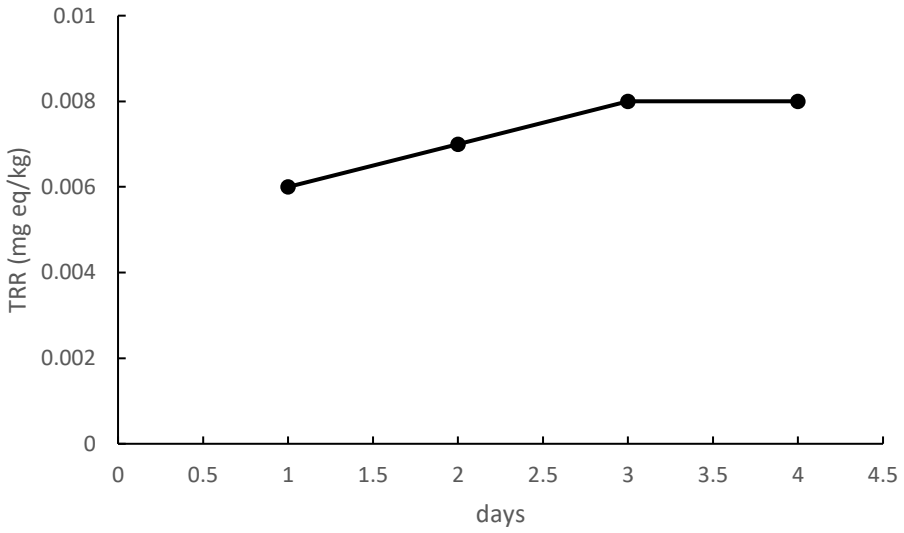


Figure 15 Residues in milk following dosing with ^{14}C-IN-TMQ01 (note last milk sample not plotted as does not represent a 24-hour sample, i.e. residues in milk are higher in the first milking collected after dosing).

In milk and tissues containing residues greater than 0.01 mg eq/kg, nearly all of the radioactive residues (66.1 percent to 100.0 percent TRR) were extracted with acetonitrile:(100 mM ammonium formate) (9:1). Digestion with protease released the remaining radioactive residues in liver increasing the total extracted in this tissue to 100 percent TRR (Table 65).

Table 64 TRR in milk following daily oral administration of [^{14}C]-IN-TMQ01 to a goat for five consecutive days

Sampling Time (Day)	Sampling Time (Hours)	Total mg excreted	Concentration (mg eq/kg)
1	24	0.010	0.006
2	48	0.012	0.007
3	72	0.017	0.008
4	96	0.017	0.008
5[A]	104[B]	0.006	0.009

Notes:

[A] Partial day milk sample (0-6 hour) after last dose

[B] 104 h refers to the sample ID only, the goat was milked directly before sacrifice which was *ca.* 102 hour (6 hour after last dose)

The majority of radioactive residues (66.1–100 percent TRR) were identified and/or characterised in the various tissues. Unchanged IN-TMQ01 accounted for 42.7–86.7 percent TRR in tissues. IN-F4106 accounted for 1.0–43.6 percent TRR in tissues and essentially all of the residue in milk (97.5 percent TRR; 0.007 mg eq/kg). Several minor unidentified metabolites were also detected, none of which individually exceeded 4.8 percent TRR, with the exception of muscle and subcutaneous fat in which a single unknown component accounting for 13.7–22.7 percent TRR was detected, however, these unknowns only equated to a low concentration of ≤ 0.001 mg eq/kg.

The major components in kidney and faeces were IN-TMQ01 and IN-F4106. The metabolite IN-UNS90 (expected to be as the *R*-enantiomer IN-TQD54) was also tentatively identified in the faeces.

Notes:

NA = Not applicable.

ND = Not detected (detection limit typically 0.001 mg eq/kg).

[A] 2 unknowns (individually ≤ 0.001 mg eq/kg, ≤4.8 percent TRR) totalling 0.002 mg eq/kg (8.9 percent TRR).

[B] 2 unknowns (individually ≤ 0.006 mg eq/kg, ≤ 2.8 percent TRR) totalling 0.011 mg eq/kg (4.8 percent TRR).

[C] 1 unknown ≤ 0.001 mg eq/kg, 13.7 percent TRR.

[D] One unknown 0.001 mg eq/kg, 22.7 percent TRR.

[E] Fat samples were first extracted with dichloromethane which removed negligible amount of radioactivity (<LOQ) before proceeding with acetonitrile/buffer.

Proposed metabolic pathway of IN-TMQ01 in the lactating goat

The proposed metabolic pathway of [^{14}C]-IN-TMQ01 in the lactating goat is shown in Figure 16. IN-TMQ01 was eliminated from the goat and remained unchanged in tissues, urine and faeces with minor metabolism observed. The primary biotransformation pathway of IN-TMQ01 involved hydrolysis of the amide bond to form the cleaved metabolite IN-F4106. O-demethylation of IN-TMQ01 to IN-UNS90 (expected to be as the R-enantiomer IN-TQD54) occurred to a small extent.

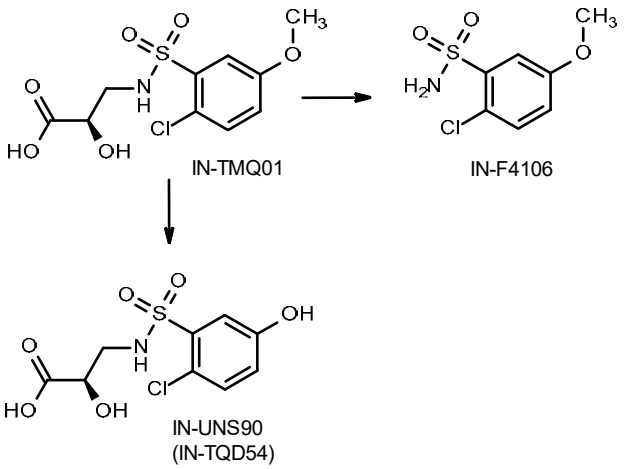

Figure 16 Proposed metabolic pathway of IN-TMQ01 in the lactating goat

Metabolism of [^{14}C]fluazaindolizine in laying hens

Wicksted (2013 DuPont-33572, Revision No. 1) studied the metabolism of [^{14}C]-fluazaindolizine in laying hens.

Two groups of Hy-Line Layer hens (5 per group, 1.72–2.08 kg bw) were dosed orally *via* capsules, once a day for 14 consecutive days, with [Ph-^{14}C]-fluazaindolizine or [IP-2-^{14}C]-fluazaindolizine at doses averaging 13.1 and 13.6 ppm of fluazaindolizine in the diet (dry weight basis). These dose rates were equivalent to 0.875 and 0.880 mg fluazaindolizine/kg bw) for the ([Ph-^{14}C] and ([IP-2-^{14}C]fluazaindolizine) dosed hens, respectively. Average feed consumption of 0.123–0.130 g/day during the dosing period. Egg samples were collected twice a day while excreta samples were collected daily. Hens were sacrificed 6 hours after the final dose, and samples of liver, muscle, abdominal fat, and subcutaneous fat with skin was collected from each hen. All whole egg, tissue and excreta samples were pooled by dose group. Composite whole egg samples (Day 9–13), and excreta (Day 1–14) were prepared for analysis for both dose groups.

Tissue samples were homogenised in dry ice. Equal amounts (10 percent) of daily excreta from Days 1-14 were pooled by dose group and equal amounts (10 percent) of whole egg from Day 9–13 were pooled by matrix and dose group. Subsamples (*ca.* 25–30 g) of composite samples of tissues, whole egg and excreta were prepared for metabolite extraction and analysis. Samples were extracted using acetonitrile:0.1 M ammonium formate, pH 7 (9:1). The resulting extracts were combined by matrix, concentrated, and analysed by LSC and HPLC. All extracts were stored at -20 °C prior to HPLC analysis and HPLC profiles were conducted within 6 months of sacrifice.

The recovery of the administered dose was 94.6 percent for [Ph-^{14}C]-fluazaindolizine and 93.5 percent for the [IP-2-^{14}C]fluazaindolizine. For both [^{14}C]-labels, 92.9–94 percent of the dose was recovered from the excreta and cage wash. For both [^{14}C]-labels, <0.1 percent of the dose was recovered in eggs, muscle, and fat with 0.6 percent of the dose recovered in liver (Table 66). Total radioactive residue levels in edible tissues were 0.732 mg eq/kg in liver, 0.043 in muscle and 0.020 mg eq/kg in abdominal fat from the [Ph-^{14}C]-fluazaindolizine dosed hens, and 0.701 mg eq/kg in liver, 0.047 in muscle and 0.027 mg eq/kg in abdominal fat from the [IP-2-^{14}C]-fluazaindolizine dosed hens. Radioactivity plateaued in whole eggs within 10 days from the start of dosing at *ca.* 0.017 mg eq/kg in the [Ph-^{14}C]-fluazaindolizine and within 8 days at *ca.* 0.018 mg eq/kg in the [IP-2-^{14}C]-fluazaindolizine (Table 67, Figure 17).

Table 66 Percent administered dose recovered in eggs, tissues and excreta of laying hens following 14 consecutive daily oral doses of [Ph-^{14}C]-fluazaindolizine or [IP-2-^{14}C]-fluazaindolizine (% dose)

Sample	[Ph-^{14}C]-fluazaindolizine	[IP-2-^{14}C]-fluazaindolizine

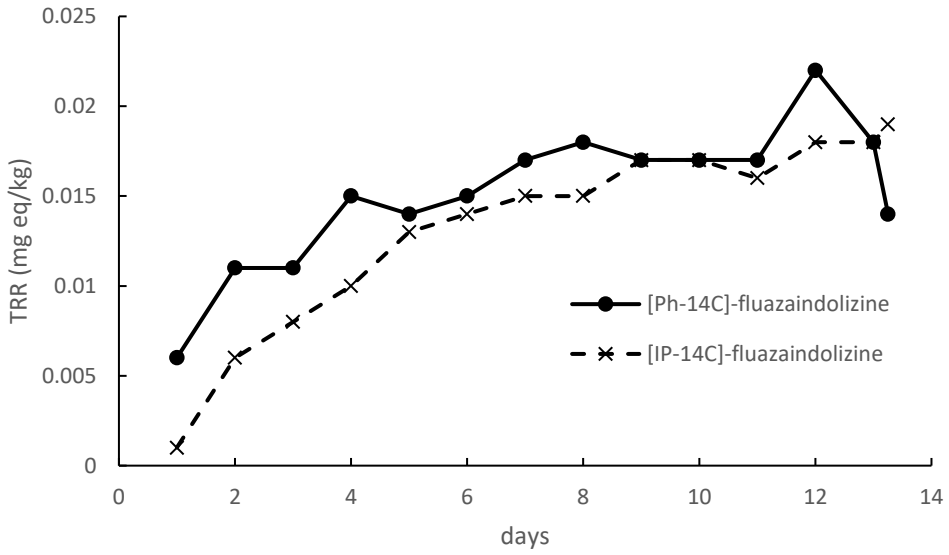

Figure 17 Residues in eggs following dosing with ^{14}C-fluazaindolizine.

Identification and characterisation of radioactive residues

The initial acetonitrile/buffer extractions released 87.3–99.2 percent TRR [Ph-^{14}C] and 89.8–99.0 percent TRR IP-2-^{14}C] from tissues and whole eggs (Table 68).

The majority of radioactive residues (82.4–98.0 percent TRR) was identified and/or characterised in liver and eggs from the [Ph-^{14}C]fluazaindolizine dosed hens (Table 68). Fluazaindolizine was a major [^{14}C] residue, accounting for 67.5–96.5 percent TRR in liver and eggs. The concentration of fluazaindolizine was 0.013 mg/kg in eggs, 0.680 mg/kg in liver, 0.041 mg/kg in muscle and 0.014 mg/kg in fat.

In eggs and tissues, the phenyl-derived metabolites included IN-F4106 (maximum 5.7 percent TRR) and IN-REG72 (maximum 1.1 percent TRR). Several minor unidentified metabolites were also

detected, none of which individually were greater than 11.3 percent TRR, which combined accounted for 0.9–11.3 percent TRR in eggs and tissues.

The majority of radioactive residues (73.1-97.9 percent TRR) was identified and/or characterised in tissues and eggs from the [IP-2-^{14}C]fluazaindolizine dosed hens (Table 69). Fluazaindolizine was a major [^{14}C]-residue, accounting for 66.2–97.1 percent TRR in all tissues and eggs. The concentration of fluazaindolizine was 0.012 mg/kg in eggs, 0.639 mg/kg in liver, 0.046 mg/kg in muscle and 0.018 mg/kg in fat.

In eggs and tissues, the imidazopyridine-derived metabolites included IN-QEK31 (maximum 4.9 percent TRR), IN-REG72 (maximum 1.1 percent TRR), IN-RYC33 (maximum 11.0 percent TRR) and methyl ester of IN-QEK31 (IN-R2W56) (maximum 1.9 percent TRR). An unidentified metabolite was detected in abdominal fat which accounted for 2.5 percent TRR (0.001 mg/kg).

ND Not Detected.

Day 1–14 excreta composite from hens dosed with [Ph-^{14}C]-fluazaindolizine was extracted and analysed by HPLC. Fluazaindolizine was a major component representing 67.1 percent of the total administered dose. The metabolites IN-A5760 sulphate (3.1 percent dose), IN-A5760 (3.8 percent dose), IN-F4106 (0.4 percent dose) and IN-REG72 (6.1 percent dose) were detected. Two minor unknown components were also detected which accounted for 0.6 and 2.8 percent dose.

Day 1–14 excreta composite from hens dosed with [IP-2-^{14}C]-fluazaindolizine was extracted and analysed by HPLC. Fluazaindolizine was a major component representing 67.1 percent of the total administered dose. The metabolites IN-QEK31 (5.5 percent dose) and IN-REG72 (5.5 percent dose) were detected. Several minor unknown components were also detected none of which individually accounted for > 0.7 percent dose.

The proposed metabolic pathway of fluazaindolizine in laying hens is shown in Figure 18. The metabolism of fluazaindolizine was complex and is based on metabolites identified in the tissues and in the excreta. The following metabolic pathway is proposed: biotransformation of fluazaindolizine in the hen occurred primarily through *O*-demethylation to form IN-REG72 followed by hydrolysis of the amide bond to form the cleaved metabolites IN-QEK31 and IN-A5760. Direct hydrolysis of fluazaindolizine yielded the metabolite IN-F4106 which was *O*-demethylated to IN-A5760. A sulphate conjugate of IN-A5760 was formed and eliminated in the excreta. IN-RYC33 was formed from the hydrolysis of the sulfonamide bond of fluazaindolizine. The metabolite IN-R2W56 was formed *via* methylation of the carboxylic acid group of IN-QEK31.

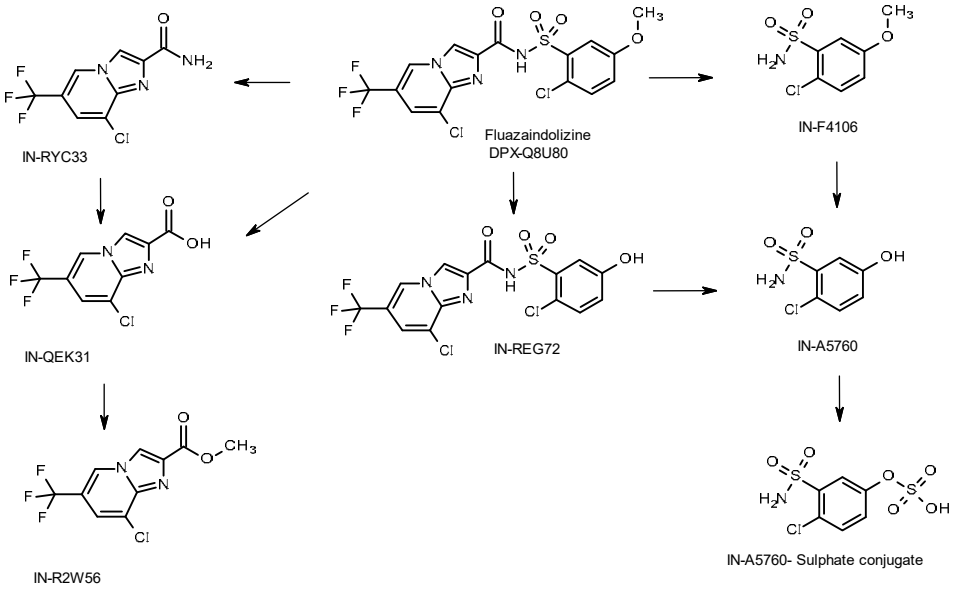

Figure 18 Proposed metabolic pathway of fluazaindolizine in the laying hen

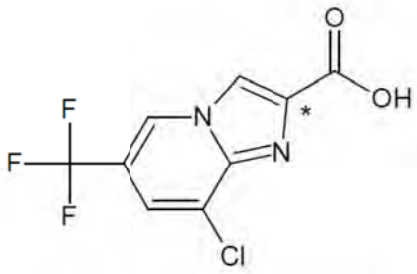
Metabolism of [IP-2-^{14}C]-IN-QEK31 in laying hens

Cochrane (2018 DuPont-43221 Revision 1) studied the metabolism of [^{14}C]-IN-QEK31 in laying hens.



* – Denotes position of radiolabel

[Imidazo[1,2-a]pyridine-2-^{14}C]-IN-QEK31was administered *via* capsules to five laying hens (Novogen Brown, 56 weeks old, 1.726–2.154 kg bw) as a single daily oral dose for 14 consecutive days. The average daily dose administered to the five hens was 9.96 ppm [IP-2-^{14}C]-IN-QEK31 diet (dry weight equivalent) and 0.68 mg [IP-2-^{14}C]-IN-QEK31/kg bw. Average feed consumption of 0.129 g/day.

Excreta was collected once daily, and eggs collected twice daily. All hens were sacrificed approximately 6 h after the last dose and liver, muscle, abdominal fat, bile, gastrointestinal tract, and contents were collected. All samples were stored at *ca.* -20 °C until taken for analysis. All samples were extracted within 68 days and extracts initially analysed within 408 days following the extraction procedure. The longest storage interval (between sample collection and analysis of sample extracts) recorded for any individual sample (liver, kidney, and renal fat) was 476 days (*ca.* 16 months).

Tissue samples were homogenised with the aid of dry ice. Composite samples of whole egg (Days 9-13) and excreta (Days 1–14) were prepared by combining equal amounts of each daily sample by matrix. Subsamples (*ca.* 30 g) of tissues, whole egg (Days 9–13 composite) and excreta (Days 1–14 composite) were prepared for metabolite extraction and analysis. Samples were extracted with acetonitrile:0.1 M ammonium formate, pH 7 (9:1). The extraction mixtures were homogenised followed by centrifugation and the resulting supernatants analysed by LSC. Extracts warranting analysis were combined by matrix (where applicable), concentrated, and analysed by LSC and HPLC. All extracts were stored at -20 °C prior to HPLC.

IN-QEK31 was rapidly eliminated from hens into the excreta (approximately 93.2 percent of the dose). The total recovery was 100.9 percent of the administered dose, of which 100.7 percent of the dose was recovered from the excreta and cage wash with a further 0.2 percent found in the gastrointestinal tract (Table 70). Less than 0.1 percent of the dose was recovered in whole eggs.

TRR in edible tissues were 0.014 mg eq/kg in liver and 0.002 mg eq/kg in abdominal fat (Table 70). There was no measurable radioactivity found in muscle (< 0.001 mg eq/kg).

Radioactivity in whole eggs reached plateau within 5 days post first dose *ca.* 0.005 mg/kg (Table 71, Figure 19). Negligible amounts of radioactivity were recovered in the edible tissues (< 0.1 percent of the administered total dose).

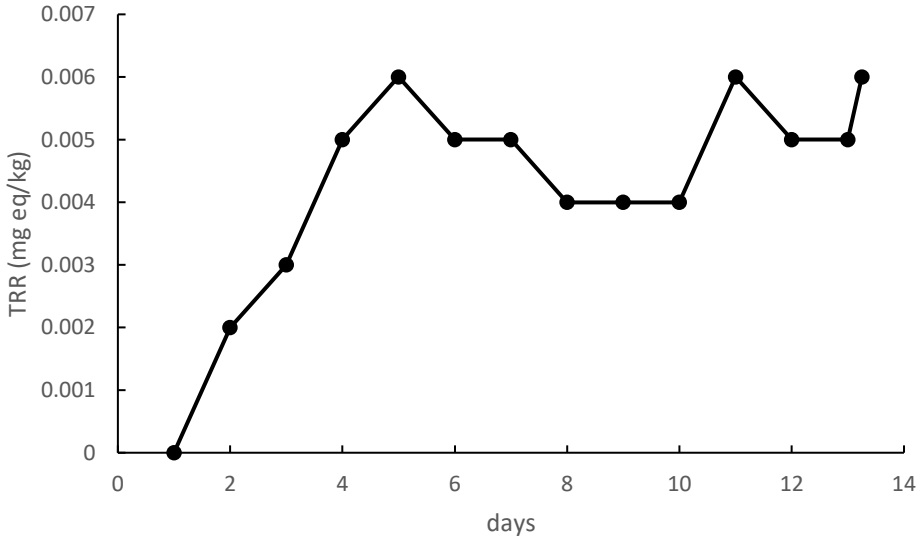

Figure 19 Residues in eggs following dosing with ^{14}C-IN-QEK31

Liver tissues contained residues greater than 0.01 mg eq/kg, and the majority of the radioactive residues (≥ 71.1 percent TRR) were extractable with acetonitrile:(100 mM ammonium formate) (9:1). A summary of the metabolites identified in liver is provided in Table 72. Unchanged IN-QEK31 accounted for 71.1 percent TRR in liver. As radioactive residues in composite whole egg, muscle and fat samples were very low (< 0.01 mg eq/kg) metabolite profiling of these tissues was not conducted. Unchanged IN-QEK31 (93.2 percent dose) was identified in faeces.

In summary, [IP-2-^{14}C]-IN-QEK31 was eliminated from the hens and remained unchanged in tissues and excreta with no significant metabolism observed.

ENVIRONMENTAL FATE

The FAO Manual on the Submission and Evaluation of Pesticide Residues Data for the Estimation of Maximum Residue Levels in Food and Feed (2009) explains the data requirements for studies of environmental fate. The focus should be on those aspects that are most relevant to MRL setting. For fluazaindolizine, supervised residue trials data following soil application are available for cucumbers, melons, squash, tomatoes, peppers, carrots and potatoes. Aerobic degradation in soil is relevant, as well as the normal requirements for hydrolysis, soil photolysis and rotational crop studies.

The Meeting received information on soil aerobic and anaerobic metabolism, aqueous hydrolysis and soil photolysis properties of fluazaindolizine.

Route of degradation in soil

Aerobic degradation of fluazaindolizine in soil

Wardrope and Anderson (2013 DuPont-35135) studied the aerobic soil metabolism of [^{14}C]fluazaindolizine in two soils, Sassafras and Nambsheim using [Ph-^{14}C] label or [IP-5,8a-^{14}C]-label. The radiolabelled test item was applied to the soil at a nominal rate of 1.0 μg/g oven dry soil which corresponded to a 1 kg ai/ha application assuming 10 cm incorporation and 1.0 g/cm3 soil density. The soil samples were continuously aerated throughout the 150-day incubation period. Traps for volatiles included ethanediol, and two 1M NaOH traps to collect organic volatiles and CO_2. Table 73 shows the soil characteristics used in the study

Table 73 Characteristic of soils used for aerobic degradation (DuPont-35135)

Soil	Texture	pH 0.01 M $CaCl_2$	% OM [Walkley-Black]	CEC (meq/100 g)	Biomass (mg C/kg soil)
Sassafras, United States	Sandy loam	5.7	2.0	5.3	383.9
Nambsheim, France	Sandy loam	7.5	2.7	9.0	430.5

Soil samples were sequentially extracted with acetonitrile:water (9:1 , with 2 percent formic acid) followed by acetonitrile:water (4:1, with 2 percent formic acid), acetonitrile:water (1:1, with 2 percent formic acid), both at 50 °C.

The material balance for both labels was good at 90.64 to 107.68 percent AR for the [Ph-^{14}C]-label and 74.49 to 107 percent AR for the [IP-5,8a-^{14}C]-label. The lower mass balances observed for the [IP-5,8a-^{14}C]-labelled samples at late sampling intervals were likely due to formation and loss a portion of the volatile degradate, IN-VM862.

Substantial degradation of fluazaindolizine was obvious in both soils, as noted by a significant amount of $^{14}CO_2$ generation as well as incorporation of radiocarbon into natural carbon pool.

The distribution of radioactivity for the two soils is shown in Figure 20. In the Sassafras soil treated with [^{14}C]-fluazaindolizine, the solvent extracted ^{14}C-residues in the soil decreased from mean values of 104–105 percent AR at Day 0 to 66.2 percent AR for the [Ph-^{14}C]-label and 44.2 percent AR for the [IP-5,8a-^{14}C]-label after 150 days of aerobic incubation. Unextracted residues increased to a maximum value of 19.6 percent AR at Day 80 in the [Ph-^{14}C]-label and 22.1 percent for the [IP-5,8a-^{14}C]-label on Day 120. There was some decline in the unextracted residue by Day 150 for both labels. At the same time, $^{14}CO_2$ accounted for 10.1 percent AR for the [Ph-^{14}C]-label and 14.6 percent for the [IP-5,8a-^{14}C]-label over the course of the study.

In the Nambsheim soil system treated with [^{14}C]-fluazaindolizine the solvent extracted ^{14}C-residues in the soil decreased to 38.1 percent AR in the [Ph-^{14}C]-label and 49.3 percent AR for the [IP-5,8a-^{14}C]-label after 150 days aerobic incubation. Unextracted residues increased to a maximum value of 37.41 percent AR and 22.4 percent AR for the same two labels by Day 150. Radiolabelled $^{14}CO_2$ cumulatively accounted for 16.2 percent AR for the [Ph-^{14}C]-label and 5.1 percent AR for the [IP-5,8a-^{14}C]-label over the course of the study.

Fluazaindolizine degraded extensively *via* the molecule splitting into two portions at the sulphonamide bridge between the two rings. Fluazaindolizine decreased to about 1.5-1.6 percent AR in for both labels by Day 150 for the Sassafras soil and 15.0–15.6 percent AR by Day 150 for the Nambsheim soil.

Three main degradation products (>5 percent of AR) were IN-F4106, IN-QEK31 and IN-VM862, and they all resulted from the cleavage of the molecule into two portions. IN-F4106 and IN-QEK31 were formed due to molecule splitting into two portions. IN-F4106 was detected in the [Ph-^{14}C]-label samples and IN-QEK31 with the [IP-5,8a-^{14}C]-label. IN-VM862, presumably formed from further degradation of IN-QEK31, was also detected in the [IP-5,8a-^{14}C]-label. IN-REG72, the only metabolite with most of the structure staying intact, was a minor degradation product in both soils (<5 percent AR). IN-A5760 was also a minor degradation product reaching a mean maximum of 2.6 percent AR at Day 60 in the Sassafras samples and a maximum of 2.7 percent AR at Day 80 in the Nambsheim samples. No unidentified metabolites exceeded 5 percent AR at any sampling interval.

Unextracted residues were characterised using organic matter fractionation into humin, fulvic acid and humic acid fractions. The largest portion of the unextracted radioactivity (≥ *ca* 9.4–34.7 percent

AR, day 150) was associated with the humin fraction of the soil organic matter, while the balance was found in humic (0.5–4.9 percent AR) and fulvic acid (2.5–7.3 percent AR) fractions indicating substantial incorporation of ^{14}C into natural constituents.

Parent only kinetics was assessed using the single first-order (SFO) and additional biphasic decline models, where appropriate. The Sassafras data set was also assessed using the Indeterminate Order Rate Equation (IORE) model. The kinetic analysis results are in Table 74.

Table 74 Summary of degradation kinetics for fluazaindolizine in Sassafras and Nambsheim soils, study DuPont-35135

Soil	DT_{50} (days)	DT_{90} (days)	χ^2	r^2	Model
Sassafras	11.8	47.0	4	0.991	DROP
	11.8	48.4	4	0.990	IORE
Nambsheim	43.9	145.7	6	0.976	SFO

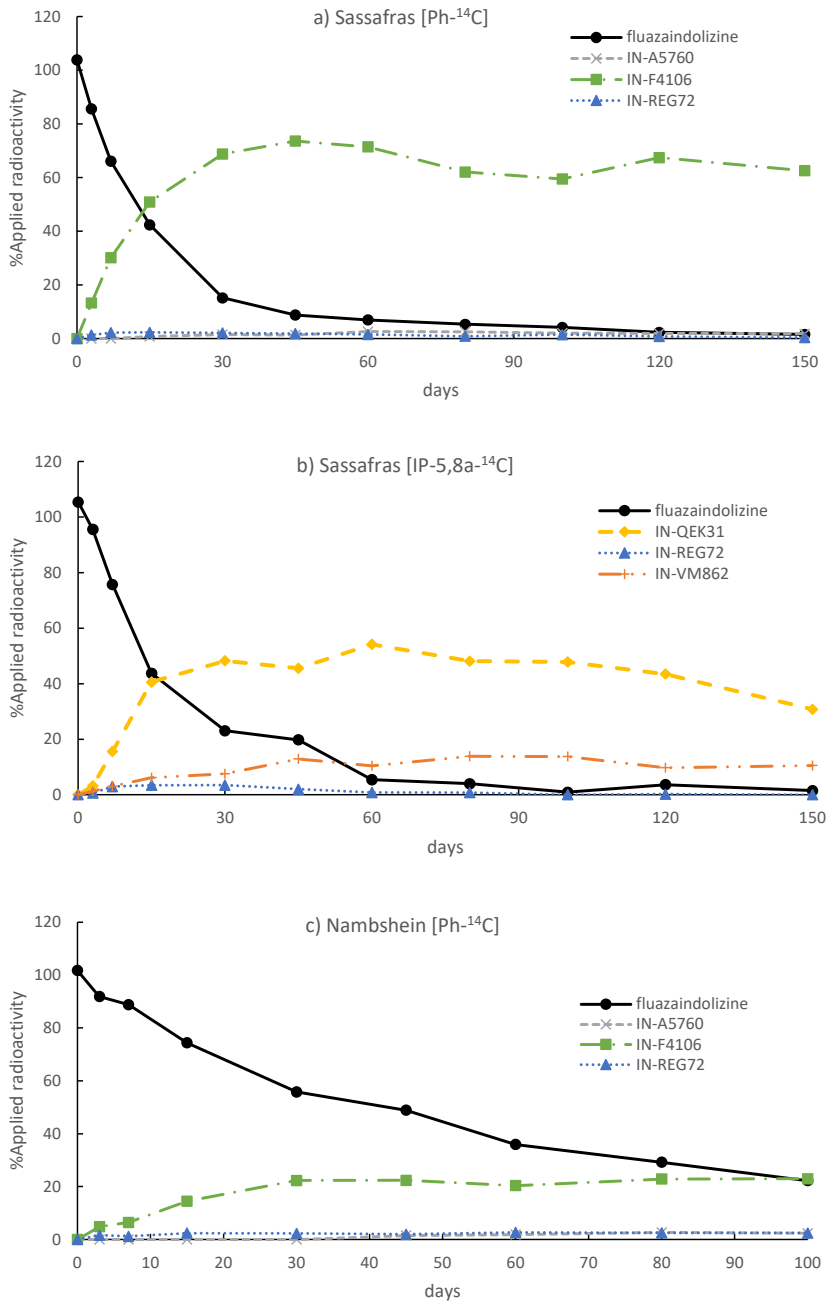

Figure 20 Aerobic soil degradation of ^{14}C-fluazaindolizine on Sassafras and Nambsheim sandy loam soils

The degradation pathway for fluazaindolizine in aerobic soil is shown in Figure 21.

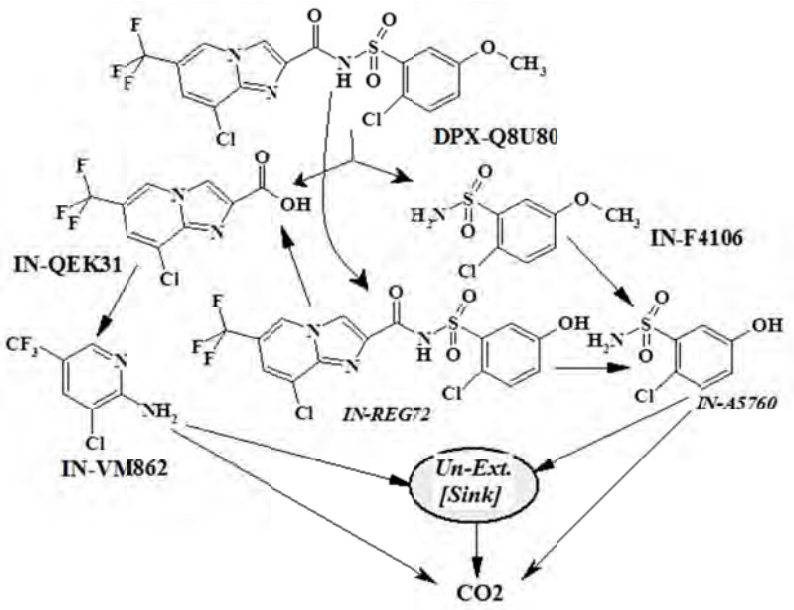

Figure 21 Degradation pathway for fluazaindolizine in aerobic soil

Grant and Wardrope (2015 DuPont-37393) investigated the aerobic soil metabolism of ^{14}C-fluazaindolizine in four soils in the dark at 20 ± 2 °C for up to 150 days. The soils used were Speyer 2.2, Thessaloniki, Graffignana and Lleida, collected from Hanofen, Germany; Thessaloniki, Greece; Graffignana, Italy and Lleida, Spain (Table 75). In addition, aerobic degradation in sterilized Speyer 2.2 was included to determine the effect of microbial activity on the rate of degradation.

Table 75 Characteristic of soils used for aerobic degradation (DuPont-37393)

Soil	Texture	pH 0.01 M $CaCl_2$	% OM [Walkley-Black]	CEC (meq/100 g)	Biomass (mg C/kg dry soil)
Speyer 2.2, Germany	Loamy sand	5.2	2.9	7.6	387.33
Thessaloniki, Greece	Loam	6.7	2.4	17.4	1203.00
Graffignana, Italy	Loam	6.0	1.9	12.2	689.00
Lleida, Spain	Silty clay loam	7.7	2.8	16.6	816.93

Two radiolabelled forms were used, [Ph-^{14}C] or [IP-5,8a-^{14}C]-fluazaindolizine with application at a nominal rate of 1.0 mg/kg oven dry soil, which corresponded a field application at 1000 g ai/ha assuming 10 cm incorporation and 1.0 g/cm^3 soil density. The soil samples were continuously aerated throughout the 150-day incubation period. Traps for volatiles included ethanediol, and two 1M NaOH traps to collect organic volatiles and CO_2. Soil samples were extracted sequentially with acetonitrile:2 percent aqueos formic acid (9:1), acetonitrile:2 percent aqueous formic acid (4:1); and twice with acetonitrile:2 percent aqueous formic acid (1:1). For each extraction soil/solvent slurries were sonicated at 50 °C for 45 minutes, and the soil and supernatant separated by centrifugation. Solvent unextracted ^{14}C-residues were quantified by combustion analysis and characterized *via* strong base extractions.

The material balance for all [Ph-^{14}C]-label samples ranged between, 91.8 to 106.8 percent AR and for the [IP-5,8a-^{14}C]-label samples between 88.7 to 109.5 percent AR. The <90 percent AR recovery was for day 150 analysis for [IP-5,8a-^{14}C]-label and was attributed to the formation of a substantial amount of a volatile metabolite IN-VM862.

The distribution of radioactivity for the two soils is shown in Figure 22. The extracted ^{14}C decreased from close to 100 percent at zero-time to 44-87 percent AR by 150 days while unextracted ^{14}C increased to a maximum of 6.6 to 22.6 percent AR by the end of the study. Mineralisation to $^{14}CO_2$ was 0.2-12.5 percent AR and was greater for the [IP-5,8a-^{14}C]-label in all soils.

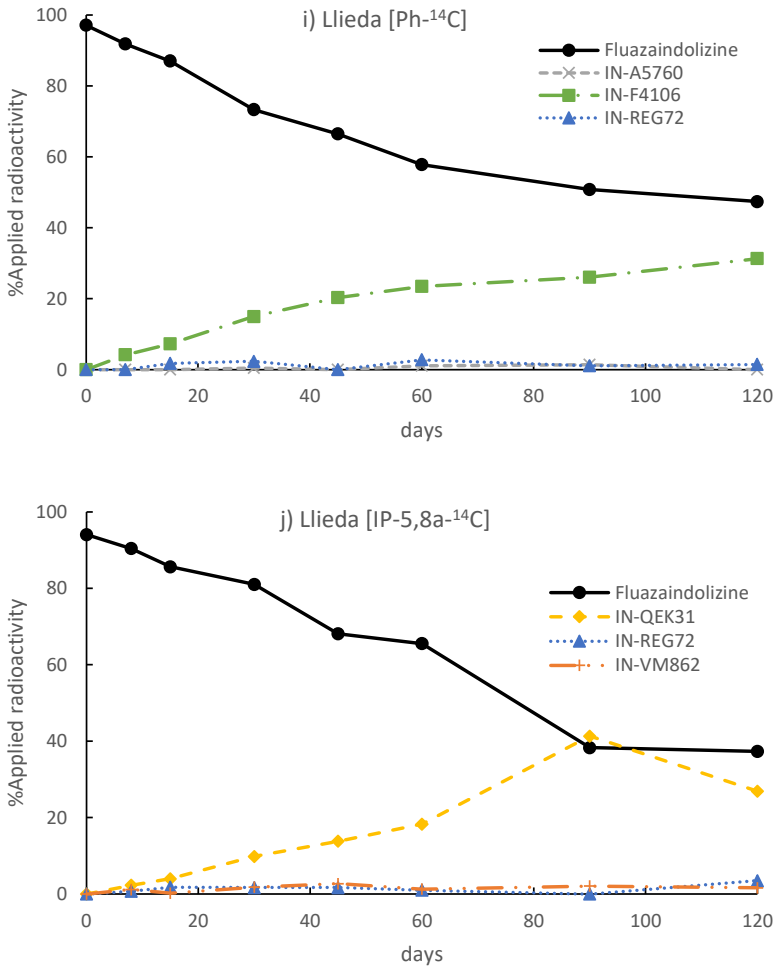

Figure 22 Aerobic degradation of ^{14}C-fluazaindolizine on Speyer 2.2, loamy sand, Thessaloniki loam, Graffignana loam and Lleida silty clay loam soils

Unextracted residues were characterised using organic matter fractionation into humin, fulvic acid and humic acid fractions. The largest portion of the unextracted radioactivity (≥ *ca* 5.1–12.5 percent AR, day 50–150) was associated with the humin fraction of the soil organic matter, while the balance was found in humic (0.4–2.9 percent AR) and fulvic acid (3.1–7.0 percent AR) fractions indicating substantial incorporation of ^{14}C into natural constituents.

Degradation in all soils proceeded primarily *via* cleavage of the fluazaindolizine molecule into two major metabolites, IN-QEK31 and IN-F4106. Peak levels of these two metabolites were found after 30–50 days in Speyer 2.2 soil and at later sampling intervals in other soils due to different rates of degradation of the parent compound. Smaller amounts of one other metabolite, IN-A5760 were observed in all soils from the [Ph-^{14}C]-label treatments and a volatile metabolite IN-VM862 was found in all [IP-5,8a-^{14}C]-label treatments. IN-REG72, accounted for <5 percent in all viable soils

The lack of any significant metabolites in the sterile Speyer 2.2 samples demonstrated that degradation observed in all soils was primarily due to microbial processes. The degradation rates (DT_{50} and DT_{90}) in each soil were determined using SFO kinetics (Table 76).

Table 76 SFO kinetics summary for fluazaindolizine in four soils

Soil	DT_{50} (days)	DT_{90} (days)	χ^2
Speyer 2.2	10.3	34.2	9.9
Speyer 2.2 (sterile)	2790	9280	2.9
Thessaloniki	63.8	212	3.2
Graffignana	19.5	64.6	4.9
Lleida	91.9	305	2.1

Manikandan (2014 DuPont-35133) studied the rate of degradation of [^{14}C]-fluazaindolizine in three soils, incubated in dark for 120 days under aerobic conditions at 20 ± 2 °C. The soils used in this study were shown in Table 77.

Table 77 Characteristic of soils used for aerobic degradation, study DuPont-35133

Soil	Texture	pH 0.01 M $CaCl_2$	% OM [Walkley-Black]	CEC (meq/100 g)	Biomass (mg C/kg soil)
Tama, United States	Silty clay loam	5.9	3.5	17.6	1437.49
Porterville, United States	Sandy loam	6.4	0.97	14.8	1340.97
Speyer 2.2, Germany	Loamy sand	5.4	3.0	9.4	1182.04

The moisture content of the soils was adjusted to 50 percent MWHC which corresponded to 35.8, 26.5 and 26.2 percent moisture for Tama, Porterville and Speyer soils, respectively. Application as at a nominal rate of 1 mg/kg dry soil. The soil samples were continuously aerated throughout the 120-day incubation period. Traps for volatiles included ethanediol, and two 1M KOH traps to collect organic volatiles and CO_2. Soil samples were sequentially extracted with acetonitrile:2 percent aqueous formic acid, 9:1; acetonitrile:2 percent aqueous formic acid, 4:1; followed by two extractions with acetonitrile:2 percent aqueous formic acid, 1:1. The distribution of radioactivity for the two soils is shown in Figure 23. IN-QEK31 and IN-F4106 were the main degradation products exceeding 5 percent AR.

The mean material balance was 91.2, 92.3 and 82.5 percent AR for Tama, Porterville and Speyer soils, respectively. Mass balance had declined to less than 90 percent towards the late stages of the study in two soils. Largest loss of ^{14}C was associated with Speyer soil, which also showed the fastest degradation rate and mineralization to $^{14}CO_2$. Due to inaccurate counting of the trap solutions, $^{14}CO_2$ was not appropriately accounted for and caused inaccurate material balance. It was quite certain that all losses were due to the low counting of $^{14}CO_2$. Porterville soil, which showed slower degradation and low CO_2 production displayed acceptable material balance. Therefore, the degradation rates, which are based on the amounts of parent and metabolites, are still valid.

Extracted ^{14}C recovered in soils treated with ^{14}C-fluazaindolizine and incubated at 20°C, was near quantitative at zero time with recoveries ranging from 94.1 and 98.2 percent AR. The amount of extracted radioactivity then decreased to a range of 48-86 percent of AR in soils incubated for 120 days, and unextracted ^{14}C increased to 4.9-15.2 percent AR. The ^{14}C associated with volatile traps at 120 days was ≤ 1.7 percent in all soils; however, it was recognized that the amount of $^{14}CO_2$ had been under-estimated.

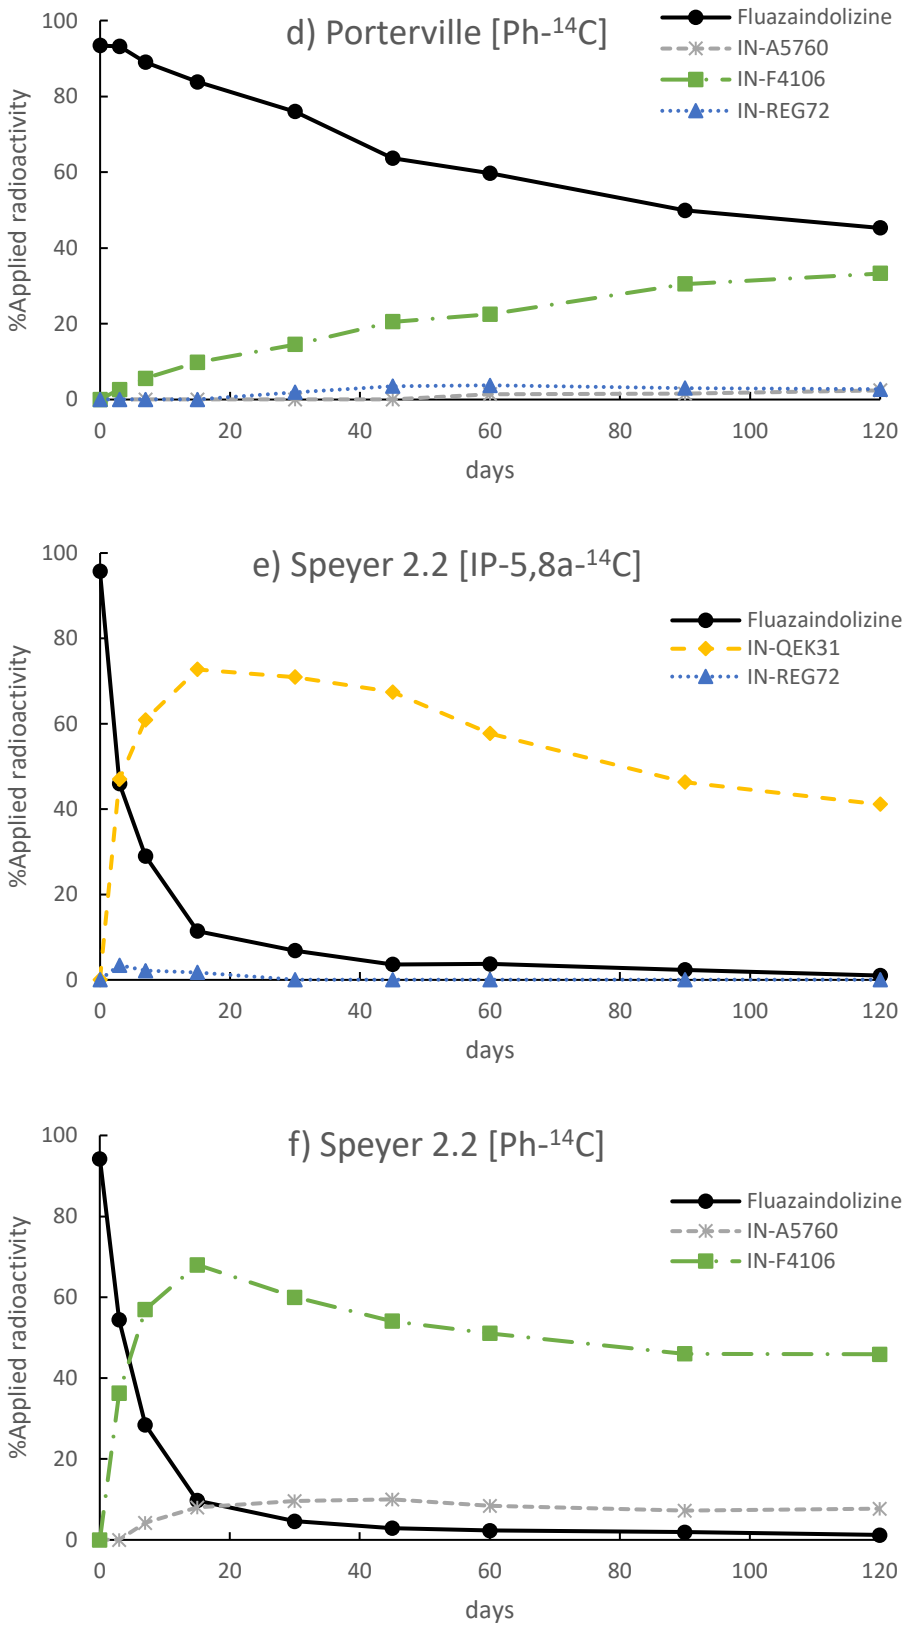

Figure 23 Aerobic degradation of ^{14}C-fluazaindolizine on Tama silty clay loam, Porterville sandy loam and Speyer 2.2 loamy sand soils

The non-normalized DT_{50} and DT_{90} values for fluazaindolizine are summarised in Table 78.

Table 78 Summary degradation kinetics for fluazaindolizine in three soils

Soil	DT_{50} (days)	DT_{90} (days)	χ^2	r^2	Best fit model
Tama	14.3	78.5	5	0.99	DFOP
Porterville	97.8	325	2	0.99	SFO
Speyer	3.4	18.1	8	0.998	DFOP

In a separate study, Manikandan (2017 DuPont-40810, Revision No. 1) investigated the rate of degradation of [^{14}C]-fluazaindolizine at a nominal rate of 1.0 mg/kg in four soils, incubated for 120 days in dark under aerobic conditions at 20 ± 2 °C. The moisture content of the soils was adjusted to pF 2.0 (moisture at 1/10 bar) which corresponded to 45.2, 28.7, 31.8 and 24.9 percent moisture for Tama, Hidalgo, Penn, and Woodland soils, respectively. The soils used in this study are shown in Table 79.

Table 79 Characteristic of soils used for aerobic degradation (DuPont-40810)

Soil	Texture	pH 0.01 M $CaCl_2$	% OM Walkley-Black	CEC (meq/100 g)	microbial (mg C/kg soil)
Tama, IL United States	Clay loam	6.7	6.4	20.2	207
Hidalgo, TX United States	Sandy clay loam	7.9	0.65	16.4	253
Penn NJ United States	Loam	6.0	2.1	8.3	213
Woodland CA United States	Loam	5.9	2.3	16.1	241

The soil samples were continuously aerated throughout the 120-day incubation period. Traps for volatiles included ethanediol, and two 1M KOH traps to collect organic volatiles and CO_2. Since the purpose of the study was to obtain aged sorption data as well as the degradation rate data, at each sampling occasion, a desorption step was carried out first by extracting the soil samples overnight (12 to 18 hours) with 0.01 M $CaCl_2$ using a 2:1 solvent to soil ratio. Subsequently, each soil sample was sequentially extracted for 45 minutes at 50 °C using acetonitrile:water, 9:1, (v/v), acetonitrile:water, 4:1, (v/v) and finally with acetonitrile:water, 1:1, (v/v).

Material balances were quantitative for all samples (overall mean 98.2 ± 4.5 percent), with individual values in the range of 90.2–108.3 percent AR. The distribution of radioactivity for the two soils is shown in Figure 24.

Total extracted ^{14}C in all soils treated with [IP-2-^{14}C]-label and [Ph-^{14}C]-label of [^{14}C]-fluazaindolizine, was near quantitative at zero time and thereafter declined as the incubation progressed. Between 55.5-72.7 and 74.9-89.3 percent AR of the ^{14}C was extracted with 11.0-28.3 and 8.1-17.0 percent AR of the ^{14}C unextracted at the end of the incubation in soil samples treated with [IP-2-^{14}C]-label and [Ph-^{14}C]-label of fluazaindolizine, respectively. Traps for volatiles recovered 9.3-13.1 and 0.7-3.1 percent AR by 120 days the incubation for the [IP-2-^{14}C]- and [Ph-^{14}C]-label experiments, respectively.

Degradation of [^{14}C]-fluazaindolizine proceeded *via* the molecular cleavage of sulphonamide linkage to generate IN-QEK31 and IN-F4106. Demethylation of the phenyl-ether linkage leading to IN-REG72 also provided a parallel degradation pathway. Further degradation of metabolites led to substantial amounts of $^{14}CO_2$ and incorporation of ^{14}C into soil organic matter.

Unextracted residues were characterised using organic matter fractionation into humin, fulvic acid and humic acid fractions. Humin accounted for 3.1-9.4 percent AR, fulvic acid 4.3–17.3 percent AR and humic acid 0.5-1.9 percent AR indicating substantial incorporation of ^{14}C into natural constituents.

In all soils, for the [IP-2-^{14}C]-label IN-QEK31 was the main metabolite observed, while its counterpart, IN-F4106, was found in the [Ph-^{14}C] label experiment in amounts similar to IN-QEK31. Minor components (mostly <5 percent AR) were IN-REG72 and IN-A5760. There were no unidentified metabolites and no other component exceeding the LOQ

Aerobic rate of degradation for fluazaindolizine metabolites in soil

[^{14}C]IN-VM862: Rate of dissipation in five aerobic soils

Grant (2015 DuPont-40719) studied the aerobic transformation of [^{14}C]-IN-VM862 in five soils under aerobic conditions in the dark at 20 ± 2 °C for 60 days. A radiolabelled form of the test item with carbon 14 in the pyridine-2,6 position was used in the test substance. [^{14}C]-IN-VM862 was applied at a nominal rate of 1.0 mg/kg oven dry soil. Soil characteristics are shown in Table 81.

Table 81 Characteristic of soils used for aerobic degradation of [^{14}C]-IN-VM862 (DuPont-40719)

Soil Name	Texture	pH 0.01 M $CaCl_2$	% OM Walkley-Black	CEC (meq/100 g)	Microbial (mg C/kg soil)
Tama United States	Silty clay loam	6.7	4.9	20.9	673.13
Saasafras United States	Sandy loam	4.7	2.4	6.1	296.67
Nambsheim France	Sandy loam	7.4	2.5	9.5	698.33
Porterville United States	Loam	7.5	1.3	10.8	193.27
Speyer 2.2 Germany	Loamy sand	6.1	2.5	6.8	452.20

The soil samples were continuously aerated throughout the 60-day incubation period however volatilization was difficult to control, even with reduced rates of airflow. Traps for volatiles included ethanediol, and two 1M NaOH traps to collect organic volatiles and CO_2. Soil samples was sequentially with acetonitrile:2 percent formic acid (aq) (9:1); followed by acetonitrile:2 percent formic acid (aq) (4:1); and then acetonitrile:2 percent formic acid (aq, 1:1).

The material balance for all samples ranged between 90.2-122.9 percent AR. Samples with high material balance had a disproportionately high recovery from the polyurethane plug associated with the sample. In the Tama soil system treated with [^{14}C]IN-VM862 the solvent extracted ^{14}C in the soil decreased from mean values of 102.6 percent AR at Day 0 to approximately 51.0 percent AR after 60 days aerobic incubation while another 49.5 percent was found in the polyurethane plug extracts. A maximum of 13.6 percent was unextracted. A minor portion of the unextracted ^{14}C was mineralized to CO_2 ($^{14}CO_2$ cumulatively accounted for 0.4 percent AR).

Porterville soil system treated with [^{14}C]IN-VM862 also showed similar behaviour as Tama soil. Solvent extracted ^{14}C-residues in the soil decreased from mean values of 100.7 percent AR at Day 0 to 48.8 percent AR after 60 days aerobic incubation, with 49.9 percent of the parent compound appearing in the polyurethane plug extracts. Non-extracted residues increased to a mean maximum value of 4.4 percent AR at Day 40 before decreasing to 3.8 percent AR at Day 60. Radiolabelled $^{14}CO_2$ cumulatively accounted for 0.5 percent AR, indicating a minor portion of the applied test substance undergoing degradation.

The remaining three soils showed even higher degree of volatilization of [^{14}C]IN-VM862. In the Sassafras, Nambsheim and Speyer 2.2 soil systems treated with [^{14}C]IN-VM862, 80-105 percent of the applied test substance evaporated over 60 days and was found unchanged in the polyurethane plugs used to collect the volatile materials. The solvent extracted ^{14}C-residues in the soils decreased from mean values of approximately 100 percent AR at Day 0 to only 10 to 20 percent by Day 60. Unextracted ^{14}C resulting from degradation of IN-VM862 only accounted for 2.7 to 8.7 percent AR at Day 60 while $^{14}CO_2$ cumulatively accounted for 0.3 to 0.4 percent AR.

Volatilised ^{14}C collected in these polyurethane plugs was unchanged IN-VM862. Modelling of the data was used to separate volatilization from rate of degradation, using a model which accounted for both processes simultaneously. The volatilisation rate was directly correlated to the rate of air flow. Volatilization dominated the overall dissipation from soil. A summary of volatilization rate constants and degradation rate is shown in Table 82.

Table 82 Summary of volatilization and degradation rates for IN-VM862

Soil	K_evaporation (% $mL^{-1}day^{-1}$)	K_degradation (day^{1})	Degradation DT_{50} (days)
Tama	1.10×10^{-6}	0.0019	361
Sassafras	3.30×10^{-6}	0.0031	226
Nambsheim	5.43×10^{-6}	0.0006	>1000
Porterville	8.55×10^{-7}	0.0012	>500

Soil	K_evaporation (% $mL^{-1}day^{-1}$)	K_degradation (day^{1})	Degradation DT_{50} (days)
Speyer 2.2	3.05×10^{-6}	0.0016	>400

In a separate study, Hussain and McCorquodale (2017 DuPont-42493) studied the rate of degradation of [^{14}C]IN-VM862 in four soils. This study was conducted with minimum possible airflow needed for aerobic soil conditions to minimize volatilization. The soils used are shown in Table 83.

Table 83 Characteristic of soils used for aerobic degradation of [^{14}C]-IN-VM862, study DuPont-42493

Soil	Texture	pH 0.01 M $CaCl_2$	% OM Walkley-Black	CEC (meq/100 g)	M0icrobial (mg C/kg soil)
Lleida, Spain	Silty clay	7.6	1.3	16.1	431.2
Vimagano, Italy	Loam	5.9	1.4	11.2	291.5
Sindos, Greece	Sandy loam	6.9	1.4	12.7	566.3
Nambsheim, France	Silty loam	7.6	1.0	11.3	264.7

The test system was acclimatized for up to 17 days prior to treatment. [^{14}C]IN-VM862 labelled in the pyridine-2,6 position was used on this study and was applied to the soil at a nominal rate of *ca* 3.0 mg/kg dry soil weight. Treated vessels were incubated for up to 120 days under aerobic conditions in the dark at 20 $\pm$ 2 °C at pF 2 moisture. The soil samples were continuously aerated throughout the 120-day incubation period. Ethanediol and 2 1M NaOH traps. Each sample also utilised two polyurethane plugs to trap IN-VM862 and any volatile degradation products.

Soil samples were sequentially extracted with solvents acetonitrile:2 percent formic acid (9:1); followed by acetonitrile:2 percent formic acid (4:1) and then acetonitrile:2 percent formic acid (1:1) and finally THF:0.1 percent formic acid (aq) (9:1). Polyurethane plugs were replaced at each sampling interval and were extracted with 20 mL acetonitrile.

The mean material balance was quantitative for all samples and was in the range 94.7–99.6 percent AR, 94.8–99.3 percent AR, 94.3–99.0 percent AR, and 91.2–98.6 percent AR for Lleida, Vimagano, Sindos and Nambsheim soils, respectively.

Soil extraction of ^{14}C was essentially quantitative at Day 0 in all soils (> 97.3 percent) and decreased progressively to 21.0, 27.9, 21.0 and 20.0 percent AR at Day 120 in Lleida, Vimagano, Sindos and Nambsheim soils, respectively. This decrease was mainly attributable to volatilisation, although degradation, in the form of evolved $^{14}CO_2$, and potentially indicated by unextracted ^{14}C, also contributed. Volatilized IN-VM862 accounted for 67.8, 59.3, 64.7 and 68.3 percent AR at Day 120 in Lleida, Vimagano, Sindos and Nambsheim soils, respectively. Unextracted ^{14}C accounted for 5.3, 7.8, 8.6 and 4.7 percent AR in Lleida, Vimagano, Sindos and Nambsheim soils, respectively while cumulative $^{14}CO_2$ accounted for 0.6, 0.5, 0.9 and 0.5 percent AR at Day 120 in Lleida, Vimagano, Sindos and Nambsheim soils, respectively. Unidentified components accounted for a mean maximum of <3 percent AR in soil or polyurethane plug extracts in each soil.

The decline of parent IN-VM862 in soil extracts and the amount which volatilised, was analysed using a model to distinguish between degradation and volatilisation, and the degradation rate (DT_{50} degradation) and overall dissipation rate (DT_{50} dissipation) determined using SFO kinetics. Table 84 shows the DT_{50} values for each soil type.

Table 84 Summary of degradation rates for IN-VM862

Soil	Degradation DT_{50} (days)	Dissipation DT_{50} (days)
Lleida	409	45
Vimagano	352	57

Soil	Degradation DT_{50} (days)	Dissipation DT_{50} (days)
Sindos	347	49
Nambsheim	451	42

IN-VM862 degrades mainly to unextracted soil components *via* microbial degradation and dissipates from the environment by a combined process of degradation and volatilisation.

[^{14}C]IN-A5760: Rate of degradation

Yogeesha (2015b DuPont 40734) studied the rate of degradation of IN-A5760 in five soils, incubated in dark under aerobic conditions at a nominal temperature of 20 ± 2 °C for a study duration of 120 days. The soils used in this study were as follows.

Table 85 Characteristic of soils used for aerobic degradation of [^{14}C]-IN-A5760, study DuPont-40734

Soil	Texture	pH 0.01 M $CaCl_2$	% OM Walkley-Black	CEC (meq/100 g)	Microbial (mg C/kg soil)
Nambsheim France	Sandy loam	7.1	4.0	10.4	321
Tama United States	Silty clay loam	6.7	6.4	20.2	309
Penn	Loam	6.0	2.1	8.3	192
Woodland	Loam	5.9	2.3	16.1	190
Saasafras United States	Sandy loam	4.7	1.9	6.4	262

The moisture content of the soils was adjusted to pF 2.0 (moisture at 1/10 bar) which corresponded to 23.5, 45.2, 31.8, 24.9 and 23.6 percent moisture for Nambsheim, Tama, Penn, Woodland, and Sassafras soils, respectively. The soils were allowed to acclimate for 8 days prior to test item application. The test item was radiolabelled on phenyl-(U)-^{14}C and was applied at a nominal rate of 1.0 mg/kg dry soil. The soil samples were continuously aerated throughout the 120-day incubation period. A series of traps containing ethanediol and potassium hydroxide was used for the retention of non-specific ^{14}C-volatile organic compounds and $^{14}CO_2$, respectively. Soil samples were sequentially extracted by sonication at 50 ± 5 °C for 45 minutes with acetonitrile:water, 80:20 (v/v) and then acetonitrile:water, 50:50 (v/v).

Material balances were quantitative for all samples (overall mean 93.3 ± 1.7 percent AR), with individual values in 91-101 percent AR range. The distribution of radioactivity for the two soils is shown in Figure 25.

Total extracted radioactivity in all soils showed a rapid decrease soon after test substance application. As an example, extracted ^{14}C in Nambsheim (sandy loam) soil was 97.3 percent AR at zero time decreased to 12.8 percent AR after 120 days. Concurrently, the unextracted ^{14}C increased from 0.3 percent AR at zero time to 62.2 percent AR after 120 days. A similar trend was noted in all five soils, and the extracted ^{14}C ranged from a low 12.5 percent AR in Nambsheim soil to a high of 60.0 percent AR in Woodland soil. Higher unextracted ^{14}C correlated with the amount of $^{14}CO_2$ collected in the volatile traps. Percent $^{14}CO_2$ reached a peak level of 17.6 percent AR after 120 days in Nambsheim and ranged between 7–19 percent AR in other soils by the end of the study. Levels of $^{14}CO_2$ and unextracted ^{14}C indicated rapid and extensive degradation of IN-A5760 in all soils.

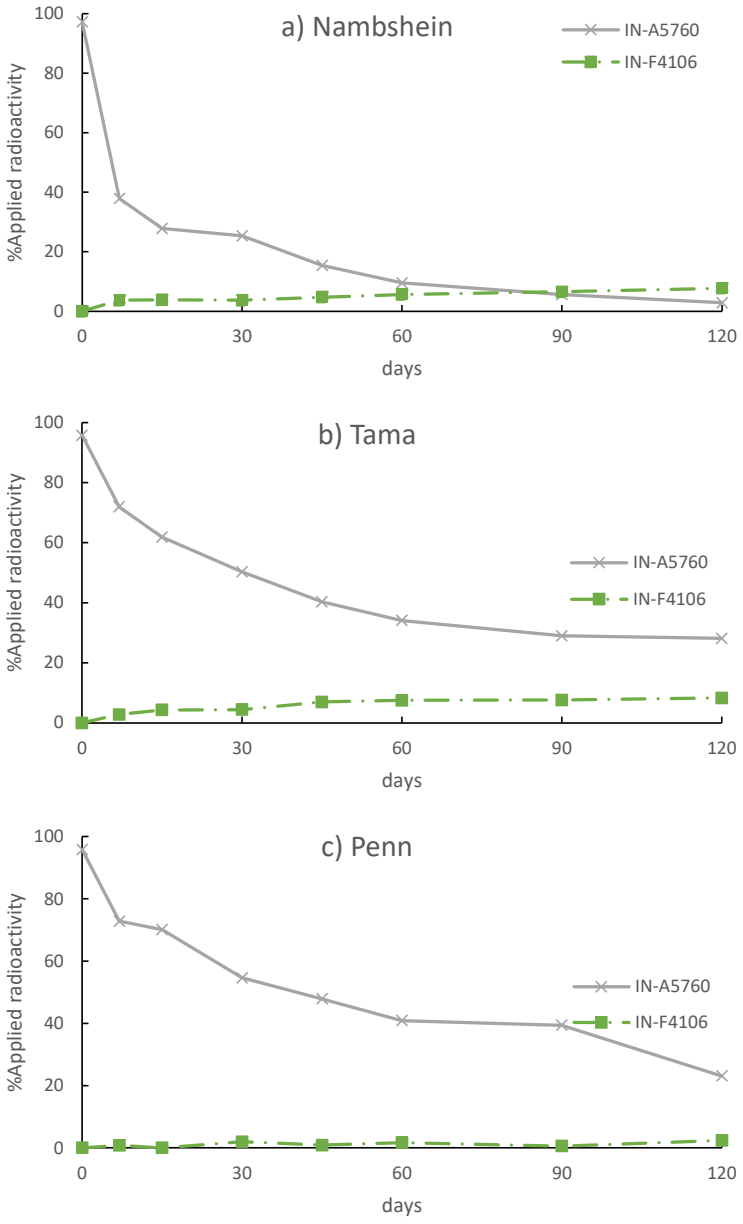
Surprisingly, a small amount (max. 7.7–8.3 percent AR) of IN-F4106 was observed in two soils (Nambsheim and Tama). It remained below 5 percent in the other three soils. Observation of IN-F4106 was surprising because IN-A5760 is itself formed from degradation of IN-F4106 (or from IN-REG72).

The calculated DT_{50} and DT_{90} values for IN-A5760 are summarised in Table 86.

Table 86 Summary of degradation rates for IN-A5760

Soil	DT_{50} (days)	DT_{90} (days)	χ^2	r^2	Model
Nambsheim	3.66	66.5	5.43	0.9632	DFOP
Tama	30.2	948	2.5	0.9466	FOMC
Penn	48.8	227	5.22	0.8825	DFOP
Woodland	88.6	728	2.67	0.8676	DFOP
Sassafras	29.9	931	3.72	0.964	DFOP

In soil, IN-A5760 degrades primarily by forming unextracted ^{14}C and CO_2. Kinetics modelling of the data suggests that unextracted ^{14}C continues to be mineralized and generate $^{14}CO_2$.



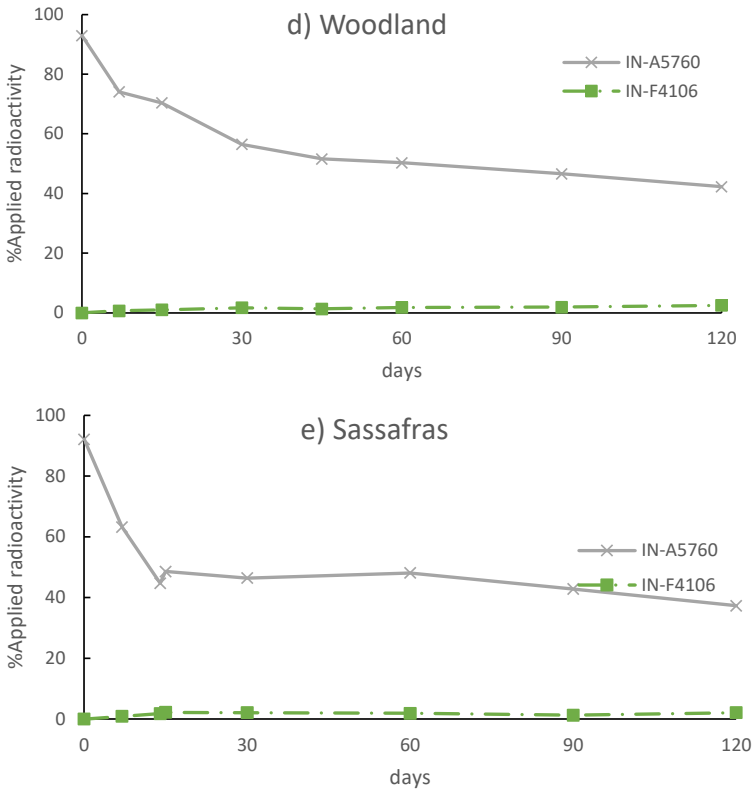


Figure 25 Aerobic degradation of ^{14}C-IN-A5760 on Nambsheim sandy loam, Tama silty clay loam, Penn loam, Woodland loam and Sassafras sandy loam soils

[^{14}C]IN-F4106: Rate of degradation

The rate of degradation of IN-F4106 was studied using [^{14}C]IN-F4106 at a nominal rate of 1.0 μg/g (dry soil) in five soils, incubated in dark under aerobic conditions at a nominal temperature of 20 ± 2 °C for a study duration of 150 days (Yogeesha 2015a DuPont-35485). The moisture content of the soils was adjusted to pF 2.0 (moisture at 1/10 bar) which corresponded to 20.8, 41.7, 33.4, 10.3 and 20.6 percent moisture for Nambsheim, Tama, Cajon (Porterville), Speyer and Sassafras soils, respectively. The soils used in this study are shown in Table 87.

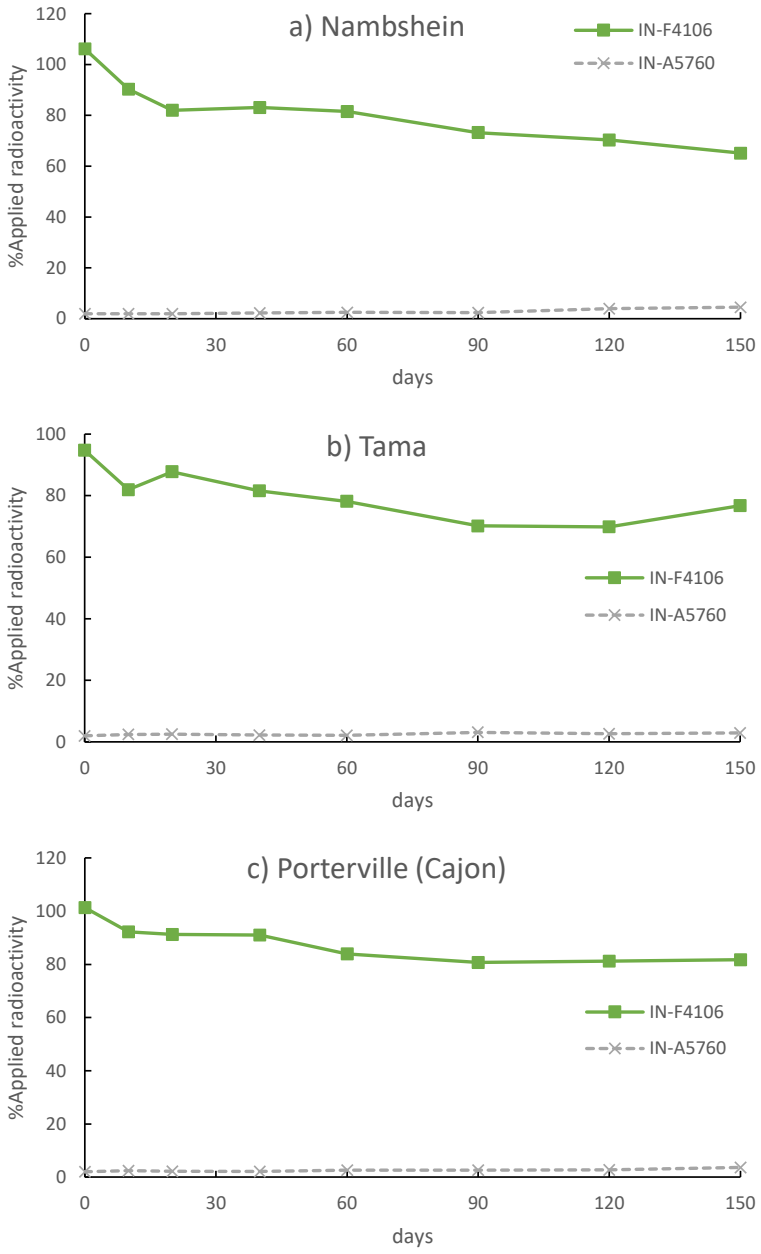
Table 87 Characteristic of soils used for aerobic degradation of [^{14}C]-IN-F4106, study DuPont-35485

Soil	Texture	pH 0.01 M $CaCl_2$	% Organic matter Walkley-Black	CEC (meq/100 g)	Microbial (mg C/kg)
Nambsheim France	Sandy loam	7.4	2.5	9.5	239
Tama United States	Silty clay loam	6.7	4.9	20.9	285
Cajon (Porterville) United States	Loam	7.5	1.3	10.8	213
Speyer 2.2 Germany	Loamy sand	6.1	2.5	6.8	211
Sassafras United States	Sandy loam	4.7	2.4	6.1	277

The soil samples were continuously aerated throughout the 150-day incubation period. Material balances were quantitative for all samples (overall mean 100.4 ± 5.2 percent), with individual values in the range of 92.6–111.1 percent of applied radioactivity (AR). The distribution of radioactivity for the two soils is shown in Figure 26.

Total extracted ^{14}C in all soils showed a moderate decline as the incubation progressed and it reflected partial degradation of IN-F4106 during the study. Between 69.6–87.1 percent AR of the ^{14}C was extracted at the end of the incubation with 6.8-20.7 percent AR unextracted. In general, higher amounts of unextracted ^{14}C corresponded with more degradation of the parent compound. Volatile traps accounted for 2.2–6.9 percent AR by the end of the incubation.

IN-A5760 was the primary degradation product in all soils, and it accounted for as much as 21.9 percent in one of the soils. Low levels of this metabolite were partly due to a slow degradation of the parent compound and presumably a faster degradation of the metabolite.



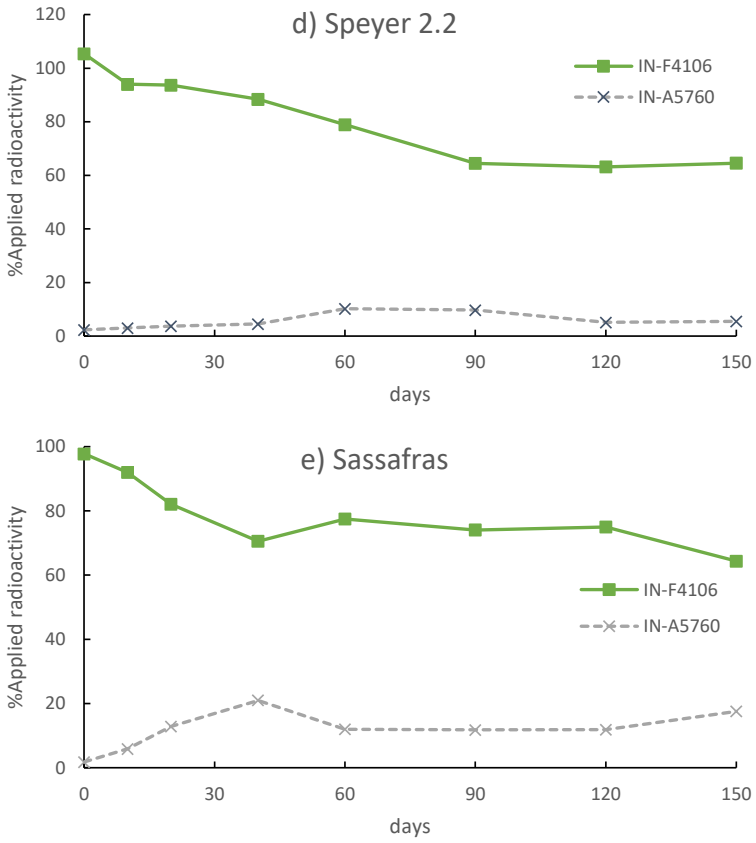


Figure 26 Aerobic degradation of ^{14}C-IN-F4106 on Nambsheim sandy loam, Tama silty clay loam, Porterville loam, Speyer 2.2 loamy sand and Sassafras sandy loam soils

In soil, IN-F4106 degrades by multiple processes forming IN-A5760, CO_2 and bound residues. DT50 and DT90 are shown in Table 88.

Table 88 The DT_{50} and DT_{90} values for IN-F4106 calculated for various soils.

Soil	DT_{50} (days)	DT_{90} (days)	Fit Model
Nambsheim	235	782	SFO
Tama	384	1280	SFO
Porterville (Cajon)	461	1530	SFO
Speyer 2.2	177	586	SFO
Sassafras	292	968	SFO

[^{14}C]IN-QEK31: Rate of degradation

Lowrie, C., Anderson, C. (2016 DuPont-35484, Revision No. 1) studied the rate of degradation and time dependent sorption of [^{14}C]IN-QEK31 was studied in five aerobic soils in the dark under aerobic conditions at 20 ± 2 °C for 119 days. The soils were Tama, Sassafras, Nambsheim, Porterville (Cajon) and Speyer 2.2. All soils (Table 89) were incubated under non-sterile conditions.

Table 89 Characteristic of soils used for aerobic degradation of [^{14}C]-IN-F4106 (DuPont-3548)

Soil	Texture	pH 0.01 M $CaCl_2$	% Organic matter Walkley-Black	CEC (meq/100 g)	Microbial (mg C/kg)
Nambsheim France	Sandy loam	7.4	2.5	9.5	239

Soil	Texture	pH 0.01 M $CaCl_2$	% Organic matter Walkley-Black	CEC (meq/100 g)	Microbial (mg C/kg)
Tama United States	Silty clay loam	6.7	4.9	20.9	285
Cajon (Porterville) United States	Loam	7.5	1.3	10.8	213
Speyer 2.2 Germany	Loamy sand	6.1	2.5	6.8	211
Sassafras United States	Sandy loam	4.7	2.4	6.1	277

Radiolabelled test item with ^{14}C in the imidazo[1,2-a]pyridine-5,8a ([IP-5,8a-^{14}C]) label, was applied to the soil at a nominal rate of 1.0 mg/kg oven dry soil. The soil samples were continuously aerated throughout the 119-day incubation period. Polyurethane plugs (inserted into the necks of soil flasks were used for retention of the volatile metabolite IN-VM862, in addition to ethanediol and sodium hydroxide traps for the collection of non-specific volatile organic compounds and $^{14}CO_2$, respectively.

Soil samples were sequentially extracted using acetonitrile:2 percent formic acid (aq) (9:1); followed by acetonitrile:2 percent formic acid (aq) (4:1); and then with acetonitrile:2 percent formic acid (aq) (1:1), all at 50°C in an ultrasonic bath.

The material balance for all samples was quantitative with the exception of Sassafras Day 40 (Replicate 1, 86 percent AR), Sassafras Day 90 [87 percent AR] and Porterville Day 119 (Replicate 2, 111 percent AR) samples. The distribution of radioactivity for the two soils is shown in Figure 27.

The amount of extracted ^{14}C declined gradually over the study period due to degradation of the applied material, IN-QEK31, and its partial incorporation into the soil organic matter. Unextracted ^{14}C increased to nearly 20 percent AR in three of the five soils (Sassafras, Nambsheim and Speyer 2.2). Percentages of 19.3, 7.4, 10.9 percent AR as $^{14}CO_2$ and 14.3, 23.4, 15.1 percent AR captured as volatilised IN-VM862 in the Sassafras, Nambsheim and Speyer 2.2 soils, respectively, were noted at the final sampling interval in these soils.

The degradation of IN-QEK31 in all soils resulted in the formation of one major metabolite, IN-VM862. A substantial amount of IN-VM862 had volatilised from the soil. The formation of IN-VM862 increased throughout the duration of the study in all five soils reaching mean maximum values of 21.5, 27.4, 48.8, 11.4 and 32.1 percent AR in the Tama, Sassafras, Nambsheim, Porterville and Speyer 2.2 soils at Day 119 (Tama Day 90), respectively.

Unextracted ^{14}C in all soils were characterised using organic matter fractionation into humin, fulvic acid and humic acid fractions. In four of the soils (Tama, Sassafras, Porterville, and Speyer 2.2) the majority of the radioactivity was associated with the humin and fulvic acid fractions of the soil organic matter, in nearly equal quantities, while the balance was found in the humic acid fractions.

The decline of IN-QEK31 was plotted against sampling intervals and the degradation rates (DT_{50} and DT_{90}) determined using SFO kinetics. Table 90 shows the SFO DT_{50}, DT_{90} and χ^2 values for each soil type. Porterville soil failed to display meaningful decline of parent past the 10-day sampling interval, therefore, DT_{50} was not calculated.

Table 90 The DT_{50} and DT_{90} values for IN-QEK31

Soil [A]	Model	k-parent	r^2	χ^2	DT_{50} (days)	DT_{90} (days)
Tama	SFO	0.0038	0.76	5.83	182	605
Sassafras	SFO	0.0121	0.87	10.3	57.2	190
Nambsheim	SFO	0.0116	0.95	6.39	59.7	198
Speyer 2.2	SFO	0.0070	0.91	5.59	99.1	329

Notes:

[A] Porterville degradation data did not display a consistent pattern and was therefore not modelled.

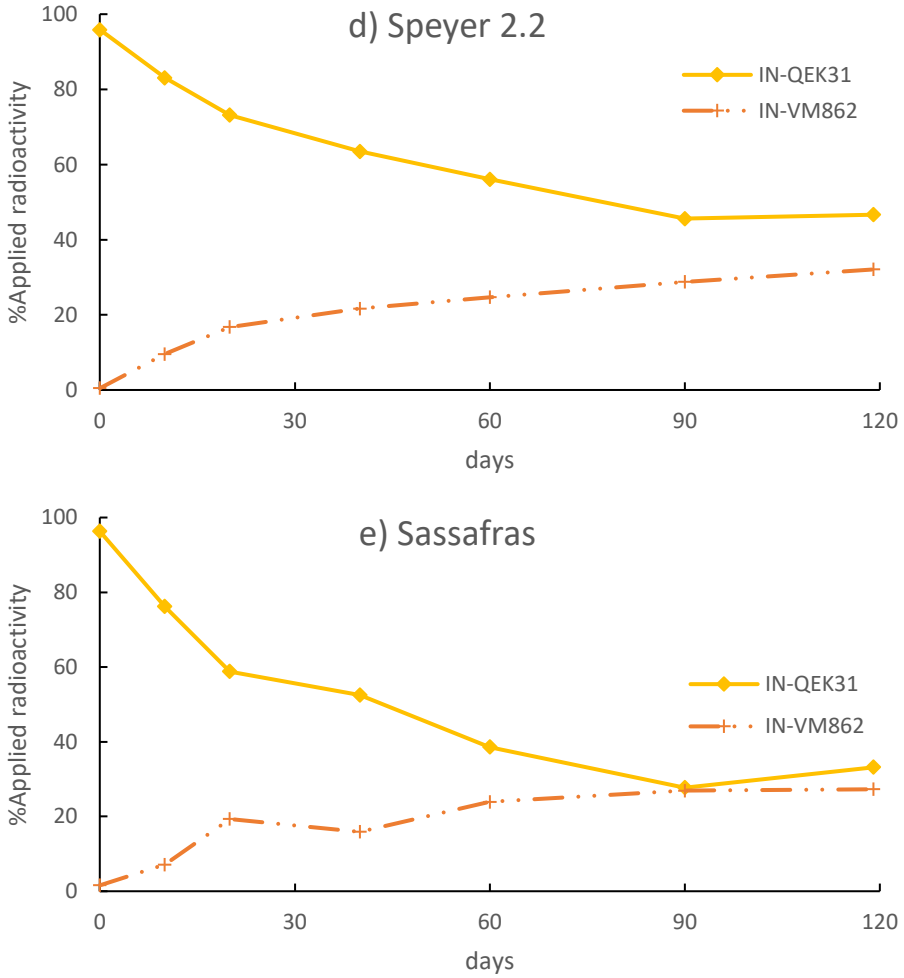

Figure 27 Aerobic degradation of ^{14}C-IN-QEK31 on Tama silty clay loam, Sassafras sandy loam, Namsheim sandy loam, Porterville loam and Speyer 2.2 loamy sand

[^{14}C]IN-REG72: Rate of degradation

The rate of degradation and aged desorption of IN-REG72 was studied using [^{14}C]IN-REG72 (uniformly labelled in the phenyl ring) at a nominal rate of 1.0 μg/g (dry soil) in five soils, incubated in dark under aerobic conditions at a nominal temperature of 20 ± 2 °C for a study duration of 120 days (Sannappa, H, 2015; Report No.: DuPont-39229).

The moisture content of the soils was adjusted to pF 2.0 (moisture at 1/10 bar) which corresponded to 20.8, 41.7, 33.4, 10.3 and 20.6 percent moisture for Nambsheim, Tama, Cajon (Porterville), Speyer and Sassafras soils, respectively. The soils used in this study are shown in Table 91.

Table 91 Characteristic of soils used for aerobic degradation of [^{14}C]-IN-REG72, study DuPont-39229

Soil	Texture	pH 0.01 M $CaCl_2$	% OM Walkley-Black	CEC (meq/100 g)	Microbial (mg C/kg soil)
Tama United States	Silty clay loam	6.7	4.9	20.9	254
Saasafras United States	Sandy loam	4.7	2.4	6.1	217
Nambsheim France	Sandy loam	7.4	2.5	9.5	235
Porterville United States	Loam	7.5	1.3	10.8	217
Speyer 2.2 Germany	Loamy sand	6.1	2.5	6.8	152

The soil samples were continuously aerated throughout the 119-day incubation period. Soils were sequentially extracted with acetonitrile:water (4:1), and finally with acetonitrile:water (1:1).

Material balances were quantitative for all samples (overall mean 96.0 ± 3.7 percent), with individual values in the range of 91.7–105.2 percent AR. Total extracted ^{14}C in all soils showed a decline as the incubation progressed and it reflected partial degradation of IN-REG72 during the study. For the five soils used, 42.0–80.1 percent AR of the ^{14}C remained extracted at the end of the incubation and 12.6–43.3 percent AR was unextracted. Recoveries of cumulative radioactivity associated with volatile traps reached 2.0–7.2 percent AR by the end of incubation.

IN-A5760 was the primary degradation product noted in all soils and it accounted for as much as 30.5 percent AR in one of the soils. The degradation profiles are shown in Figure 28 and calculated DT_{50} and DT_{90} in Table 92.

Soil photolysis

The rate and route of photo-degradation of [^{14}C]fluazaindolizine ([Ph-^{14}C]- or [IP-5,8a-^{14}C]-) were determined by Bell (2014 DuPont 35079) on the surface of Sassafras soil, a sandy loam soil from Maryland, United States. The test was conducted under continuous irradiation using a xenon arc lamp for approximately 15 days at ca 20 $\pm$ 2 °C. [Ph-^{14}C]-) or [IP-5,8a-^{14}C]-fluazaindolizine was applied, at a nominal rate of 1.0 mg ai/kg to thinly-layered soil (moist soil samples at ca 9.1 percent moisture, 75 percent field capacity) and irradiated using a lamp equipped with filters to eliminate wavelengths of $<$ 290 nm and reduce wavelengths greater than 800 nm to give a spectral distribution similar to natural sunlight. Non-irradiated (dark control) samples were also prepared for each radiolabel and maintained in the dark at ca 20 $\pm$ 2 °C.

Soil samples were extracted with acetonitrile:2 percent formic acid (aq) (9:1) followed by acetonitrile:2 percent formic acid (aq) (4:1) and then acetonitrile:2 percent formic acid (aq) (1:1).

[Ph-^{14}C]fluazaindolizine declined from quantitative levels at Day 0 to *ca* 48–53 percent AR following 15 days irradiation. IN-F4106 increased with irradiation duration. reaching 24.15 percent AR following 15 days of irradiation. Multiple minor metabolites were detected but not identified as none of these individually accounted for greater than 5.5 percent AR at two consecutive sampling intervals. Corresponding dark control soil extracts indicated that [Ph-^{14}C]fluazaindolizine also declined from quantitative levels at Day 0 to *ca* 44–58 percent AR following 15 days in dark conditions and contained one main degradation product identified as IN-F4106 reaching 36.53 percent AR after 15 days of incubation.

The [IP-5,8a-^{14}C]-labelled samples displayed a similar decline of fluazaindolizine as the [Ph-^{14}C] label, in dark control as well as irradiated soil extracts. One main degradation product (IN-QEK31) was identified in the dark control samples and this product was observed in minimal amounts in irradiated samples. This degradation product co-eluted with an authentic reference standard of IN-QEK31 and it was detected in the [IP-5,8a-^{14}C] label samples only. It reached a maximum value of 28.97 percent AR following 12 days of incubation, before declining slightly to 26.45 percent AR after 15 days incubation in the dark control soils. However, this degradate was not detected in substantial amounts in irradiated soils. Absence of IN-QEK31 in irradiated soils suggested that it was degraded by light almost as readily as it was generated. Multiple minor metabolites were detected in the irradiated [IP-5,8a-^{14}C] label samples as well, but not identified as none of these individually accounted for greater than 5 percent AR at any sampling interval.

Degradation of [^{14}C]fluazaindolizine in irradiated soil samples occurred primarily *via* non-photolytic degradation because the rate of degradation in irradiated and dark control soils did not differ appreciably. The main degradation products IN-F4106 ([Ph-^{14}C]-label) and IN-QEK31 ([IP-5,8a-^{14}C]-label) form on cleavage of parent molecule. Under irradiated conditions, IN-F4106 appeared to be stable and was therefore observed in similar amounts in light as well as dark soil. On the other hand, IN-QEK31 degraded quickly under irradiated conditions and was therefore, only observed in dark soil.

The DT_{50} and DT_{90} values of [^{14}C]fluazaindolizine were calculated using a simple first-order (SFO) model. Kinetics analysis for decline of the parent compound is summarised in Table 93.

Table 93 Summary of soil photolysis degradation rates for fluazaindolizine

System	k for fluazaindolizine (days^{-1})	DT_{50} (days)	DT_{90} (days)
Irradiated	0.0418 ± 0.005	16.6	55.1
Dark control	0.0368 ± 0.006	18.9	62.6
Corrected for dark control	0.0050	138	457

Fluazaindolizine does not undergo significant photolytic degradation on moist soil when exposed to artificial sunlight. Soil metabolite IN-QEK31 degrades readily on moist soil surface in the presence of light.

Field studies

Soil dissipation studies

According to the degradation pathway shown, monitoring of fluazaindolizine and five degradation products (IN-A5760, IN-F4106, IN-QEK31, IN-REG72, and IN-VM862) is adequate to characterize the behaviour of fluazaindolizine in soil environment. The metabolites analysed represented all significant metabolites in soil. IN-RYC33, an additional metabolite observed only in the confined rotation study as a minor metabolite in soil was also included for analysis in the dissipation studies. The data were used to determine the dissipation kinetics.

Ten field studies were conducted during 2013 through 2016 seasons in Canada, the European Union and the United States of America with SC formulations applied to bare soil. All studies in Europe were conducted with a use rate of 1 kg ai/ha while the studies in the North American region were conducted with use rates from 1.26 to 4 kg ai/ha. Five of the studied plots received two sequential applications at intervals ranging from 16 to 90 days, and the remaining plots received a single application.

While all major degradates were detected in the field studies, IN-QEK31, IN-F4106, and IN-VM862 made up the largest portion of observed residues. The remaining degradates (IN-A5760 and IN-REG72) were detected at levels below 3 percent of the applied material. Most fluazaindolizine and degradate residues in terrestrial field dissipation studies remained in the top 30–50 cm of soil, however residues were detected in the lowest sampled core depth (70–90 cm) in all studies.

The field dissipation half-lives of fluazaindolizine ranged from 5.0–171 days which is similar to the aerobic soil metabolism degradation half-lives of 3.4–241 days. A summary of terrestrial field dissipation data is provided in Table 94.

The dissipation of fluazaindolizine and metabolites (IN-QEK31, IN-F4106, IN-A5760, IN-REG72, IN-VM862 and IN-RYC33) under relevant growing conditions at four sites in Europe, one in Nambsheim France (Doig 2016 DuPont 36981), Thessaloniki Greece (Doig 2016 DuPont 36979), Lodigiano Italy (Doig 2016 DuPont 36980) and Lleida Spain (Doig 2016 DuPont 36978). Fluazaindolizine was applied to bare soil at a nominal rate of 1.0 kg ai/ha with 10-30 mm irrigation applied within 24 hours of application. Soil samples were collected to a depth of 0.9 m at predetermined intervals over an 18-month period. Residues of fluazaindolizine and metabolites were extracted using acetonitrile: 2 percent formic acid (aq) (1:1) at ambient temperature and with quantification by LC-MS/MS.

Additional dissipation studies were conducted at six sites in North America, Woodland California (2×2.0 kg ai/ha, 90 day interval, Shepard 2016 DuPont 40812), Porterville California (2 kg ai/ha and also 2×1 kg ai/ha at 90 day interval Theil 2016 DuPont-36687), Frenchtown New Jersey (0.76 and 0.5 kg ai/ha

at 16 day interval Theil 2016 DuPont-36688), Branchton Ontario Canada (2 kg ai/ha Shepard 2017 DuPont-40811), Raymonville Texas (2 kg ai/ha and also 2×1 kg ai/ha at 90 day interval Theil 2016 DuPont 36689) and Oviedo Florida (2×1 kg ai/ha at 35 day interval Theil DuPont-36690).

All six of the metabolites monitored were detected at some sampling intervals during these studies. Five metabolites, all except IN-A5760, were found immediately after the application. IN-QEK31 and IN-F4106 accounted for the largest proportion of the metabolites observed. With the exception of IN-VM862 the remaining components generally did not exceed 5 percent. The profiles of soil dissipation of fluazaindolizine at different locations in Europe and North America are shown in Figure 29.

Environmental fate in water

Hydrolysis

Fluazaindolizine hydrolysis

Anand (2013 DuPont-35131) studied the hydrolysis of fluazaindolizine at 50°C and at pH 4, 7 and 9. The study duration was 30 days. Fluazaindolizine was stable with DT_{50} estimated as >429 days.

Based on the results of this study, hydrolysis is not expected to be a route of degradation of fluazaindolizine in the environment.

IN-F4106 hydrolysis

Manikandan (2015 DuPont-42585) studied the hydrolysis of ^{14}C-IN-F4106 at 50 °C for 5 days and at pH 4, 7 and 9. IN-F4016 was essetially stable (<6 percent degradtation) with an estimated DT_{50} at 25 °C of >1 year.

Based on the results of this study, hydrolysis is not expected to be a route of degradation of IN-F4106 in the environment.

IN-QEK31 hydrolysis

Yogeesha (2015 DuPont-40399) studied the hydrolysis of ^{14}C-IN-QEK31 at 50 °C for 5 days and at pH 4, 7 and 9. The hydrolysis of IN-QEK31 at 50 $\pm$ 0.5 °C after 5 days of incubation was <3 percent in pH 4, 7 and 9 buffer solutions (DT_{50} at 25 °C >1 year).

Based on the results of this study, hydrolysis is not expected to be a route of degradation of IN-QEK31 in the environment.

Photochemical degradation of fluazaindolizine and its photolysis products

Bell and Jewkes (2015 DuPont-37450) studied the aqueous photolysis of fluazaindolizine in sterile buffers and natural waters. Sterile pH 4 and 9 buffers and sterile natural water containing [Ph-^{14}C] or [IP-5,8a-14C] at a nominal concentration of 2 μg/mL were continuously irradiated using a xenon arc lamp for 10 to 15 days. Mass balance was satisfactory during the first 3-4 days of irradiation in all cases and for all pH 9 phenyl incubates. However, a decline in mass balance at the final timepoint was observed for pH 4 and natural water samples, accounting for recovery of 72.91 and 86.46 percent AR, respectively. In all of the test systems, no significant quantity of radioactivity was detected in the volatile trapping agents.

[^{14}C]fluazaindolizine degraded extensively and quite rapidly due to light in all irradiation experiments, such that the parent compound degraded to <10 percent AR within *ca.* 5 days.

In the pH 4 [Ph-^{14}C]fluazaindolizine samples, photodegradation products were identified as 2-chloro-5-methoxy benzene sulfonic acid, IN-UHC58, IN-UGA26, IN-F4106, IN-UGA22, IN-URA40 and fluazaindolizine hydroxylated in the phenyl ring, detected in proportions ranging from *ca.* <1-24 percent at various intervals. In addition, there was a cluster of polar unidentified components which consisted of

multiple degradation products, as well as minor components throughout the column elution. The minor components did not individually exceed 5 percent AR (except at one timepoint; 8.7 percent AR at Day 12). The maximum combined radioactivity attributed to all unknown minor degradation products at any one sampling interval was 20.5 percent AR at Day 12. The only degradates which exceeded 10 percent AR at multiple sampling intervals were IN-UGA22, IN-F4106 and 2-chloro-5-methoxy benzene sulfonic acid.

In pH 4 buffer samples treated with [IP-5,8a-^{14}C]-fluazaindolizine, the test item also showed degradation similar to that observed in [Ph-^{14}C]-fluazaindolizine, except for the observation of additional label specific degradates. Identified degradates included, IN-R6P21, IN-UGA22, IN-URA40 and hydroxylated fluazaindolizine, IN-UHC58, IN-UGA26, IN-VM862, hydroxylated IN-RYC33 and IN-RYC33. In addition, there was a cluster of polar unidentified components, as well as minor components throughout the column elution. The minor components did not individually exceed 5 percent. The maximum combined radioactivity attributed to the multiple unknown minor degradation products at any one sampling interval was 13.7 percent AR at Day 12.

Photodegradation at pH 9 and natural water samples was equally facile and showed little differences from the behaviour noted in pH 4 buffered solutions. More than 90 percent of the parent compound degraded by Day 4 or shortly afterwards. The degradation products found in the pH 4 buffers were also noted in pH 9 buffer and in natural water, except IN-QEK31 was also detected in pH 9 and natural water samples.

Fluazaindolizine remained unchanged in the pH 4 buffer, pH 9 buffer and natural water dark control samples. DT_{50} and DT_{90} are shown in Table 95.

Table 95 Calculated kinetics parameters for fluazaindolizine under constant irradiation of simulated sunlight

System	Kinetic model	k (days^{-1})	r^2	DT_{50} (days)	DT_{90} (days)
Irradiated pH 4 buffer	SFO	0.6281	0.999	1.1	3.7
Irradiated pH 9 buffer	SFO	0.5608	0.986	1.2	4.1
Irradiated natural water	SFO	0.4327	0.993	1.6	5.3

Fluazaindolizine is susceptible to rapid photolysis in sterile pH 4 and 9 buffer and natural water. The calculated quantum yield for the actinometer was 3.972×10^{-3} molecules degraded/photon. The quantum yield for [^{14}C]fluazaindolizine was calculated as 5.340×10^{-4} molecules degraded/photon.

Lin *et al*. (2019, Chemosphere 214:543-552) studied the photodegradation of fluazaindolizine in water and the effects of solution pH, humic acids (HA), nitrates (NO_3^-) and Fe(III) ions on photolysis of fluazaindolizine were studied. The results indicated that pH did not significantly affect its photodegradation. At low concentration (up to 5 mg/L), HA slightly facilitated the photodegradation of fluazaindolizine, while at high concentration (10–20 mg/L), HA inhibited its photodegradation. The presence of NO_3^- (0-10 mg/L) and Fe(III) (0–5 mg/L) noticeably accelerated the photodegradation of fluazaindolizine. Eleven transformation products were isolated and identified by LC-TOF-MS. The predominant photoproduct came from ring opening of imidazole-ring and dechlorination. Other transformation products resulted from a series of photochemical reactions involving hydroxyl substitution, ring-opening, cleavage, oxidation, and decarboxylation. The half-life in water at pH 4, 7.2 and 9.0 were 20.2, 19.0 and 18.6 hours, respectively.

A proposed patway for fluazaindolizine photolysis in water in shown in Figure 30.

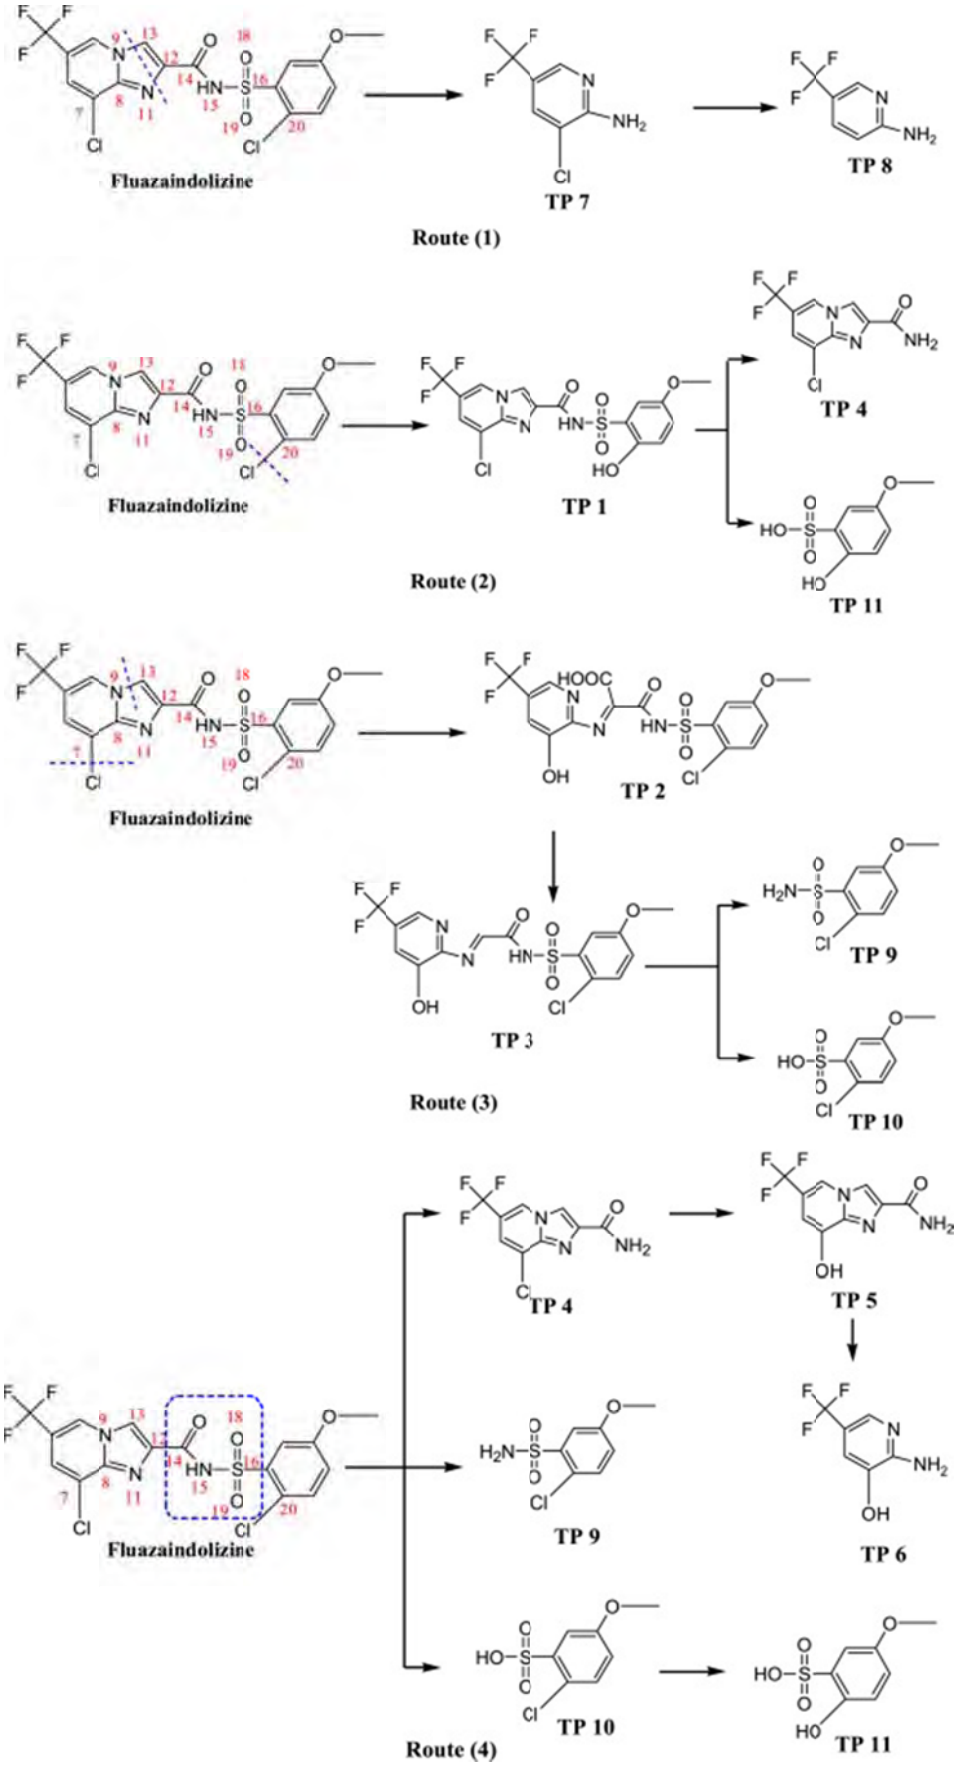

Figure 30 Proposed photolysis of fluazaindolizine in water

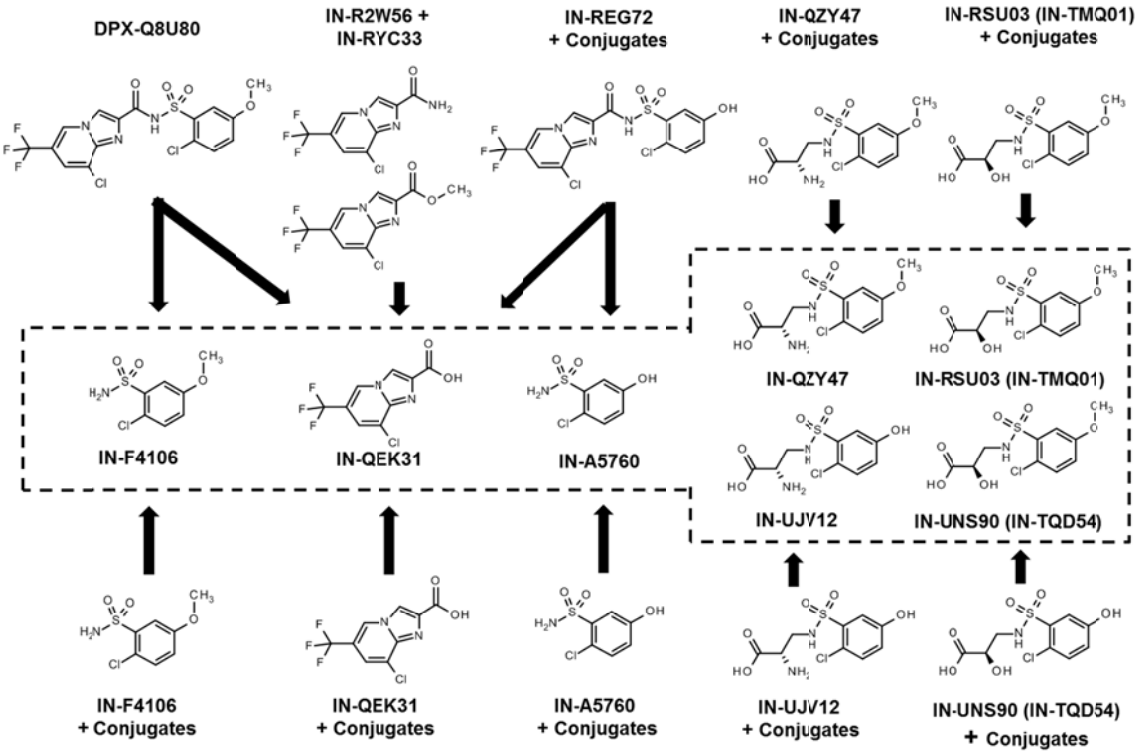
METHODS OF RESIDUE ANALYSIS

Plant matrices

The metabolism of fluazaindolizine in crops results in a complex mixture of metabolites that arise from hydrolysis of the amide bond resulting in cleavage of the molecule to produce IN-F4106 and IN-QEK31 which are subject to further metabolism including conjugation. A number of minor metabolites are formed by hydrolysis at the sulphonamide bond to form IN-RYC33, and O-demethylation to form IN-REG72 which may also form conjugates. Methods have been developed to measure fluazaindolizine as well as major metabolites. The methods involve analysis without (fluazaindolizine and free IN-F4106, IN-QEK31, IN-QZY47, IN-R2W56, IN-REG72, IN-TEQ01, IN-RYC33) and also with hydrolysis of conjugates (IN-AS5760, IN-F4106, IN-QEK31, IN-QZY47, IN-TMQ01, IN-UJV12, IN-UNS90). Hydrolysis of fluazaindolizine results in cleavage of the amide bond and formation of IN-F4106 and IN-QEK31.



Residues are reported in terms of the analytes but may be converted to parent equivalents using molecular weight conversion factors: 2.26 for IN-A5760, 2.11 for IN-F4106, 1.77 for IN-QEK31, 1.52 for INQZY47, 1.51 for IN-TMQ01, 1.59 for IN-UJV12 and 1.58 for IN-UNS90.

Method DuPont-47054 utilises different hydrolysis conditions to allow for higher throughput of samples as well as modified clean-up, and recovery data was supplied in support of this method. A summary of the LC-MS/MS methods to analyse fluazaindolizine and metabolites in plants is shown in Tables 96.

Table 96 Overview of the methods for determination of fluazaindolizine in crops

Method	DuPont-33681 (Revision 3)
Analytes	Pre-hydrolysis Fluazaindolizine, IN-F4106, IN-QEK31, IN-QZY47, IN-R2W56, IN-REG72, IN-RSU03, IN-RYC33 Post-hydrolysis

	IN-A5760, IN-F4106, IN-QEK31, IN-QZY47, IN-RSU03, IN-UJV12, IN-UNS90
Matrix	Watery, acidic, oily, and dry crops
Extraction	Part 1 (pre-hydrolysis) Fluazaindolizine and metabolites were extracted from watery, acid, and oily matrices with methanol/water (70/30) and centrifuged to separate supernatant and solids. For oily crops, the extract is partitioned with hexane and the hexane discarded. For all crops, an aliquot of the extract is diluted with 0.1 M aqueous formic acid and filtered for analysis by LC-MS/MS. . Dry crop matrices are extracted with 10 mM ammonium formate:methanol (1:2 v:v) with the ammonium formate added first and allowed to sit for 5 minutes before adding the methanol, then re-extracted 2× with methanol:10 mM ammonium formate (70:30 v:v), centrifuged and the combined extracts concentrated under nitrogen and diluted with water:methanol ((75:25 v:v containing 0.1 percent formic acid) for analysis by LC-MS/MS. Part 2 (hydrolysis) Watery, acidic, oily crops: An aliquot of the combined extracts concentrated to <0.5 mL under N_2, mixed with 1.2 M HCl and heated at 80°C for 16 hours. Dry crops: An aliquot of the part 1 extract is concentrated to <0.5 mL under N_2, mixed with 2 M HCl and heated at 80°C for 16 hours.
Column/sorbent	Part 1 (pre-hydrolysis) Watery, acidic, oily crops: Optional. The extract is diluted with 0.1 M aqueous formic acid and loaded onto a Bond-Elut LRC-CN-U SPE cartridge, the eluate collected and the cartridge rinsed with 0.1 M aqueous formic acid methanol (50:50 v:v). The combined eluate/reinstate is diluted with 0.1 M Aqueous formic acid for analysis by LC-MS/MS Part 2 (hydrolysis) Watery, acidic, oily, dry crops: The hydrolysed extract is applied to a Bond-Elut SAX SPE cartridge, the eluate collected and the cartridge rinsed with acetate buffer. The combined eluate, rinsate is adjusted to volume (acetate buffer for watery and acidic crops or methanol:water 25:75 v:v, containing 0.1 percent formic acid for oily and dry crops) for analysis by LC-MS/MS.
Column	Phenomenex Kinetex biphenyl, 4.6×100 mm, 2.6 micron particle size
Mobile phase	A: water methanol (75:25), 0.01 percent formic acid in methanol
Quantitative detection	ESI in positive mode for: IN-QEK31, IN-R2W56, IN-RYC33, and negative mode for all other analytes fluazaindolizine: 466 → 157 (quantification) and 466 → 142 (confirmation) IN-AS5760: 206 → 142 (quantification) and 206 → 122 (confirmation) IN-F4106 : 220 → 156 (quantification) and 220 → 141 (confirmation) IN-QEK31: 265 → 247, 265 → 192, (quantification) and 265 → 219, 265 → 184 (confirmation) IN-QZY47: 307 → 220 (quantification) and 307 → 156, 307 → 78 (confirmation) IN-R2W56: 279 → 247 (quantification) and 279 → 219 (confirmation) IN-REG72: 452 → 143 (quantification) and 452 → 123 (confirmation) IN-RSU03: 308 → 220 (quantification) and 308 → 156, 308 → 78 (confirmation) IN-RYC33: 264 → 157 (quantification) and 264 → 219, 264 → 184 (confirmation) IN-UJV12: 293 → 206 (quantification), 293 → 142, 293 → 78 (confirmation) IN-UNS90: 294 → 206 (quantification), 294 → 142, 294 → 78 (confirmation)
LOQ	0.01 mg/kg per analyte before adjusting for parent equivalents (LOD 0.003 mg/kg)
Whole method linearity (r^2)	0.02-10 ng/mL $r^2 \geq 0.9951$ (1/*x* weighting)

Method	Method DuPont-47054
Analytes	Fluazaindolizine, IN-A5760, IN-F4106, IN-QEK31, IN-RYC33, IN-QZY47, IN-TMQ01 (IN-RSU03), IN-R2W56, IN-UJV12, and IN-TQD54 (IN-UNS90)
Extraction	Part 1: same as DuPont 33681. Part 2: Fluazaindolizine and metabolites were extracted from watery, acid, oily and dry matrices with methanol/water (70/30 v/v) and centrifuged to separate supernatant and solids. The extracts are reduced in volume under a flow of N_2 at 60 °C and 4 M HCl added and heated at 100 °C for 1.25 hours.
Column	Part 1: same as DuPont 33681. Part 2: For watery, acid, oily, an aliquot of the hydrolysed extract is diluted and applied to an Oasis® MCX SPE cartridge to isolate IN-QEK31, IN-TMQ01 (IN-RUS03) and IN-A5760. A separate aliquot was applied to an ENVI™ - Carb SPE cartridge to isolate IN-UJV12, INQZY47, IN-TQD54 (IN-UNS90) and IN-F4106. For dry crops, an aliquot

Method	Method DuPont-47054
	of the hydrolysed extract is diluted and applied to an Oasis® MCX SPE cartridge to isolate IN-QEK31, IN-TMQ01 (IN-RUS03) and IN-A5760. A separate aliquot was applied to an ENVI™ -Carb followed by an Oasis®-MCX SPE cartridge to isolate IN-UJV12, INQZY47, IN-TQD54 (IN-UNS90) and IN-F4106.
Eluent	Part 1: same as DuPont 33681. Part 2: Watery, acid, oily matrices: Oasis® MCX - 1 percent formic acid in methanol water (60:40 v:v). The eluate is concentrated under a stream of N_2 and bought to volume with 15 mM aqueous citric acid for LC-MS/MS. ENVI-Carb – 15 mM citric acid in methanol. The eluate is concentrated under a stream of N_2 and bought to volume with water for LC-MS/MS. Dry matrices: Oasis® MCX - 1 percent formic acid in methanol water (60:40 v:v). The eluate is concentrated under a stream of N_2 and bought to volume with 15 mM aqueous citric acid for LC-MS/MS. ENVI-Carb – 15 mM citric acid in methanol, the eluate added to an Oasis(r) MCX cartridge and eluted with 5 percent ammonium hydroxide in methanol. Water is added prior to concentration under a stream of N_2, 150 mM aqueous citric acid is added and the extract bought to volume with water for LC-MS/MS.
Quantitation	ESI in positive mode for: IN-QEK31, IN-R2W56, IN-RYC33, and negative mode for all other analytes fluazaindolizine: 466 → 157 (quantification) and 466 → 142 (confirmation) IN-AS5760: 206 → 142 (quantification) and 206 → 122 (confirmation) IN-F4106 : 220 → 156 (quantification) and 220 → 141 (confirmation) IN-QEK31: 265 → 247, 265 → 192, 265 → 184 (quantification/confirmation) and 265 → 219 (confirmation) IN-QZY47: 307 → 220, 307 → 156 (quantification/confirmation) and 307 → 78 (confirmation) IN-R2W56: 279 → 247 (quantification) and 279 → 219 (confirmation) IN-REG72: 452 → 143 (quantification) and 452 → 123 (confirmation) IN-RSU03: 308 → 220, 308 → 156 (quantification/confirmation) and 308 → 78 (confirmation) IN-RYC33: 264 → 157 (quantification) and 264 → 219, 264 → 184 (confirmation) IN-TMQ01: 308 → 220 (quantification) and 466 → 142 (confirmation) IN-UJV12: 293 → 206 (quantification), 293 → 142 (quantification/confirmation), 293 → 78 (confirmation) IN-UNS90: 294 → 206, 294 → 142, 294 → 78 (quantification/confirmation)

LOQ	0.01 mg/kg per analyte before adjusting for parent equivalents (LOD 0.003 mg/kg)

Method DuPont 33861 (Klems 2017 DuPont 33861, Revision No. 3, Rebstock 2021 DuPont-37832 Revision No. 1)

The residue method for the determination of fluazaindolizine residues in tomatoes, dried peas, soya beans, corn stover, oranges, grapes, wheat straw, and wheat grain involves simple extraction, clean-up,

and analytical determination by LC-MS/MS detection. Samples were also analysed after hydrolysis to determine if conjugated residue was present.

The recoveries of IN-QEK31, IN-F4106, IN-A5760, IN-TQD54 (IN-UNS90), IN-TMQ01 (IN-RSU03), IN-QZY47 and IN-UJV12 from crop samples fortified at 0.01 (LOQ) and 0.10 mg/kg and carried through the subsequent hydrolysis and clean-up procedures support the satisfactory performance of this method.

The solvent mixture used for extracting fluazaindolizine and its metabolites from crop samples (70/30 methanol/water) are based on the same solvent mixture/sample ratio used in the primary crop metabolism studies conducted with radiolabelled fluazaindolizine (DuPont-34947, DuPont-34948, DuPont-34946, DuPont-43220 and DuPont-41849). The extraction efficiency data ranged from 72.2 to 93.9 percent and averaged 84.6 percent of the total radioactivity in the various commodities.

The fortification data reported in the method for determination of residues in grape (high water), soya bean seed (high oil/high protein), tomato (high acid) and wheat straw (dry) are summarised in Tables 97 to 100. The average recovery were within the range 70 to 120 percent (pre-hydrolysis 72–113 percent, percent RSD 1.3–15 percent; post-hydrolysis 77–114 percent, percent RSD 1.1-13 percent).

Recovery and repeatability data for the determination of IN-QEK31, IN-F4106, IN-A5760, IN-TQD54 (IN-UNS90), IN-TMQ01 (IN-RSU03), IN-QZY47 and IN-UJV12 in crops using method DuPont-47054 are presented in Tables 101 and 103. Fluazaindolizine and its metabolites were extracted from plant matrices using a mixture of methanol and water. The final determination of fluazaindolizine and its metabolites was performed by LC-MS/MS.

The LOQ was defined by the lowest fortification level successfully tested, which was 0.01 mg/kg in grape (high water), soya bean seed (high oil/high protein), tomato (high acid) and wheat straw (dry). Good linearity was observed in the range of 0.2-10 ng/mL (nominal) for fluazaindolizine and its metabolites IN-REG72, IN-RYC33, IN-R2W56, IN-QEK31, IN-A5760, IN-F4106, IN-UJV12, IN-QZY47, IN-TQD54 (IN-UNS90) and IN-TMQ01 (IN-RSU03). These ranges corresponded to residue values of approximately 0.004-0.2 mg/kg for watery, oily, and acidic crops and 0.006–0.3 mg/kg for dry crops. At least five-point standard curves were prepared utilizing matrix-matched standards with r2 values ≥ 0.9989 (pre-hydrolysis) and ≥ 0.9954 (post-hydolysis).

Method DuPont-47054 is suitable to determine residues of fluazaindolizine and metabolites in the matrices investigated. The specificity of the method is provided using a mass selective detector. The method was successfully validated for fluazaindolizine metabolites.

Table 97 Recovery data for the analytical method for the determination of fluazaindolizine residues in food of plant origin (Klems, 2017 DuPont-33861, Revision No. 3)

Matrix	Fortification level (mg/kg)	Mean (%)	% RSD	Mean (%)	%RSD

Notes:

[A] Post-hydrolysis grapes: 307 m/z 156 m/z used for quantitation of IN-QZY47, 308 m/z 156 m/z used for quantitation of IN-TMQ01 (IN-RSU03), 294 m/z 142 m/z used for quantitation of IN-TQD54 (IN-UNS90).

[B] Post-hydrolysis wheat straw: 294 m/z 78 m/z used to quantify IN-TQD54 (IN-UNS90), 293 m/z 142 m/z used to quantify IN-UJV12.

CIN-TQD54 is the R enantiomer contained in IN-UNS90 (racemic mixture).

DIN-TMQ01 is the R enantiomer contained in IN-RSU03 (racemic mixture).

The method of Klems (2017) was also validated by Rebstock (2021). The recovery data obtained are summarised in Table 98. The successful validation demonstrates the reproducibility of this method.

The fortification data reported in the method for determination of residues in tomato (high acid/high water), wheat grain (high starch), oranges (high acid), corn stover (dry), soya bean seed (high oil/high protein) and dried peas (high protein) are summarised in Table 98. The average recovery were generally within the range 70 to 120 percent (pre-hydrolysis 69-102 percent (69 percent was for confirmation ion for IN-QZY47 in field stover at the LOQ, percentRSD ≤17 percent except one percentRSD 23 percent (confirmation ion for IN-F4106 at LOQ in dry pea seed); post-hydrolysis 73-119 percent, percentRSD generally ≤19 percent except two RSDs of 21 percent and 27 percent occurred for the quantitation ion transition for IN-F4106 in field corn stover and soya bean seed, respectively, each at the LOQ. For field corn stover, the high RSD is due to 1 high recovery (125 percent) out of five samples. For soya bean seed, the high RSD is due to two recoveries of 57 percent and 123 percent, out of 5 samples.

Recovery and repeatability data for the determination of IN-QEK31, IN-F4106, IN-A5760, IN-TQD54 (IN-UNS90), IN-TMQ01 (IN-RSU03), IN-QZY47 and IN-UJV12 in crops using method DuPont-47054 are presented in Table 104 and 105. Fluazaindolizine and its metabolites were extracted from plant matrices using a mixture of methanol and water. The final determination of fluazaindolizine and its metabolites was performed by LC-MS/MS.

The LOQ was defined by the lowest fortification level successfully tested, which was 0.01 mg/kg in tomato (high acid/high water), wheat grain (high starch), oranges (high acid), corn stover (dry), soya bean seed (high oil/high protein) and dried peas (high protein). Good linearity was observed in the range of 0.2-10 ng/mL (nominal) for fluazaindolizine and its metabolites IN-REG72, IN-RYC33, IN-R2W56, IN-QEK31, IN-A5760, IN-F4106, IN-UJV12, IN-QZY47, IN-TQD54 (IN-UNS90) and IN-TMQ01 (IN-RSU03). These ranges corresponded to residue values of approximately 0.004-0.2 mg/kg for watery, oily, and acidic crops and 0.006-0.3 mg/kg for dry crops. At least five-point standard curves were prepared utilizing matrix-matched standards with r^2 values ≥ 0.9989 (pre-hydrolysis) and ≥ 0.9954 (post-hydolysis).

The stability of pre- and post-hydrolysis extracts from matrices fortified at 0.01and 0.1 mg/kg, as well as matrix-matched calibration standards was investigated for three matrices (grape, spinach, wheat straw) following 14–15 days storage at 5 °C. Mean recoveries of fluazaindolizine, IN-F4106, IN-QEK31, IN-QZY47, IN-R2W56, IN-REG72, IN-RSU03, and IN-RYC33 pre-hydrolysis were 96-106 percent with RSDs ≤8 percent. Mean post-hydrolysis recoveries of IN-A5760, IN-F4106, IN-QEK31, IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 were 96-113 percent with RSDs of 1–14 percent. The matrix-matched standards showed linearity with r^2 values of ≥0.999, and RSDs for the response factors of ≤18 percent.

Recovery data to validate the optional SPA cleanup step were provided for tomato, reflecting one sample fortified with each analyte at the LOQ and 10×LOQ, which indicated adequate recovery for each of the pre- and post-hydrolysis analytes.

Table 98 Recovery data (n=5) for the analytical method for the determination of fluazaindolizine residues in food of plant origin (Rebstock, 2021 DuPont-37832, Revision No. 1)

[C] IN-TMQ01 is the *R* enantiomer contained in IN-RSU03 (racemic mixture).

[D] IN-TQD54 is the *R* enantiomer contained in IN-UNS90 (racemic mixture).

This method is suitable for residue data collection for risk assessment purposes and may also be considered suitable for enforcement of the MRL of fluazaindolizine (parent). The instrumentation required to perform both the analysis and confirmatory methods is available in most well equipped analytical laboratories.

Method DuPont-47054 (Gesell, 2020 DuPont-47054, Revision No. 2)

Method DuPont-47054 is a modification of method DuPont-33681. The residue method for the determination of fluazaindolizine residues involves simple extraction, clean-up, and analytical determination by LC-MS/MS detection. Samples were also analysed after hydrolysis to determine if conjugated residue was present. The extraction procedure implemented in Part One (pre-hydrolysis) is identical for each of the methods, and it is the acidic hydrolysis step described in Part Two of the method that was the focus of the validation work.

The recoveries of IN-QEK31, IN-F4106, IN-A5760, IN-TQD54 (IN-UNS90), IN-TMQ01 (IN-RSU03), IN-QZY47 and IN-UJV12 from crop samples fortified at 0.01 (LOQ) and 0.10 mg/kg and carried through the subsequent hydrolysis and clean-up procedures support the satisfactory performance of this method.

The solvent mixture used for extracting fluazaindolizine and its metabolites from crop samples (70/30 methanol/water) are based on the same solvent mixture/sample ratio used in the primary crop metabolism studies conducted with radiolabelled fluazaindolizine (DuPont-34947, DuPont-34948, DuPont-34946, DuPont-43220 and DuPont-41849). The extraction efficiency data ranged from 72.2 to 93.9 percent and averaged 84.6 percent of the total radioactivity in the various commodities.

The fortification data reported in the method for determination of residues in limes, dried peas, tomatoes, and soya beans are summarised in Table 101. The average recovery were within the range 70 to 120 percent (75–118 percent), with RSD values ≤ 20 percent (2–11 percent).

Recovery and repeatability data for the determination of IN-QEK31, IN-F4106, IN-A5760, IN-TQD54 (IN-UNS90), IN-TMQ01 (IN-RSU03), IN-QZY47 and IN-UJV12 in crops using method DuPont-47054 are presented in Table 101. Fluazaindolizine and its metabolites were extracted from plant matrices using a mixture of methanol and water. The final determination of fluazaindolizine and its metabolites was performed by LC-MS/MS.

The LOQ was defined by the lowest fortification level successfully tested, which was 0.01 mg/kg in tomatoes, dried peas, soya beans and limes. The percentRSDs ranged from 2 to 11. Calibration curves over the range 0.1–50 ng/mL for IN-QEK31, IN-A5760 and IN-TMQ01 (IN-RSU03) and 0.2–50 ng/mL for IN-F4106, IN-UJV12, IN-QZY47 and IN-TQD54 (IN-UNS90). These ranges corresponded to residue values of 0.003-1.7 mg/kg and 0.003-0.7 mg/kg, respectively. At least five-point standard curves were prepared utilizing standards in solvent with r^2 for calibration curves all > 0.9995.

Method DuPont-47054 is suitable to determine residues of fluazaindolizine and metabolites in the matrices investigated. The specificity of the method is provided using a mass selective detector. The method was successfully validated for fluazaindolizine metabolites.

Notes:

[A] IN-TQD54 is the *R* enantiomer contained in IN-UNS90 (racemic mixture).

[B] IN-TMQ01 is the *R* enantiomer contained in IN-RSU03 (racemic mixture).

The modification hydrolysis conditions and clean-up in the residue method for the determination of residues of IN-QEK31, IN-F4106, IN-A5760, IN-UNS90, IN-TMQ01, IN-QZY47, and IN-UJV12 in tomatoes, soya beans, limes, and dried peas was successfully validated over the range of 0.01–0.1 mg/kg, with an LOQ of 0.01 mg/kg.

Method DuPont-39990, AP.224685A and B (Brown 2020 DuPont-39990)

The recovery data reported in the methods for determining residues of fluazaindolizine and its metabolites in tomato, grape, wheat grain, dried bean, wheat straw and soya bean seed are summarised in Table 104. For some metabolites, analyte standards were provided in salt form. MW back calculations are required to correct these values since this discrepancy was not taken into consideration during weighing of the analytical standards. MW conversions would result in a 0.89 conversion factor; therefore, actual values fortified were approximately 0.0089 and 0.089 mg/kg.

Average recoveries for pre- and post-hydrolysis fortification samples were within 70–120 percent, with percentRSD values ≤ 20 percent, with a few, minor exceptions: In each case other transitions were available that met performance criteria. Pre-hydrolysis results for individual ion transitions outside acceptable ranges were wheat grain IN-REG72 two transitions individual mean recoveries 65 percent and 69 percent and one transition for others, IN-QZY47 individual mean recovery 69 percent; wheat straw fluazaindolizine RSD 22 percent; IN-F4106 individual mean recovery 67 percent, IN-QZY47 69 percent, IN-QEK31 69 percent; dried beans fluazaindolizine 68 percent. Post-hydrolysis tomato fluazaindolizine RSD 25 percent, IN-RSU03 RSD 21 percent, IN-QEK31 RSD 21 percent;wheat grain IN-F4106 RSD 21 percent, IN-UNS90 RSD 23 percent; wheat straw IN-QZY47 RSD 21 percent, soya bean seed IN-UNS90 individual mean recovery 69 percent, dried bean IN-UJV12 RSD 31 percent, IN-UNS90 RSD 24 percent.

The LOQ of the method for quantifying residues of fluazaindolizine and its metabolites is nominally 0.01 mg/kg. Good linearity was observed in the range of 0.15 to 10 ng/mL (nominal) for fluazaindolizine and its metabolites IN-REG72, IN-QEK31, IN-F4106, IN-QZY47, IN-TMQ01 (IN-RSU03), IN-RCY33, and IN-R2W56 (pre-hydrolysis). Similarly, good linearity was observed in the range of 0.15 to 10 ng/mL for IN-F4106, IN-TMQ01 (IN-RSU03), IN-QZY47, IN-UJV12, IN-A5760, IN-TQD54 (IN-UNS90), and IN-QEK31 (post-hydrolysis). These ranges correspond to residue values of approximately 0.003–0.2 mg/kg. The observed r^2 values were ≥0.99. At least five-point standard curves were prepared utilizing standards in solvent.

The majority of the relative standard deviations for all analytes and concentration levels, in each matrix were less than 20 percent, with a few minor exceedances. Therefore, it can be concluded that the repeatability of this method is adequate for the determination of residues of fluazaindolizine and its metabolites in tomatoes, wheat grain, grapes, wheat straw, soya bean seeds, and dried beans (pre-and post-hydrolysis) (Table 104.

Table 104 Recovery data for the analytical method for the determination of residues of fluazaindolizine and its metabolites in tomato – pre-hydrolysis (Brown, 2020 DuPont-39990, Revision No. 1)

Radiovalidation

MacDonald (2018 DuPont-48155) studied the hydrolysis step in the analytical method using selected samples from crop rotation and plant metabolism studies which utilised [Ph-^{14}C]- or ([IP-5,8a-^{14}C]-fluazaindolizine. For both sites of label, samples of 30DAA wheat hay, 30DAA radish roots. 30DAA mature spinach and soya bean hay were taken from the confined crop rotation study (DuPont-34945, Revision No. 1) and soya bean seeds were taken from the plant metabolism study (DuPont-34948).

Samples were, or had been, extracted with a methanol:water (70:30) mixture which removed the majority of the radioactive residues (77.1–95.8 percent TRR). The initial extraction solvents used in this study (methanol:water (7:3)) are identical to those used in the analytical method for the determination of fluazaindolizine and metabolites in crops using LC-MS/MS (DuPont-33861). The resulting extracts were combined to form a single extract, and a 10 mL aliquot was evaporated and hydrolysed with 4N HCl (*ca.* 100 °C, 1 hour). The samples were processed using SPE and LC conducted on any fractions which contained significant levels of radioactivity. Recoveries of the radioactive residues were measured throughout. The overall recoveries were calculated as a percentage of the extracted radioactive residues (percent TER).

With the exception of [IP-5,8a-^{14}C]fluazaindolizine soya bean seeds, subsamples of homogenised tissue were freshly extracted three times with methanol:water (7:3) at ambient temperature. Each extract was separated from solids by centrifugation. [IP-5,8a-^{14}C]fluazaindolizine soya bean seeds extracts were generated in the exact same way under DuPont-34948. For each sample, extracts 1-3 were combined to form a single extract.

Acid hydrolysis, using HCl, was conducted on combined extracts for each commodity. A 10 mL aliquot of was reduced to *ca.* 0.5 mL under a stream of nitrogen gas at 60 °C prior to reconstitution in 4M HCl and incubated at 100 °C for one hour. Hydrolysed samples were cleaned up by Oasis HLB SPE column previously conditioned with acetonitrile followed by 0.1M HCl. The hydrolysate was loaded onto the column which was rinsed with 1 percent acetic acid; twice with 5 mL of acetonitrile:50 mM ammonium acetate (90:10) and finally with acetonitrile. The acetonitrile:ammonium acetate eluates were reduced to dryness at 60 °C under a gentle stream of nitrogen and reconstituted in 1 mL of 50 mM ammonium acetate for analysis by LC-UV. Reference standards were analysed under the same conditions. Quantification of radioactivity in the column effluent was confirmed by fraction collection.

For each sample, the main components were hydrolysed to the expected products that were observed previously when crop sample extracts were hydrolysed under milder conditions (*ca.* 1N HCl at 80 °C for *ca.* 16 hrs). For example, fluazaindolizine was hydrolysed to IN-F4106/IN-QEK31, IN-REG72 was hydrolysed to IN-A5760/IN-QEK31, conjugates of IN-QZY47 were hydrolysed to IN-QZY47 and IN-UGA20 was hydrolysed to IN-QEK31.

Radiovalidation of residue extraction method

The radiochromatograms of the extracted ^{14}C using the metabolism based extraction method and that used in method DuPont-33861, Revision No. 3 were compared. The extraction solvents and proportions of solvent to sample in both methods are identical. Extractability of the majority of the ^{14}C was similar in

both the metabolism and method DuPont-33861 with both generating similar HPLC profiles, an example for hay from the [Ph-^{14}C]fluazaindolizine is shown in Table 116 with the extraction efficiency ≥ 67 percent for each analyte (Table 116).

Table 116 Comparison of the extraction efficiency of fluazaindolizine and various metabolites using the residue analytical method and the extraction method used in soya bean metabolism study ([Ph-^{14}C]fluazaindolizine hay)

Component	Metabolism Method		Method DuPont-33861		Extraction Efficiency (hydrolysis) [A] (% TRR)
	% TRR	mg/kg	% TRR	mg/kg	
Fluazaindolizine	6.1	0.040	4.8	0.032	80
IN-REG72	1.2	0.008	1.4	0.009	113
Malonyl conjugate of IN-QZY47 (IN-TUT81)	53.5	0.353	47.0	0.308	87
IN-QZY47	5.1	0.033	3.8	0.025	76
IN-RSU03 (IN-TMQ01)	0.5	0.003	-	-	- [B]
IN-F4106	2.7	0.018	1.9	0.012	67
Conjugate of IN-UJV12	2.4	0.016	1.7	0.011	69

Notes:
[A] 100×(% TRR method DuPont-33861)/(%TRR metabolism method) = % extraction efficiency of each analyte.
[B] IN-RSU03 levels were too low to determine extraction efficiency in this case.

Multiresidue methods

The applicability of the US Food and Drug Administration, Pesticide Analytical Manual (PAM), Volume I multiresidue methods for analysis of fluazaindolizine, IN-F4106, IN-QEK31, INQZY47 and IN-TMQ01 were evaluated by Ballard (2018 DuPont-42610). The study specifically evaluated the usefulness of the MRM described in the FDA PAM – Volume I, Appendix II, Third Edition, Jan. 1994: Multi-residue Protocols A, B, C, D, E, and F only for measuring residues of fluazaindolizine and its four metabolites. Protocols A, B, and C were tested to provide fluorescence detection and GC chromatography detection information. Protocol A was tested using instructions in PAM I, Section 401, module DL2 to determine if the compound was naturally fluorescent as required in the protocol. If the compound was fluorescent and provided reasonable sensitivity, this would have required additional work (Section 401 E1 + C1) to determine stability of chemical in methanol, short-term and long-term recovery of chemical through charcoal/silanised Celite clean up column and recovery through completed method with one substrate.

For protocol A, fluazaindolizine and IN-QEK31 were not fluorescent while IN-F4106, IN-QZY47 and IN-TMQ01 were weakly fluorescent. Protocol B was tested as per protocol guidelines for the carboxylic acid metabolites, IN-QEK31, IN-QZY47 and IN-TMQ01 (IN-RSU03). The methyl ester for the metabolite IN-QEK31 (IN-R2W56) was provided and run through GC module DG1. A peak was detected with suitable sensitivity to continue testing. All metabolites, IN-QEK31, IN-QZY47 and IN-TMQ01 (IN-RSU03), were methylated per Section 402 C1b. None of the compounds were successfully recovered through the Florisil® clean-up. Further testing through Protocol B was discontinued.

Section 302 GLC responses were determined by Protocol C guidelines for compounds fluazaindolizine, IN-QEK31, IN-F4106, IN-QZY47, and IN-TMQ01 (IN-RSU03). Compounds IN-F4106 and IN-QZY47 were deemed suitable for GC analysis under DG1 conditions and Protocol D was conducted according to the decision tree.

Extraction without clean-up was not attempted since the only module with adequate sensitivity, DG1, utilised electron capture detection. Compounds IN-F4106 and IN-QZY47 were tested through Section 302 C5 Florisil® clean up. Neither compound was adequately recovered so further work on Protocol D was discontinued.

Protocol E testing was not attempted because no compounds were successfully recovered through Protocol D (Section 302). Protocol F was tested as per protocol guidelines for IN-F4106 and IN-QZY47. The two components were tested through Section 304 C1 and C2 Florisil® Clean up. Neither compound was adequately recovered so further work on Protocol F was discontinued. Protocol G was not conducted because none of the compounds were substituted ureas.

In conclusion, the FDA MRMs are not suitable for detection and enforcement of MRL for fluazaindolizine, IN-QEK31, IN-F4106, IN-QZY47 or IN-TMQ01 (IN-RSU03) in non-fatty or fatty matrices.

Multi-Residue Method DFG-S19 was assessed for the detection, quantification, and confirmation of residues of fluazaindolizine and its metabolites IN-QEK31, IN-F4106, IN-A5760, IN-RYC33, IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 in tomato, soya bean, grapefruit, and wheat straw (Čermák and Kwiecien 2017, DuPont-42611). Samples were extracted with acetone using a homogenizer, and water is added beforehand in an amount that takes into account the water content of the matrix so that acetone/water ratio remains constant at 2/1. For wheat grain and soya bean seed, the water is heated to 40 °C and samples were allowed to soak for approximately 30 minutes. For grapefruit, a pH value is adjusted to approximately pH 7 by adding sodium hydrogen carbonate.

After addition of sodium chloride and ethyl acetate/cyclohexane (1/1) and repeated homogenization, the organic layer containing fluazaindolizine and its metabolites, is allowed to separate from the aqueous layer. The evaporated residue of an aliquot of the organic phase is cleaned up by gel permeation chromatography (GPC) on Bio Beads S-X3 (polystyrene gel) using a mixture of ethyl acetate and cyclohexane (1/1) as eluent and an automated gel permeation chromatograph. The residue-containing GPC fraction is concentrated, re-dissolved in the chromatography solvent and analyzed by LC-MS/MS.

The recovery data reported in the method for determining residues of fluazaindolizine and its metabolites in tomato, soya bean, grapefruit, and wheat straw are summarised in Table 117.

Good linearity was observed in the range of 0.20 to 20 ng/mL for fluazaindolizine and its metabolites IN-QEK31, IN-F4106, IN-A5760, IN-RYC33, IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90. These ranges correspond to residue values of approximately 0.002-0.2 mg/kg. The observed coefficients of determination r^2 were found to be ≥0.99. At least five-point standard curves were prepared utilizing standards in solvent.

The method was not validated due to unsatisfactory recovery for fluazaindolizine in wheat straw and grapefruit, for IN-QEK31, IN-TMQ01, and IN-UNS90 in all matrices except tomato and for IN-UJV12 and IN-QZY47 in all matrices. The determination of IN-4106, IN-A5760, and IN-RYC33 was successful in all matrices (except some small limitation in wheat straw). Repeatability is only adequate (RSD < 20 percent) for the determination of residues of IN-F4106, IN-A5760, and IN-RYC33 in tomato, soya bean, and grapefruit. In conclusion, the method was only validated for IN-F4106, IN-A5760, and IN-RYC33 in tomato, soya bean, and grapefruit at a LOQ of 0.01 mg/kg.

Table 117 Recovery data for the analytical method for the determination of residues of fluazaindolizine and its metabolites in commodities of plant origin (Čermák, Kwiecien, 2017 DuPont-42611)

Confirmatory method

Confirmation of results obtained by this HPLC-MS/MS method was performed by quantifying a separate daughter ion signal for each analyte. The recovery data obtained using the confirmatory procedure are summarised in Table 118. For fluazaindolizine, IN-QEK31, IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90, sufficient recovery was not obtained for most of the matrices under investigation. The method was considered validated for the determination of residues of IN-F4106, IN-A5760, and IN-RYC33 in tomato, soya bean, and grapefruit, but not wheat straw.

Table 118 Confirmation data for the analytical method for the determination of residues of fluazaindolizine and its metabolites in commodities of plant origin (Čermák., Kwiecien, 2017 DuPont-42611)

Matrix	Fortification level (mg/kg)	N	Mean (%)	% RSD	Mean (%)	% RSD

Substrates of animal origin - Description of methods for animal matrices

The study summary presented below encompasses the regulatory studies completed to create a suitable method for monitoring animal tissues for fluazaindolizine residue. An additional validation of this method was performed at Charles River Laboratories in the United Kingdom to support cattle feeding study under DuPont-42572, Revision No. 1 and is presented as an additional summary at the end of this section.

Table 119 Overview of the LC-MS/MS methods for determination of fluazaindolizine in animal commodities

Method	Charles River AP.225144.02 used in feeding study (modification of DuPont 39226) Du-Pont 42572	DuPont 39226 (see also modification Charles River AP.225144.02 used in feeding study)
Analytes	Fluazaindolizine, IN-AS5760, IN-F4106, IN-REG72, IN-QEK31, IN-R2W56 and IN-RYC33	
Extraction	Samples are homogenized and extracted with 0.01 M ammonium formate in 9:1 acetonitrile:water.	
Clean-up	The resulting extracts were cleaned-up using sequential dispersive SPE steps prior to LC-MS/MS analysis. A Strong Cation Exchange (SCX) step was followed by Strong Anion Exchange/C18/formic acid step to reduce matrix interferences. The cleaned-up extracts were concentrated under N_2 and diluted with water:formic acid (100:0.01 equivalent to 0.003 M formic acid)	
Analytical column	Phenomenex Kinetex Biphenyl column, 4.6×100 mm. 2.6 micron particle size	Agilent Zorbax Eclipse Plus® Phenyl-Hexyl column, 2.1×50 mm, 1.8 micron particle size
Mobile phase	Gradient mobile phase from water:methanol (75:25) with 0.01 % formic acid to methanol with 0.01 % formic acid	Gradient mobile phase water and 0.01 % formic acid in methanol
Ionization	ESI in the negative ion mode for fluazaindolizine, IN-AS5760, IN-F4106, IN-REG72 and the positive ion mode for IN-QEK31, IN-R2W56 and IN-RYC33	

Method	Charles River AP.225144.02 used in feeding study (modification of DuPont 39226) Du-Pont 42572	DuPont 39226 (see also modification Charles River AP.225144.02 used in feeding study)
Transitions	Fluazaindolizine: 466 → 157 (quantification) and 466 → 142 (confirmation) IN-AS5760: 206 → 122 (quantification) and 206 → 142 (confirmation) IN-F4106 : 220 → 156 (quantification) and 220 → 141 (confirmation) IN-QEK31: 265 → 219, (quantification) and 265 → 184 (confirmation) IN-R2W56: 279 → 247 (quantification) and 279 → 219 (confirmation) IN-REG72: 452 → 123 (quantification) and 452 → 244 (confirmation) IN-RYC33: 264 → 247 (quantification) and 264 → 192 (confirmation)	Fluazaindolizine: 466 → 157 (quantification) and 466 → 142 (confirmation) IN-AS5760: 206 → 142 (quantification) and 206 → 122 (confirmation) IN-F4106 : 220 → 156 (quantification) and 220 → 141 (confirmation) IN-QEK31: 265 → 184, (quantification) and 265 → 219 (confirmation) IN-R2W56: 279 → 247 (quantification) and 279 → 219 (confirmation) IN-REG72: 452 → 123 (quantification) and 452 → 244 (confirmation) IN-RYC33: 264 → 157 (quantification) and 264 → 184 (confirmation)
LOQ	0.01 mg/kg per analyte before adjusting for parent equivalent	
Linearity (r^2)	0.1-25 ng/mL r^2≥0.9932 for solvent standards and 0.9927 for fat matrix-matched standards	0.05-5 ng/mL r^2≥0.9997

Method DuPont-39226, Revision No. 1

Method DuPont-39226, Revision No. 1 (Klems, 2017) was developed for the detection, quantification, and confirmation of residues of fluazaindolizine and its metabolites IN-REG72, IN-QEK31, IN-F4106, IN-A5760 and IN-RYC33 in milk (cream, skim and whole), chicken eggs (yolks and whites), bovine muscle (ground beef), beef fat and beef liver.

The recovery data reported in the method for determining fluazaindolizine residues in animal tissues are summarised in Table 120. Recoveries outside the 70-120 percent range occurred for liver fortified at 0.01 mg/kg with fluazaindolizine (69 percent) and IN-QEK31 (65 percent); muscle fortified with IN-QEK31 at 0.01 mg/kg (68 percent); whole milk fortified with fluazaindolizine at the 0.01 mg/kg (123 percent) and 0.1 mg/kg (121 percent); whole milk fortified with IN-RYC33 at 0.01 mg/kg (64 percent); skim milk fortified with fluazaindolizine at 0.01 mg/kg (125 percent); and cream fortified with fluazaindolizine at 0.01 mg/kg (129 percent) and 0.1 mg/kg (125 percent). At the 0.010 and 0.1 mg/kg fortification levels, the mean recoveries at each level were within the range of 77–117 percent, with RSDs of 1–15 percent. Good linearity was observed in the range of 0.05 to 5.0 ng/mL for fluazaindolizine and its metabolites IN-REG72, IN-RYC33, IN-QEK31, IN-A5760 and IN-F4106. These ranges correspond to residue values of approximately 0.005-0.5 mg/kg. At least five-point standard curves were prepared utilizing standards in solvent with r2 ≥0.9997.

The LOQ of the method proposed for quantifying fluazaindolizine and metabolites is 0.01 mg/kg. Analysis of control samples consistently showed no detectable residues of fluazaindolizine or its metabolites. The response in the area of the fluazaindolizine and its metabolite peaks always corresponded to less than 30 percent of the LOQ. Relative standard deviations of less than 20 percent were consistently obtained for fortifications made at 0.01 mg/kg for each matrix and 0.1 mg/kg.

Table 120 Recovery data for the analytical method for the determination of fluazaindolizine residues in commodities of animal origin (Klems, 2017 DuPont-39226, Revision No. 1)

The method's reproducibility was demonstrated by an independent laboratory validation (Xu, 2012, DuPont-44351) for the determination of fluazaindolizine and metabolites in liver, eggs and muscle. The recovery data is summarised in Table 121.

The ILV laboratory modified the solution used for preparation of analytical standards from 0.1 M aqueous formic acid: methanol (9:1) to 0.01 M formic acid in water:acetonitrile (80:20) containing 0.001

M ammonium formate and the solution for final dilution of extracts from 0.1M aqueous formic acid to 12.2 percent acetonitrile in water. In addition the amount of SCX sorbent was reduced for eggs and linear regression used for calculating analytical results.

Extraction efficiency

The solvents and procedures for extracting fluazaindolizine and its metabolites from animal matrices in this method are the same as those used in the radio-validated extractions performed in DuPont-33572, Revision No. 1 and DuPont-33573, Revision No. 1 (Extraction efficiency of 9/1 acetonitrile/0.1 M aqueous ammonium formate) and ranged from 80.4 to 99.2 percent TRR, mean 91.4 percent TRR.

Confirmatory method

Confirmation of results obtained by LC-MS/MS method DuPont-39226 was performed by quantifying a separate daughter ion signal for each analyte. The recovery data obtained using the confirmatory procedure are summarised in Table 122.

Table 122 Confirmation data for the analytical method for the determination of fluazaindolizine residues in processed commodities origin (Klems, 2017 DuPont-39226, Revision No. 1)

Notes:

[A] Value of 918 percent considered an outlier and not included in the calculation of mean and % RSD.

The method's reproducibility was demonstrated by an independent laboratory validation for fluazaindolizine, IN-REG72, IN-QEK31, IN-F4106, IN-RYC33 and IN-A5760. The recovery data obtained during the ILV is summarised in Table 124. IN-R2W56 was not included in the ILV as the residue of this molecule was deemed to be insignificant.

Table 124 Independent laboratory recovery data for the analytical method for the determination of fluazaindolizine residues in animal tissue (Xu, 2017 DuPont-44351)

Matrix	Fortification level (mg/kg)	N	Mean (%)	% RSD	Mean (%)	% RSD

Confirmatory method

Confirmation of results obtained by this LC-MS/MS method was performed by quantifying a separate daughter ion signal for each analyte. The recovery data obtained using the confirmatory procedure are summarised in Table 125. Individual mean recoveries for samples fortified at 0.01 mg/kg or 0.1 mg/kg were 81–113 percent with RSDs 1–16 percent.

Notes:

[A] Value of 891 percent considered an outlier and not included in the calculation of mean and percent RSD.

The analytical method validation described in DuPont-44365 (Čermák and Kwiecien, 2017) was performed for the detection, quantification, and confirmation of residues of fluazaindolizine and its metabolites IN-REG72, IN-QEK31, IN-F4106, IN-A5760, and IN-RYC33 in milk, egg, bovine meat, fat, and liver, using Multi-Residue Method DFG-S19. The method LOQ was 0.01 mg/kg and the LOD was 30 percent of the LOQ, or 0.003 mg/kg.

Samples were extracted with acetone using a homogenizer. Water is added beforehand in an amount that takes into account the natural water content of the specimen so that during extraction, the acetone/water ratio remains constant at 2/1. For milk, a liquid-liquid extraction was performed using sodium chloride and dichloromethane. Eggs and tissues samples were previouly homogenized with a mixture of ethyl acetate/cyclohexane (1/1) and sodium chloride and fat tissue samples were dissolved in a mixture of ethyl acetate and cyclohexane (1/1). Following the separation of phases, an aliquot of the organic phase was evaporated and then cleaned-up by GPC on Bio Beads S-X3 (polystyrene gel) using a mixture of ethyl acetate/cyclohexane (1/1) as the eluent. The GPC fractions were concentrated, re-dissolved in the HPLC solvent and analysed by LC-MS/MS. Validation data is shown in Table 126.

STABILITY OF PESTICIDES RESIDUES IN STORED ANALYTICAL SAMPLES

Rebstock (2021 DuPont-39883, Revision No. 1) studied the freezer storage stability of crops fortified with fluazaindolizine and metabolites. Separate representative homogenised control crop sample replicates were fortified with 0.2 mg/kg each of fluazaindolizine and metabolites (IN-A5760, IN-F4106, IN-QEK31, IN-QZY47, IN-R2W56, IN-REG72, IN-RYC33, IN-TMQ01, IN-UJV12, and IN-UNS90). Samples were stored at approximately -20 °C. Samples were analysed using procedures based on DuPont-33861, Revision No. 3.

Analysis of crop samples for fluazaindolizine-related residues involves extraction followed by quantification of fluazaindolizine and seven metabolites (IN-F4106, IN-QEK31, IN-QZY47, IN-R2W56, IN-REG72, IN-TMQ01 (IN-RSU03), and IN-RYC33). An aliquot of the extract then undergoes a hydrolysis procedure and SPE clean-up prior to a second analysis for seven metabolites (IN-A5760, IN-F4106, IN-QEK31, IN-QZY47, IN-TMQ01 (IN-RSU03), IN-UJV12 and IN-UNS90). The post-hydrolysis analysis was not included in this study as there was no freezer storage of samples after hydrolysis. The time intervals between fortification of samples for freezer storage and analysis of 0-day time point samples ranged from 0 to 3 days depending on the analyte and matrix combinations, with the exception of IN-RYC33 in dried pea seeds at day zero that was re-analysed 16 days after fortification.

Residues of fluazaindolizine and metabolites (IN-A5760, IN-F4106, IN-QEK31, IN-QZY47, IN-R2W56, IN-REG72, IN-RYC33, IN-TMQ01, IN-UJV12, and IN-UNS90) are stable in representative crop matrices for at least 23 months (pea hay), 24 months (wheat grain, oranges, field corn stover, and dried pea seeds), or 33 months (tomato and soya bean seed) when stored at -20 °C. The results are shown in Table 130.

Table 130 Summary of fluazaindolizine and metabolite residues in crop samples fortified at 0.20 mg/kg and stored at approximately -20 °C

Maximum storage intervals for supervised residue trials are listed in Table 131

Table 131 Maximum periods of frozen storage before extraction for residue analysis

	Maximum periods of frozen storage before analysis	
	Days	Months
Cucurbit vegetables	470[A]	15.4
Fruiting vegetables	683	22.5
Carrots	152	5.0
Potatoes	481	15.8
Tomato processing	616	20.2
Potato processing	391	12.8
Wheat processing	197	6.5
Field corn processing	217	7.1
Soya bean processing	127	4.2
Strawberry processing	313	10.3
Row crop/ crop rotation North American region	619[B]	20.3[B]
Row crop/ crop rotation Europe	907[C]	31[C,D]
Vegetable and fruit crop rotation North America region	616	20.2
Vegetable and fruit crop rotation Europe	647	22
Limited field crop rotation North America region	881	28.9
Limited field crop rotation Europe	–	24
Demonstrated stability	Days	Months
High water (tomatoes)		33
High acid (oranges)		24
Very dry (field corn stover, pea hay)		24/23
High starch (wheat grain)		24
High oil (soya bean seeds)		33
High protein (pea seeds, dry)		24

Notes:

[A] 443 days or about 14.6 months for analysis of two melon peel samples.

[B] 18 exceptions for re-analysis of samples. Maximum storage intervals for reanalysis of samples were 631 days/20.8 months for soya beans, 1001 days/32.9 months for peas and 812 days/26.6 months for corn. No residue values were changed as a result of reanalysis of samples.

[C] Maximum of 25 months for pea forage, dried peas, oilseed rape straw, maize forage, maize immature ears, maize grain, maize stover, wheat hay and wheat grain. A maximum 29 months for pea vines, pea hay, oilseed rape seed, oilseed rape forage and wheat straw and a maximum of 31 months for wheat forage.

[D] The majority of samples in the study were analysed after less than 24 months of frozen storage.

Dunlop *et al*. (2019 DuPont-42563, Revision No 1) studied the freezer storage stability of fluazaindolizine and metabolites in bovine whole milk, fat, muscle, liver and kidney. Separate representative homogenised control milk and tissue samples were fortified with 0.1 mg/kg each of fluazaindolizine and metabolites (IN-REG72, IN-F4106, IN-A5760, IN-QEK31, IN-RYC33, IN-R2W56). Samples were stored at about -20 °C. Samples were analysed for residues of fluazaindolizine, IN-AS5760, IN-F4106, IN-QEK31, IN-R2W56, IN-REG72 and IN-RYC33 using Charles River Analytical Procedure AP.225144.02, a modified version of method DuPont-39226 (LOQ 0.01 mg/kg for each analyte). The results of the stability testing are given by commodity and analysis interval in Table 132 below.

Fluazaindolizine and metabolites (IN-A5760, IN-F4106, IN-QEK31, IN-R2W56, IN-REG72, IN-RYC33) are stable on frozen storage in milk for at least 6.8 months, in muscle for at least 6.7 months, in fat for at least 8.5 months and for analytes other than IN-R2W56 in kidney for at least 8.3 months. IN-R2W56 was stable in kidney for 7 days but not in a sample stored for 250 days. Fluazaindolizine, IN-

QEK31 and IN-R2W56 were stable in liver for at least 0.77 months (23 days), IN-RYC33 for 0.47 months (14 days) and IN-REG72, IN-F4106 and IN-A5760 for 0.23 months (7 days) (Table 133).

Table 132 Summary of fluazaindolizine and metabolite residues in animal commodities fortified at 0.1 mg/kg and stored at approximately -20 °C

Table 133 Frozen stability of fluazaindolizine and metabolites in bovine matrices

Matrix	Maximum freezer storage interval (days)	Demonstrated stability on frozen storage (days)
Whole Milk	125	206
Skimmed Milk	107	206
Cream	112	206
Muscle	83	200
Liver	9	7 (IN-REG72, IN-F4106, IN-A5760) 14 (IN-RYC33) 23 (fluazaindolizine, IN-QEK31, IN-R2W56)
Kidney	7[A]	7 (IN-R2W56) 250 (all other analytes)
Fat	93	255

Notes:

[A] 134 days for the repeat analysis from one animal in the 2 ppm dose group.

Note: The initial stability analyses for IN-R2W56 in liver showed too much variability in the recovery values. Therefore, the liver stability assessment was restarted for this analyte.

USE PATTERN

Fluazaindolizine is a nematicide that controls or supresses parasitic root-knot nematodes in cucurbit vegetables, non-cucurbit fruiting vegetables and also carrots and tuberous and corm vegetables. The use patterns relevant for this evaluation are shown in Table 134.

Table 134 Fluazaindolizine use patterns

Crop	Country	Application rate (kg ai/ha)	Spray volume (L/ha)	No. (interval, days)	PHI (days)	Comments
Tuberous and corm vegetables (crop subgroup 1C)	Canada	1.12-2.24, max 2.24/year	>140, incorporate 10-15 cm soil	2 (14)	40	Pre-plant of broadcast followed by soil incorporation.
		1.12-2.24, max 2.24/year (10.1-20.25 g ai/100 m based on 90 cm row spacing)		2 (14)	40	In-furrow
		0.56-1.12, max 2.24/year		2 (14)	40	Supplemental in-season chemigation following pre-plant or at-plant application
Carrot	Canada	1.12-2.24, max 2.24/year	>140, incorporate 10-	2 (14)	65	Pre-plant or broadcast followed by soil incorporation.

Crop	Country	Application rate (kg ai/ha)	Spray volume (L/ha)	No. (interval, days)	PHI (days)	Comments
		0.56-1.12, max 2.24/year	15 cm soil	2 (14)	65	Chemigation (post-plant). Supplemental in-season chemigation following pre-plant or at-plant application
Cucurbit vegetables (crop group 9)	Canada	1.12-2.24, max 2.24/year	>140, incorporate 10-15 cm soil	4 (14)	1	Pre-plant or broadcast followed by soil incorporation.
		1.12-2.24, max 2.24/year		4 (14)	1	Chemigation (pre-plant or at-plant)
		0.56-1.12, max 2.24/year		4 (14)	1	Chemigation (post-plant)
Fruiting vegetables (crop group 8-09)	Canada	1.12-2.24, max 2.24/year	>140, incorporate 10-15 cm soil	3 (14)	1	Pre-plant or broadcast followed by soil incorporation.
		1.12-2.24, max 2.24/year		3 (14)	1	Chemigation (pre-plant or at-plant)
		0.56-1.12, max 2.24/year		3 (14)	1	Chemigation (post-plant)
Cucurbits (field and protected)	Australia	2, max 2/year		2	0	Drip/trickle irrigation at establishment up to 3 days before to 1 day after planting, soil applied and incorporated by irrigation of mechanical incoporation up to 3 days before planting.
		1+1, max 2/year		2	0	Pre-plant (up to 3 days before to 1 day after planting) & post-plant drip irrigation (14-28 days after transplanting)
		1 or 2, max 2/year			0	Post-plant drip irrigation)
Fruiting vegetables (field and protected)	Australia	2, max 2/year		2	0	Drip/trickle irrigation at establishment up to 3 days before to 1 day after planting, soil applied and incorporated by irrigation of mechanical incoporation up to 3 days before planting.
		1+1, max 2/year		2	0	Pre-plant (up to 3 days before to 1 day after planting) & post-plant drip irrigation (14-28 days after transplanting)
		1 or 2, max 2/year			0	Post-plant drip irrigation
Root & tuber vegetables	Australia	2, max 2/year			Not required	Pre-plant incorporated or in-furrow soil treatment, up to 3 days before planting
Sweet potato	Australia	2, max 2/year			Not required	At establishment drip/trickle irrigation, apply 3 days before to 3 days after planting
		2, max 2/year			Not required	Soil applied and incorporated by irrigation of mechanical incorporation, apply up to 3 days before transplanting

Crop	Country	Application rate (kg ai/ha)	Spray volume (L/ha)	No. (interval, days)	PHI (days)	Comments
		1+1, max 2/year		2	Not required	Pre-plant (up to 3 days before to 1 day after planting) & post-plant drip irrigation (14-21 days after transplanting)
		1 or 2, max 2/year			Not required	Post-plant drip irrigation, do not apply later than 21 days after transplanting
Eggplant (protected)	Mexico	0.5-1.0, max 2 applications/season with max 4 applications/year		2	1	Perform 1 application at least one day before transplantation through drip irrigation
Chili (protected)	Mexico			2	1	
Pepper (protected)	Mexico			2	1	
Tomato (protected)	Mexico			2	1	
Pumpkin (protected)	Mexico			2	1	
Zucchini (protected)	Mexico			2	1	
Melon (protected)	Mexico			2	1	
Cucumber (protected)	Mexico			2	1	
Watermelon (protected)	Mexico			2	1	
Eggplant (field)	Mexico	0.75-1.0, max 2 applications/season with max 4 applications/year		2	1	
Chili (field)	Mexico			2	1	
Tomato (field)	Mexico			2	1	
Pepper (field)	Mexico			2	1	
Pumpkin (field)	Mexico	0.5-0.75, max 2 applications/season with max 4 applications/year		2	1	
Zucchini (field)	Mexico			2	1	
Melon (field)	Mexico			2	1	
Cucumber (field)	Mexico			2	1	
Watermelon (field)	Mexico			2	1	
Potato (field)	Mexico	0.75-1.0, max 2 applications/season with max 4 applications/year	350-450	2	1	Application to the bottom of the furrow at the time of planting. Make 1 application at the time of sowing directed to the bottom of the furrow.

Notes:

Tuberous and corm vegetables (Canada Crop subgroup 1C): Arrowroot, chayote root, Chinese artichoke, Jerusalem artichoke, edible canna, chufa, dasheen, ginger, potato, sweet potato, and true yam.

Cucurbit vegetables (Canada Crop group 9): (Chayote, Chinese waxgourd, citron melon, cucumber, gherkin, edible gourd [hyotan, cucuzza, hechima and Chinese okra], Momordica spp. [balsam apple, balsam pear, bitter melon and Chinese cucumber], muskmelon [true cantaloupe, cantaloupe, casaba, crenshaw melon, golden pershaw melon, honeydew melon, honey balls, mango melon, Persian melon, pineapple melon, Santa Claus melon and snake melon], pumpkin, summer squash [crookneck squash, scallop squash, straightneck squash, vegetable marrow and zucchini], winter squash [butternut squash, calabaza, hubbard squash, acorn squash and spaghetti squash], and watermelon).

Fruiting vegetables (Canada Crop group 8-09): African eggplant, currant tomato, eggplant, garden huckleberry, goji berry, ground cherry, martynia, okra, pea eggplant, pepino, bell pepper, non-bell pepper, scarlet eggplant, sunberry, tomatillo and tomato.

Australia: ALL CROPS: Fluazaindolizine rates should only be applied to the portion of the field/greenhouse that requires protection from nematode infestation. For example, if the inter-row accounts for 30 percent of the area the use rate over the full hectare will be 2 or 4 litres per ha × 70 percent.

The product label from Canada also includes information on plant-back intervals. All crops on the label may be replanted at any time following the last application of Salibro Nematicide. All other crops listed below can be planted 14 days following the last application of Salibro Nematicide.

Rotational Crops	Planting Time from Last Application
Carrots, CSG1C, CG8-09, CG9[A]	Immediately
Root vegetables, except sugar beets (CSG1B, except carrot roots)	14 days
Leaves of root and tuber vegetables (crop group 2)	
Bulb vegetables (crop group 3-07)	
Leafy vegetables (crop group 4-13)	
Brassica head and stem vegetable (crop group 5-13)	
Legume vegetables, succulent or dried (crop group 6)	
Foliage of legume vegetables (crop group 7)	
Low growing berries (crop subgroup 13-07G)	
Cereal grain (crop group 15)	
Forage, fodder, and straw of cereal grains (crop group 16)	
Grass forage, fodder, and hay (crop group 17)	
Oilseeds revised (crop group 20)	
Stalk, stem, and leaf petioles (crop group 22)	
All other crops	365 days

Notes:

[A] Tuberous and corm vegetables (Canada crop subgroup 1C); Cucurbit vegetables (Canada crop group 9); Fruiting vegetables (Canada crop group 8-09)

Mexico labels state that the following crops can be replanted immediately after the last application: carrots, cucurbits, solanacea, trees that will not bear fruit 12 months after application (citrus, stone fruit trees and tree nuts), vines and potatoes. The following crops can be replanted 14 days after the last application: brassicaceae, bulbs, cereals, leafy vegetables, legumes, strawberry, pastures established in paddocks, oilseeds, roots and tubers, asparagus and celery

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received information on supervised field trials for fluazaindolizine on the following crops:

Crop	Table No.
Cucumber	135
Melon	136, 137
Squash	138
Tomato	139
Pepper	140
Carrot	141
Potato	142

Trials were generally well documented, with laboratory and field reports. Laboratory reports included method validation with procedural recoveries from spiking at residue levels similar to those occurring in samples from the supervised trials. Dates of analyses or duration of residue sample storage were also provided. Although trials included control plots, no control data are recorded in the tables except where residues in control samples exceeded the LOQ. Control samples are indicated in the summary tables with a "c". Unless stated otherwise, residue data are recorded unadjusted for recovery.

Residues and application rates have generally been rounded to two significant figures or, for residues near the LOQ, to one significant figure. Residue values from the trials conducted according to maximum GAP have been used for the estimation of maximum residue levels. Those results included in the evaluation are underlined.

Conditions of the supervised residue trials were generally well reported in detailed field reports. Trial designs used non-replicated plots. Field reports provided data on the sprayers used, plot size, field sample size and sampling date.

Residue concentrations are expressed in terms of the individual compounds and not as fluazaindolizine equivalents. In some studies, a molecular weight back-calculation was applied to residue values of IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 to account for reference standards which were supplied in salt form but not taken into consideration during weighing.

To convert residues in the tables to fluazaindolizine equivalents, correction for differences in molecular weight need to be made. The required correction factors are:

Analyte	Fluazaindolizine MW/metabolite MW	Correction factor
IN-A5760	468.2/207.6	2.26
IN-F4106	468.2/221.7	2.11
IN-QEK31	468.2/264.6	1.77
IN-QZY47	468.2/308.7	1.52
IN-TMQ01	468.2/309.7	1.51
IN-UJV12	468.2/294.7	1.59
IN-UNS90	468.2/295.7	1.58

The sum of IN-A5760, IN-F4106, IN-QZY47 and IN-TMQ01, all expressed in terms of fluazaindolzine is required for use in dietary risk assessment. This is calculated as 2.26×IN-A5760 + 2.11×IN-F4106 + 1.52×IN-QZY47 + 1.51×IN-TMQ01 and reported in the Tables below.

Curcubits

Shepard (2020 DuPont-40063) conducted residue trials on cucurbit vegetables at a number of sites (13 cucumber, 13 melon, 12 summer squash) in the Canada and the United States in 2014/2015. The results are shown in Tables 135 to 138.

At each location, separate plots were treated with fluazaindolizine SC formulation was applied as soil applications (drip/drench or directed spray) at planting and then 15±2 days and 1 day before expected maturity and at the other plot as four applications at 1±2 day intervals starting 43±3 days before expected maturity. No adjuvants were used in any of the trials.

The maximum interval of frozen storage before analysis was 470 days for cucurbits with extracts quantified within 33 days of extraction. Fruit was analysed for residues of fluazaindolizine and compounds hydrolysed with acid to IN-A5760, IN-F4016, IN-QEK31, IN-QZY47, IN-TMQ01, IN-UJV12 and IN-UNS90 (IN-TQD54) using the analytical method DuPont-33861, rev. 3, with an LOQ of 0.01 mg/kg and LOD of 0.003 mg/kg for each analyte. Acceptable concurrent recovery data were obtained for all matrices.

Table 135 Residues (mg/kg) of fluazaindolizine (pre-hydrolysis) and related compounds (post hydrolysis[C]) in cucumber from trials conducted in Canada and the United States

Notes:

[A] Residue found was ≥LOD and <LOQ (reported to one significant figure) but rounds to 0.01 mg/kg.

[B] SUM = 2.26×IN-A5760 + 2.11×IN-F4106 + 1.52×IN-QZY47 + 1.51×IN-TMQ01.

[C] A molecular weight back-calculation was applied to residue values of IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 (IN-TQD54) to account for reference standards which were supplied in salt form but not taken into consideration during weighing.

Table 136 Residues (mg/kg) of fluazaindolizine (pre-hydrolysis) and related compounds (post hydrolysis[B]) in melon pulp and peel from trials conducted in Canada and the United States

Notes:

[A] Residue found was ≥LOD and <LOQ (reported to one significant figure) but rounds to 0.01 mg/kg.

[B] SUM = 2.26×IN-A5760 + 2.11×IN-F4106 + 1.52×IN-QZY47 + 1.51×IN-TMQ01.

[C] A molecular weight back-calculation was applied to residue values of IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 (IN-TQD54) to account for reference standards which were supplied in salt form but not taken into consideration during weighing.

Table 137 Residues (mg/kg) of fluazaindolizine (pre-hydrolysis) and related compounds (post hydrolysis) in whole melon, calculated from pulp and peel residues (ND = 0, >ND but <LOQ = LOQ)

Notes:

[A] Residue found was ≥LOD and <LOQ (reported to one significant figure) but rounds to 0.01 mg/kg.

[B] SUM = 2.26×IN-A5760 + 2.11×IN-F4106 + 1.52×IN-QZY47 + 1.51×IN-TMQ01.

[C] A molecular weight back-calculation was applied to residue values of IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 (IN-TQD54) to account for reference standards which were supplied in salt form but not taken into consideration during weighing.

[D] The total per hectare rate was concentrated in the application band for all sites, with the exception of Trial 38.

Fruiting Vegetables

Shepard (2020 DuPont-40062) conducted residue trials on fruiting vegetables at a number of sites (22 tomato, 21 pepper) in Canada and the United States in 2014/2015.

At each location, separate plots were treated with fluazaindolizine SC formulation was applied as soil applications (drip/drench or directed spray) at planting at 1.12 kg ai/ha and then 15±2 days and 1 day before expected maturity at 0.56 kg ai/ha and at the other plot as four applications at 14±2 day intervals starting 43±3 days before expected maturity and at 0.56 kg ai/ha. No adjuvants were used in any of the trials.

The maximum interval of frozen storage before analysis was 683 days for tomatoes and peppers prior to extraction. Fruit was analysed for residues of fluazaindolizine and its metabolites IN-A5760, IN-F4016, IN-QEK31, IN-QZY47, IN-TMQ01, IN-UJV12 and IN-UNS90 (IN-TQD54) using the analytical method DuPont-33861, rev. 3, with an LOQ of 0.01 mg/kg and LOD of 0.003 mg/kg for each analyte. Acceptable concurrent recovery data were obtained for all matrices.

Table 139 Residues (mg/kg) of fluazaindolizine (pre-hydrolysis) and related compounds (post-hydrolysis) in tomato from supervised trials conducted in Canada and the United States

Notes:

[A] Residue found was ≥LOD and <LOQ (reported to one significant figure) but rounds to 0.01 mg/kg.

[B] Average of duplicate analyses.

[C] Average of triplicate analyses.

[D] Treated sample inadvertently used as a control.

[E] Residues in untreated control samples were ND for all analytes with the exception of one tomato control sample with post hydrolysis residues of 0.010 and 0.018 mg/kg in IN-A5760 and IN QEK31, respectively.

[F] SUM = 2.26×IN-A5760 + 2.11×IN-F4106 + 1.52×IN-QZY47 + 1.51×IN-TMQ01.

[G] A molecular weight back-calculation was applied to residue values of IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 (IN-TQD54) to account for reference standards which were supplied in salt form but not taken into consideration during weighing.

Table 140 Residues (mg/kg) of fluazaindolizine (pre-hydrolysis) and related compounds (post- hydrolysis) in peppers from supervised trials conducted in Canada and the United States

Notes:

[A] Residue found was ≥LOD and <LOQ (reported to one significant figure) but rounds to 0.01 mg/kg.

[B] Treated sample inadvertently used as a control.

[C] SUM = 2.26×IN-A5760 + 2.11×IN-F4106 + 1.52×IN-QZY47 + 1.51×IN-TMQ01.

[D] A molecular weight back-calculation was applied to residue values of IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 (IN-TQD54) to account for reference standards which were supplied in salt form but not taken into consideration during weighing.

Carrots

Shepard (2020 DuPont-43192 rev 1) conducted residue trials on carrots at 11 sites in Canada and the United States in 2014/2015. At each location, separate plots were treated with fluazaindolizine SC formulation was applied as a single soil application (in-furrow spray) at planting at 2.24 kg ai/ha and at the other plot as a soil application (in-furrow spray) at planting followed by a soil directed spray 14±1 days later, both applications at 1.12 kg ai/ha. Adjuvants were not used at most of trial sites, with the exception of Uvalde, Texas, second of two applications and Jerome, Idaho, second of two applications which both included non-ionic surfactant at 0.25 percent. The first sample collected was of immature carrot roots with the remaining of mature carrots.

The maximum interval of frozen storage before analysis was 152 days before extraction. Carrots were analysed for residues of fluazaindolizine and its metabolites IN-A5760, IN-F4016, IN-QEK31, IN-QZY47, IN-TMQ01, IN-UJV12 and IN-TQD54 using the analytical method DuPont-33861, rev. 3, with an

LOQ of 0.01 mg/kg and LOD of 0.003 mg/kg for each analyte. Acceptable concurrent recovery data were obtained for all matrices.

At the Richland IA, Woodland CA and Porterville CA trial sites, the per hectare application was concentrated in the band or furrow at planting and for the Woodland CA also for the later applications. The practice gave rise to higher residues compared to the other trials.

Table 141 Residues (mg/kg) of fluazaindolizine (pre-hydrolysis) and related compounds (post-hydrolysis) in carrot from trials conducted in Canada and the United States

Notes:

[A] Residue found was ≥LOD and <LOQ (reported to one significant figure) but rounds to 0.01 mg/kg.

[B] SUM = 2.26×IN-A5760 + 2.11×IN-F4106 + 1.52×IN-QZY47 + 1.51×IN-TMQ01.

[C] A molecular weight back-calculation was applied to residue values of IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 (IN-QD54) to account for reference standards which were supplied in salt form but not taken into consideration during weighing.

Potatoes

Shepard (2020 DuPont-43193 rev 1) conducted residue trials on potatoes at 22 sites in the Canada and the United States in 2014/2015 (Table 142).

At each location, separate plots were treated with fluazaindolizine SC formulation applied as a soil application (in-furrow spray) at planting at 2.24 kg ai/ha and at the other plot as a soil application (in-furrow spray) at planting at 2.24 kg ai/ha followed by a soil directed spray 14±1 days later at 1.12 kg ai/ha. Adjuvants were not used at most of trial sites, with the exception of Lyons, New York, second of two applications included non-ionic surfactant at 0.25 percent. The per-hectare application rates were concentrated in the furrow for the applications at plant at 18 of the 22 test sites and were concentrated in a band over the row for the second application at 11 of the 22 test sites.

The maximum interval of frozen storage before analysis was 481 days before extraction. Potato tubers were analysed for residues of fluazaindolizine and its metabolites IN-A5760, IN-F4016, IN-QEK31, IN-QZY47, IN-TMQ01, IN-UJV12 and IN-TQD54 using the analytical method DuPont-33861, rev. 3, with an LOQ of 0.01 mg/kg and LOD of 0.003 mg/kg for each analyte. Acceptable concurrent recovery data were obtained for all matrices.

Table 142 Residues (mg/kg) of fluazaindolizine (pre-hydrolysis) and related compounds (post-hydrolysis) in potato from trials conducted in Canada and the United States

Notes:

[A] Residue found was ≥LOD and <LOQ (reported to one significant figure) but rounds to 0.01 mg/kg.

[B] SUM = 2.26×IN-A5760 + 2.11×IN-F4106 + 1.52×IN-QZY47 + 1.51×IN-TMQ01.

[C] A molecular weight back-calculation was applied to residue values of IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 (IN-TQD54) to account for reference standards which were supplied in salt form but not taken into consideration during weighing.

ROTATIONAL CROPS

A number of studies investigated residues of fluazaindolizine and metabolites in follow crops. Doig (2020 DuPont-36790) conducted residue trials on wheat, lettuce, radish and bean in North (Alpicat, Catalunya) and South (Aguadulce, Andalucia) Spain in 2013/2014.

At each location, bare plots were treated with a fluazaindolizine SC formulation as either a single application at 1.25 kg ai/ha or two applications at 1.25 kg ai/ha and at an interval of 60±10 days and follow crops planted at target plant-back intervals of 7-30, 60-270, and 270-365 days. Duplicate field specimens were collected from each plot consisting of 50 percent mature lettuce, wheat (forage and hay), immature bean seeds, mature lettuce, mature radish (roots and tops), wheat (grain and straw) and mature beans (seeds, vines and whole plant).

The maximum interval of frozen storage before analysis was; wheat forage 15 months, wheat grain 29 months, wheat hay 30 months, wheat straw 33 months, immature lettuce 15 months, mature lettuce 15 months, bean hay 33 months, immature bean seeds 14 months, mature bean seeds 12 months, bean vines 14 months, radish roots 15 months and tops 15 months. Samples were analysed for residues of fluazaindolizine and its metabolites IN-A5760, IN-F4016, IN-QEK31, IN-QZY47, IN-TMQ01, IN-UJV12 and IN-UNS90 using method AP.224685 based on the analytical method DuPont-33861, rev. 3, with an LOQ of 0.01 mg/kg and LOD of 0.003 mg/kg for each analyte. Average recovery values (±RSD) per analyte/matrix combination ranged from 73 ± 10 percent to 111 ± 5 percent for 4-17 fortifications per analyte/matrix combination from combined recoveries of all fortification levels. The RSD were below 20 percent with two exceptions. The RSD was 25 percent each for analysis of parent fluazaindolizine on legume hay and IN-UNS90 on radish tops.

In a separate study Doig (2020 DuPont-40828) conducted residue trials on oilseed rape, wheat, peas in South France (Charantonnay, Rhone Alpes), North Spain (Alpicat, Catalunya and Termens, Catalunya) and South Spain (Los Palacios, Andalucia and Aguadulce, Andalucia) Spain in 2014-2016.

At each location, bare plots were treated with a fluazaindolizine SC formulation as four applications at 0.825 kg ai/ha and at 14 day intervals and follow crops (oilseed rape, wheat, peas and maize) planted at target plant-back intervals of 7-10, 60-270, and 358-365 days. Duplicate field specimens were collected from each plot.

The maximum interval of frozen storage before analysis was; wheat forage 31 months, wheat grain 24 months, wheat hay 23 months, wheat straw 28 months, pea forage 25 months, dried peas 23 months, pea vines 29 months, pea hay 28 months, rape forage 26 months, rape seed 27 months, rape straw 20 months, maize forage 25 months, maize immature ears 20 months, maize grain 21 months and maize stover 18 months. Samples were analysed for residues of fluazaindolizine and its metabolites IN-A5760, IN-F4016, IN-QEK31, IN-QZY47, IN-TMQ01, IN-UJV12 and IN-UNS90 (IN-TQD54) using method AP.224685 based on the analytical method DuPont-33861, rev. 3, with an LOQ of 0.01 mg/kg and LOD of 0.003 mg/kg for each analyte. Average recovery values (±RSD) per analyte/matrix combination ranged from 71±13 percent to 111±13 percent for 19–29 fortifications per analyte/matrix combination for combined data from all fortification levels. Average recoveries for the 304 analyte/matrix/fortification level combinations for pre-hydrolysis residues of fluazaindolizine and the 7 post-hydrolysis metabolites ranged from 51 to 115 percent. All but 10 of the 304 average recovery values were in the range of 70–110 percent. The 10 exceptions are:

- Fluazaindolizine on wheat straw and dried peas were 66 and 68 percent, respectively, for the 0.01 mg/kg level fortifications.
- IN-RSU03 (IN-TMQ01) average recoveries on wheat forage, dried peas and pea hay were 62, 57 and 56 percent, respectively, for the 1.0 mg/kg level fortifications.
- IN-QEK31 and IN-UNS90 average recoveries on pea hay were 68 and 65 percent, respectively, for the 1.0 mg/kg level fortifications.
- IN-QEK31 average recoveries on dried peas at 1.0 mg/kg had an average recovery of 51 percent.
- IN-QZY47 average recovery on wheat grain was 115 percent for the 0.10 mg/kg level fortifications.
- IN-F4106 average recovery on dried peas was 64 percent for the 1.0 mg/kg fortifications.

Standard deviations for the 304 analyte/matrix/fortification level combinations for pre-hydrolysis residues of fluazaindolizine and the seven post-hydrolysis metabolites ranged from 1 to 28 percent. All but nine of the 304 standard deviation values were 20 percent or less. The nine exceptions are:

- Fluazaindolizine standard deviation for wheat grain recoveries at the 0.01 mg/kg fortification level was 23 percent.
- IN-UNS90 (IN-TQD54) standard deviations for the 0.01 mg/kg fortification recoveries were 23 and 21 percent, respectively, for oilseed rape straw and wheat grain.
- IN-UNS90 (IN-TQD54) standard deviations for the 0.1 mg/kg fortification recoveries were 21 percent for pea vines.
- IN-UNS90 (IN-TQD54) standard deviation for wheat forage recoveries at the 0.1 mg/kg fortification level was 21 percent.
- IN-F4106 standard deviations for oilseed rape seed and wheat grain recoveries at the 0.01 mg/kg fortification level were 21 and 22 percent, respectively.
- IN-A5760 standard deviation for pea hay recoveries at the 0.10 mg/kg fortification level was 21 percent.
- IN-UJV12 standard deviation for maize immature ears recoveries at the 0.01 mg/kg fortification level was 28 percent.

In another study Doig (2020 DuPont-41762) conducted residue trials on tomato, strawberry, Swiss chard or celery, turnip, broccoli and lettuce in South France (Lucenay, Rhone Alpes), North Spain (Lleida, Catalunya and Termens, Catalunya) and South Spain (Los Palacios, Andalucia and Aguadulce, Andalucia) Spain in 2014-2016.

At each location, bare plots were treated with a fluazaindolizine SC formulation as four applications at 1.1 kg ai/ha and at 14-day intervals and follow crops (tomato, strawberry, Swiss chard or celery, turnip, broccoli and lettuce) planted at target plant-back intervals of 7–10, 60–270, and 358–365 days. Replicate field specimens were collected from each plot.

The maximum interval of frozen storage before analysis was 647 days (22 months). Samples were analysed for residues of fluazaindolizine and its metabolites IN-A5760, IN-F4016, IN-QEK31, IN-QZY47, IN-TMQ01, IN-UJV12 and IN-UNS90 (IN-TQD54) using method AP.224685 based on the analytical method DuPont-33861, rev. 3, with an LOQ of 0.01 mg/kg and LOD of 0.003 mg/kg for each analyte. Average recoveries for the 104 analyte/matrix/fortification level combinations for pre-hydrolysis residues of fluazaindolizine and the 7 post-hydrolysis metabolites ranged from 67 to 110 percent. All but 1 of the 104 average recovery values were in the range of 70–110 percent. The average recovery of IN-UNS90 (IN-TQD54) on tomato fruit for the ca 0.01 mg/kg fortification level was 67 percent. Standard deviations for the 104 analyte/matrix/fortification level combinations for pre-hydrolysis residues of fluazaindolizine and the 7 post-hydrolysis metabolites ranged from 1 to 22 percent. All but 2 of the 104 standard deviation values were 20 percent or less. The standard deviation for recovery of IN-UNS90 (IN-TQD54) at ca 0.01 mg/kg level fortifications on celery/Swiss chard was 22 percent. The standard deviation for recovery of IN-QEK31 0.01 mg/kg level fortifications on strawberry fruit was 21 percent.

A series of studies conducted in Canada and the United States in 2013-2015 also investigated residues in follow crops. In the first by Shepard (2020 DuPont-36791 rev 1), bare soil was treated with an SC formulation of fluazaindolizine at either 1.25 kg ai/ha or as two application each of 1.25 kg ai/ha and at an interval of 2 months. Crops (spinach, lettuce, radish, wheat, sorghum or soya bean) were planted at PBIs in the following ranges: 7-30, 60-120, 60-270 and 270-365 days.

The maximum interval of frozen storage before analysis was 881 days except for two lettuce leaf samples which were re-extracted for IN-TMQ01 analysis at 1251 days (41 months). Samples were analysed for residues of fluazaindolizine and its metabolites IN-A5760, IN-F4016, IN-QEK31, IN-QZY47, IN-TMQ01, IN-UJV12 and IN-UNS90 (IN-TQD54) using the analytical method DuPont-33861, rev. 3, with an LOQ of 0.01 mg/kg and LOD of 0.003 mg/kg for each analyte. Mean values per analyte/matrix

combination ranged from 78 to 107 percent for 4 to 18 fortifications per analyte/matrix combination. The standard deviations ranged from 2.9 to 27 percent per analyte/matrix combination.

In the second by Shepard (2020 DuPont-40012 rev 1), bare soil was treated with an SC formulation of fluazaindolizine as four applications of 1.12 kg ai/ha and at 7-day intervals. Crops (broccoli, leaf lettuce, carrot or radish, celery or Swiss chard, strawberry, and tomato) were planted at PBIs in the following ranges: 7-30, 60-270 and 270-365 days.

The maximum interval of frozen storage before analysis was 616 days (20 months). Samples were analysed for residues of fluazaindolizine and its metabolites IN-A5760, IN-F4016, IN-QEK31, IN-QZY47, IN-TMQ01, IN-UJV12 and IN-UNS90 (IN-TQD54) using the analytical method DuPont-33861, rev. 3, with an LOQ of 0.01 mg/kg and LOD of 0.003 mg/kg for each analyte. Mean values per analyte/matrix combination ranged from 82 to 99 percent for 2 to 22 fortifications per analyte/matrix combination. The standard deviations ranged from 4.5 to 16 percent per analyte/matrix combination.

In the third study by Shepard (2020 DuPont-41070 rev 1), bare soil was treated with an SC formulation of fluazaindolizine as four applications of 1.12 kg ai/ha and at 7-day intervals. Crops (peas, soya bean, maize, wheat) were planted at PBIs in the following ranges: 7–30, 60–270 and 270–365 days.

The maximum interval of frozen storage before analysis was 1001 days (33 months). Samples were analysed for residues of fluazaindolizine and its metabolites IN-A5760, IN-F4016, IN-QEK31, IN-QZY47, IN-TMQ01, IN-UJV12 and IN-UNS90 (IN-TQD54) using the analytical method DuPont-33861, rev. 3, with an LOQ of 0.01 mg/kg and LOD of 0.003 mg/kg for each analyte. Mean values per analyte/matrix combination ranged from 70 to 114 percent for 3 to 28 fortifications per analyte/matrix combination. The standard deviations ranged from 1.0 to 19 percent per analyte/matrix combination, with one exception. The standard deviation was 23 percent for analysis of IN-A5760 on soya bean seed.

Notes:

① Shepard 2020 DuPont-36791 rev 1

[A] Residue found was ≥LOD and <LOQ (reported to one significant figure) but rounds to 0.01 mg/kg.

[B] A molecular weight back-calculation was applied to residue values of IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 (IN-TQD54) to account for reference standards which were supplied in salt form but not taken into consideration during weighing.

Table 149 Residues (mg/kg) of fluazaindolizine (pre-hydrolysis) and related compounds (post-hydrolysis) in spinach rotational crops scaled to soil plateau levels (3.87 kg ai/ha for IN-F4106 and 2.24 kg ai/ha for other compounds)

Notes:

① Shepard 2020 DuPont-36791 rev 1.

② Shepard 2020 DuPont-40012 rev 1.

④Doig 2020 DuPont-36790 rev 1.

[A] Average of duplicate analyses.

[B] Average of triplicate analyses.

[C] Residue found was ≥LOD and <LOQ (reported to one significant figure) but rounds to 0.01 mg/kg.

[D] For trials conducted in the United States, a molecular weight back-calculation was applied to residue values of IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 (IN-TQD54) to account for reference standards which were supplied in salt form but not taken into consideration during weighing.

Table 151 Residues (mg/kg) of fluazaindolizine (pre-hydrolysis) and related compounds (post-hydrolysis) in radish rotational crops scaled to soil plateau levels (3.87 kg ai/ha for IN-F4106 and 2.24 kg ai/ha for other compounds)

[A] Average of duplicate analyses.

[B] Residue found was ≥LOD and <LOQ (reported to one significant figure) but rounds to 0.01 mg/kg.

[C] For trials conducted in the United States, a molecular weight back-calculation was applied to residue values of IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 (IN-TQD54) to account for reference standards which were supplied in salt form but not taken into consideration during weighing.

Table 153 Residues (mg/kg) of fluazaindolizine (pre-hydrolysis) and related compounds (post hydrolysis) in lettuce rotational crops scaled to soil plateau levels (3.87 kg ai/ha for IN-F4106 and 2.24 kg ai/ha for other compounds)

Notes:

① Shepard 2020 DuPont-36791 rev 1.

③ Shepard 2020 DuPont-41070 rev 1. Residues were found of IN-UJV12 in a soya bean hay control sample @ 0.01 mg/kg.

④Doig DuPont-36790 rev 1.

⑥ Doig 2020 DuPont-40828.

[A] Average of duplicate analyses.

[B] Residue found was ≥LOD and <LOQ (reported to one significant figure) but rounds to 0.01 mg/kg.

[C] Average of triplicate analyses.

[D] a molecular weight back-calculation was applied to residue values of IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 (IN-TQD54) to account for reference standards which were supplied in salt form but not taken into consideration during weighing.

Table 159 Residues (mg/kg) of fluazaindolizine (pre-hydrolysis) and related compounds (post-hydrolysis) in soya bean rotational crops scaled to soil plateau levels (3.87 kg ai/ha for IN-F4106 and 2.24 kg ai/ha for other compounds) in the United States

Notes:

① Shepard 2020 DuPont-36791 rev 1.

③ Shepard 2020 DuPont-41070 rev 1. Residues were found of IN-UJV12 in a soya bean hay control sample @ 0.01 mg/kg.

④Doig DuPont-36790 rev 1.

⑥ Doig 2020 DuPont-40828.

[A] Average of duplicate analyses.

[B] Residue found was ≥LOD and <LOQ (reported to one significant figure) but rounds to 0.01 mg/kg.

[C] Average of triplicate analyses.

[D] For trials conducted in the a molecular weight back-calculation was applied to residue values of IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 (IN-TQD54) to account for reference standards which were supplied in salt form but not taken into consideration during weighing.

Table 161 Residues (mg/kg) of fluazaindolizine (pre-hydrolysis) and related compounds (post-hydrolysis) in pea rotational crops scaled to soil plateau levels (3.87 kg ai/ha for IN-F4106 and 2.24 kg ai/ha for other compounds)

Notes:

② Shepard (2020 DuPont-40012 rev 1).

[A] Residue found was ≥LOD and <LOQ (reported to one significant figure) but round to 0.01 mg/kg.

[B] Average of duplicate analyses.

[C] Control inadvertently switched with treated sample, as evidenced by residues found after duplicate analyses of both samples.

[D] A molecular weight back-calculation was applied to residue values of IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 (IN-TQD54) to account for reference standards which were supplied in salt form but not taken into consideration during weighing.

Table 165 Residues (mg/kg) of fluazaindolizine (pre-hydrolysis) and related compounds (post-hydrolysis) in carrot rotational crops scaled to soil plateau levels (3.87 kg ai/ha for IN-F4106 and 2.24 kg ai/ha for other compounds) in the United States

Notes:

② Shepard (2020 DuPont-40012 rev 1).

⑤ Doig 2020 DuPont-41762.

[A] For trials conducted in the a molecular weight back-calculation was applied to residue values of IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 to account for reference standards which were supplied in salt form but not taken into consideration during weighing.

Table 169 Residues (mg/kg) of fluazaindolizine (pre-hydrolysis) and related compounds (post-hydrolysis) in celery stalks rotational crops scaled to soil plateau levels (3.87 kg ai/ha for IN-F4106 and 2.24 kg ai/ha for other compounds)

Notes:

③ Shepard 2020 DuPont-41070 rev 1.

⑥ Doig 2020 DuPont-40828.

[A] Residue found was ≥LOD and <LOQ (reported to one significant figure) but rounds to 0.01 mg/kg.

[B] For trials conducted in the a molecular weight back-calculation was applied to residue values of IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 (IN-TQD54) to account for reference standards which were supplied in salt form but not taken into consideration during weighing.

Table 171 Residues (mg/kg) of fluazaindolizine (pre-hydrolysis) and related compounds (post-hydrolysis) in maize rotational crops scaled to soil plateau levels (3.87 kg ai/ha for IN-F4106 and 2.24 kg ai/ha for other compounds)

Notes:

① Shepard (2020 DuPont-36791 rev 1). A molecular weight back-calculation was applied to residue values of IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 to account for reference standards which were supplied in salt form but not taken into consideration during weighing.

Table 173 Residues (mg/kg) of fluazaindolizine (pre-hydrolysis) and related compounds (post-hydrolysis) in sorghum rotational crops scaled to soil plateau levels (3.87 kg ai/ha for IN-F4106 and 2.24 kg ai/ha for other compounds) in the United States

[A] Average of duplicate analyses.

[B] Residue found was ≥LOD and <LOQ (reported to one significant figure) but rounds to 0.01 mg/kg.

[C] Control inadvertently switched with treated sample, as evidenced by residues found after duplicate analyses of both samples.

[D] For trials conducted in the a molecular weight back-calculation was applied to residue values of IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 (IN-TQD54) to account for reference standards which were supplied in salt form but not taken into consideration during weighing.

Table 175 Residues (mg/kg) of fluazaindolizine (pre-hydrolysis) and related compounds (post-hydrolysis) in wheat rotational crops scaled to soil plateau levels (3.87 kg ai/ha for IN-F4106 and 2.24 kg ai/ha for other compounds)

FATE OF RESIDUES IN STORAGE AND PROCESSING

Anand (2013 DuPont-35131) studied the nature of fluazaindolizine residue following high-temperature hydrolysis simulating industrial processing and/or household preparation. There is no demonstrated significant degradation of fluazaindolizine at any pH or temperature for any duration studied. It is not expected that hydrolysis will be a significant route of fluazaindolizine degradation in the environment or in food processing.

High-temperature hydrolysis was investigated to address the potential for metabolites to be found during processing of crop commodities with the test solutions prepared in 0.01 M citrate buffer solutions of pH 4, 5 and 6 which were incubated at 90 °C for 20 minutes, 100 °C for 60 minutes and 120 °C at 103.4 kPa, for 20 minutes, respectively. All these experiments were conducted at a concentration of 10 mg/kg, which was less than one-half of the solubility of fluazaindolizine in water.

During high-temperature hydrolysis experiments, at the end of the incubation periods (pasteurization: pH 4 90 °C for 20 minutes., baking: pH 5 100 °C for 60 minutes and sterilization: pH 6, 120 °C at 103.4 kPa, for 20 minutes), samples were analysed directly by LSC to determine the quantity of radioactivity present in each sample. Radioactivity was quantitatively recovered from each test solution with mass balances 100.0 to 101.4 percent AR.

In all samples, the applied radioactivity was recovered as unchanged fluazaindolizine and no detectable levels of any degradation products. Fluazaindolizine is hydrolytically stable under conditions representative of pasteurization (pH 4, 90 °C, for 20 min.), baking (pH 5, 100 °C, for 60 min.) and sterilization (pH 6, 120 °C at 103.4 kPa, for 20 min.).

Strawberry

Shepard (2020 DuPont-43226, Revision No. 1) studied the distribution of fluazaindolizine residues upon processing of strawberries. The strawberries from trials 1 and 3 were received frozen. The samples were placed in frozen storage prior to processing, except the control sample from trial 3, which was placed in cool storage overnight prior to processing. Strawberries from trial 2 were received cool and placed in cool storage prior to processing.

Samples were removed from cooler or freezer storage and batch rinsed in stainless steel draining baskets using high-pressure cold-water spray at approximately 483-689 kPa for 30 seconds per batch. Any damaged or unacceptable fruit was discarded.

Washed fruit were crushed using a hammermill. The crushed strawberries were transferred to a 35 L steam jacketed swept surface kettle and heated to approximately 30 °C, followed by pressing with a fruit press. The recovered fresh juice was filtered using a US #20 screen to remove any coarse solids, centrifuged to remove fine particulate matter, with an aliquot was reserved for making syrup for the canned fruit fraction. The remainder was vacuum filtered with a Buchner filter (juice).

Washed fruit was trimmed, spread on trays, and placed in the freezer (about -20 to -12 °C) for 2–6 hours or until sufficiently frozen (frozen fruit). The aliquot of washed fruit reserved for drying was trimmed and sliced in half by hand using a paring knife. The sliced strawberries were placed on Teflon covered drying trays and placed in a dryer with a temperature set point of 57-60 °C. Trays were periodically removed and weighed until a target moisture of approximately 15–20 percent moisture was obtained. A representative sample of the dried (dried) strawberries was removed, packaged, labelled, and placed in frozen storage for the required sample fraction.

Washed strawberries were trimmed then crushed in a food processor using the pulse mode and placed in a pot on the electric stovetop and sugar added at 1.65 kg per 1 kg fruit. The mixture was brought to a boil and 3.5 percent by weight of liquid pectin was added. The mixture was returned to a boil and boiled for one minute. Jars were filled with the cooked jam mixture, excess foam skimmed off with a spoon, the rims and threads wiped, and lids placed on. The jars were inverted for several minutes on the counter then turned upright. The finished jam was labelled and then left to cool at room temperature for up to 24 hours to allow the pectin to thicken (jam).

Syrup for canning was produced by adding 2.02 kg sugar to 1 kg strawberry juice and boiled. Washed strawberries were trimmed, packed into #303 cans, and filled with syrup. The cans were sealed using the Dixie Can Sealer, heated in boiling water for approximately 15 minutes, and cooled in cold tap water (canned). Residues found in strawberry processed commodities are shown in Table 178.

Notes:

[A] A molecular weight back-calculation was applied to residue values of IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 (IN-TQD54) to account for reference standards which were supplied in salt form but not taken into consideration during weighing.

Tomato

Shepard (2020 DuPont-40345, Revision No. 1) conducted a study on the distribution of fluazaindolizine and metabolites residues on processing of tomatoes.

The fruit was inspected and sorted, the weight of the culls (cannery waste) was recorded, and the culls discarded. The fruit for juice, purée, and paste was batch soaked in a steam jacketed stainless steel kettle with ~91 kg of water and 454 grams of sodium hydroxide at ~52–60 °C for 3 minutes, batch rinsed using a high-pressure spray warm water rinse at 68–74 °C for 30 seconds per batch and fed into a hammermill assembly for crushing. The crushed tomatoes were transferred to a steam jacketed kettle, rapidly heated to 79–85 °C, and held within that temperature range for 30 seconds. The hot break juice

was hand fed into a pulper finisher for the separation of pomace and juice. The wet pomace recovered was pressed (wet pomace). The recovered press juice was weighed and returned to the finished juice. A representative sample of the wet pomace was removed.

For purée preparation, an aliquot of approximately 9.0 kg of the tomato juice for tomato purée was then transferred to a vacuum evaporator. The purée was removed from the evaporator when the desired Brix range was achieved. Distilled water and 1.0 percent salt were added to adjust the Brix to the desired range of 12.0–13.0°. The purée was heated to 82–88 °C and packed and sealed in cans. The sealed cans were then processed in a boiling water bath for ~15 minutes at 96–100 °C and then cooled under running cold tap water (purée).

For paste preparation, an aliquot of at least 11.0 kg of the tomato juice for tomato paste was transferred to a vacuum evaporator. Tomato juice in excess was weighed and discarded. The paste was removed from the evaporator when the desired Brix range was achieved. An aliquot of paste was reserved for juice from concentrate. Prior to canning the paste, 0.5 percent salt and if necessary, distilled water was added to adjust the Brix of the paste to the desired range of approximately 24.0–33.0°. The paste was heated to 82–88 °C, the heated paste packed and sealed in cans and the sealed cans were then processed in a boiling water bath for ~15 minutes at 96–100 °C and then cooled in cold tap water (paste).

For juice preparation, an aliquot of paste reserved for juice was mixed with water, targeting a Brix range of ~4.5–5.5°, 0.5 percent salt was added to the juice and the juice was heated to 85 °C. The heated juice from concentrate was packed and sealed in cans. The sealed cans were then processed in a boiling water bath for approxiamtely 15 minutes at 96–100 °C and then cooled in cold tap water (juice).

For preparation of peeled fruit and canned tomatoes, fruit were spray-washed and then placed in a water bath and boiled for ~1 minute to crack the skin prior to removal. The peel was then removed by hand with a paring knife and the core, stem, and peel of the fruit was discarded (peeled tomatoes). Whole peeled tomatoes were packaged in cans and 1 teaspoon of salt was added to each can. The cans were then placed in wire baskets, and the baskets placed in a steam cabinet and steam exhausted for ~10 minutes until ~80 °C temperature was achieved. After the steam exhaust, the cans were sealed and processed in a boiling water bath for ~15 minutes. The cans were cooled in cold tap water (canned tomatoes).

For preparation of dried tomatoes, fruit were spray-washed and placed on a table, and the cores and stems of the fruits were removed by hand with a paring knife. The fruit was then cut into quarters with a paring knife and placed on drying trays with the peel down, contacting the metal of the drying tray, and placed in the dryer. The fruit was removed from the dryer once the desired moisture (<16 percent) was achieved (sun-dried tomatoes). Residues found in tomato processed commodities are shown in Table 179.

Notes:

Untreated control samples were collected and analysed. Residues in untreated controls were ND for fluazaindolizine IN-QZY47, IN-TMQ01, and IN-UJV12; and <LOQ for IN-F4106; however, controls from Sanger CA showed residues as high as 0.046 mg/kg for IN-A5760, 0.14 mg/kg for IN-QEK31, and 0.010 mg/kg for IN-UNS90.

[A] A molecular weight back-calculation was applied to residue values of IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 (IN-TQD54) to account for reference standards which were supplied in salt form but not taken into consideration during weighing.

[B] residue was ≥LOD but <LOQ (reported to one significant figure) but rounds to 0.01 mg/kg.

[C] average duplicate analysis.

Potato

Shepard (2020 DuPont-43188, Revision No. 1) studied the distribution of fluazaindolizine residues upon processing of potatoes. Potatoes were batch tub washed for 5 minutes to produce washed potatoes and a specific gravity analysis conducted on the washed potatoes. Culled potatoes were removed (culls).

For preparation of flakes, washed potatoes were batch steam peeled 45 seconds at 689–827 kPa (100–120 psi). The potatoes were batch scrubbed for 30 seconds and the peel collected from the steam peeling and scrubbing process (wet peel). The steam peeled potatoes (steam peeled potatoes) were inspected and hand trimmed to remove additional peel, green, rot or otherwise damaged potatoes and the trim waste retained. The collected peel was hydraulically pressed and blended with the cut trim waste (steam waste).

For preparation of flakes, steam peeled potatoes were cut into slabs using a slicer. The potato slabs were batch spray-washed in cold tap water for about 30 seconds to remove free starch and

precooked at about 70–77 °C (targeting 71–74 °C) for 20 minutes in a 150 L steam jacketed kettle and cooled for 20 minutes to less than 32°C (pre-cooked potatoes). The cooled potato slabs were steam-cooked at 94–l00 °C for 40 minutes, mashed using a meat grinder and the mash mixed for about 40 seconds with an emulsion of pre-weighed food additives. The cooked mash was fed into a drum dryer to dry into a thin sheet and initially broken into large flakes by hand. The flakes were then milled into uniform potato flakes.

Moisture analysis was conducted on the potato flakes and if required dried (not required as all <9 percent) – (flakes).

For preparation of chips and abrasive waste, washed potatoes were batch peeled for 30 seconds using an abrasive base plate in a restaurant style peeler. The peeled potatoes were inspected by hand, and trimmed if necessary to remove rot, green or otherwise damaged potato tissue. Any trim waste collected was weighed and added to the peel (abrasive waste fraction).

A sample of the abrasion peeled tubers was removed (abrasion peeled tuber fraction). The peeled potatoes were cut into thin, approximately 0.16 cm slices using a restaurant style slicer and placed in a tub of hot water to remove free starch. The slices were drained over a screen to remove excess water and were fried at 163–191 °C in oil for about 90 seconds, drained, salted and inspected (potato chips)

For preparation of cooked potato and fresh fry, unpeeled washed potatoes reserved were divided into three subsamples for processing into peeled boiled potatoes, unpeeled boiled potatoes, and unpeeled microwaved potatoes.

Unpeeled washed potatoes were cut into quarters using a paring knife and placed into boiling water and cooked until an internal temperature of 88–92 °C was reached and drained (unpeeled boiled potato).

Unpeeled washed potatoes were hand peeled with a vegetable peeler and then cut into quarters using a paring knife. The peeled quartered potatoes were placed into boiling water and cooked until an internal temperature of 88–92 °C was reached and drained (peeled boiled potato).

Unpeeled washed potatoes were cut into quarters using a paring knife and placed into a plastic container and microwaved until an internal temperature of 88–92 °C was reached (unpeeled microwaved potato).

For preparation of French fries, washed potatoes were sliced into 0.48 cm strips using a French fry cutter. After slicing, the strips were then fried in a deep fat fryer for 2.5 to 3.0 minutes at 177–191 °C, drained and cooled before being packaged, labelled and placed into freezer storage (frozen French fries).

For preparation of French fry/frozen French fry steam peeled potatoes were pre-cooked in approximately 54 °C water for about 40 minutes and then sliced into 0.48 cm strips using a French fry cutter. After cutting, the strips were spray-washed for 30 seconds to remove free starch from the pre-cooking and cutting processes. The spray washed strips were then blanched in 79–85 °C water for 5 minutes and then dipped in a solution of 0.5 percent sodium acid pyrophosphate and 0.25 percent dextrose for 30 seconds at 71–74 °C. After blanching and dipping, the strips were dried in a tray air dryer to reduce the moisture content of the strips by approximately 15 percent and the strips dried in two stages, the first with air flowing up through the trays containing the strips and the second with the air flowing down through the trays. The air temperature of the dryer was set to and Mean temperature of about 77 °C and each drying stage was about 8 minutes. The dried strips were tempered at room temperature for 5 minutes and then par-fried in vegetable oil for 45–50 seconds at 188–191 °C. After frying, the fried strips were drained to remove excess oil and placed in the freezer for rapid cooling. After cooling in the freezer for a minimum of 12 minutes, the par-fried strips were removed, packaged, labelled

and placed back into freezer storage (finished frozen French fries). Residues in potato processed commodities are shown in Table 180.

Notes:

[A] A molecular weight back-calculation was applied to residue values of IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 (IN-TQD54) to account for reference standards which were supplied in salt form but not taken into consideration during weighing.

Soya bean

Shepard (2020 DuPont-43191, Revision No. 1) studied the distribution of fluazaindolizine residues upon processing of soya beans. Since the moisture content of the whole seed samples was greater than 13.5 percent, samples were dried in an oven at 54–71 °C until the moisture content was 10.0–13.0 percent. Samples from trial number 03 did not require drying. Following drying (if required), samples were cleaned by aspiration and screening. Light impurities were removed from the whole soya bean by aspiration. After aspiration, the samples were screened with a 'two screen' cleaner to separate large and small foreign particles (screenings) from the soya bean seed sample (cleaned whole soya bean samples). Due to sample condition, both samples from trial number 03 did not require screening.

Clean whole soya beans were fed into a roller mill to crack the hull and liberate the kernel. After cracking, the material was separated with the aspirator into hull and kernel material. For trial number 02, the aspirator and two screen cleaners were used to separate the material (hulls, kernels). Moisture content of the kernel samples was adjusted to 13.5 percent with water and the sample mixed for 13-17 minutes. Following mixing, samples were allowed to equilibrate/temper for a minimum of twelve hours.

Moisture adjusted kernel material was heated to 71–79 °C in a mixer and flaked in a flaking roll with a gap setting of 0.20–0.33 mm. Flakes were extruded in a continuous processor, where they were turned into collets by direct steam injection and compression. Collets exited the processor at 93–127 °C. After extrusion, the collets were ground in a disc mill and then dried in an oven at 66–82 °C for 30–40 minutes.

Ground collets were placed in a stainless-steel batch extractor and submerged in 49–60 °C hexane. After 30 minutes, the miscella (crude oil and hexane) was drained and hexane was added to repeat the cycle two more times. Final two washes were for 15 minutes each at the same temperature range.

After removal of crude oil, extracted material was toasted by injecting steam directly on the material until the product temperature reached 103–106 °C. Steam injection was stopped, and the material heated to 104–116 °C and held for 30–60 minutes. After toasting, the product was cooled to room temperature. Cooled material was hand screened with an 8-mesh sieve (toasted solvent extracted meal).

Miscella was passed through a laboratory vacuum evaporator unit to separate the crude oil and hexane. Crude oil was heated to 91–96 °C for hexane removal and filtered.
Cleaned soya bean samples were moisture adjusted to 16.0 percent and allowed to equilibrate overnight. Moisture adjusted seed was fed into a mechanical screw press to separate a portion of the crude oil from the presscake (mechanical meal). Resulting fractions were crude oil and presscake. Crude oil was filtered.

Crude oil samples from production of toasted meal and mechanical meal were processed separately by the following procedures.

Based on the free fatty acid content, a weighed amount of crude oil and 14° Baume sodium hydroxide was placed in a water bath at 20–24 °C and mixed for 90 minutes at high RPM, and then for 20 minutes at low RPM and 63–-67 °C. Neutralised oil was then centrifuged. Refined oil was decanted and filtered. Resulting fractions were alkali refined oil and soapstock.

Alkali refined oil was heated to 40–50 °C and an activated bleaching earth added (1.0 percent by weight of oil). The solution was stirred and placed under vacuum. Temperature was increased to 85–100 °C and held for 10 to 15 minutes. After the bleaching period, vacuum was broken, and an inert filter aid added to the mixture (1.0 percent by weight of the oil). Vacuum was resumed and the temperature reduced to 58–68 °C. Vacuum was broken and the bleached oil and spent bleaching earth/filter aid separated by vacuum filtration. Resulting fraction was bleached oil.

Bleached oil was steam bathed for 28–32 minutes under vacuum and temperature held between 220–230 °C. During the cooling period, a 0.5 percent citric acid solution was added (1 mL per 100 grams of oil deodorised). Resulting fraction was deodorised oil (RBD oil).

[B] Residue found was ≥LOD and <LOQ (reported to one significant figure) but rounds to 0.01 mg/kg

Maize

Shepard (2020 DuPont-43225, Revision No. 1) studied the distribution of fluazaindolizine residues upon processing of maize. Moisture was adjusted (54–71 °C in oven), if required, to a moisture content of 10.0–15.0 percent. Samples were cleaned by aspiration and screening. Light impurities were removed using an aspirator. After aspiration, samples were screened in a 2-screen cleaner to separate large and small foreign particles (screenings) from the cleaned grain.

Dry Milling Process

Cleaned whole corn grain were moisture conditioned to 20.0–22.0 percent and tempered for approximately 2 hours. After tempering, the samples were fed into a disc mill to crack the kernel and the resulting material dried in an oven for 30 minutes at 54–71 °C. Dried cornstock was screened with a 3.2 mm screen to separate bran, germ, and large grits from grits, meal and flour.

Material <3.2 mm (grits, meal, and flour) was sieved (two screens: 1.4 mm and 0.25 mm) sieves. The fraction on top of 1.4 mm sieve was “grits”; the fraction on top of the 0.25 mm sieve was “meal” and the fraction through the 0.25 mm sieve was “flour.”

Material on top of the 3.2 mm screen (bran, germ, and large grits) was screened again using a 4.8 mm screen (or similar size). Material above the screen was aspirated using the aspirator to remove bran (hull material) from the germ with attached hull and endosperm. Germ with attached hull and endosperm was passed through the disc mill and roller mill and screened. Material above screen was aspirated to remove hull from the germ. Material through the 3.2 mm screen was added to the large grit fraction weight for mass balance purposes.

All material through the 4.8 mm screen (large grits and detached germ) was passed over a gravity separator to separate germ and large grits. If necessary, germ was milled, screened, and/or aspirated to remove endosperm and hull material.

The two germ fractions were combined and dried at 54–71 °C to a final moisture of 14.0–16.0 percent. Control germ from trial 01 did not require drying. Requested grits, meal, and flour fractions were collected and placed into freezer storage.

Germ material was heated to 71–79 °C in a mixer and held for 10 minutes. Following heating, the material was flaked in a flaking roll with a gap setting of 0.18–0.25 mm. After flaking, the treated sample from trial 21 was sieved to remove remaining endosperm from the germ flakes. Flaked material was placed in stainless steel batch extractors and submerged in 49–60 °C solvent (hexane). After 30 minutes, the miscella (crude oil and hexane) was drained and hexane was added to repeat the cycle two more times. Final two washings were at the same temperature range and for 15–30 minutes each. Following the final draining, ambient or warm air was passed over spent flakes to remove residual hexane. Resulting fractions from solvent extraction were miscella and solvent-extracted germ flakes.

Miscella was passed through a laboratory vacuum evaporator to separate the crude oil and hexane. Crude oil was then heated to 91–96 °C for hexane removal, filtered, and collected for refining.

Based on the free fatty acid content, a weighed amount of sodium hydroxide was added to the crude oil. The mixture was placed in a water bath and mixed for 15 minutes at high RPM at 20–24 °C and then for 12 minutes at low RPM at 63–67 °C. Neutralised oil and soapstock were separated using centrifugation. Alkali refined oil samples were decanted and filtered prior to bleaching.

During bleaching, alkali refined oil was heated to 40–50 °C and activated bleaching earth added (1.0 percent by weight of oil). After addition, the solution was placed under vacuum and stirred. Temperature was increased to 85–100 °C and held for 10 to 15 minutes and allowed to cool before filtering (bleached oil).

Bleached oil was steam bathed at 220–230 °C for 28–32 minutes under vacuum. The oil was then allowed to cool. During the cooling period, a 0.5 percent citric acid solution was added (1 mL per 100 grams of oil deodorised). Resulting fractions were refined.

During bleaching, alkali refined oil was heated to 40–50 °C and activated bleaching earth added (1.0 percent by weight of oil). After addition, the solution was placed under vacuum and stirred. Temperature was increased to 85–100 °C and held for 10 to 15 minutes, then cooled and filtered (bleached oil).

Bleached oil was steam bathed at 220–230 °C for 28–32 minutes under vacuum and to cool during which, a 0.5 percent citric acid solution was added (1 mL per 100 grams of oil deodorised). Resulting fraction was refined bleached-deodorised oil (RBD oil).

Wet Milling Process

A representative sample of dried and cleaned corn grain was steeped in 49–54 °C water containing 0.1–0.2 percent sulfur dioxide (sulphurous acid) for 22–48 hours. At the end of the steeping period, steep water was drained and a representative fraction collected and placed into frozen storage. Steeped whole corn was passed through a bell disc mill and a majority of the germ and hull was removed using a hydroclone (water centrifuge). Germ and hull were dried at 74-91 °C to obtain a final moisture between 5-10 percent. After drying, the germ and hull were separated using aspiration and screening.

Cornstock (without germ and hull) ground in the disc mill was passed over a separator equipped with a 325 mesh (50 micron) screen. In commercial industry, only bran (hull material) remains on top of

the screen. Material on top of the screen was discarded. Process water (with starch and gluten) passing through the screen was separated into starch and gluten using batch centrifugation. Starch was dried in an oven at 54–71 °C until the moisture content was less than 15.0 percent (Starch).

Germ samples were moisture conditioned to 14–16 percent, heated to 88–104 °C in a mixer, flaked in a flaking roll with a gap setting of 0.2 mm, and pressed in an expeller to liberate part of the crude oil. Resulting fractions are expelled crude oil and presscake with residual crude oil.

Presscake was placed in stainless steel batch extractors and submerged in 49–0 °C hexane. After 30 minutes, the miscella was drained and fresh hexane was added to repeat the cycle two more times. Final two washings were for 15 minutes each. Following the final draining, the spent presscake was desolventised with ambient or warm air to remove residual hexane. Resulting fractions from solvent extraction were miscella and solvent extracted presscake (germ cake).

Miscella was passed through a laboratory vacuum evaporator to separate the crude oil and hexane. Crude oil was then heated to 91–96 °C for hexane removal. Crude oils from expelling and solvent extraction were filtered and combined for refining. Crude oil samples from the wet milling process were alkali refined, bleached, and deodorised utilizing the same methods used during the dry milling procedure to produce RBD oil.

Notes:

[A] molecular weight back-calculation was applied to residue values of IN-QZY47, IN-TMQ01, IN-UJV12, and IN-UNS90 (IN-TQD54) to account for reference standards which were supplied in salt form but not taken into consideration during weighing.

[B] residue was ≥LOD but <LOQ (reported to one significant figure) but rounds to 0.01 mg/kg.

Wheat

Shepard (2020 DuPont-43224, Revision No. 1) studied the distribution of fluazaindolizine residues upon processing of wheat. If the moisture content of a sample was above 13.5 percent, the sample was dried in a tray oven at 54–71 °C until the moisture content was 11.0–13.5 percent moisture. Samples from trial 02 required drying. Following drying (if required), samples were cleaned by aspiration and screening. Light impurities were separated from the sample using an aspirator. After aspiration, the sample was screened using a two-screen cleaner to separate large and small foreign particles (screenings) from the cleaned wheat sample. Due to large plant material in the grain, the treated sample from trial 03 was screened before aspiration.

Cleaned wheat was moisture adjusted (tempered) to 16 percent. After tempering for 1–1.5 hours, the wheat was passed through a disc mill. The material was sifted with a sifter equipped with an 8, 14, and 30-mesh sieve. The material on top of the 30-mesh sieve was aspirated to remove bran from the germ fraction. The germ (with endosperm) was passed through a reduction mill. The germ and reduced endosperm were sifted with a sifter equipped with 20, 24, and 28-mesh sieves to separate the germ from the endosperm. The germ material was also aspirated again to remove additional bran and milled/sieved to remove additional endosperm (germ). A 0.5–1.0 percent recovery of germ is expected.

Cleaned wheat was moisture conditioned (tempered) depending on the physical property of the wheat. The physical property of the grain kernel varies depending on whether the grain has a floury or vitreous kernel. In a floury kernel, a cross-section of the grain reveals a grainy soft white structure. The cross-section of a vitreous grain is hard and amber coloured. There are grains with an intermediate structure (a floury and vitreous part). Samples were determined to be vitreous (trial 01), intermediate structure (trial 02), and floury (trial 03) and were moisture conditioned accordingly.

- floury grain wheat: 16.5 percent moisture conditioning with 24 hour ±30 minute resting period before milling
- completely vitreous grain wheat: 17.5 percent moisture conditioning with 48 hour ±30 minute resting period before milling
- intermediate structure: 17.5 percent moisture conditioning with 24 hour ±30 minute resting period before milling

Tempered wheat was milled. Breaking of the wheat was accomplished by three break rolls. After passing through the break rolls, the material was sifted using a screen sifter (two sizes, 140 micron and 800 micron). Material passing through the 120-micron screen is “Break Flour.” Material passing through the 800 micron screen is middlings. Material not passing through was conveyed to the end of the sifter. Material exiting the end is bran (coarse).

Middlings were passed through two reduction rolls followed by a sifter screen (160 micron). Material passing through the screen is reduction flour with the remainder shorts. The break and reduction flours were mixed to produce standard mill-run flour.

Bran exiting the break sieve is conveyed through beater bars over a 128-micron screen. Material passing through the screen is “Shorts” and is added to “Shorts” from the reduction mill. Material passing over the screen and exiting the end is “Bran.” Residues in wheat processed commodities are shown in Table 183.

Table 183 Residues (mg/kg) of fluazaindolizine (pre-hydrolysis) and related compounds (post-hydrolysis) in processed wheat commodities

Livestock feeding studies

Dairy cow feeding study

The transfer of fluazaindolizine from feed to tissues and milk of dairy cows was studied by Dunlop et al (2019 DuPont-42563, Revision No 1). Three groups of three Holstein Friesian and Ayrshire cows (2.6–11.3 years old, 470–764 kg bw,) were dosed orally once daily via gelatine capsules with fluazaindolizine at doses equivalent to 2.3, 6.7, 20.3 and 19.6 (depuration) ppm in the diet (dry weight basis) for 28 days

(0.055, 0.157, 0.506 and 0.509 mg/kg bw/day). An additional three animals were dosed at the high rate and were used for the depuration phase of the study. Mean daily feed consumption during the dosing period was 15.8 kg DM/day comprising 4 kg of concentrate and hay ad libitum (2.3 ppm 15.0 kg/day, 6.7 ppm 15.8 kg/day, 20.3 ppm 16.9 kg/day, depuration 16.4 kg/day). Mean daily milk yields during dosing were 13.2, 13.3, 12.8 and 11.24 kg/cow/day respectively. Milk was collected twice daily (am and pm sampling) and pooled (am and previous day pm samples) in a ratio reflecting production. Muscle (loin, hind leg and diaphragm), liver, kidney and fat (perirenal, mesenteric and subcutaneous) were collected at sacrifice within 22–24 hours after the last dose. Milk, liver, kidney, fat and muscle were analysed for residues of fluazaindolizine, IN-A5760, IN-F4106, IN-QEK31, IN-R2W56, IN-REG72 and IN-RYC33 using Charles River Analytical Procedure AP.225144.02, a modified version of method DuPont-39226 (LOQ 0.01 mg/kg for each analyte). Procedural recoveries were within acceptable ranges (Table 185).

Table 185 Procedural recoveries for bovine matrices (DuPont-42563, Revision No 1)

Residues of IN-REG72, IN-F4106, IN-A5760, IN-RYC33, and IN-R2W56 were not detected in whole milk, skim milk, cream, and tissue samples, with the exception of IN-F4106 in cows dosed with fluazaindolizine–6.7 ppm dose level < 0.01 mg/kg in kidney, 20.3 ppm dose level < 0.01 mg/kg in liver; 0.01 mg/kg in kidney.

Residues of IN-REG72, IN-F4106, IN-A5760, IN RYC33, and IN-R2W56 were not detected in whole milk, skim milk, cream, at dose levels up to 20.3 ppm, and IN-QEK31 ≤ LOQ in all samples of milk, skim milk and cream from the fluazaindolizine dosed cows. Residues of fluazaindolizine were < LOQ for the 2.3 ppm dose group, with the exception of one day-24 sample with residues of 0.01 mg/kg; however, fluazaindolizine in milk was quantifiable in the 6.7 and 20.3 ppm dose groups. Fluazaindolizine residues in milk plateaued by day 3, with average residues of < 0.020 and 0.067 mg/kg, respectively, for the 6.7 and 20.3-ppm dose groups (including milk samples from day 3–28). Maximum residues of fluazaindolizine in milk were 0.032 mg/kg for the 6.7-ppm group on Day 17 and 0.101 mg/kg for the 20.3-ppm group on Day 28. Comparison of dose levels with the maximum residues in whole milk and skim milk across all three dose groups showed a linear correlation (r^2≥0.999) between fluazaindolizine levels in the feed and fluazaindolizine residues in these matrices. Comparison of the transfer factors (TF) for cream from the 6.7- and 20.3-ppm dose groups also indicates a linear relationship between feed levels and residues in cream. Fluazaindolizine residues in skim milk and cream were generally similar to, or slightly lower than, residue levels in whole milk. Compared to average fluazaindolizine residues in whole milk on Days 14 and 21 from the 6.7- and 20.3-ppm dose groups, residue levels were 0.7–1.1× in the related samples of cream and 0.8–1.1× in the related samples of skim milk (Table 186).

In tissue samples, residues of metabolites IN-A5760, IN-R2W56, IN-REG72, and IN-RYC33 were <LOD in all samples of liver, kidney, muscle, and fat at dose levels up to 20.3 ppm in the diet, and residues of metabolites IN-F4106 and IN-QEK31 were <LOD in all muscle and fat samples. Mean fluazaindolizine residues were 0.020 mg/kg in milk, <LOQ in muscle, 0.020 mg/kg in fat, 0.021 mg/kg in liver and 0.091 mg/kg in kidney for the 6.7 ppm dose group and 0.066 mg/kg in milk, < 0.01 mg/kg in muscle, 0.034 mg/kg in fat, 0.061 mg/kg in liver and 0.215 mg/kg in kidney for the 20.3 ppm dose group. Mean residues in tissues showed a linear relationship with dose. Once dosing stopped, residues declined with a DT_{50} of < 0.5 days (Figure 31).

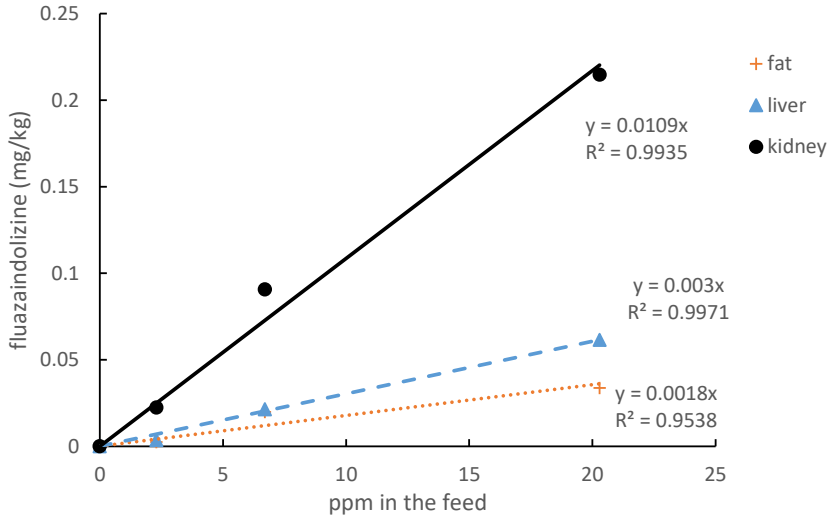

Figure 31 Mean residues of fluazaindolizine as a function of dose. Fat y=0.0018x, r2=0.954; liver y=0.003x, r2=0.997; kidney y=0.0109x, r2=0.9935.

Residues of fluazaindolizine reached a plateau in whole milk after approximately 3 days of dosing and did not appear to concentrate in the cream or skim milk fractions (Table 187).

Notes:

IN-A5760, IN-F4106, IN-REG72, IN-RYC33 all <LOD.

The transfer of IN-QEK31from feed to tissues and milk of dairy cows was also studied by Dunlop *et al.* (2019 DuPont-42563, Revision No 1). IN QEK31 was administered orally to two groups of three Holstein Friesian and Ayrshire cattle (520-674 kg bw) by gelatine capsule for 28 days. The dosage was 0.506 mg/kg bw/day, equivalent to 19.5 ppm in the feed with an additional animal dosed at the equivalent of 18.5 ppm in the feed was slaughtered 5 days after the last dose. Mean daily feed consumption during the dosing period was 16.2 kg DM/day and 14.7 kg DM/day for the depuration group. Milk yields were 12.4 and 13.6 kg/cow/day.

Residues of IN-QEK31 reached a plateau in whole milk after approximately 3 days of dosing and did not appear to concentrate in the cream or skim milk fractions. Mean IN-QEK31 residues were 0.203 mg/kg in milk, <LOQ in muscle, <LOQ in fat, 0.013 mg/kg in liver and 0.128 mg/kg in kidney. Once dosing stopped, residues declined with a DT50 of <1.2 days (Tables 188 and 189).

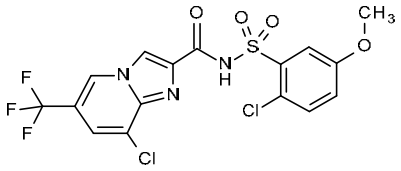
APPRAISAL

Fluazaindolizine is a new selective nematicide for the control of plant parasitic nematodes. At the Fifty-first Session of the CCPR, it was scheduled for the evaluation as a new compound in 2021 and rescheduled to the 2022 JMPR.

Fluazaindolizine is used for annual crops (e.g., fruiting vegetables, cucurbits, root vegetables, row crops) and certain perennial crops (e.g., citrus, tree nuts and stone fruits). Application methods include drip, drench, in furrow spray with or without soil incorporation either before or at planting, with the option for follow-up in crop treatment.

The Meeting received information on the metabolism of fluazaindolizine and a number of its metabolites in lactating goats and laying hens, the metabolism of fluazaindolizine in tomato, carrot, potato, soya bean and sugarcane and follow crops, methods of residue analysis, freezer storage stability, GAP information, supervised residue trials on a range of crops as well as livestock feeding studies (lactating cow).

Fluazaindolizine (company code DPX-Q8U80).



The following abbreviations are used for the major metabolites discussed below:

Based on the information on physical and chemical properties, fluazaindolizine is not volatile and is not lipid soluble with a log P_{ow} of around -0.16. Fluazaindolizine is hydrolytically stable at environmental pH. Aqueous photolysis is likely to be a major degradation pathway of fluazaindolizine in the environment.

Metabolism

The Meeting received studies on the metabolism of fluazaindolizine in plants, laboratory animals as well as lactating goats and laying hens. Metabolism studies for the metabolites IN-QEK31, IN-QZY47 and IN-

TMQ01 in lactating goat and IN-QEK31 in laying hen were also made available to the Meeting. The studies on laboratory animals were evaluated by the WHO Core Assessment Group.

Plant metabolism

Fluazaindolizine is typically applied to the soil pre- or at planting with additional soil directed applications during crop growth.

Plant metabolism studies with ^{14}C-fluazaindolizine following its use as a soil application were conducted on crops representative of fruiting vegetables (tomato), root and tuber vegetables (carrot, potato), cereals/grasses (sugarcane) and oilseeds (soya beans). Fluazaindolizine was applied either as [phenyl-^{14}C(U)]fluazaindolizine or [imidazo[1,2-a]pyridine-5,8a-^{14}C]fluazaindolizine. In all experiments, selected extracts were hydrolysed with acid or enzymes to release exocons from their conjugates.

Where conducted in the metabolism studies, chiral analysis confirmed compounds measured in the studies using the racemic standard IN-UNS90 were always present in the R-forms, designated IN-TQD54 IN-TMQ01 respectively. It is assumed these compounds are always present in their R-enantiomeric forms.

The pattern of metabolites formed in primary and rotated crops is similar with hydrolysis of fluazaindolizine at the amide bond to form IN-F4106 and IN-QEK31 and subsequent formation of conjugates, typically with sugars. The demethylated form of fluazaindolizine is also hydrolyzed at the amide bond, forming IN-A5760 and IN-QEK31 which may undergo conjugation.

In the following descriptions of the metabolism studies, the components are grouped into those "related to" various compounds. Here "related to" for IN-REG72, IN-A5760, IN-F4106, IN-UJV12, IN-TQD54, IN-TMQ01 and IN-QZY47 includes conjugates while for IN-QEK31 it includes conjugates as well as IN-R2W56 and IN-RYC33.

Soil treatments

Tomato

The metabolic fate of ^{14}C-fluazaindolizine in tomato plants maintained in a greenhouse was examined following planting seedlings into soil treated by soil drench with a SC-formulation at 1.5 kg ai/ha with a subsequent soil directed application at 0.5 kg ai/ha 30 days later. Samples of foliage and fruit were collected 30 to 62 days after the second application.

Total radioactive residues (TRR) were higher in leaves (0.44–5.7 mg eq/kg) than in fruit (0.029–0.079 mg eq/kg).

The extractability of ^{14}C with methanol:water (7:3) was good at 92–98 percent TRR for fruit and 80–94 percent TRR for foliage.

Parent fluazaindolizine was only detected at low levels in tomato fruit (≤ 0.9 percent TRR). The major components of ^{14}C identified in fruit from the [Ph-^{14}C]-experiment were those related to IN-A5760 (37–50 percent TRR), those related to IN-RSU03 (19–24 percent TRR), and those related to IN-TQD54 (2.5–13 percent TRR). The major components of ^{14}C identified in fruit from the [IP-5,8a-^{14}C]-experiment were those related to IN-QEK31 (53–72 percent TRR). Other components observed with either label were IN-REG72 (0.7–0.8 percent TRR), and IN-F4106 (3–8 percent TRR).

In foliage, fluazaindolizine parent accounted for ≤ 3.7 percent TRR. The major components of ^{14}C identified in foliage from the [Ph-^{14}C]-experiment were those related to IN-RSU03 (51–57 percent TRR), while in the [IP-5,8a-^{14}C]-experiment the major components were those related to IN-QEK31 (34–50

percent TRR). Other components observed with either label were those related to IN-A5760 (10–14 percent TRR), those related to IN-QZY47 (9–10 percent TRR), those related to IN-TQD54 (8–9 percent TRR), IN-REG72 (0.9–3 percent TRR), and IN-F4106 (4–6 percent TRR).

Soya beans

Soya bean seeds were sown into soil treated with a drench application of an SC formulation of ^{14}C-fluazaindolizine at 1 kg ai/ha. Forage was collected 48 days after sowing, fodder (hay) at 75 days and grain at maturity at 112 days.

Residue levels of ^{14}C were highest in hay (0.66 mg eq/kg) and forage (0.44 mg eq/kg) and lowest in seeds (0.27 mg eq/kg) for the [Ph-^{14}C]-experiment and highest in seeds (2.0 mg eq/kg) and lowest in hay (1.0 mg eq/kg) and forage (0.76 mg eq/kg) for the [IP-5,8a-^{14}C]-experiment.

The extractability of ^{14}C with methanol/water was good for forage (> 90 percent TRR), hay (> 87 percent TRR) and seeds (> 78 percent TRR). A further 7.0–22 percent TRR was released with additional treatments.

In forage from the [Ph-^{14}C]-experiment, fluazaindolizine accounted for 7.2 percent TRR in extracts (7.0 percent TRR in methanol:water; 0.2 percent TRR further treatments). The principal component of the ^{14}C were related to IN-QZY47 (64.2 percent TRR). Other identified metabolites included IN-F4106 (11 percent TRR) with IN-REG72 (0.7 percent TRR) and IN-RSU03 (IN-TMQ01, 1 percent TRR) at low-levels. A polar metabolite accounting for 4.2 percent TRR was tentatively assigned as a conjugate of IN-UJV12. Multiple unidentified metabolites were also detected accounting for an aggregate total of 17.6 percent TRR but each individually ≤ 2.6 percent TRR, ≤ 0.011 mg eq/kg.

In forage from the [IP-5,8a-^{14}C]-experiment, fluazaindolizine accounted for 6.9 percent TRR (0.053 mg/kg). The major component of ^{14}C was compounds related to IN-QEK31 (75 percent TRR). Other identified metabolites included IN-REG72 (1.4 percent TRR). Multiple unidentified metabolites were also detected; all ≤ 2.0 percent TRR, ≤ 0.015 mg eq/kg. A minor volatile metabolite tentatively identified as IN-VM862 accounted for 0.6 percent TRR.

In hay from the [Ph-^{14}C]-experiment, fluazaindolizine accounted for 6.1 percent TRR. The principal residue was those related to IN-QZY47 (64.8 percentT RR) those related to IN-F4106 (18 percent TRR), IN-REG72 (1.2 percent TRR), and IN-RSU03 (IN-TMQ01 1.2 percent TRR). A polar metabolite was observed accounting for 2.4 percent TRR and was tentatively assigned as a conjugate of IN-UJV12. Multiple unidentified metabolites were also detected; all ≤ 3.4 percent TRR, ≤ 0.022 mg eq/kg.

In hay from the [IP-5,8a-^{14}C]-experiment, fluazaindolizine accounted for 4.8 percent TRR. The major residue component was compounds related to IN-QEK31 (69.6 percent TRR). IN-REG72 (0.9 percent TRR) was identified at low levels.

The principal residue identified in seed in the [Ph-^{14}C]-experiment was parent fluazaindolizine (47 percent TRR) with compounds related to IN-F4106 (54 percent TRR), those related to IN-QZY47 (15 percent TRR), those related to IN-A5760 (6 percent TRR) with IN-REG72 (9.4 percent TRR). Multiple unidentified metabolites were detected; none >1.3 percent TRR.

In seed from the [IP-5,8a-^{14}C]-experiment, parent fluazaindolizine accounted for 8.3 percent TRR (0.167 mg/kg). Compounds related to IN-QEK31 accounting for 95 percent TRR. IN-REG72 was present at 1.2 percent TRR.

Carrot

Carrot seeds were sown into treated sandy loam soil about one hour after a soil drench application with an SC formulation of [^{14}C]-fluazaindolizine at a nominal application rate of 1.5 kg ai/ha. A further application was 30 days later at a nominal application rate of 0.5 kg ai/ha. Samples of foliage (30DAA1; BBCH 42), immature root and foliage sample (43DAA2, BBCH 45) and root and foliage sample at crop maturity (63DAA2, BBCH 49) were collected.

Extractability of ^{14}C using methanol:water was good for roots (86–93 percent TRR) and for foliage (67–87 percent TRR). Additional extraction using acetonitrile:water at 50°C with sonication, released a further 4.2–7.3 percent TRR while sequential treatment with driselase (a cell wall degrading enzyme), 0.1M HCl, 1M HCl and 0.1M NaOH released a further 5.2–10.4 percent TRR.

In foliage from the [Ph-^{14}C]-experiment, fluazaindolizine accounted for 20.9 percent TRR, (0.926 mg/kg) decreasing as days after application increased. The principal components were compounds related to IN-RSU03 (32–68 percent TRR), those related to IN-QZY47 (6.5–16 percent TRR). Other identified components were those related to IN-TQD54 (1.4–3.1 percent TRR), IN-F4106 (0.3–4.2 percent TRR) and IN-REG72 (0.4–1.3 percent TRR).

In foliage from the [IP-5,8a-^{14}C]-experiment, fluazaindolizine accounted for 40.6 percent TRR at 30DAA1 decreasing to 13.4 percent TRR in the mature foliage. The components identified were those related to IN-QEK31 (21–45 percent TRR). Other identified metabolites were free and conjugated IN-REG72 (2.9–5.4 percent TRR), and IN-VM862 (0.3 percent TRR).

In roots from the [Ph-^{14}C]-experiment, fluazaindolizine accounted for 1.7–8.4 percent. The principal residues were those related to IN-RSU03 (51–63 percent TRR) and those related to IN-QZY47 (20–27 percent TRR). Other identified metabolites were those related to IN-TQD54 (3.6–3.7 percent TRR). Multiple unidentified metabolites were also detected accounting for an aggregate total of 2.4–4.9 percent TRR in each sample but each individually was ≤ 2.6 percent TRR (≤ 0.003 mg eq/kg).

The major residue in the [IP-5,8a-^{14}C] experiment carrot roots was related to IN-QEK31 (62–68 percent TRR). Fluazaindolizine accounted for 12–13 percent TRR. A volatile metabolite was also detected in the mature carrot root extracts and accounted for 3.8 percent TRR. Multiple unidentified metabolites were detected accounting for an aggregate total of 1.4–6.1 percent TRR but each individually was ≤ 3.4 percent TRR (≤ 0.002 mg eq/kg).

Potato

Seed potatoes were sown into treated sandy loam soil about 2 hours prior to a soil drench application with an SC formulation of [Ph-^{14}C]- or [IP-5,8a-^{14}C]-fluazaindolizine, at a nominal application rate of 1.0 kg ai/ha and maintained in a glasshouse. A further application at a nominal rate of 1.0 kg ai/ha was made to the same plots 30 days after the initial application. Foliage samples were collected 15DAA2 and tuber and foliage 35DAA2 (immature) and 70DAA2 (mature).

Extractability of ^{14}C in tubers using methanol:water was good (> 75 percent TRR). Further treatments released an additional 11–15 percent TRR. Extractability of ^{14}C in foliage using methanol:water was also good (> 73 percent percent TRR).

In tubers from the [Ph-^{14}C]-experiment, fluazaindolizine accounted for 6.8 percent TRR, (0.006 mg/kg) in early tubers but was not detected in mature tubers. The principal residue was compounds related to IN-QZY47 (21–23 percent TRR), those related to IN-TQD54 (10–20 percent TRR), and those related to IN-RSU03 (8–12 percent TRR). Other identified metabolites were those related to IN-

F4106 (6–6.6 percent TRR), those related to IN-A5760 (3.4–3.9 percent TRR), IN-REG72 (0.4 percent TRR) and those related to IN-UJV12 (1.4–6.3 percent TRR).

In tubers from the [IP-5,8a-^{14}C]-experiment, fluazaindolizine was accounted for 9.3 percent TRR, (0.004 mg/kg) in early tubers and was not detected in mature tubers. The major residue was compounds related to IN-QEK31 (64–69 percent TRR). Multiple unidentified metabolites were also detected accounting for an aggregate total of 3.6–8.2 percent TRR in each sample but each individually was ≤ 1.7 percent TRR (≤ 0.001 mg eq/kg).

In foliage from the [Ph-^{14}C]-experiment, fluazaindolizine was present in low quantities (0.2 percent TRR; 0.010 mg/kg). The principal residues were compounds related to IN-RSU03 (12 percent TRR), those related to IN-QZY47 (16 percent TRR), those related to IN-TQD54 (14 percent TRR), and those related to IN-A5760 (12 percent TRR). Other identified metabolites were IN-F4106 (4.2 percent TRR), and those related to UJV12 (5.2 percent TRR).

In foliage from the [IP-5,8a-^{14}C]-experiment, fluazaindolizine accounted for 1.9 percent TRR, (0.015 mg/kg) with IN-REG72 (0.7 percent TRR). The principal residue was compounds related to IN-QEK31 (27–50 percent TRR). Multiple unidentified metabolites were also detected accounting for an aggregate total of 37.7 percent TRR but each individually was ≤ 3.5 percent TRR (≤ 0.027 mg eq/kg).

Sugarcane

Mature sugar cane sets (cv. NC0310) at the 2–3 leaf stage (BBCH 12) were transplanted into soil and within 2 hours of transplant, the soil was treated with [^{14}C]-fluazaindolizine applied as soil drench of an SC formulation at a nominal rate of 1.0 kg ai/ha. Samples were taken at BBCH 32, 51 days after application and whole plants above soil level at maturity (BBCH 39) which was 231 days after application.

The extractability of ^{14}C with methanol/water was good for foliage (> 69 percent TRR) and mature cane (> 80 percent TRR).

The major residue identified in [Ph-^{14}C] experiment sugarcane foliage was compounds related to IN-RSU03 (IN-TMQ01, 44–54 percent TRR), those related to IN-TQD54 (22–27 percent TRR) and those related to IN-A5760 (3.8–7.4 percent TRR). Multiple unidentified metabolites were also detected accounting for an aggregate total of 6.6–7.1 percent TRR in each sample but individually none > 2.3 percent TRR (0.004 mg eq/kg).

The principal residue in [IP-5-8a-^{14}C] experiment sugarcane foliage was compounds related to IN-QEK31 (28–46 percent TRR). IN-REG72 and its glucose conjugate were also detected at low levels (≤ 4.6 percent TRR, ≤ 0.004 mg eq/kg). Multiple unidentified metabolites were detected accounting for an aggregate total of 25.5–36.7 percent TRR in each sample but individually none > 6.2 percent TRR (0.007 mg eq/kg).

The principal residue identified in [Ph-^{14}C] mature sugarcane was compounds related to IN-RSU03 (26 percent TRR), those related to IN-A5760 (23 percent TRR), those related to IN-TQD54 (12 percent TRR), those related to IN-QZY47 (4.9 percent TRR) and those related to IN-UJV12 (8.6 percent TRR). Multiple unidentified metabolites were also detected accounting for an aggregate total of 19.0 percent TRR (< 0.005 mg eq/kg) but individually none > 7.0 percent TRR (0.001 mg eq/kg).

The principal residue identified in [IP-5-8a-^{14}C] mature sugarcane was compounds related to IN-QEK31 (65 percent TRR). The glucose conjugate of IN-REG72 was also detected at low levels (3.9 percent TRR). Multiple unidentified metabolites were also detected accounting for an aggregate total of 19.5 percent TRR but individually none > 3.1 percent TRR (0.002 mg eq/kg).

Rotational crop metabolism

The residue profile in follow crops grown in soil treated with fluazaindolizine is expected to be similar to that of primary crops as in both, plants are exposed following application to the soil.

Confined rotational crop studies

In the confined rotational crop study conducted in a glasshouse with spring wheat, spinach and radish, bare sandy loam soil was treated with ^{14}C-fluazaindolizine at the equivalent of ≈1.95 kg ai/ha (0.9× maximum seasonal rate). Fluazaindolizine was applied either as [phenyl-^{14}C(U)]fluazaindolizine or [imidazo[1,2-a]pyridine-5,8a-^{14}C]fluazaindolizine. Crops were sown 30, 120 and 300 days after soil application.

Radioactivity was >0.01 mg eq/kg in all rotated crops and at all plant-back intervals (PBIs).

Fluazaindolizine, IN-F4106, and IN-QEK31 were the major residues extracted from soil.

In general, ^{14}C residues in rotated crops were lower with longer PBIs apart from wheat commodities from the [IP-5,8a-^{14}C]-experiment soil application, where TRR levels in the various commodities at the 30- and 300-day PBIs were comparable.

The majority of residues were readily extracted across all commodities using a methanol:water mixture (70:30). In cases where residues were more extensively incorporated into the crop matrix, such as wheat straw or grain samples, additional enzymatic and acid treatments allowed for recovery of > 90 percent TRR.

Spinach

Extractability of ^{14}C in spinach using methanol:water was good (>81 percent TRR).

In the [Ph-^{14}C]-experiment, fluazaindolizine was found at all PBIs (0.4–14.1 percent TRR, ≤ 0.091 mg/kg) decreasing in later samples. The principal residue was compounds related to IN-QZY47 (42–76 percent TRR). Other identified metabolites were IN-REG72 (free and conjugated, 0.3–5.3 percent TRR), those related to IN-RSU03 (1.8–9.2 percent TRR), those related to IN-TQD54 (0.5–8.2 percent TRR), those related to IN-A5760 (1.1–7.1 percent TRR), those related to IN-UJV12 (0.5–3.1 percent TRR), and those related to IN-F4106 (0.5–21 percent TRR). Multiple unidentified metabolites were also detected accounting for an aggregate total of 6.6–14.2 percent TRR in each sample but each individually was ≤ 2.8 percent TRR (≤ 0.013 mg eq/kg).

In the [IP-5,8a-^{14}C] experiment, fluazaindolizine was identified in all spinach samples (2.9–29.0 percent TRR, ≤ 0.114 mg/kg) decreasing in concentration in later samples. The principal residue was compounds related to IN-QEK31 (48–72 percent TRR). Other identified metabolites were the IN-REG72 (free and conjugated, 1.4–11.6 percent TRR). Multiple unidentified metabolites accounted for an aggregate of 10.7–29.4 percent TRR in each sample but each individually was ≤ 5.3 percent TRR (≤ 0.011 mg eq/kg).

Radish

Extractability of ^{14}C in radish foliage using methanol:water was good (> 84 percent TRR).

In the [Ph-^{14}C] experiment, fluazaindolizine was identified in radish foliage at all PBIs (0.2–11.8 percent TRR, ≤ 0.039 mg/kg) decreasing in later samples. The principal residue was compounds related to IN-QZY47 (31–37 percent TRR), those related to IN-RSU03 (14–36 percent TRR), those related to IN-TQD54 (12–22 percent TRR), those related to IN-A5760 (5.2–6.2 percent TRR), those related to IN-UJV12

(0.8–1.6 percent TRR), those related to IN-F4106 (1.2–20 percent TRR), and IN-REG72 (free and conjugated 0.2–2.9 percent TRR).

In the [IP-5,8a-^{14}C] experiment, fluazaindolizine was found in all samples (1.0–6.8 percent TRR, ≤ 0.036 mg/kg) decreasing in concentrations at later PBIs. The major residue identified was compounds related to IN-QEK31 (65–75 percent TRR) together with IN-REG72 (free and conjugated ≤ 2.7 percent TRR).

In the [Ph-^{14}C]-experiment, fluazaindolizine was identified in radish roots at all PBIs (1.7–12.2 percent TRR, ≤ 0.047 mg/kg) decreasing in later samples. The principal residue identified was compounds related to IN-QZY47 (37–40 percent TRR), those related to IN-RSU03 (20–37 percent TRR), those related to IN-TQD54, (6.1–7.6 percent TRR), those related to IN-A5760 (1.1–6.6 percent TRR), those related to IN-F4106 (1.6–16.3 percent TRR), those related to In-UJV12 (2.5 percent TRR), and IN-REG72 (free and conjugated, 0.6–5.9 percent TRR).

In the [IP-5,8a-^{14}C]-experiment, fluazaindolizine was found in all samples (6.3–17.3 percent TRR, ≤ 0.048 mg/kg) decreasing in concentration in later samples. The principal residue identified was compounds related to IN-QEK31 (36–89 percent TRR). Other identified metabolites were IN-REG72 (free and conjugated 7.0–9.3 percent TRR).

Wheat

The highest levels of total radioactivity were found in straw from wheat grown in the [Ph-^{14}C]-fluazaindolizine treated soil. Radioactive residues in grain were considerably higher in wheat grown in soil treated with [IP-5,8a-^{14}C]-fluazaindolizine as compared to the [Ph-^{14}C]-experiment, indicating cleavage of fluazaindolizine molecule.

Extractability of ^{14}C in forage using methanol:water was good (> 83 percent TRR).

In the [Ph-^{14}C]-experiment, fluazaindolizine was only identified in wheat forage in small quantities at the 30DAA PBI (0.7 percent TRR, 0.009 mg/kg); it was not found in later PBIs. The principal residue identified in forage were compounds related to IN-TQD54 (53–67 percent TRR), those related to IN-UN-RSU03 (11–16 percent TRR), those related to IN-QZY47 (4.1–4.7 percent TRR), those related to IN-A5760 (3.3–4.1 percent TRR), and those related to IN-F4106 (1.3–2.2 percent TRR). Other identified metabolites were IN-REG72 (free and conjugated 1.3–1.7 percent TRR).

In the [IP-5,8a-^{14}C]-experiment, fluazaindolizine was identified in forage at all PBIs (0.6–3.9 percent TRR, ≤ 0.016 mg/kg) decreasing in later samples. The major residue identified in forage was compounds related to IN-QEK31 (43–76 percent TRR), IN-REG72 (free and conjugated ≤ 2.8 percent TRR).

Extractability of ^{14}C in hay using methanol:water was good (> 76 percent TRR).

In the [Ph-^{14}C]-experiment, fluazaindolizine was only identified in small quantities in wheat hay at the 30DAA PBI (0.5 percent TRR, 0.008 mg/kg) and not in later samples. The major residue was related to IN-TQD54 (46–54 percent TRR), those related to IN-RSU03 (11–17 percent TRR), those related to IN-A5760 (3.9–5.4 percent TRR), those related to IN-QZY47 (1.5–2.3 percent TRR), and those related to IN-F4106 (2.2–2.7 percent TRR). Other identified metabolites were IN-REG72 (free and conjugated 1.4–2.7 percent TRR). Chiral HPLC analysis was conducted on the isolated IN-RSU03 and it was demonstrated that only the *R*-enantiomer, IN-TMQ01, was present.

In the [IP-5,8a-^{14}C]-experiment, fluazaindolizine was identified only in the 30 and 120DAA samples at low concentrations (0.7–1.4 percent TRR, ≤ 0.016 mg/kg). The principal residues identified were compounds related to IN-QEK31 (32–71 percent TRR), with IN-REG72 (free and conjugated ≤ 8.0 percent TRR, ≤ 0.091 mg/kg).

Extractability of ^{14}C in straw using methanol:water was good for the [Ph-^{14}C]-experiment (> 72 percent TRR) and poor for the [IP-5,8a-^{14}C] experiment (< 65 percent TRR). Further treatments of [IP-5,8a-^{14}C]-experiment straw samples released an additional 27.7–38.9 percent TRR with terminal residues remaining in solids accounting for ≤ 8.3 percent TRR.

In the [Ph-^{14}C]-experiment, fluazaindolizine was only identified in wheat straw in small quantities at the 30-day PBI (0.7 percent TRR, 0.041 mg/kg) and was not found in later PBIs. The principal residue identified in [Ph-^{14}C] straw was compounds related to IN-TQD54 (37–43 percent TRR), those related to IN-RSU03 (15–17 percent TRR), those related to IN-A5760 (3.8–7.3 percent TRR), and those related to IN-F4106 (2.7–3.3 percent TRR). Other identified metabolites were IN-REG72 (free and conjugated 0.9–3.2 percent TRR) and IN-UJV12 (< 0.1–0.5 percent TRR).

In the [IP-5,8a-^{14}C]-experiment, fluazaindolizine was found in straw only in the 30 and 120-day PBIs (1.4–4.3 percent TRR, ≤ 0.153 mg/kg). The principal residue was compounds related to IN-QEK31 (26–40 percent TRR) with IN-REG72 (free and conjugated 0.2–7.2 percent TRR).

Extractability of ^{14}C in grain using methanol:water was poor for the [Ph-^{14}C]- (16–34 percent TRR) and [IP-5,8a-^{14}C]-experiments (54–63 percent TRR). Selected samples were subjected to further treatments which released an additional 63–84 percent TRR for the [Ph-^{14}C]- 300 DAA grain sample with terminal residues remaining in solids accounting for 2.8 percent TRR and an additional 36–46 percent TRR released for the [IP-5,8a-^{14}C] sample with terminal residues remaining in solids accounting for 0.7 percent TRR.

In the [Ph-^{14}C]-experiment, it was not possible to obtain accurate profiles from the 120 and 300-day PBI samples due to the large quantity of endogenous materials and large volumes of sample extract required to release the ^{14}C residue. The profiles obtained demonstrated that the residue was comprised of multiple metabolites although it was not possible to accurately determine their identity. The majority of the ^{14}C residues were released by enzyme and/or acidic extractions which may alter the nature of the residue in the extraction process.

In the [Ph-^{14}C]-experiment, fluazaindolizine was found in small quantities at the 30-day PBI (3.3 percent TRR, 0.003 mg/kg). The major residue identified in [Ph-^{14}C] grain was IN-A5760 (3.5–6.1 percent TRR, 0.002–0.005 mg eq/kg). Other identified metabolites were compounds related to IN-TQD54 (4.4 percent TRR), those related to IN-RSU03 (0.9–8.4 percent TRR), and IN-F4106 (≤ 3.3 percent TRR) and those related to IN-QZY47 (≤ 2.3 percent TRR). IN-REG72 was tentatively observed in the 300DAA grain at 7.9 percent TRR.

In the [IP-5,8a-^{14}C]-experiment, fluazaindolizine was not found in the grain samples. The principal residue identified in grain was compounds related to IN-QEK31 (69–76 percent TRR) with a glucose conjugate of IN-REG72 (≤ 2.6 percent TRR, ≤ 0.040 mg eq/kg).

In summary, the metabolism of fluazaindolizine and various metabolites taken up from the soil (such as major metabolites IN-F4106 and IN-QEK31) was consistent across all crops with differences mainly in the degree and complexity of conjugation that occurs in the various crops. The major metabolic route in primary and rotated crops was the hydrolysis of fluazaindolizine at the amide bond, resulting in IN-F4106 and IN-QEK31. Fluazaindolizine was also *O*-demethylated to form IN-REG72, which also was hydrolyzed to IN-A5760 and IN-QEK31. A less prominent pathway was hydrolysis of fluazaindolizine at the sulfonamide bond, resulting in IN-RYC33 or the further degradation of IN-QEK31 to IN-VM862. Several conjugates were also formed, typically with various sugars.

Table 190 Residue profiles for fluazaindolizine and metabolites in different plant matrices

	Percent TRR								
Component	Fluaza-indolizine	IN-REG72	IN-F4106	IN-A5760	IN-QEK31	IN-QZY47	IN-TQD54	IN-RSU03	IN-UJV12

Animal metabolism

The Meeting received animal metabolism studies on rats, lactating goats and laying hens dosed with fluazaindolizine and separate studies following dosing with IN-QEK31 (lactating goats, laying hens) and IN-QZY47 and IN-TMQ01 (lactating goats). Lactating goats and laying hens were dosed with [Ph-^{14}C(U)]-fluazaindolizine and [imidazo-(1,2-α)-pyridine-2-^{14}C]-fluazaindolizine.

Rats

Metabolism of fluazaindolizine in rats was evaluated by the WHO Core Assessment Group of the 2021 JMPR. Metabolites identified in rats included: IN-REG72, IN-UHD20, IN-UHD21, IN-F4106, IN-QEK31, IN-A5760 and sulfate or glucuronide conjugates of IN-A5760.

On dosing of laboratory animals with IN-F4106, IN-A5760 and conjugates were identified. Following dosing with IN-QZY47, acetylated IN-QZY47 was the predominant metabolite and following dosing with IN-TMQ01, IN-F4106 and IN-TQD54 were identified.

Lactating goats

Lactating goats were orally dosed by gavage once daily for seven consecutive days with ^{14}C-fluazaindolizine at doses equivalent to 12 ppm in the diet and sacrificed within 6 hours of the last dose. Milk samples were collected daily.

By 6 hours after the last dose, the majority of the ^{14}C was recovered in faeces (51–52 percent of the administered dose (AD)) and urine (21–33 percent AD). Milk accounted for < 0.1 to 0.1 percent AD while tissues accounted for 0.8–0.9 percent AD. The material balance was 97–108 percent AD.

Residues in milk reached a plateau by 5 days of dosing.

TRR levels in edible tissues from the [Ph-^{14}C]/[IP-2-^{14}C]-fluazaindolizine dosed goats were 0.223/0.275 mg eq/kg in liver, 0.358/0.357 mg eq/kg in kidney, 0.011/0.010 mg eq/kg in muscle, 0.015/0.008 mg eq/kg in omental fat, 0.028/0.014 mg eq/kg in renal fat and 0.024/0.013 mg eq/kg in subcutaneous fat. Radioactive residues did not selectively partition into skim milk or cream or into the various fat types.

Extractability from tissues with acetonitrile:0.1 M ammonium formate, pH 7 (9:1) was good for liver, kidney, muscle and fat (> 85 percent TRR) and Day 4–6 milk (> 96.9 percent TRR). Digestion of liver PES with protease released additional residues, with overall ≥ 96 percent TRR extracted.

In the [Ph-^{14}C] experiment, fluazaindolizine accounted for 17.5–84.6 percent TRR in tissues and milk. The phenyl-derived metabolites included IN-A5760 (maximum 4.1 percent TRR), IN-F4106 (maximum 38.4 percent TRR) and IN-REG72 (maximum 7.0 percent TRR). Several minor unidentified metabolites were also detected, none of which individually were greater than 7.3 percent TRR, which combined accounted for 5.5–12.8 percent TRR in milk and tissues.

In the [IP-2-^{14}C] experiment, fluazaindolizine accounted for 25.0–83.2 percent TRR in tissues and milk. The imidazopyridine-derived metabolites included IN-QEK31 (maximum 42.8 percent TRR), IN-REG72 (maximum 11.6 percent TRR) and IN-R2W56 (maximum 0.6 percent TRR). Several minor unidentified metabolites were also detected, none of which individually were greater than 4.0 percent TRR, which combined accounted for 4.0–8.3 percent TRR in milk and tissues.

Laying hens

The metabolism of ^{14}C-fluazaindolizine was studied in laying hens. Hens were dosed orally via capsules, once a day for a total of 14 days, with ^{14}C-fluazaindolizine at doses equivalent to 13 ppm in the diet. Hens were sacrificed 6 hours after the final dose.

The recovery of the administered dose was 94.6 percent for [Ph-^{14}C]-fluazaindolizine and 93.5 percent for the [IP-2-^{14}C]-fluazaindolizine. For both [^{14}C]-labels, 92.9–94 percent of the dose was recovered from the excreta and cage wash. For both [^{14}C]-labels, < 0.1 percent of the dose was recovered in eggs, muscle and fat with 0.6 percent of the dose recovered in liver.

Total radioactive residue levels in edible tissues were 0.732 mg eq/kg in liver, 0.043 in muscle and 0.020 mg eq/kg in abdominal fat from the [Ph-^{14}C]-fluazaindolizine dosed hens, and 0.701 mg eq/kg in liver, 0.047 in muscle and 0.027 mg eq/kg in abdominal fat from the [IP-2-^{14}C]-fluazaindolizine dosed hens. Radioactivity plateaued in whole eggs within 10 days from the start of dosing at *ca.* 0.017 mg eq/kg in the [Ph-^{14}C]-fluazaindolizine and within 8 days at *ca.* 0.018 mg eq/kg in the [IP-2-^{14}C]-fluazaindolizine.

Extractability of eggs, liver, muscle, and fat with acetonitrile/buffer extractions > 87.3 percent TRR.

Most of the radioactive residues (82.4–98.0 percent TRR) was identified and/or characterised in liver and eggs from the [Ph-^{14}C]-fluazaindolizine dosed hens. Fluazaindolizine was a major residue, accounting for 67.5–96.5 percent TRR in liver and eggs at levels of 0.013 mg/kg in eggs, 0.680 mg/kg in liver, 0.041 mg/kg in muscle and 0.014 mg/kg in fat. IN-F4106 (maximum 5.7 percent TRR) and IN-REG72 (maximum 1.1 percent TRR) were also detected. Several minor unidentified metabolites were also detected, none of which individually were greater than 11.3 percent TRR, which combined accounted for 0.9–11.3 percent TRR in eggs and tissues.

The majority of radioactive residues (73.1–97.9 percent TRR) was identified and/or characterised in tissues and eggs from the [IP-2-^{14}C]-fluazaindolizine dosed hens. Fluazaindolizine was a major residue, accounting for 66.2–97.1 percent TRR, levels of 0.012 mg/kg in eggs, 0.639 mg/kg in liver, 0.046 mg/kg in muscle and 0.018 mg/kg in fat. In eggs and tissues, IN-QEK31 (maximum 4.9 percent TRR), IN-REG72 (maximum 1.1 percent TRR), IN-RYC33 (maximum 11.0 percent TRR) and IN-R2W56 (maximum 1.9 percent TRR) were detected. An unidentified metabolite was detected in abdominal fat which accounted for 2.5 percent TRR (0.001 mg/kg).

In summary, the major residue in tissues, milk and eggs following dosing with fluazaindolizine is the parent compound.

Metabolism of IN-QEK31

A lactating goat received repeated oral administration of [IP-2-^{14}C]-IN-QEK31 by gelatine capsule once daily on five consecutive days at a dose level equivalent to 12.5 ppm in the feed. Animals were euthanized approximately 6 hours after the last dose.

The majority of the ^{14}C was recovered in urine (57 percent AD) and faeces (14 percent AD). Milk accounted for 2.1 percent AD while tissues for < 0.1 percent AD. Residues in milk reached a plateau by 1 to 4 days of dosing.

TRR in edible tissues were 0.035 mg eq/kg in liver, 0.282 in kidney, < 0.001 in muscle, 0.005 in omental fat, 0.046 in renal fat and 0.002 mg eq/kg in subcutaneous fat.

Extractability of milk and tissues with acetonitrile:(100 mM ammonium formate) (9:1) was good with > 90 percent TRR released, the exception being liver for which (79.7 percent TRR). Extraction of the bound liver residues with more polar and acidic extraction methods did not release any further radioactivity; however, PES were low (0.007 mg eq/kg).

Unchanged IN-QEK31 accounted for 74.3-95.4 percent TRR in tissues and milk. A single metabolite was present at greater than 10 percent TRR which was identified as IN-R2W56 and detected only in renal fat. Several minor unidentified metabolites were also detected, none of which individually were greater than 5.0 percent TRR, which combined accounted for 6.2 percent TRR in milk and tissues.

Hens were dosed orally *via* capsule with [IP-2-^{14}C]-IN-QEK31 once a day for 14 days, at a dose equivalent to 10 ppm in the diet and sacrificed 6 hours after the final dose-IN-QEK31 at a dose equivalent to 10 ppm in the diet. Hens were sacrificed 6 hours after the final dose.

IN-QEK31 was rapidly eliminated from hens into the excreta (approximately 93.2 percent of the dose). Edible tissues and eggs contained negligible amounts of radioactivity (< 0.1 percent) of the administered total dose. Radioactivity in whole eggs reached plateau within 5 days post first dose (*ca.* 0.005 mg/kg).

TRR were 0.014 mg eq/kg in liver and 0.002 mg eq/kg in abdominal fat and < 0.001 mg eq/kg in muscle. Most of the radioactive residues (≥ 71.1 percent TRR) were extracted with acetonitrile:(100 mM

ammonium formate). Unchanged IN-QEK31 accounted for 71 percent TRR in liver. As TRR in egg, muscle and fat samples were very low (< 0.01 mg eq/kg), metabolite profiling was not conducted.

In summary, the major residue in tissues, milk and eggs following dosing with IN-QEK31 is IN-QEK31.

Metabolism of IN-QZY47

The metabolism of [Phenyl-^{14}C(U)]-IN-QZY47 was investigated in a lactating goat following repeated oral administration by gelatine capsule once daily for five consecutive days at a dose level equivalent to 20 ppm in the feed. Animals were euthanized approximately 6 hours after the last dose

The majority of the ^{14}C was recovered in urine (75 percent AD) and faeces (7.2 percent AD). Milk accounted for 20.2 percent AD while tissues for < 0.1 percent AD. Residues in milk reached a plateau by 1 to 4 days of dosing.

TRR were 0.344 mg eq/kg in liver, 0.824 mg eq/kg in kidney, 0.057 mg eq/kg in muscle, 0.034 mg eq/kg in omental fat, 0.044 mg eq/kg in renal fat and 0.050 mg eq/kg in subcutaneous fat. There was no selective partitioning of residues (less than 2-fold) in the milk fractions.

Extractability of milk and tissues with acetonitrile:(100 mM ammonium formate) (9:1) was good (> 81 percent TRR). The majority of radioactive residues (74.6-98.6 percent TRR) were identified and/or characterised. In milk and tissues, metabolites included IN-F4106 (maximum 81.4 percent TRR), IN-A5760 (maximum 11.4 percent TRR) and IN-A5760 conjugates (maximum 41.0 percent TRR). IN-QZY47 was detected in milk (5.3 percent TRR) but not in tissues. Several minor unidentified metabolites were also detected, none of which individually were greater than 8.3 percent TRR or 0.017 mg eq/kg

Metabolism of IN-TMQ01

The metabolism of [Phenyl-^{14}C(U)]-IN-TMQ01 was investigated in a lactating goat following oral administration by gelatine capsule, once daily for five consecutive days at a dose level equivalent to 11 ppm in the feed. Animals were euthanized approximately 6 hours after the last dose.

Most of the residues was recovered in faeces (44 percent AD) and urine (34 percent AD). Milk and tissues accounted each for < 0.1 percent AD. Residues in milk reached a plateau by 1 to 4 days of dosing.

In milk and tissues containing residues greater than 0.01 mg eq/kg, the radioactive residues (from 66.1 percent for liver to 100.0 percent TRR for muscle and fat) were extracted with acetonitrile: 100 mM ammonium formate. Digestion with protease released the remaining radioactive residues in liver.

The majority of radioactive residues (66.1–100 percent TRR) were identified and/or characterised. Unchanged IN-TMQ01 accounted for 42.7–86.7 percent TRR in tissues. IN-F4106 accounted for 1.0–43.6 percent TRR in tissues and essentially all of the residue in milk (97.5 percent TRR; 0.007 mg eq/kg). Several minor unidentified metabolites were also detected, none of which individually exceeded 4.8 percent TRR, with the exception of muscle and subcutaneous fat in which a single unknown component accounting for 13.7–22.7 percent TRR was detected, however, these unknowns only equated to a low concentration of ≤ 0.001 mg eq/kg.

Environmental fate

The Meeting received aqueous and soil photolysis, aqueous hydrolysis and aerobic soil studies for fluazaindolizine.

Fluazaindolizine and metabolites (IN-F4106, IN-QEK31) are stable to hydrolysis (aqueous and soil) at environmental pHs, however aqueous photolysis is fast and may be a significant route of degradation with DT_{50} values ≤ 1.6 days for fluazaindolizine.

Fluazaindolizine does not undergo significant photolytic degradation on moist soil when exposed to artificial sunlight (DT_{50} 138 days). Soil metabolite IN-QEK31 degrades readily on moist soil surface in the presence of light while IN-F4106 was stable.

In laboratory aerobic soil degradation studies on fluazaindolizine the major soil degradates were IN-F4106, IN-QEK31 and IN-VM862. The laboratory DT_{50} values for fluazaindolizine in different soils were 3.4–241 days (geometric mean 28.1 days). DT_{50} were 177–461 days (geometric mean 216 days) for IN-F4106, 57.2-182 days (geometric mean 89 days) for IN-QEK31, 347-452 days for aerobic soil degradation and 42–57 days overall dissipation including volatilisation for IN-VM862, 28.4–117 days (geometric mean 58 days) for IN-REG72 and 3.7–88.6 days (geometric mean 27 days) for IN-A5760.

In field dissipation studies, the DT_{50} values for fluazaindolizine degradation ranged from 5.0 to 171 days (geometric mean of 28.1 days), indicating non-persistency. Soil metabolites show limited potential to accumulate following application on consecutive years, with the exception of IN-F4106 which may accumulate.

Field rotational crop studies

The persistence in soil and potential uptake of fluazaindolizine and degradates by plants was further evaluated in field studies at locations in Europe and the United States.

Fluazaindolizine (SC formulation) was applied as 1×1.25 kg ai/ha, 2×1.25 kg ai/ha (total 2.5 kg ai/ha), 4×0.82 kg ai/ha applications (total 3.3 kg ai/ha) or 4×1.12 kg ai/ha applications (total 4.48 kg). Three PBIs were targeted at each site, 7–30, 60–270 and 270–365 days.

Fluazaindolizine residues were observed at levels above the LOQ (0.01 mg/kg) in a variety of crops: up to 0.018 mg/kg in leafy vegetables (radish tops), 0.023 mg/kg in broccoli, 0.039 mg/kg in celery, 0.023 mg/kg in root crops (radish roots), immature pea seed 0.18 mg/kg, pulses 1.5 mg/kg (pea seed), rape seed 0.022 mg/kg, forages 0.035 mg/kg (soya bean), and fodders 0.8 mg/kg (pea hay).

Compounds hydrolyzed by acid to IN-A5760, IN-F4106, IN-QEK31, IN-QZY47, IN-TMQ01, IN-UJV12, IN-TQD54 were observed in all commodities and generally at levels greater than parent fluazaindolizine with residues up to 2.3 mg/kg (pea hay) for IN-A5760, 1.3 mg/kg (pea ay) for IN-F4106, 1.3 mg/kg (pea mature seed) for IN-QEK31, 9.2 mg/kg (pea hay) for IN-QZY47, 3.7 mg/kg (carrot tops) for IN-TMQ01, 1.4 mg/kg (pea hay) for IN-UJV12 and 0.62 mg/kg (corn stover) for IN-TQD54.

In summary, at the maximum use pattern considered by the Meeting, soil application at up to 2.24 kg ai/ha, residues of fluazaindolizine and metabolites are expected in rotated crops. Residues associated with follow crops will be assessed in the section on supervised trials.

Methods of analysis

The Meeting received information on analytical methods for fluazaindolizine and components of interest in plant and animal matrices.

The methods for plants involve two parts. Part 1 is analysis without hydrolysis (fluazaindolizine and free IN-F4106, IN-QEK31, IN-QZY47, IN-R2W56, IN-REG72, IN-TEQ01, IN-RYC33) and part 2 with hydrolysis of compounds to IN-A5760, IN-F4106, IN-QEK31, IN-QZY47, IN-TMQ01, IN-UJV12, IN-TQD54. Hydrolysis of fluazaindolizine and IN-REG72 results in cleavage of the amide bond and formation of IN-F4106 plus IN-QEK31 and IN-A5760 plus IN-QEK31 respectively, as shown in the Figure 32 below.

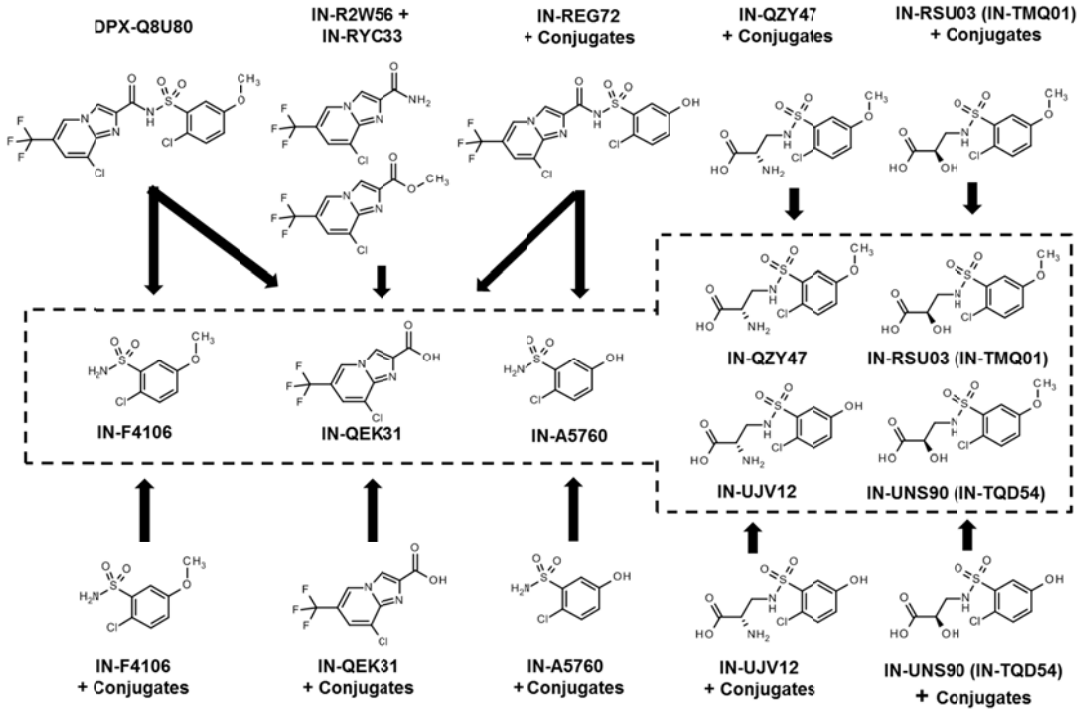

Figure 32 Metabolites of fluazaindolizine determined in the analytical methods

Residues are reported in terms of the analytes but may be converted to parent equivalents using molecular weight conversion factors: 2.26 for IN-A5760, 2.11 for IN-F4106, 1.77 for IN-QEK31, 1.52 for IN-QZY47, 1.51 for IN-TMQ01, 1.59 for IN-UJV12 and 1.58 for IN-TQD54.

In methods for plants, fluazaindolizine and its metabolites (free IN-F4106, IN-QEK31, IN-QZY47, IN-R2W56, IN-REG72, IN-TEQ01, IN-RYC33) are extracted using methanol:water. For oily crops the extract is partitioned against hexane, and the hexane discarded. The final determination is by LC-MS/MS, with validated LOQs typically of 0.01 mg/kg for each compound. This method is used to measure parent fluazaindolizine residues.

To measure compounds hydrolysed to IN-A5760, IN-F4106, IN-QEK31, IN-QZY47, IN-TMQ01, IN-UJV12, IN-TQD54, a separate aliquot of the methanol:water extract is hydrolysed with concentrated HCl (1.2-2 M HCl, 80°C overnight), followed by clean-up on a SAX SPE column and analysis by LC-MS/MS. The LOQs for plant commodities are typically 0.01 mg/kg for each compound. In the hydrolysis step, exocons are released from their conjugates, fluazaindolizine is converted to IN-F4106 and IN-QEK31, IN-REG72 to IN-A5760 and IN-QEK31 and IN-RYC33 to IN-QEK31.

In the method for animal commodities residues of fluazaindolizine and metabolites (free IN-A5760, IN-F4106, IN-REG72, IN-QEK31, IN-R2W56 and IN-RYC33) are extracted with acetonitrile:water followed by clean-up on strong cation exchange and strong anion exchange columns and analysis by LC-MS/MS. The validated LOQ is 0.01 mg/kg for tissues and milk for the individual compounds.

The Meeting concluded that the presented methods were sufficiently validated and are suitable to measure fluazaindolizine and metabolites in plant and animal commodities.

The multi-residue method, DFG S19 is not suitable for analysis of fluazaindolizine, IN-QEK31, IN-QZY47, IN-TMQ01, IN-UJV12, and IN-TQD54 in crops, but is considered valid for the determination of residues of IN-F4106, IN-A5760, and IN-RYC33 in tomato, soya bean and grapefruit (but not wheat straw).

The multi-residue method, DFG S19 is not suitable for analysis of fluazaindolizine, IN-REG72 and IN-QEK31 in animal commodities but is considered valid for the determination of residues of IN-F4106, IN-A5760, and IN-RYC33 in milk, egg, bovine meat, fat, and liver.

Stability of pesticide residues in stored analytical samples

The Meeting received information on storage stability of fluazaindolizine and metabolites (IN-A5760, IN-F4106, IN-QEK31, IN-QZY47, IN-R2W56, IN-REG72, IN-RYC33, IN-TMQ01, IN-UJV12, IN-TQD54) in raw/processed plant commodities.

Fluazaindolizine and metabolites are stable on frozen storage in a high-acid commodities (orange at least 24 months), high-water commodities (tomato at least 34 months), high-oil (soya bean seed at least 33 months), and high-starch (wheat grain at least 24 months), high-protein commodities (dry pea seed at least 24 months), dry crop commodities (field corn stover at least 24 months, pea hay at least 23 months).

The demonstrated stability intervals on frozen storage generally encompass the duration of storage in the residue trials evaluated by the Meeting.

Fluazaindolizine and metabolites (IN-A5760, IN-F4106, IN-QEK31, IN-R2W56, IN-REG72, IN-RYC33) are stable on frozen storage in milk for at least 6.8 months, in muscle for at least 6.7 months, in fat for at least 8.5 months and for analytes other than IN-R2W56 in kidney for at least 8.3 months. IN-R2W56 was stable in kidney for 7 days but not in a sample stored for 250 days. Fluazaindolizine, IN-QEK31 and IN-R2W56 were stable in liver for at least 0.77 months (23 days), IN-RYC33 for 0.47 months (14 days) and IN-REG72, IN-F4106 and IN-A5760 for 0.23 months (7 days).

Most of the samples in the livestock feeding study were analysed within 14 days.

Definition of the residue

Plant commodities

The metabolism of fluazaindolizine was similar in the primary treated crops (tomato, carrot, potato, sugarcane, soya bean) and in rotational crops (spinach, radish, wheat).

Parent fluazaindolizine was a minor component of the ^{14}C residue, detected in all crops, often at low levels (tomato fruit ≤ 0.9 percent TRR, tomato foliage ≤ 3.7 percent TRR, soya bean seed ≤ 46 percent TRR, soya bean forage ≤ 7 percent TRR, soya bean hay ≤ 6.1 percent TRR, carrot mature root ≤ 12 percent TRR, carrot foliage ≤ 41 percent TRR, potato tuber ≤ 9 percent TRR, potato foliage ≤ 1.9 percent TRR).

The main components of the ^{14}C residues were free and conjugated IN-RSU03, IN-TQD54, IN-QZY47, IN-A5760, IN-F4106 and IN-QEK31.

In the [Ph-^{14}C]-experiments the sum of IN-RSU03 and its conjugates accounted for; tomato fruit ≤2 4 percent TRR, tomato foliage 49–57 percent TRR, carrot root ≤ 63 percent TRR, carrot foliage ≤ 68 percent TRR, potato tuber/foliage ≤ 12 percent TRR and in sugarcane foliage/cane ≤ 54 percent TRR, the sum of IN-TQD54 and its conjugates accounted for; tomato fruit ≤ 13 percent TRR, potato tuber/foliage ≤ 20 percent TRR, sugarcane foliage/cane ≤ 32 percent TRR, the sum of IN-QZY47 and its conjugates accounted for; tomato foliage ≤ 10 percent TRR, soya bean forage/hay ≤ 62 percent TRR, carrot root ≤ 27 percent TRR, carrot foliage ≤ 16 percent TRR, potato tuber/foliage ≤ 23 percent TRR, the sum of IN-A5760 and its conjugates accounted for; tomato fruit ≤ 50 percent TRR, tomato foliage ≤ 14 percent TRR, potato tuber 12 percent TRR, sugarcane ≤ 23 percent TRR, the sum of IN-F4106 and its conjugates accounted for; soya bean forage/hay ≤ 17.8 percent TRR, soya bean seed 53.5 percent TRR.

In the [IP-5,8a-^{14}C]-experiments the sum of IN-QEK31 and its conjugates accounted for; tomato fruit 53–72 percent TRR, tomato foliage ≤ 50 percent TRR, soya bean forage/hay/seed ≤ 95 percent TRR, carrot root ≤ 66 percent TRR, carrot foliage ≤ 45 percent TRR, potato tubers ≤ 69 percent TRR, potato foliage ≤ 50 percent TRR, sugarcane foliage/cane ≤ 65 percent TRR.

In studies on rotational crops, also reflecting uptake from soil, residues were detected at levels above the LOQ for a number of compounds and residues may occur in rotational (follow) crops. The compounds were fluazaindolizine as well as free and sometimes conjugated forms of the metabolites IN-REG72, IN-RSU03, IN-QZY47, IN-TQD54, INA5760, IN-F4106, IN-UJV12, IN-R3Z85 for the [Ph-^{14}C]-experiments and free and conjugated forms of IN-REG72, IN-RYC33, IN-UJU44, IN-R2W56, IN-QEK31, IN-UGA20 for the [IP-5,8a-^{14}C]-experiments.

Parent fluazaindolizine was detected at low levels or <LOD in rotated crops (wheat forage/hay/straw ≤ 0.7 percent TRR, spinach ≤ 29 percent TRR, radish foliage/roots ≤ 17 percent TRR).

In the [Ph-^{14}C]-experiments the sum of IN-RSU03 and its conjugates accounted for; wheat forage/hay/straw ≤ 17 percent TRR, radish foliage/roots ≤ 37 percent TRR, the sum of IN-TQD54 and its conjugates accounted for; wheat forage/hay/straw ≤ 67 percent TRR, radish foliage ≤ 22 percent TRR, the sum of IN-QZY47 and its conjugates accounted for; spinach ≤ 76 percent TRR, radish foliage/roots ≤ 40 percent TRR, the sum of IN-F4106 and its conjugates accounted for; spinach ≤ 27 percent TRR, radish roots ≤ 16 percent TRR.

In the [IP-5,8a-^{14}C]-experiments the sum of IN-QEK31 and its conjugates accounted for; wheat forage/hay/straw ≤ 71 percent TRR, wheat grain ≤ 76 percent TRR, spinach ≤ 72 percent TRR, radish foliage ≤ 75 percent TRR, radish root ≤ 89 percent TRR. IN-UGA20 was also a significant metabolite (wheat hay ≤17 percent TRR, radish roots ≤ 14 percent TRR).

Supervised field trials monitored fluazaindolizine, as well as compounds hydrolysed with acid to IN-A5760, IN-F4106, IN-QEK31, IN-QZY47, IN-TMQ01, IN-UJV12, and IN-TQD54 with residues of all analytes detected.

As fluazaindolizine occurs in most crops that have detectable residues and provides a pragmatic option as analysis of other compounds involves an intensive hydrolysis step, the Meeting decided the residue definition for compliance with MRLs in plants should be fluazaindolizine.

In deciding which compounds should be included in the residue definition for risk assessment for plant commodities the Meeting considered the likely occurrence of the compounds and the toxicological properties of the candidates. Compounds considered were fluazaindolizine, IN-REG72, IN-A5760, IN-F4106, IN-QEK31, IN-QZY47, IN-RYC33, IN-TMQ01, IN-UJV12, and IN-TQD54 and their conjugates.

Based on toxicological properties the following compounds are assumed to be covered by the fluazaindolizine HBGVs: fluazaindolizine, and free and conjugated forms of IN-REG72, IN-A5760, IN-F4106, IN-QEK31, IN-QZY47, IN-RYC33 and IN-TMQ01.

Each of the compounds is variously the predominant or a significant residue in primary and rotated crops. The Meeting agreed that the residue definition for dietary risk assessment for plant commodities should account for residues of fluazaindolizine, and free and conjugated forms of the following compounds: IN-REG72, IN-QEK31, IN-A5760, IN-F4106, IN-QZY47, IN-RYC33, and IN-TMQ01.

It is noted the analytical method utilising acid hydrolysis converts conjugates to their free form and also hydrolyses fluazaindolizine to IN-QEK31 and IN-F4106, IN-REG72 to IN-QEK31 and IN-A5760 and converts IN-RYC33 to IN-QEK31. To avoid double counting when expressing all residues in terms of fluazaindolizine, the Meeting considered the maximum of the sum of IN-A5760, IN-F4106, IN-QZY47 and

IN-TMQ01 or IN-QEK31 measured after hydrolysis to provide the best measure of the compounds included in the residue definition.

For example, for hydrolysis products containing the imidazopyridine ring

- IN-A5760 when expressed in parent equivalents would account for IN-A5760 and its conjugates as well as IN-REG72 and its conjugates and IN-QEK31,
- IN-F4106 would account for IN-F4106 and its conjugates as well as fluazaindolizine and IN-QEK31,
- IN-QZY47 would account for IN-QZY47 and its conjugates and IN-QEK31 and
- IN-TMQ01 for IN-TMQ01 and its conjugates and IN-QEK31.

For the hydrolysis products containing the phenyl ring,

- IN-QEK31, when expressed in parent equivalents accounts for IN-A5760, IN-F4106, IN-QZY47, IN-TMQ01, fluazaindolizine, IN-REG72 as well as IN-RYC33 and IN-R2W56.

To implement the residue definition for dietary risk assessment for plant commodities the maximum concentration of the sum of compounds containing the imidazopyridine ring and hydrolysed using acid to IN-A5760, IN-F4106, IN-QZY47 and IN-TMQ01 (expressed as fluazaindolizine) or the compounds containing the phenyl ring and hydrolysed to IN-QEK31 (expressed as fluazaindolizine) should be used.

Insufficient toxicological data was available for IN-TDQ54 and IN-UJV12 and the Meeting considered they could be assessed using the threshold of toxicological concern (TTC) approach Cramer class III (1.5 µg/kg bw/day).

Animal commodities

Livestock will be exposed to residues in feed, both from treated and rotated crops.

The metabolism of fluazaindolizine in lactating goats and laying hens was qualitatively similar. Fluazaindolizine was a major component of the ^{14}C residue in both the lactating goat and laying hen metabolism studies (goat: muscle > 62 percent TRR, fat > 67 percent TRR, kidney > 65 percent TRR, liver > 18 percent TRR, milk > 72 percent TRR; hen: egg > 76 percent TRR, fat > 66 percent TRR, liver > 91 percent TRR). The predominant metabolite was IN-F4106 (goat: muscle 26 percent TRR, fat 7 percent TRR, kidney 7 percent TRR, liver 39 percent TRR; hen: egg 6 percent TRR, fat 4 percent TRR, liver 3 percent TRR) together with small amounts of IN-A5760 (goat: muscle 3.4 percent TRR, liver 4.8 percent TRR, kidney 0.8 percent TRR), IN-REG72 (goat: liver 12 percent TRR, kidney 3.3 percent TRR, fat 5 percent TRR, milk 5 percent TRR; hen: liver 1.1 percent TRR) and IN-RYC33 (hen: egg 11 percent TRR, fat 2.5 percent TRR, liver 0.7 percent TRR).

In studies on the metabolism of IN-QEK31, limited metabolism occurred with IN-QEK31 the major component of the ^{14}C residue (goat: fat 74 percent TRR, liver 69 percent TRR, kidney 94 percent TRR, milk 95 percent TRR; hen: liver 71 percent TRR).

In a study on the metabolism on IN-QZY47, only low levels of IN-QZY47 were detected in milk (3.1 percent TRR) with no residues detected in tissues. The predominant residue in tissues was IN-F4106 (milk 23 percent TRR, liver 41 percent TRR, kidney 15 percent TRR, muscle 81 percent TRR, fat >60 percent TRR) with lower levels of IN-A5760 (milk 2.3 percent TRR, liver 10 percent TRR, kidney 5.3 percent TRR, fat 5 percent TRR).

In a metabolism study on IN-TMQ01 in a lactating goat, IN-TMQ01 was the predominant ^{14}C residue in liver (48 percent TRR), kidney (87 percent TRR), muscle (43 percent TRR) and fat (50 percent TRR) with IN-F4106 the predominant ^{14}C residue in milk (98 percent TRR) and muscle (44 percent TRR).

Fluazaindolizine is present in milk, eggs and all tissues in the lactating goat and most tissues in laying hen metabolism studies and would be suitable for monitoring compliance.

Methods are available for the determination of fluazaindolizine and IN-A5760, IN-F4106, IN-REG72, IN-QEK31, IN-R2W56 and IN-RYC33 in tissues, milk and eggs.

The Meeting agreed the residue for compliance monitoring for tissues, milk and eggs should be fluazaindolizine.

In deciding which compounds should be included in the residue definition for risk assessment, the Meeting considered the likely occurrence of the compounds and the toxicological properties of the candidates. The compounds fluazaindolizine, IN-A5760, IN-F4106, IN-REG72, IN-QEK31, IN-QZY47, IN-RYC33, and IN-TMQ01 are considered to be covered by the HBGV for fluazaindolizine.

The predominant residues livestock are exposed to are IN-A5760, IN-F4106, IN-QEK31, IN-QZY47 and IN-TMQ01 at similar levels and these compounds, together with fluazaindolizine will comprise the majority of residues. The metabolism study with IN-QZY47 suggests no residues of IN-QZY47 are expected in tissues, and only very low residues in milk. Residues of IN-QZY47 in poultry commodities are also expected to be insignificant. IN-REG72 and IN-RYC33 are only found at low levels in livestock feed items and the Meeting considered IN-REG72 and IN-RYC33 would not be found at significant levels in livestock tissues, milk, or eggs. When expressed in terms of fluazaindolizine, IN-QEK31 residues are accounted for by the sum of IN-A5760, IN-F4106 and IN-TMQ01 and noting that metabolism and feeding studies with IN-QEK31 suggest only low residues are expected, the Meeting agreed it was not necessary to include IN-QZY47, IN-REG72 or IN-QEK31 in the residue definition for risk assessment.

The Meeting agreed the residue definition for risk assessment for animal commodities should be the sum of fluazaindolizine, IN-A5760, IN-F4106, and IN-TMQ01 (expressed as fluazaindolizine).

Consideration of metabolites using TTC approach

The Meeting also considered that IN-TDQ54 and IN-UJV12, metabolites relevant for livestock dietary burden, could be assessed using the threshold of toxicological concern for Cramer Class III compounds of 1.5 µg/kg bw per day.

The Meeting recommended the following residue definitions for fluazaindolizine.

Definition of the residue for compliance with MRL for plant and animal commodities: *fluazaindolizine.*

Definition of the residue for dietary risk assessment for plant commodities:

fluazaindolizine, and free and conjugated forms of the following compounds: 2-chloro-5-hydroxybenzenesulfonamide (IN-A5760), 2-chloro-5-methoxybenzenesulfonamide (IN-F4106), 8-chloro-6-(trifluoromethyl)imidazo[1,2-a]pyridine-2-carboxylic acid (IN-QEK31), 3-[[(2-chloro-5-methoxyphenyl)sulfonyl]amino]-L-alanine (IN-QZY47), 8-chloro-N-[(2-chloro-5-hydroxyphenyl)sulfonyl]-6-(trifluoromethyl)imidazo[1,2-a]pyridine-2-carboxamide (IN-REG72), 8-chloro-6-(trifluoromethyl)imidazo[1,2-a]pyridine-2-carboxamide (IN-RYC33) and 3-[[(2-chloro-5-methoxyphenyl)sulfonyl]amino]-(2R)-hydroxypropanoic acid (IN-TMQ01) (expressed as fluazaindolizine). This can be implemented by taking the maximum of the sum of compounds containing the imidazopyridine ring and hydrolysed using acid to IN-A5760, IN-F4106, IN-QZY47 and IN-TMQ01 (expressed as fluazaindolizine) ***OR*** *compounds containing the*

phenyl ring and hydrolysed to 8-chloro-6-(trifluoromethyl)imidazo[1,2-a]pyridine-2-carboxylic acid (IN-QEK31) (expressed as fluazaindolizine).

Definition of the residue for dietary risk assessment for animal commodities:

Sum of fluazaindolizine, 2-chloro-5-hydroxybenzenesulfonamide (IN-A5760), 2-chloro-5-methoxybenzenesulfonamide (IN-F4106), and 3-[[(2-chloro-5-methoxyphenyl)sulfonyl]amino]-(2R)-hydroxypropanoic acid (IN-TMQ01) (expressed as fluazaindolizine).

In deciding whether the residue for compliance is regarded as fat-soluble, the Meeting noted mean residues at the highest dose level (20.3 ppm) in the lactating cow study according to the compliance residue definition were 0.0066 mg/kg in muscle and 0.034 mg/kg in fat while residues in milk were similar in milk fat compared to whole milk (day-14 whole milk 0.061 mg/kg, cream 0.065 mg/kg, skim milk 0.07 mg/kg). In the laying hen metabolism study, residues of fluazaindolizine were 0.041 mg/kg in muscle and 0.0135 mg/kg in skin+fat.

The Meeting considers overall the residue for compliance is not fat-soluble.

To estimate livestock dietary burdens, the Meeting noted residues of fluazaindolizine, IN-A5760, IN-F4106 and IN-TMQ01 in feeds are required. In addition, IN-QZY47 is transformed into IN-F4106 and IN-A5760 in livestock and residue levels in feed are also required for IN-QZY47.

Results of supervised residue trials on crops

Supervised trials were available for the use of fluazaindolizine on a range of crops with product labels available from Australia and Canada.

The residue concentrations in the evaluation tables are expressed in terms of the individual compounds and not as fluazaindolizine equivalents.

In evaluating the crop residue data, a range of values are required to be derived. Estimates are made for residues of:

- fluazaindolizine for estimation of maximum residue levels and livestock dietary burden
- Maximum of 2.26×IN-A5760+2.11×IN-F4106+1.52×IN-QZY47+1.51×IN-TMQ01 or 1.77×IN-QEK31 for estimation of STMR and HR values
- IN-F4106+1.068×IN-A5760 for estimation of livestock dietary burden
- IN-QZY47 for estimation of livestock dietary burden
- IN-TMQ01 for estimation of livestock dietary burden
- Inputs required for compounds being assessed using the TTC approach
- IN-UJV12 for estimation of livestock dietary burden and median and highest values
- IN-TDQ54 for estimation of livestock dietary burden and median and highest values

In calculating sums, residues present at < 0.01 mg/kg are assumed present at 0.01 mg/kg.

	Residue (mg/kg)	Factor to convert to fluazaindolizine equivalents	Converted residue (mg/kg)
IN-A5760	0.01	2.26	0.0226
IN-F4106	0.05	2.11	0.1055
IN-QZY47	0.01	1.52	0.0152
IN-TMQ01	0.01	1.51	0.0151
Sum			0.1584

Fruiting vegetables, cucurbits (cucumber, melon, squash)

In Canada, cGAP for cucurbits consists of four soil applications at pre-plant or broadcast followed by soil incorporation/chemigation at 0.56–2.24 kg ai/ha and at 14-day intervals with a PHI of 1 day with a maximum application of 2.24 kg ai/ha/year.

The Meeting received supervised residue trials on cucumber and summer squash conducted in Canada and the United States.

In nine trials on cucumber approximating cGAP residues: < 0.01 (4), 0.0105, 0.012, 0.0155, 0.0535, 0.0755 mg/kg for fluazaindolizine.

In nine trials approximating cGAP residues in squash were: < 0.01 (6), 0.011, 0.0455, 0.089 mg/kg for fluazaindolizine.

The Meeting noted that residues in cucumber and summer squash are similar, confirmed by a Mann-Whitney U test, and decided the combine the data sets for mutual support. The combined data is: < 0.01 (10), 0.0105, 0.011, 0.012, 0.0155, 0.0455, 0.0535, 0.0755, 0.089 mg/kg.

Residues of the sum 2.26×IN-A5760+2.11×IN-F4106+1.52×IN-QZY47+1.51×IN-TMQ01: 0.0740, 0.0740, 0.0740, 0.0740, 0.0755, 0.0763, 0.0808, 0.0909, 0.1078, 0.1105, 0.1261, 0.1310, 0.1331, 0.1416, 0.1648, 0.1720, 0.2729, 0.3674 mg/kg.

The Meeting estimated a maximum residue level of 0.15 mg/kg, an STMR of 0.1092 mg/kg and an HR of 0.3674 for fluazaindolizine in the fruiting vegetable cucurbit subgroup of cucumbers and summer squashes.

Residues of IN-UJV12 in cucumber and squash were: < 0.01 (11), 0.0105, 0.0105, 0.0135, 0.0155, 0.0165, 0.0165, 0.0205 mg/kg.

Residues of IN-TQD54 in cucumber and squash were: < 0.01 (18) mg/kg.

The Meeting received supervised residue trials on melon conducted in Canada and the United States.

In 10 trials approximating cGAP residues in whole melons were: < 0.01 (5), 0.011, 0.012, 0.012, 0.041, 0.056 mg/kg for fluazaindolizine, maximum individual analytical result 0.089 mg/kg.

In 10 trials approximating cGAP residues of 2.26×IN-A5760+2.11×IN-F4106+1.52×IN-QZY47+1.51×IN-TMQ01 in pulp were: 0.0740, 0.0763, 0.0900, 0.0960, 0.1340, 0.1355, 0.1835, 0.2144, 0.3380, 0.3937 mg/kg for fluazaindolizine.

The Meeting estimated a maximum residue level of 0.1 mg/kg (OECD calculator estimate 0.07 mg/kg but highest individual whole melon residue 0.089 mg/kg), an STMR of 0.1348 mg/kg and an HR of 0.3937 mg/kg for melon pulp.

Residues of IN-UJV12 in pulp were: < 0.01 (9), 0.0125 mg/kg

Residues of IN-TQD54 in pulp were: < 0.01 (9), 0.0105 mg/kg.

Fruiting vegetables, other than cucurbits (tomato, peppers including chili)

In Canada cGAP for fruiting vegetables is for three soil applications at pre-plant or broadcast followed by soil incorporation or chemigation at 0.56–2.24 kg ai/ha and at 14-day intervals with a PHI of 1 day with a maximum application of 2.24 kg ai/ha/year.

The Meeting received supervised residue trials on tomato conducted in Canada and the United States.

In 17 trials approximating cGAP residues in tomato were: < 0.01 (15), 0.025, 0.0665 mg/kg for fluazaindolizine.

In 17 trials approximating cGAP residues of 2.26×IN-A5760+2.11×IN-F4106+1.52×IN-QZY47+1.51×IN-TMQ01 in tomatoes were: 0.0740 (8), 0.0748, 0.0751, 0.0751, 0.0797, 0.0808, 0.0842, 0.0967, 0.1204, 0.9630 mg/kg.

The Meeting estimated a maximum residue level of 0.15 mg/kg (OECD calculator estimate 0.07 mg/kg but highest individual analytical result 0.11 mg/kg), a STMR of 0.0748 mg/kg and an HR of 0.9630 mg/kg for fluazaindolizine in tomato.

Residues of the sum of IN-F4106+1.068×IN-A5760 were: 0.0207 (10), 0.0212, 0.0212, 0.0234, 0.0239, 0.0255, 0.0427, 0.3385 mg/kg.

Residues of IN-QZY47 in tomatoes were: < 0.01 (15), 0.0125, 0.058 mg/kg.

Residues of IN-TMQ01 in tomatoes were: < 0.01 (13), 0.0105, 0.0135, 0.025, 0.14 mg/kg.

Residues of IN-UJV12 in tomatoes were: < 0.01 (17) mg/kg

Residues of IN-TQD54 in tomatoes were: < 0.01 (15), 0.011, 0.061 mg/kg.

The Meeting agreed to extrapolate the results for tomato to eggplant and estimated a maximum residue level of 0.15 mg/kg, a STMR of 0.0748 mg/kg and an HR of 0.9630 mg/kg for fluazaindolizine in eggplant.

The Meeting received supervised residue trials on pepper, including chili peppers, conducted in Canada and the United States.

In 13 trials approximating cGAP residues in peppers were: < 0.01 (12), 0.0265 mg/kg for fluazaindolizine.

In 13 trials approximating cGAP residues of 2.26×IN-A5760+2.11×IN-F4106+1.52×IN-QZY47+1.51×IN-TMQ01 in peppers were: 0.0740 (9), 0.0755, 0.0909, 0.1209, 0.3102 mg/kg.

The Meeting estimated a maximum residue level of 0.03 mg/kg, a STMR of 0.0740 mg/kg and an HR of 0.3102 mg/kg for fluazaindolizine in peppers.

Residues of IN-UJV12 in peppers were: < 0.01 (13) mg/kg

Residues of IN-TQD54 in peppers were: < 0.01 (11), 0.0205, 0.0375 mg/kg.

Using a default concentration factor of 10, the Meeting estimated a maximum residue level of 0.3 mg/kg for fluazaindolizine in dried chili pepper.

Root and tuber vegetables

Carrot

In Canada cGAP for carrot is for two soil applications at pre-plant or broadcast followed by soil incorporation or chemigation at 0.56–2.24 kg ai/ha and at 14-day intervals with a PHI of 65 days with a maximum application of 2.24 kg ai/ha/year.

The Meeting received supervised residue trials on carrots conducted in Canada and the United States.

In 11 trials on carrots conducted in Canada and the United States approximating cGAP, residues in carrots were: < 0.01 (6), 0.02, 0.0235, 0.04, 0.0995, 0.265 mg/kg for fluazaindolizine.

Total residues for dietary risk assessment were: 0.0740, 0.0740, 0.1034, 0.1271, 0.1329, 0.1485, 0.1503, 0.4375, 0.5862, 0.7679, 1.973 mg/kg.

The Meeting estimated a maximum residue level of 0.4 mg/kg, a STMR of 0.1485 mg/kg and an HR of 1.973 mg/kg for fluazaindolizine in carrots.

For livestock dietary burden, residues in carrot were (n=11):

[IN-F4106+1.068×IN-A5760]: 0.0207 (6), 0.0232, 0.0287, 0.0332, 0.0737, 0.1489 mg/kg, with a median of 0.0297 mg/kg and a highest residue of 0.1489 mg/kg

IN-QZY47: <0.01 (3), 0.014, 0.0205, 0.031, 0.0335, 0.089, 0.1095, 0.115, 0.5 mg/kg, with a median of 0.031 and a highest residue of 0.5 mg/kg

IN-TMQ01: <0.01 (2), 0.012, 0.024, 0.0245, 0.045, 0.0535, 0.0765, 0.24, 0.39, 0.595 mg/kg, with a median of 0.01 mg/kg and a highest residue of 0.595 mg/kg

For the TTC approach, residues were (n=11):

IN-UJV12: <0.01 (11) mg/kg, with a median and a highest residue of 0.01 mg/kg

IN-TQD54: <0.01 (8), 0.025, 0.042, 0.049 mg/kg, with a median of 0.01 mg/kg and a highest residue of 0.049 mg/kg

Tuberous and corm vegetables

In Canada cGAP for tuberous and corm vegetables is for two soil applications at pre-plant or broadcast followed by soil incorporation or chemigation at 0.56–2.24 kg ai/ha and at 14-day intervals with a PHI of 40 days with a maximum application of 2.24 kg ai/ha/year.

In 19 trials on potatoes conducted in Canada and the United States approximating cGAP, residues in were: < 0.01 (4), 0.012, 0.014, 0.0165, 0.0165, 0.021, 0.028, 0.0305, 0.031, 0.0415, 0.0435, 0.0465, 0.0515, 0.068, 0.1075, 0.16 mg/kg for fluazaindolizine.

Total residues for dietary risk assessment were: 0.0740 (3), 0.0751, 0.0983, 0.1014, 0.1057, 0.1095, 0.1182, 0.1231, 0.1558, 0.1816, 0.2089, 0.2272, 0.2515, 0.2856, 0.3709, 0.4116, 0.7356 mg/kg.

The Meeting estimated a maximum residue level of 0.2 mg/kg, a STMR of 0.1231 mg/kg and an HR of 0.7356 mg/kg for fluazaindolizine in tuberous and corm vegetables.

For livestock dietary burden, residues in potatoes were (n=19):

[IN-F4106+1.068×IN-A5760]: 0.0207 (4), 0.0212, 0.0247, 0.0302, 0.0317, 0.0322, 0.0337 (2), 0.0357, 0.0372, 0.0419, 0.0437, 0.0452, 0.0570, 0.0717, 0.1127 mg/kg, with a median of 0.0337 mg/kg and a highest residue of 0.1127 mg/kg.

IN-QZY47: <0.01 (9), 0.011, 0.012, 0.015, 0.02, 0.022, 0.024, 0.038, 0.0425, 0.0455, 0.072 mg/kg , with a median of 0.011 mg/kg and a highest residue of 0.072 mg/kg.

IN-TMQ01: <0.01 (8), 0.0115, 0.0205, 0.024, 0.031, 0.0425, 0.046, 0.0475, 0.12, 0.17, 0.19, 0.335 mg/kg, with a median of 0.0205 mg/kg and a highest residue of 0.335 mg/kg.

For the TTC approach, residues were:

IN-UJV12: <0.01 (15), 0.011, 0.0115, 0.012, 0.016 mg/kg, with a median of 0.01 mg/kg and a highest residue of 0.016 mg/kg.

IN-TQD54: <0.01 (11), 0.0105, 0.0115, 0.0235, 0.0305, 0.031, 0.034, 0.044, 0.0865 mg/kg, with a median of 0.01 mg/kg and a highest residue of 0.0865 mg/kg.

Residues in rotational crops

Fluazaindolizine and metabolites are moderately persistent to persistent in the environment and may contribute to residues in follow/rotational crops through uptake from soil.

In assessing the potential uptake of residues, the Meeting considered the maximal season rate to be 2.24 kg ai/ha as detailed for all crops on the Canadian label. Application rates relevant for plateau concentrations in soil for the various compounds of interest can be calculated using the compound aerobic soil degradation DT_{50} (median) values for the various compounds of interest. Geometric mean DT_{50} value of 28.1 days for fluazaindolizine, 89 days for IN-QEK31, 293 days for IN-F4106 and 27 days for IN-A5760. For compounds not formed in soil, the concentration for fluazaindolizine is used (IN-QZY47, IN-TMQ01, IN-UJV12 and IN-TQD54). The estimated application rate for plateau residues in soil for fluazaindolizine, IN-A5760 and IN-QEK31 is 2.24 kg ai/ha, for IN-F4106 3.87 kg ai/ha.

Field rotational crop studies were used to derive estimates of residues in various commodities if the field were treated at the maximal seasonal rate. In combining residues from different trials to derive the various inputs required, individual analyte residues were scaled to the maximum seasonal rate.

The commodity groups studied in the field crop rotational studies were:

Fruit (strawberry)

Fruiting vegetables (tomato)

Leafy vegetables/Brassicas (lettuce, spinach, radish tops, turnip tops, broccoli, Swiss chard)

Root and tuber - tops (carrot tops, radish tops, turnip tops)

Root and tuber (carrots, radish, turnip)

Cereals (corn/maize, sorghum, wheat) – forage, straw or stover, hay, grain

Oilseeds/pulses (rape, beans, peas, soya beans) – forage, hay, grain

Bulb and stem vegetable (celery)

For each trial location/year, the highest residue from the PBIs that were longer than the PBI on the Canada label were used: 0 days for carrots, 14 days for root vegetables, except sugar beets (except carrot roots), leaves of root and tuber vegetables, bulb vegetables, leafy vegetables, brassica head and stem vegetable, legume vegetables, succulent or dried, foliage of legume vegetables, low growing berries, cereal grain, forage, fodder, and straw of cereal grains, grass forage, fodder, and hay, oilseeds, stalk, stem, and leaf petioles, and 365 days for all other crops.

Table 191 Example of scaled residues (mg/kg) in radish tops in one trial

kg ai/ha	PBI (days)	Fluazaindolizine	IN-A5760	IN-F4106	IN-QZY47	IN-TMQ01	IN-UJV12	IN-TQD54
4.67	68	0.01	0.038	0.0115	0.16	0.35	0.0305	0.245
Scaling factor		2.24/4.67	2.24/4.67	3.87/4.67	2.24/4.67	2.24/4.67	2.24/4.67	2.24/4.67
Scaled residues		0.0048	0.0182	0.0095	0.0767	0.1679	0.0146	0.1175

The sum of IN-F4106+1.068×IN-A5760 was 0.0289 mg/kg (expressed as IN-F4106).

When there were multiple crops within a rotational crop category, for example leafy vegetables, where residue data were available for lettuce, spinach, radish tops, turnip tops and Swiss chard, the highest of the STMR/median residues and HR/highest residues for the individual crops were selected for the STMR/median and HR/highest residue for the crop grouping.

Strawberry (Canada PBI 14 days, n=9)

Residues of fluazaindolizine: < 0.005 (4), < 0.0051 (5) mg/kg.

Total residues for dietary risk assessment were: 0.0446, 0.0455, 0.0459, 0.0494, 0.0530, 0.0585, 0.0637, 0.0996, 0.1416 mg/kg.

The Meeting estimated a maximum residue level of 0.015 mg/kg for strawberries, an STMR of 0.0530 mg/kg and an HR of 0.1416 mg/kg.

Residues of IN-UJV12 were: 0.0050 (4), 0.0051 (5) mg/kg, with a median of 0.005 mg/kg and a highest residue of 0.0051 mg/kg.

Residues of IN-TQD54 were: 0.0050 (4), 0.0051 (4), 0.0084 mg/kg, with a median of 0.0051 mg/kg and a highest residue of 0.0084 mg/kg.

Tomato (Canada PBI not relevant, n=10)

Residues of fluazaindolizine: 0.0050 (6), 0.0051, 0.0051, 0.0052, 0.0052 mg/kg.

Total residues for dietary risk assessment were: 0.0445, 0.0451, 0.0455, 0.0464, 0.0467, 0.0475, 0.0526, 0.0526, 0.0706, 0.1889 mg/kg.

Residues in tomatoes for livestock dietary burden were (n=10):

[IN-F4106+1.068×IN-A5760]: 0.0139, 0.0141, 0.0142, 0.0145, 0.0146, 0.0150, 0.0155, 0.0166, 0.0216, 0.0379 mg/kg

IN-QZY47: 0.0050 (6), 0.0051 (2), 0.0052 (2) mg/kg

IN-TMQ01: 0.0050 (2), 0.0051, 0.0052 (2), 0.0058, 0.0065, 0.0082, 0.0114, 0.0669 mg/kg,

Residues for the TTC approach were:

IN-UJV12: 0.0050 (6), 0.0051 (2), 0.0052 (2) mg/kg

IN-TQD54: 0.0050 (4), 0.0051, 0.0052 (2), 0.0070, 0.0105, 0.0249 mg/kg

Residues arising from rotational crops are lower than the ones found in treated tomatoes, peppers and eggplant and the Meeting confirms it previous estimations based on trials conducted with the primary crops.

Group 010 Brassica vegetables (except Brassica leafy vegetables)

Broccoli (Canada PBI 14 days, n=10)

Residues of fluazaindolizine: 0.0050 (4), 0.0051 (3), 0.0056, 0.0069, 0.0072 mg/kg.

Total residues for dietary intake assessment were: 0.0443, 0.0446, 0.0450, 0.0451, 0.0460, 0.0467, 0.0487, 0.0514, 0.0564, 0.0705 mg/kg.

The Meeting estimated a maximum residue level of 0.02 mg/kg, an STMR of 0.04335 mg/kg and a HR of 0.0705 mg/kg for fluazaindolizine in the Group 010 Brassica vegetables (except Brassica leafy vegetables).

Residues for livestock dietary burden were:

[IN-F4106+1.068×IN-A5760]: 0.0139 (3), 0.0140, 0.0141 (3), 0.0143 (2), 0.0144 mg/kg, with a median of 0.0141 mg/kg and a highest residue of 0.0144 mg/kg.

IN-QZY47: 0.0050 (4), 0.0051, 0.0061, 0.0069, 0.0082, 0.0087, 0.0187 mg/kg, with a median of 0.0056 mg/kg and a highest residue of 0.0187 mg/kg.

IN-TMQ01: 0.0050 (4), 0.0051 (2), 0.0054, 0.0059, 0.0085, 0.0092 mg/kg, with a median of 0.0051 mg/kg and a highest residue of 0.0092 mg/kg.

Residues for the TTC approach were:

IN-UJV12: 0.0050 (6), 0.0051 (4) mg/kg, with a median of 0.0050 mg/kg and a highest residue of 0.0051 mg/kg.

IN-TQD54: 0.0050 (6), 0.0051 (4) mg/kg, with a median of 0.0050 mg/kg and a highest residue of 0.0051 mg/kg.

Group 013 Leafy vegetables (including Brassica leafy vegetables)

Spinach (Canada PBI 14 days, n=2)

Residues of fluazaindolizine in spinach: 0.0143, 0.0178 mg/kg.

Total residues for dietary risk assessment: 0.4982, 0.6035 mg/kg.

Residues for the TTC approach were:

IN-UJV12: 0.0129, 0.0187 mg/kg.

IN-TQD54: 0.0089, 0.0179 mg/kg.

Radish tops (Canada PBI 14 days, n=6)

Residues of fluazaindolizine in radish tops were: 0.0048, 0.0050, 0.0178, 0.0179 (3) mg/kg.

Total residues for dietary risk assessment: 0.1656, 0.3259, 0.3444, 0.4315, 0.6248, 1.275 mg/kg.

Residues for livestock dietary burden:

[IN-F4106+1.068×IN-A5760]: 0.0290, 0.0296, 0.0501, 0.0589, 0.0630, 0.0954 mg/kg.

IN-QZY47: 0.0251, 0.0548, 0.0767, 0.0824, 0.1742, 0.2276 mg/kg.

IN-TMQ01: 0.0179, 0.0645, 0.1472, 0.1502, 0.1679, 0.4819 mg/kg.

Residues for the TTC approach were:

IN-UJV12: 0.0146, 0.0179, 0.0179, 0.0182, 0.0320, 0.0602 mg/kg.

IN-TQD54: 0.0179, 0.0842, 0.1175, 0.1333, 0.1493, 0.6782 mg/kg.

Turnip tops (Canada PBI 14 days, n=5)

Residues of fluazaindolizine in turnip tops were: 0.005, 0.0051, 0.0051, 0.0051, 0.0051 mg/kg.

Total residues for dietary risk assessment : 0.0503, 0.0642, 0.0890, 0.1043, 0.1122 mg/kg.

Residues for livestock dietary burden:

[IN-F4106+1.068×IN-A5760]: 0.0141, 0.0142, 0.0142, 0.0143, 0.0165 mg/kg.

IN-QZY47: 0.0086, 0.0173, 0.0333, 0.0339, 0.0426 mg/kg.

IN-TMQ01: 0.0051, 0.0051, 0.0051, 0.0117, 0.0124 mg/kg.

Residues for the TTC approach were:

IN-UJV12: 0.0051, 0.0051, 0.0051, 0.0051, 0.0084 mg/kg.

IN-TQD54: 0.0051, 0.0051, 0.0051, 0.0112, 0.0144 mg/kg.

Carrot tops (Canada PBI 0 days, n=3)

Residues of fluazaindolizine in carrot tops: 0.0050, 0.0050, 0.0060 mg/kg.

Total residues for dietary risk assessment : 0.2177, 0.5851, 2.857 mg/kg.

Residues for the TTC approach were:

IN-UJV12: 0.0050 (3) mg/kg.

IN-TQD54: 0.0050, 0.0100, 0.0609 mg/kg.

Swiss chard (Canada PBI 14 days, n=5):

Residues of fluazaindolizine in Swiss chard: 0.0049, 0.0050, 0.0051, 0.0051, 0.0077mg/kg.

Total residues for dietary risk assessment: 0.0452, 0.0456, 0.0460, 0.0697, 0.1007 mg/kg.

Residues for the TTC approach were:

IN-UJV12: 0.0050, 0.0050, 0.0051, 0.0051, 0.0069 mg/kg.

IN-TQD54: 0.0049, 0.0050, 0.0050, 0.0051, 0.0051 mg/kg.

Lettuce (Canada PBI 14 days, n=13)

Residues of fluazaindolizine in lettuce: 0.0049 (3), 0.0050 (3), 0.0051 (3), 0.0061, 0.0178, 0.0179 (2) mg/kg.

Total residues for dietary risk assessment: 0.0458, 0.0536, 0.0647, 0.0716, 0.0773, 0.1134, 0.1579, 0.1601 (2), 0.1663, 0.1700, 0.1828, 1.388 mg/kg.

IN-UJV12: 0.0049, 0.0049, 0.0049, 0.0050, 0.0050, 0.0050, 0.0051, 0.0051, 0.0051, 0.0051, 0.0178, 0.0179, 0.0179 mg/kg.

IN-TQD54: 0.0049, 0.0049, 0.0049, 0.0050, 0.0050, 0.0050, 0.0051, 0.0051, 0.0051, 0.0051, 0.0178, 0.0179, 0.0179 mg/kg.

Of the leafy vegetable datasets available (spinach, lettuce, Swiss chard, carrot tops, radish tops and turnip tops) with five or more residue trials on rotational crops, radish tops had the highest fluazaindolizine residues, while residues of the other analytes of interest were sometimes highest in lettuce. The Meeting agreed to use the radish tops data to estimate a maximum residue level for leafy vegetables and the highest of the radish and lettuce data to estimate STMR and HR, respectively.

The Meeting estimated a maximum residue level of 0.04 mg/kg, an STMR of 0.3880 mg/kg (radish) and a HR of 1.388 mg/kg (lettuce) for fluazaindolizine in Group 013 Leafy vegetables (including Brassica leafy vegetables).

For livestock dietary burden, the Meeting estimated based on radish tops data:

[IN-F4106+1.068×IN-A5760]: median and highest residues of 0.0501 and 0.0954 mg/kg, respectively

IN-QZY47: median and highest residues of 0.07955 and 0.2276 mg/kg, respectively.

IN-TMQ01: median and highest residues for 0.1472) and 0.4819 mg/kg, respectively

For TTC the approach, also based on radish top data,

IN-UJV12: median and highest residues of 0.0182 and 0.0602 mg/kg, respectively

IN-TQD54: median and highest residues of 0.1175 and 0.6782 mg/kg, respectively

Group 14 Legume vegetables

Soya bean immature seed = seed+pod (Canada PBI 14 days, n=7)

Residues of fluazaindolizine: 0.0050, 0.0050, 0.0050, 0.0050, 0.0051, 0.0178, 0.0178 mg/kg.

Total residues for dietary risk assessment: 0.0449, 0.0451, 0.0456, 0.0470, 0.1228, 0.1589, 0.1589 mg/kg.

Residues for the TTC approach were:

IN-UJV12: 0.0050 (4), 0.0051, 0.0178, 0.0178 mg/kg.

IN-TQD54: 0.0050 (4), 0.0051, 0.0178, 0.0178 mg/kg.

Pea immature, seed plus pod (Canada PBI 14 days, n=6)

Residues of fluazaindolizine were: 0.0049 (2), 0.0050, 0.0051, 0.0072, 0.0090 mg/kg.

Total residues for dietary risk assessment: 0.0442, 0.0453, 0.0681, 0.0737, 0.1021, 0.1420 mg/kg.

Residues for the TTC approach were:

IN-UJV12: 0.0049, 0.0050, 0.0051, 0.0062, 0.0066, 0.0094 mg/kg.

IN-TQD54: 0.0049, 0.0049, 0.0050, 0.0050, 0.0050, 0.0051 mg/kg.

Bean immature seed (Canada PBI 14 days, n=2)

Residues of fluazaindolizine were: 0.0179 (2) mg/kg.

Total residues for dietary risk assessment were: 0.1601 (2) mg/kg.

Residues for the TTC approach were:

IN-UJV12: 0.0179 (2) mg/kg.

IN-TQD54: 0.0179 (2) mg/kg.

The Meeting agreed to use the highest of the soya bean and pea data (both seed with pods) to estimate STMR and HR values.

The Meeting estimated a maximum residue level of 0.04 mg/kg, an STMR of 0.0709 mg/kg (pea) and an HR of 0.1589 (soya) mg/kg for fluazaindolizine in Group 014 Legume vegetables [immature seed with pod]

For TTC approach, the Meeting estimated:

IN-UJV12: median and highest residues of 0.00565 (pea) and 0.0178 (soya) mg/kg, respectively.

IN-TQD54: median and highest residues of 0.0050 (soya) and 0.0178 (soya) mg/kg, respectively.

Group 15 Pulses

Soya bean seed (dry) (Canada PBI 14 days, n=7)

Residues of fluazaindolizine: 0.0050 (3), 0.0051, 0.0073, 0.0178, 0.0178 mg/kg.

Total residues for dietary risk assessment were: 0.0456, 0.0463, 0.0507, 0.0593, 0.1589, 0.1589, 0.1974 mg/kg.

Residues for livestock dietary burden were:

IN-F4106+1.068×IN-A5760: 0.0139, 0.0140, 0.0140, 0.0141, 0.0143, 0.0497, 0.0497 mg/kg.

IN-QZY47: 0.0050, 0.0050, 0.0050, 0.0051, 0.0053, 0.0178, 0.0178 mg/kg.

IN-TMQ01: 0.0050, 0.0050, 0.0050, 0.0050, 0.0051 0.0178, 0.0178 mg/kg.

Residues for the TTC approach were:

IN-UJV12: 0.0050, 0.0050, 0.0050, 0.0050, 0.0051, 0.0178, 0.0178 mg/kg.

IN-TQD54: 0.0050, 0.0050, 0.0050, 0.0050, 0.0051, 0.0178, 0.0178 mg/kg.

Pea seed (dry) (Canada PBI 14 days, n=11)

Residues of fluazaindolizine: 0.0049, 0.0050, 0.0051, 0.0072, 0.0073, 0.0094, 0.0148, 0.0220, 0.0264, 0.0343, 0.0565 mg/kg.

Total residues for dietary risk assessment: 0.0464, 0.0503, 0.0631, 0.0646, 0.0656 (2), 0.1141, 0.1150, 0.2716, 0.2738, 1.2392 mg/kg.

Residues for livestock dietary burden:

[IN-F4106+1.068×IN-A5760]: 0.0138, 0.0141, 0.0142, 0.0169, 0.0198, 0.0202, 0.0205 (2), 0.0462, 0.0659, 0.3567 mg/kg.

IN-QZY47: 0.0064, 0.0071, 0.0072, 0.0073 (2), 0.0084, 0.0473, 0.0505, 0.0821, 0.1110, 0.2960 mg/kg.

IN-TMQ01: 0.0049 (2), 0.0050 (3), 0.0051, 0.0071, 0.0072, 0.0073 (2), 0.0235 mg/kg.

Residues for the TTC approach were:

IN-UJV12: 0.0049, 0.0051, 0.0071, 0.0072, 0.0073 (2), 0.0123, 0.0126, 0.0222, 0.0261, 0.0740 mg/kg.

IN-TQD54: 0.0049 (2), 0.0050 (3), 0.0051, 0.0071, 0.0072, 0.0073 (2), 0.0101 mg/kg.

Bean seed (dry) (Canada PBI 14 days, n=2)

Residues of fluazaindolizine: 0.0179 (2) mg/kg.

Total residues for dietary risk assessment: 0.1601 (2) mg/kg.

Residues for livestock dietary burden:

[IN-F4106+1.068×IN-A5760]: 0.0501 (2) mg/kg.

IN-QZY47: 0.0179 (2) mg/kg.

IN-TMQ01: 0.0179 (2) mg/kg.

Residues for the TTC approach were:

IN-UJV12: 0.0179 (2) mg/kg.

IN-TQD54: 0.0179 (2) mg/kg.

Residues were highest in peas dry and the Meeting agreed to use the peas dry dataset to make the estimations.

The Meeting estimated a maximum residue level of 0.09 mg/kg and an STMR of 0.0656 mg/kg for fluazaindolizine in Group 015 Pulses.

For livestock dietary burden, the Meeting estimated median residues of 0.0202 mg/kg for [IN-F4106+1.068×IN-A5760], 0.0084 mg/kg for IN-QZY47 and 0.0051 mg/kg for IN-TMQ01.

For TTC approach, the Meeting estimated a median residue of 0.0073 mg/kg for IN-UJV12 and of 0.0051 mg/kg for IN-TQD54Group 16 Root and tuber vegetables

Carrot roots (Canada PBI 0 days, n=3)

Residues of fluazaindolizine were: 0.0050 (3) mg/kg.

Total residues for dietary risk assessment : 0.0449, 0.1096, 0.2055 mg/kg.

Residues for livestock dietary burden:

[IN-F4106+1.068×IN-A5760]: 0.0139 (3) mg/kg.

IN-TMQ01: 0.0052, 0.0403, 0.0998 mg/kg.

Residues for the TTC approach were:

IN-UJV12: 0.0050 (3) mg/kg.

IN-TQD54: 0.0050 (2), 0.0060 mg/kg.

Radish root (Canada PBI 14 days, n=6)

Residues of fluazaindolizine were: 0.0048, 0.0072, 0.0178, 0.0179 (3) mg/kg.

Total residues for dietary risk assessment: 0.1583, 0.1628, 0.1662, 0.2472, 0.3127, 0.9322 mg/kg.

Residues for the TTC approach were:

IN-UJV12: 0.0050, 0.0050, 0.0178, 0.0179, 0.0179, 0.0245 mg/kg.

IN-TQD54: 0.0070, 0.0152, 0.0178, 0.0179, 0.0215, 0.2008 mg/kg.

Turnip roots (Canada PBI 14 days, n=5)

Residues of fluazaindolizine were: 0.0050, 0.0051, 0.0077, 0.0091, 0.0106 mg/kg.

Total residues for dietary risk assessment: 0.0539, 0.0610, 0.0650, 0.0799, 0.1090 mg/kg.

Residues for livestock dietary burden

[IN-F4106+1.068×IN-A5760]: 0.0140, 0.0141, 0.0142 (2), 0.0143 mg/kg.

IN-QZY47: 0.0107, 0.0159, 0.0179, 0.0279, 0.0470 mg/kg.

IN-TMQ01: 0.0050, 0.0051 (4) mg/kg.

Residues for the TTC approach were:

IN-UJV12: 0.0050, 0.0051 (4) mg/kg.

IN-TQD54: 0.0050, 0.0051 (4) mg/kg.

Radish and turnip roots had the highest fluazaindolizine residues of the root and tuber vegetable datasets available.

Based on radish data, the Meeting estimated a maximum residue level of 0.04 mg/kg, an STMR of 0.1935 mg/kg and a HR of 0.9322 mg/kg for fluazaindolizine in Group 16 root vegetables (except carrot)

For livestock dietary burden, the Meeting estimated, based on turnip data:

[IN-F4106+1.068×IN-A5760]: median and highest residues of 0.0142 and 0.0143 mg/kg, respectively.

IN-QZY47: median and highest residues of 0.0179 and 0.0470 mg/kg, repectively.

IN-TMQ01: median and highest residues of 0.0051 and 0.0051 mg/kg, respectively.

For TTC approach, the Meeting estimated based on radish data:

IN-UJV12: median and highest residues of 0.0178 and 0.0245 mg/kg, respectively.

IN-TQD54: median and highest residues of 0.0178 and 0.2008 (radish) mg/kg, respectively.

Group 17 Stalk and stem vegetables

Celery (Canada PBI 14 days, n=5):

Residues of fluazaindolizine were: 0.0050, 0.0051, 0.0087, 0.0091, 0.0197 mg/kg.

Total residues for dietary risk assessment: 0.0458, 0.0666, 0.0674, 0.1595, 0.8281 mg/kg.

The Meeting estimated a maximum residue level of 0.04 mg/kg, an STMR of 0.0674 mg/kg and a HR of 0.8281 mg/kg for fluazaindolizine in Group 17 Stalk and stem vegetables.

The Meeting agreed to extrapolate the conclusions to bulb vegetables and estimated a maximum residue level of 0.04 mg/kg, an STMR and HR of 0.0674 and 0.8281 mg/kg, respectively for Bulb vegetables.

For the TTC approach the Meeting also estimated:

IN-UJV12: 0.0050, 0.0051 (2), 0.0052, 0.0088 mg/kg, median of 0.0051 mg/kg and highest residues of 0.0088 mg/kg.

IN-TQD54: 0.0050, 0.0051 (2), 0.0052, 0.0121 mg/kg, median of 0.0051 mg/kg and highest residues of 0.0121 mg/kg.

Group 020 Cereal Grains

Field corn grain (Canada PBI 14 days, n=10)

Residues of fluazaindolizine were: 0.0050 (5), 0.0067 (4), 0.0068 mg/kg.

Total residues for dietary risk assessment: 0.0457, 0.0477, 0.0497, 0.0596, 0.0599, 0.0601 (2), 0.0607, 0.0654, 0.1015 mg/kg.

Residues for livestock dietary burden

[IN-F4106+1.068×IN-A5760]: 0.0139 (3), 0.0140, 0.0141, 0.0186, 0.0187, 0.0188 (2), 0.0190 mg/kg.

IN-QZY47: 0.0050 (3), 0.0052, 0.0063, 0.0067 (4), 0.0068, mg/kg.

IN-TMQ01: 0.0050, 0.0057, 0.0067 (4), 0.0068, 0.0086, 0.0117, 0.0181 mg/kg.

Residues for the TTC approach were:

IN-UJV12: 0.0050 (5), 0.0067 (4), 0.0068 mg/kg.

IN-TQD54: 0.0050 (3), 0.0067 (4), 0.0068, 0.0077, 0.0098 mg/kg.

Sorghum grain (Canada PBI 14 days, n=1)

Residues of fluazaindolizine were: 0.0178 mg/kg.

Total residues for dietary risk assessment: 0.1589 mg/kg.

Residues for livestock dietary burden

[IN-F4106+1.068×IN-A5760]: 0.0497 mg/kg.

IN-QZY47: 0.0178 mg/kg.

IN-TMQ01: 0.0178 mg/kg.

Residues for the TTC approach were.

IN-UJV12: 0.0178 mg/kg.

IN-TQD54: 0.0178 mg/kg.

Wheat grain (Canada PBI 14 days, n=13)

Residues of fluazaindolizine were: 0.0050 (4), 0.0051, 0.0070, 0.0072, 0.0073, 0.0073, 0.0076, 0.0178, 0.0179, 0.0179 mg/kg.

Total residues for dietary risk assessment: 0.0445, 0.0478, 0.0622, 0.0642, 0.0652, 0.0674, 0.0676, 0.1025, 0.1060, 0.1601 (2), 0.2517, 0.6799 mg/kg.

Residues for livestock dietary burden

[IN-F4106+1.068×IN-A5760]: 0.0139, 0.0140, 0.0141, 0.0143, 0.0194, 0.0201, 0.0204, 0.0205, 0.0212, 0.0480, 0.0497, 0.0501 (2) mg/kg.

Sweet corn (Canada PBI 14 days, n=10) Field corn, immature

Residues of fluazaindolizine were: 0.0050 (5), 0.0067 (4), 0.0068 mg/kg.

Total residues for dietary risk assessment: 0.0446 (2), 0.0450, 0.0465, 0.0540, 0.0596, 0.0599, 0.0601, 0.0607, 0.1401 mg/kg.

Residues for livestock dietary burden

[IN-F4106+1.068×IN-A5760]: 0.0139 (3), 0.0140, 0.0141, 0.0186, 0.0187, 0.0188, 0.0190, 0.0351 mg/kg.

IN-TMQ01: 0.0050 (3), 0.0062, 0.0067 (3), 0.0068, 0.0070, 0.0370 mg/kg.

Residues for the TTC approach were:

IN-UJV12: 0.0050 (5), 0.0067 (4), 0.0068 mg/kg.

IN-TQD54: 0.0050 (5), 0.0067 (3), 0.0068, 0.0471 mg/kg.

As there was only one trial on sorghum, the Meeting considered the wheat data to make the estimations for cereal grains

The Meeting estimated a maximum residue level of 0.03 mg/kg, and an STMR of 0.0676 mg/kg, for fluazaindolizine in Group 20 Cereal Grains

For livestock dietary burden, the Meeting estimated median residues of 0.0204 mg/kg for [IN-F4106+1.068×IN-A5760], of 0.0072 mg/kg for IN-QZY47 and of 0.0073 mg/kg for IN-TMQ01.

For TTC approach, the Meeting estimated median residues for IN-UJV12 of 0.0072 mg/kg and of 0.0073 mg/kg for IN-TQD54.

Group 023 Oilseeds

Rape seed (Canada PBI 14 days, n=5)

Residues of fluazaindolizine were: 0.0071, 0.0072, 0.0073, 0.0073, 0.0075 mg/kg.

Total residues for dietary risk assessment: 0.0631, 0.0642, 0.0656 (2), 0.0669 mg/kg.

Residues for livestock dietary burden.

[IN-F4106+1.068×IN-A5760]: 0.0198, 0.0201, 0.0205 (2), 0.0209 mg/kg.

IN-QZY47: 0.0071, 0.0072, 0.0073 (2), 0.0075 mg/kg.

IN-TMQ01: 0.0071, 0.0072, 0.0073 (2), 0.0075 mg/kg.

Residues for the TTC approach were:

IN-UJV12: 0.0071, 0.0072, 0.0073, 0.0073, 0.0075 mg/kg.

IN-TQD54: 0.0071, 0.0072, 0.0073, 0.0073, 0.0075 mg/kg.

Soya bean seed (dry) (Canada PBI 14 days, n=7)

Residues of fluazaindolizine were: 0.0050, 0.0050, 0.0050, 0.0051, 0.0073, 0.0178, 0.0178 mg/kg.

Total residues for dietary intake assessment: 0.0456, 0.0463, 0.0507, 0.0593, 0.1589 (2), 0.1974 mg/kg.

Residues for livestock dietary burden

[IN-F4106+1.068×IN-A5760]: 0.0139, 0.0140 (2), 0.0141, 0.0143, 0.0497 (2) mg/kg.

IN-QZY47: 0.0050 (3) 0.0051, 0.0053, 0.0178 (2) mg/kg.

IN-TMQ01: 0.0050 (4), 0.0051 0.0178 (2) mg/kg.

Residues for the TTC approach were.

IN-UJV12: 0.0050, 0.0050, 0.0050, 0.0050, 0.0051, 0.0178, 0.0178 mg/kg.

IN-TQD54: 0.0050, 0.0050, 0.0050, 0.0050, 0.0051, 0.0178, 0.0178 mg/kg.

Highest residues in soya bean, max of analytes for others

The Meeting estimated a maximum residue level of 0.04 mg/kg (based on soya beans) and an STMR of 0.0656 mg/kg (based on rape seed) for Oilseeds

For livestock dietary burden, the Meeting estimated, based on rape seed data, median residues of 0.0205 mg/kg for [IN-F4106+1.068×IN-A5760], of 0.0073 mg/kg for IN-QZY47 and of 0.0073 mg/kg for IN-TMQ01

For the TTC approach, the Meeting estimated, also based on rape seed data, median residues of 0.0073 mg/kg for IN-UJV12 and IN-TQD54.

Residues in animal feeds

All residues in forages and fodders discussed below were reported on an as received basis.

Legume forages

Bean vines (Canada PBI 14 days, n=2)

Fluazaindolizine: 0.0179, 0.0179 mg/kg.

[IN-F4106+1.068×IN-A5760]: 0.0501 (2) mg/kg.

IN-QZY47: 0.3136, 2.150 mg/kg.

IN-TMQ01: 0.0179 (2) mg/kg.

Residues for the TTC approach were:

Based on soya bean forage data, the Meeting estimated a median and highest residue of 0.0107 and 0.0178 mg/kg respectively, for fluazaindolizine in Legume forages (bean, cowpea, crown vetch, Lespedeza, pea, peanut, soya bean, trefoil and vetch).

The Meeting also estimated based on soya bean or pea data:

[IN-F4106+IN-A5760]: median of 0.0214 mg/kg (soya bean) and highest residue of 0.0509 mg/kg (pea)

IN-QZY47: median and highest residues of 0.1062 and 0.3391 mg/kg, respectively, based on soya bean

IN-TMQ01: median of 0.0072 mg/kg (pea) and highest residue of 0.0178 mg/kg (soya bean)

For TTC approach

IN-UJV12: median of 0.0178 mg/kg and highest residues of 0.0651 mg/kg, based on soya bean

IN-TQD54: median of 0.0072 mg/kg (pea) and highest residues of 0.0178 mg/kg (soya bean)

Legume fodder

Bean hay (Canada PBI 14 days, n=2)

Fluazaindolizine residues were: 0.0179, 0.0305 mg/kg.

IN-F4106+1.068×IN-A5760: 0.0501, 0.1073 mg/kg.

IN-TMQ01: 0.0179, 0.0179 mg/kg.

Residue for the TTC approach were:

IN-UJV12: 0.0323, 0.1971 mg/kg.

IN-TQD54: 0.0179, 0.0179 mg/kg.

Soya bean hay (Canada PBI 14 days, n=7)

Fluazaindolizine residues were: 0.0050, 0.0123, 0.0178, 0.0274, 0.0283, 0.0355, 0.0619 mg/kg.

IN-F4106+1.068×IN-A5760: 0.0156, 0.0539, 0.0571, 0.0660, 0.0733, 0.1047, 0.1889 mg/kg.

Pea hay (Canada PBI 14 days, n=11)

Fluazaindolizine residues were: 0.0049, 0.0051, 0.0073, 0.0118, 0.0182, 0.0188, 0.0194, 0.0318, 0.0491, 0.0548, 0.0848 mg/kg.

IN-F4106+1.068×IN-A5760: 0.0202, 0.0205, 0.0229, 0.0612, 0.1678, 0.1687, 0.1922, 0.1968, 0.3336, 0.4945, 0.8342 mg/kg.

IN-QZY47: 0.0072, 0.0078, 0.0279, 0.0296, 0.1144, 0.3012, 0.4005, 0.5121, 0.5662, 1.4933, 1.6035 mg/kg.

IN-TMQ01: 0.0049, 0.0051, 0.0071, 0.0072, 0.0073, 0.0073, 0.0110, 0.0114, 0.0116, 0.0118, 0.0305 mg/kg.

Residues for the TTC approach were:

IN-UJV12: 0.0071, 0.0072, 0.0073, 0.0073, 0.0303, 0.0462, 0.0710, 0.1438, 0.1452, 0.3478, 0.3559 mg/kg.

IN-TQD54: 0.0049, 0.0051, 0.0057, 0.0059, 0.0061, 0.0067, 0.0070, 0.0071, 0.0072, 0.0073, 0.0073 mg/kg.

Residues were highest in pea hay and soya bean hay.

Based on pea hay data, the Meeting estimated a maximum residue level of 0.17 mg/kg (dry weight basis) (assumed 88 percent dry matter) for fluazaindolizine in Legume fodders (bean, cowpea, crown vetch, Lespedeza, pea, peanut, soya bean, trefoil, vetch).

The Meeting also estimated, on a fresh weight basis:

Fluazaindolizine: median and highest residue of 0.0274 (soya bean) and 0.0848 (pea) mg/kg, respectively.

[IN-F4106+1.068×IN-A5760]: median and highest residues of 0.1687 and 0.8342 mg/kg, based on pea.

IN-QZY47: median and highest residues of 0.3296 (soya bean) and 1.6035 (pea) mg/kg,

IN-TMQ01: median and highest residues for of 0.0109 and 0.1150 mg/kg, based on soya bean

For the TTC approach

IN-UJV12: median and highest residues of 0.0669 (soya bean) and 0.3559 (pea) mg/kg

IN-TQD54: median and highest residues for of 0.0067 (pea) and 0.0200 (soya bean) mg/kg.

Cereal forages

Residues for the TTC approach were:

IN-UJV12: 0.0050, 0.0050, 0.0050, 0.0050, 0.0051, 0.0070, 0.0073, 0.0073, 0.0076, 0.0136, 0.0178, 0.0179, 0.0179 mg/kg.

IN-TQD54: 0.0488, 0.0650, 0.0672, 0.1211, 0.1233, 0.1735, 0.2204, 0.2269, 0.2688, 0.2991, 0.3027, 0.4622, 0.7526 mg/kg.

The number of residue trials on sorghum was too few to allow estimation of median and highest residues for sorghum fodder. Of the crops with sufficient trials, residues were highest in maize and wheat fodders.

Based on wheat data, the Meeting estimated a maximum residue level of 0.09 mg/kg (dry weight basis) (assumed 88 percent dry matter) for fluazaindolizine in cereal straw and fodder dry,

The Meeting also estimated, based on a fresh weight basis:

Fluazaindolizine: median and highest residues of 0.0073 and 0.0553 mg/kg respectively, based on wheat.

[IN-F4106+1.068×IN-A5760]: median and highest residues of 0.1328 and 0.5487 mg/kg, respectively, based on wheat.

IN-QZY47: median and highest residues of 0.0076 and 0.0315 mg/kg, respectively, based on wheat.

IN-TMQ01: median and highest residues of 0.1067 (maize) and 0.6133 (wheat) mg/kg, respectively.

Residues for the TTC approach were:

IN-UJV12: median and highest residues of 0.0073 (wheat) and 0.0384 (maize) mg/kg, respectively.

IN-TQD54: median and highest residues of 0.2204 and 0.8673 mg/kg, respectively, based on wheat.

Group 052A Miscellaneous Feed Products with high water (≥20 percent) content

Rape seed, forage (Canada PBI 14 days, n=5)

Fluazaindolizine residues found were: 0.0071, 0.0072, 0.0073, 0.0073, 0.0075 mg/kg.

IN-F4106+1.068×IN-A5760: 0.0198, 0.0201, 0.0205, 0.0205, 0.0209 mg/kg.

IN-TMQ01: 0.0071, 0.0072, 0.0073, 0.0073, 0.0079 mg/kg.

Residues for the TTC approach:

IN-UJV12: 0.0071, 0.0072, 0.0073, 0.0073, 0.0075 mg/kg.

IN-TQD54: 0.0071, 0.0072, 0.0081, 0.0130, 0.0319 mg/kg.

Based on rape forage data, the Meeting estimated for oilseed forages, all on a fresh weight basis:

Fluazaindolizine: median and highest residue of 0.0073 (and 0.0075 mg/kg respectively.

[IN-F4106+1.068×IN-A5760]: median and highest residues of 0.0205 and 0.0209 mg/kg, respectively.

IN-QZY47: median and highest residues of 0.0110 and 0.0462 mg/kg, respectively.

IN-TMQ01: median and highest residues of 0.0073 and 0.0079 mg/kg, respectively.

Residues for the TTC approach:

IN-UJV12: median and highest residues of 0.0073 and 0.0075 mg/kg, respectively.

IN-TQD54 and median and highest residues of 0.0081 and 0.0319 mg/kg, respectively.

Group 052B Miscellaneous Feed Products with low water (<20 percent) content (hay, straw)

Rape seed, straw (Canada PBI 14 days, n=5)

Fluazaindolizine residues found were: 0.0073, 0.0073, 0.0075, 0.0170, 0.0251 mg/kg.

IN-F4106+1.068×IN-A5760: 0.0245, 0.0270, 0.0442, 0.0455, 0.2330 mg/kg.

IN-QZY47: 0.0073, 0.0129, 0.0181, 0.0219, 0.0777 mg/kg.

IN-TMQ01: 0.0072, 0.0073, 0.0073, 0.0190, 0.0210 mg/kg.

Residues for the TTC approach:

IN-UJV12: 0.0072, 0.0073, 0.0088, 0.0094, 0.0608 mg/kg.

IN-TQD54: 0.0266, 0.0731, 0.1018, 0.1084, 0.2968 mg/kg.

The Meeting estimated a maximum residue level of 0.05 mg/kg (dry weight basis) for Oilseed fodders.

The Meeting also estimated, on fresh weight basis, for: Fluazaindolizine: median and highest residue of 0.0075 and 0.0251 mg/kg, respectively.

[IN-F4106+1.068×IN-A5760]: median and highest residues of 0.0442 and 0.2330) mg/kg, respectively.

IN-QZY47: median and highest residues of 0.0181 and 0.0777) mg/kg, respectively.

IN-TMQ01: median and highest residues of 0.0073 and 0.0210 mg/kg, respectively.

Residues for the TTC approach:

IN-UJV12: median and highest residues of 0.0088 and 0.0608) mg/kg , respectively.

IN-TQD54: median and highest residues of 0.1018 and 0.2968 mg/kg, respectively.

Fate of residues during processing

The Meeting received information on the fate of fluazaindolizine residues during conditions simulating commercial processing.

The hydrolytic stability of fluazaindolizine, was studied in sterile aqueous buffers at pH 4 at 90 °C for 20 minutes, pH 5 at 100 °C for 60 minutes and pH 6 at 120 °C for 20 minutes. Fluazaindolizine was not degraded and is hydrolytically stable under conditions simulating pasteurization (pH 4, 90 °C), baking/brewing/boiling (pH 5, 100 °C) and sterilization (pH 6, 120 °C).

Information on the fate of residues during processing was made available to the Meeting for strawberries, tomatoes, potatoes, soya beans, maize and wheat. In some cases residues for individual compounds were <LOQ and processing factors could not be calculated. In these cases residues are assumed to be zero.

Processing factors (PF) are estimated by dividing the residues of analyte in processed commodity by the sum of potential source residues in the raw commodity, expressed in terms of analyte.

The Table 1 summarises the processing factors for fluazaindolizine. Residues concentrated (PF> 1) on processing for dried tomato, tomato wet pomace, tomato paste and soya bean meal.

Table 192 Processing factors and median and highest residue values for fluazaindolizine used for estimation of maximum residue levels including livestock dietary burdens

Processed commodity	Raw commodity [median residue]	Raw commodity [highest residue]	Individual processing factors	Median or best estimate processing factor	Median residue-P (mg/kg)	Highest residue-P (mg/kg)
Tomato dried	0.01	0.0665	1.8 4.9	3.35	0.0335	0.2228
Tomato canned			0 0.22	0.11	0.0011	
Tomato juice			0 0.53	0.265	0.0026	
Tomato wet pomace			1 2.4	1.7	0.017	
Tomato paste			1.2 1.3	1.25	0.0125	
Tomato purée			0.53 0.8	0.665	0.0066	
Potato , flakes/granules	0.028	0.16	0 0.07	0.035	0.001	
Potato crisps			0.03 0.18	0.105	0.0029	
French fries peeled			0 0.04	0.02	0.0006	

Processed commodity	Raw commodity [median residue]	Raw commodity [highest residue]	Individual processing factors	Median or best estimate processing factor	Median residue-P (mg/kg)	Highest residue-P (mg/kg)
French fries unpeeled			0.08 0.91	0.495	0.01386	
Potato boiled unpeeled			0.07 0.15	0.11	0.00308	0.0176
Potato boiled peeled			0 0.02	0.01	0.00028	0.0016
Potato microwaved unpeeled			0.4 1.3	0.85	0.0238	0.1615
Soya bean meal (mechanically extracted)	0.0051		1.3 1.3 1.6	1.3	0.0066	
Soya bean meal (solvent extracted)			1.3 1.4 1.4	1.4	0.0071	
Soya bean hulls			0.9 0.9 1.7	0.9	0.0046	
Soya bean refined oil			0 0 0	0	0	

Using the estimated maximum residue level of 0.15 mg/kg for tomatoes and applying the processing factor of 3.35 for dried tomato, the Meeting estimated a maximum residue level of 0.5 mg/kg for tomato dried.

Inputs for estimation of dietary exposure are required for processed commodities. Table 3 summarises estimated STMR-P and HR-P values, calculated using information on the concentration of the relevant compounds on processing also summarised in the series of tables on processing that follow. The STMR-P and HR-P values were calculated as 2.26×IN-A5760+2.11×IN-F4106+1.52×IN-QZY47+1.51×IN-TMQ01.

Residues in animal commodities

The dietary risk assessment definition for animal commodities includes fluazaindolizine, IN-A5760, IN-F4106 and IN-TMQ01.

Farm animal feeding studies

The Meeting received a study on the transfer of fluazaindolizine to cow tissues and milk. Dairy cows were oral dosed once daily with fluazaindolizine at the equivalent of 2.3, 6.7 and 20.3 ppm in the feed for 28 days, with sacrifice 22–24 hours after the last dose.

Residues of fluazaindolizine in milk were <LOQ for the 2.3 ppm dose group, with the exception of one day-24 sample with residues of 0.01 mg/kg; however, fluazaindolizine in milk was quantifiable (≥ 0.01 mg/kg) in milk from the 6.7 and 20.3 ppm dose groups.

Fluazaindolizine residues in milk plateaued by day three, with average residues of 0.020 and 0.066 mg/kg, respectively, for the 6.7- and 20.3-ppm dose groups (milk samples from day 3–28). Fluazaindolizine residues in skim milk and cream were generally similar to or slightly lower than residue levels in whole milk. Mean fluazaindolizine residues were 0.020 mg/kg in milk, < 0.01 mg/kg in muscle, 0.020 mg/kg in fat, 0.021 mg/kg in liver and 0.091 mg/kg in kidney for the 6.7 ppm dose group. Maximum fluazaindolizine residues were <0.01 mg/kg in muscle, 0.022 mg/kg in fat, 0.023 mg/kg in liver and

0.096 mg/kg in kidney for the 6.7 ppm dose group. Mean residues in tissues showed a linear relationship with dose. Once dosing stopped, residues declined with a DT_{50} of < 0.5 days.

Residues of IN-REG72, IN-F4106, IN-A5760, IN-RYC33, and IN-R2W56 were not detected (< 0.003 mg/kg) in whole milk, skim milk, cream, and tissue samples, with the exception of IN-F4106 in cows dosed with fluazaindolizine – 6.7 ppm dose group < 0.01 mg/kg kidney, 20.3 ppm dose group < 0.01 mg/kg liver; 0.01 mg/kg kidney. IN-QEK31 was ≤ 0.01 mg/kg in all samples of milk, skim milk and cream.

In another study, lactating cows were dosed orally once daily with IN-QEK31 for 28 days at the equivalent of 19.5 ppm in the feed. IN-QEK31 was detected at above 0.01 mg/kg (LOQ) in milk and tissues. Residues in milk appeared to reach a plateau at 3 days of dosing. Mean IN-QEK31 residues were 0.203 mg/kg in milk, < 0.01 mg/kg in muscle, < 0.01 mg/kg in fat, 0.013 mg/kg in liver and 0.13 mg/kg in kidney. Maximum IN-QEK31 residues were < 0.01 mg/kg in muscle, < 0.01 mg/kg in fat, 0.016 mg/kg in liver and 0.19 mg/kg in kidney. Once dosing stopped, residues declined with a DT_{50} of <1.2 days.

IN-A5760 and IN-F4106 residues in tissues and milk may arise from feeding IN-A5760 and IN-F4106, from feeding IN-QZY47 or from feeding IN-TMQ01. Metabolism studies are available to allow estimation of the contribution from the various sources. IN-TMQ01 residues arise from the feeding of IN-TMQ01.

Farm animal dietary burden

Inputs for the livestock dietary burdens were obtained from primary treated crops (carrot culls, tomato pomace, potato culls) and from residues in rotational crops (cereal and legume forages, cereal and legume fodders, cereal grain and pulse seeds, oilseed fodder, kale, cabbage leaves, turnip roots and by-products from processing).

Dietary burdens were calculated for beef cattle, dairy cattle, broilers and laying poultry based on feed items evaluated by the JMPR by the current Meeting. The dietary burdens, estimated using the most recent version of the OECD livestock dietary burden calculator, are presented in Annex 6 and summarised below.

Separate feeding studies were carried out in lactating cattle with fluazaindolizine and IN-QEK31 to determine residues. Metabolism studies in lactating goats were available for IN-QEK31, IN-QZY47, IN-TMQ01. For laying hens, metabolism studies were available for fluazaindolizine and IN-QEK31. The livestock dietary burdens were calculated separately for components required for dietary risk assessment:

- Fluazaindolizine;
- the sum of IN-F4106+1.068×IN-A5760
- IN-QZY47;
- IN-TMQ01;

In addition, livestock burdens were calculated for compounds being assessing using the TTC approach:

- IN-UJV12;
- IN-TQD54.

Inputs for the livestock dietary burdens were obtained from primary treated crops (carrot culls, tomato pomace, potato culls) and from residues in rotational crops (cereal and legume forages, cereal and legume fodders, cereal grain and pulse seeds, oilseed fodder, kale, cabbage leaves, turnip roots).

Residues in animal commodities from the fluazaindolizine transfer studies with lactating cows and laying hens were used in estimating maximum residue levels.

Table 199 Estimated maximum and mean dietary burdens of farm animals (fluazaindolizine)

	Animal dietary burden: fluazaindolizine, ppm of dry matter diet							
	United States-Canada		European Union		Australia		Japan	
	Max	Mean	Max	Mean	Max	Mean	Max	Mean
Beef cattle	0.27	0.05	0.57	0.11	0.38	0.10	0.04	0.01
Dairy cattle	0.32	0.06	0.57 ❶ ❷	0.10	0.35	0.11 ❸ ❹	0.07	0.02
Broilers	0.01	0.002	0.23	0.02	0.01	0.01	0.01	-
Layers	0.01	0.002	0.28 ❺	0.04❻	0.01	0.01	0.01	-

Notes:

❶ Highest maximum beef or dairy cattle dietary burden suitable for HR estimates for mammalian tissues.

❷ Highest maximum dairy cattle dietary burden suitable for HR estimates for mammalian milk.

❸ Highest mean beef or dairy cattle dietary burden suitable for STMR estimates for mammalian tissues.

❹ Highest mean dairy cattle dietary burden suitable for STMR estimates for milk.

❺ Highest maximum poultry dietary burden suitable for HR estimates for poultry tissues and eggs.

❻ Highest mean poultry dietary burden suitable for STMR estimates for poultry tissues and eggs.

Additionally, metabolism studies with the various compounds were used to estimate the source of these compounds to the residues for dietary risk assessment.

Table 200 Estimated maximum and mean dietary burdens of farm animals (sum of IN-F4106+1.068×IN-A5760)

	Animal dietary burden: sum of IN-F4106+1.068×IN-A5760, ppm of dry matter diet							
	United States-Canada		European Union		Australia		Japan	
	Max	Mean	Max	Mean	Max	Mean	Max	Mean

Animal commodity maximum residue levels

Cattle

The calculations used to estimate highest residues for use in estimating maximum residue levels, STMR and HR values are shown below.

Table 205 Animal commodity maximum residue levels for cattle

	Feed Level (ppm) for milk residues	Fluazaindolizine residues (mg/kg) in milk	Feed Level (ppm) for tissue residues	Fluazaindolizine residues (mg/kg)			
				Muscle	Liver	Kidney	Fat
Highest residue for maximum residue level estimation (beef or dairy cattle)							
Feeding Study	6.7	0.0199	6.7	< 0.01	0.0233	0.0957	0.0217
Dietary burden and estimate of highest residue	0.57	0.0017	0.57	0.00085	0.0020	0.0081	0.0018
Median Determination (beef or dairy cattle)							
Feeding Study	6.7	0.0199	6.7	< 0.01	0.0223	0.0912	0.0195
Dietary burden and estimate of median residue	0.11	0.00033	0.11	0.00016	0.00037	0.0015	0.00032

The Meeting estimated the following maximum residue levels: milk 0.01(*) mg/kg; meat (mammalian except marine mammals) 0.01(*) mg/kg, mammalian fat (except milk fat) 0.01(*) mg/kg and edible offal 0.01 mg/kg.

To estimate HR and STMR values for animal commodities, the residues in the following tables are combined according to the residue definition for risk assessment (total = fluazaindolizine + 2.11×(IN-F4106+1.068×IN-A5760) + 1.51×IN-TMQ01).

The Meeting estimated STMRs for fluazaindolizine of 0.0096 mg/kg in mammalian muscle, of 0.0098 mg/kg in mammalian fat, of 0.2217 in mammalian offal (based on liver) and of 0.0033 mg/kg in milk

The Meeting estimated HRs of 0.0415 mg/kg in mammalian muscle, 0.0431 mg/kg in mammalian fat and 0.7592 mg/kg in mammalian offal (based on kidney).

Residues of the fluazaindolizine were similar in milk fat compared to whole milk. Using this information, the Meeting estimated a maximum residue level of 0.01(*) mg/kg for milk fat and an STMR value of 0.0033 mg/kg.

Extrapolation of residues in the IN-QZY47 metabolism study with a lactating goat were used to estimate residues of IN-F4106 and IN-A5760.

Table 206 Residues of IN-F4106+1.068×IN-A5760 from feeding IN-F4106+1.068×IN-A5760

	Feed Level (ppm) for milk residues	IN-F4106+ 1.068×IN-A5760 (mg eq/kg) in milk	Feed Level (ppm) for tissue residues	IN-F4106+1.068×IN-A5760 residues (mg/kg)

RECOMMENDATIONS

On the basis of the data obtained from supervised trials, the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessments.

Definition of the residue for compliance with the MRL for plant and animal commodities: *fluazaindolizine*.

Definition of the residue for dietary risk assessment for plant commodities:

fluazaindolizine, and free and conjugated forms of the following compounds: 2-chloro-5-hydroxybenzenesulfonamide (IN-A5760), 2-chloro-5-methoxybenzenesulfonamide (IN-F4106), 8-chloro-6-(trifluoromethyl)imidazo[1,2-a]pyridine-2-carboxylic acid (IN-QEK31), 3-[[(2-chloro-5-methoxyphenyl)sulfonyl]amino]-L-alanine (IN-QZY47), 8-chloro-N-[(2-chloro-5-hydroxyphenyl)sulfonyl]-6-

(trifluoromethyl)imidazo[1,2-a]pyridine-2-carboxamide (IN-REG72), 8-chloro-6-(trifluoromethyl)imidazo[1,2-a]pyridine-2-carboxamide (IN-RYC33) and 3-[[(2-chloro-5-methoxyphenyl)sulfonyl]amino]-(2R)-hydroxypropanoic acid (IN-TMQ01) (expressed as fluazaindolizine). *This can be implemented by taking the maximum of the sum of compounds containing the imidazopyridine ring and hydrolysed using acid to IN-A5760, IN-F4106, IN-QZY47 and IN-TMQ01 (expressed as fluazaindolizine)* ***OR*** *compounds containing the phenyl ring and hydrolysed to 8-chloro-6-(trifluoromethyl)imidazo[1,2-a]pyridine-2-carboxylic acid (IN-QEK31) (expressed as fluazaindolizine).*

Definition of the residue for dietary risk assessment for animal commodities: the sum of fluazaindolizine, 2-chloro-5-hydroxybenzenesulfonamide (IN-A5760), 2-chloro-5-methoxybenzenesulfonamide (IN-F4106), and 3-[[(2-chloro-5-methoxyphenyl)sulfonyl]amino]-(2R)-hydroxypropanoic acid (IN-TMQ01) (expressed as fluazaindolizine).

The residue is not fat-soluble.

Table 217 Residue levels suitable for establishing maximum residue limits and for IEDI and IESTI assessments

CCN	Commodity	Recommended Maximum residue level (mg/kg)		STMR or STMR-P mg/kg	HR or HR-P mg/kg

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The ADI for fluazaindolizine is 0–0.3 mg/kg bw. The International Estimated Daily Intakes (IEDIs) for fluazaindolizine were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the JMPR. The results are shown in Annex 3 of the 2022 JMPR Report.

The IEDIs ranged from 0–1 percent of the maximum ADI.

Acute dietary exposure

The ARfD for fluazaindolizine is 1 mg/kg bw. The International Estimate of Short-Term Intakes (IESTIs) for fluazaindolizine were calculated for the food commodities and their processed commodities for which HRs/HR-Ps or STMRs/STMR-Ps were estimated by the present Meeting and for which consumption data were available. The results are shown in Annex 4 of the 2022 JMPR Report.

The IESTIs varied from 0–9 percent of the ARfD for children and 0–5 percent of the ARfD for the general population. The Meeting concluded that acute dietary exposure to residues of fluazaindolizine from uses considered by the present Meeting is unlikely to present a public health concern.

Threshold of toxicological concern (TTC) consideration for metabolites

The Meeting agreed that metabolites IN-UJV12 and IN-TDQ54 could be assessed using the TTC approach (Cramer Class III threshold of 1.5 µg/kg bw per day).

The current Meeting estimated dietary exposures of 0.14–0.30 µg/kg bw per day for IN-UJV12 and of 0.15–0.44 µg/kg bw per day for IN-TQD54.

The Meeting concluded that the estimated dietary exposures to residues of IN-UJV12 and IN-TQD54 from uses considered by the JMPR are below the TTC for Cramer Class III compounds and are unlikely to present a public health concern. Should further uses be considered in the future, these conclusions may need to be re-evaluated.

FLUDIOXONIL (211)

First draft prepared by M. Le, Pest Management Regulatory Agency, Canada

EXPLANATION

Fludioxonil is a phenylpyrrole fungicide that was reviewed by the JMPR in 2004 (T, R), 2010 (R), 2012 (R), 2013 (R), and 2018 (R). The 2004 Meeting established and ADI of 0–0.4 mg/kg bw and decided that an ARfD was not necessary.

The residue definition for compliance with the MRLs and estimation of dietary intake in plant commodities is *fludioxonil*. The residue definition for compliance with the MRLs and estimation of dietary intake in animal commodities is the *sum of fludioxonil and its benzopyrrole metabolites, determined as 2,2-difluorobeno[1,1]dioxole-4-carboxylic acid and expressed as fludioxonil*. The residue is fat-soluble.

Fludioxonil was listed by the Fifty-second Session of CCPR for the evaluation of additional uses by the 2022 JMPR. Residue data for analytical methods, supervised residue trials, and processing studies for banana, mango, papaya, beans with pods, dry beans, dry peas, sugar beets, and tree nuts were submitted to the present Meeting.

RESIDUE ANALYSIS

Analytical methods

Method REM 133.06

Method REM 133.06 was reviewed by the 2012 JMPR and determined to be suitable for the analysis of fludioxonil in orange, kiwi, lettuce, wheat (grain, straw), grape, wine, sunflower seed, and mango, with an LOQ of 0.01 mg/kg in all crop matrices tested. In the current evaluation, Method REM 133.06 was used for the analysis of fludioxonil residues in banana, mango, papaya, fresh beans with pods, dry pea, and sugar beet matrices from the submitted supervised residue trials.

Method validation and concurrent recoveries of fludioxonil submitted to the current Meeting, from banana, mango, papaya, fresh beans with pods, dry pea, and sugar beet matrices, were determined at fortifications ranging from 0.01 mg/kg up to 40 mg/kg. Adequate recoveries (mean 76–108 percent) were demonstrated at all fortification levels in all matrices. Relative standard deviations (RSDs) were ≤ 15 percent in all matrices indicating that repeatability was also acceptable.

The method was adequately validated at an LOQ of 0.01 mg/kg for residues of fludioxonil in all matrices. Although there were a low number of samples at each fortification level in fresh beans with pods, at the highest fortification level in dry peas, and in numerous sugar beet matrices, Method REM 133.06 has been adequately validated in matrices from each of the five OECD commodity categories.

Method AG-597B

Method AG-597B was reviewed by the 2004 and 2006 JMPR and determined to be suitable for the analysis of fludioxonil in plant materials, with LOQs ranging from 0.008–0.05 mg/kg. In the current evaluation, Method AG-597B was used for the analysis of fludioxonil residues in dry edible beans and tree nuts from the submitted supervised residue trials.

Method validation and concurrent recoveries of fludioxonil submitted to the current Meeting, from dry edible beans were determined at fortifications ranging from 0.0033 mg/kg up to 0.4 mg/kg, in almond and pecan nutmeat at fortifications ranging from 0.01 mg/kg up to 0.50 mg/kg, and in almond

hulls at fortifications ranging from 0.01 mg/kg up to 10 mg/kg. Adequate recoveries (mean 96–117 percent) were demonstrated at all fortification levels in all matrices. Relative standard deviations (RSDs) were within the acceptable range for each fortification level indicating that repeatability was also acceptable.

The method was adequately validated at an LOQ of 0.01 mg/kg for residues in fludioxonil in dry edible beans, almond nutmeat, pecan nutmeat, and almond hulls. Although method validation data was conducted in dry edible beans at a fortification level of 0.003 mg/kg, given the limited number of samples validated at this level (i.e. n=3), the Meeting has determined that the LOQ for in dry edible beans using Method AG-597B is 0.01 mg/kg for residues of fludioxonil (n = 6). Although there were a low number of samples at most of the fortification levels in dry edible beans, at the higher fortification levels in almond nutmeat and hulls, and in almond processed commodities, Method AG-597B has been adequately validated in numerous matrices from each of the five OECD commodity categories.

Recovery data for all of the analytical methodsused to analyse samples from the supervised residue trials for fludioxonil reviewed by the current Meeting are summarized below.

Table 1 Summary of method validation (MV) and concurrent recovery (CR) data for fludioxonil from plant matrices.

Commodity	Analyte	Fortification level (mg/kg)	n	Recoveries (%)	Mean Recovery (%)	RSD (%)	Reference

Notes:

n = Number of replicates; RSD = relative standard deviation.

[A] In this study two MRM transitions were monitored for fludioxonil in each matrix tested. The 1st MRM is for quantitation while the second MRM was confirmatory.

STABILITY OF RESIDUES IN STORED ANALYTICAL SAMPLES

The stability of residues in samples during frozen storage was evaluated by the 2004 and 2010 JMPR in a range of commodities. Residues of fludioxonil are stable under freezer storage conditions for at least:

- 24 months in cereal (grain and straw), apples, tomatoes, fresh peas, rapeseed, maize (forage, grain, ears), sorghum hay, and potato tubers.

- 27 months in maize meal and potato flakes; 29 months in grapes.
- 427 days (~14 months) in whole grapefruit, 289 days (~9.5 months) in canned lemon juice, 303 days (~9.9 months) in lemon pulp, 312 days (~10.2 months) in sweet potato, and 159 days (approximately 5.2 months) in yam.

The stability data covered commodities that are representative of high water content (apples, tomatoes, fresh peas, maize forage, maize ears), high oil content (rapeseed), high starch content (cereal grain, maize grain, potato tubers, potato flakes, sweet potato, yam), and high acid content (grapes, whole grapefruit, canned lemon juice, lemon pulp) and can be extrapolated to the commodities considered at the current Meeting. Storage stability data are not available for any high protein content commodity, however it is noted that stability of fludioxonil was observed in cereal straw and sorghum hay (i.e. commodities that do not fall into any of the 5 OECD commodity categories) for at least 24 months.

Maximum storage to analysis intervals for samples from the submitted supervised field trials were: 5.3 months for bananas, 2.7 months for mangoes, 2.9 months for papayas, 13 months for beans with pods, 1.5 months for dry beans, 8.2 months for dry peas, 8.7 months for sugar beet roots and processed commodities, 3.0 months for pecan nutmeat, 10.4 months for almond nutmeat, 10.8 months for almonds hulls, and 1.7 months for almond processed commodities (i.e. roasted nutmeats and oil). The periods of demonstrated stability cover the frozen storage intervals used in the residue studies on crops.

USE PATTERN

The registered uses of fludioxonil relevant to the supervised residue studies made available to the current Meeting are summarized in Table 2.

Table 2 Registered uses of fludioxonil

Crop	Country	Form.	Application						PHI (days)
			Method, GS/Timing	Max. No.	Rate/ application	Interval (days)	Water (L/ha)	Max. Rate/ season	
006B Assorted tropical and sub-tropical Inedible Smooth Peel - Large									
Banana	Columbia	SC	Spray, Post-harvest	1	15–20 g ai/hL[A]	-	-	20 g ai/hL	-
Mango, papaya	Brazil	SC	Dip[B] or spray[C], Post-harvest	1	60–120 g ai/hL	-	-	120 g ai/hL	-
014 Legume Vegetables									
Peas, beans, fresh with pods	Latvia	WG	Foliar. Spray as a preventative measure in conditions favourable to the spread of disease.	3	250 g ai/ha	10–14	400–800	750 g ai/ha	14
Succulent beans[D]	Canada	WG	Foliar. Begin applications prior to or at the onset of disease.	3	194–244 g ai/ha	7	175–225	730 g ai/ha	7
015 Pulses									
Peas, beans, for dry consumption	Latvia	WG	Foliar. Spray as a preventative measure in conditions favourable to the spread of disease.	2	250 g ai/ha	10	400–800	500 g ai/ha	28
Dried shelled pea and bean (except soybean)[E]	Canada	WG	Foliar. Begin applications prior to or at the onset of disease.	3	194–244 g ai/ha	7	175–225	730 g ai/ha	7
016A Root Vegetables									
Sugar beets	United States	SC	In-line aqueous spray. Post-harvest	1	4.5 g ai/1000 kg of roots	-	0.2 L/kg	4.5 g ai/1000 kg of roots	-

Crop	Country	Form.	Application						PHI (days)
			Method, GS/Timing	Max. No.	Rate/ application	Interval (days)	Water (L/ha)	Max. Rate/ season	
02 Tree Nuts									
Tree Nuts[F]	United States	WG	Foliar. Make first application during early bloom. Repeat if conditions remain favourable for disease development.	4[G]	247 g ai/ha	14	≥ 187 (air); ≥ 94 (ground)	1009 g ai/ha	14

Notes:

Form = Formulation, NS = not specified.

[A] Use the lower rate when transport of fruit in shipments for a duration of < 15 days and the higher rate when duration is > 15 days.

[B] Use an equipment that allows complete immersion of the fruits in a water solution containing fludioxonil for 2 minutes. Then, move the fruits to a drying chamber.

[C] Ensure a homogeneous and uniform coverage of the fruits with an application system located within the process line, containing a closed chamber, through which the fruits pass, using controlled flow nozzles, avoiding leaks from the application chamber. Then, move the fruits to a drying chamber.

[D] Bean (*Phaseolus* spp.) (includes lima bean, snap bean and wax bean), Bean (*Vigna* spp.) (includes blackeyed pea, asparagus bean), Broad bean (fava bean) (*Vicia faba*).

[E] Chickpea (garbanzo bean) (*Cicer arietinum*), beans (*Lupinus* spp. including grain lupin, sweet lupin, white lupin, white sweet lupin), beans (*Phaseolus* spp. including field bean, kidney bean, lima bean (dry), navy bean, pinto bean, tepary bean), broad bean (fava bean) (*Vicia faba*), beans (*Vigna* spp. adzuki bean, black-eyed pea, catjang, cowpea, Crowder pea, moth bean, mung bean, rice bean, southern pea, urd bean); Guar (*Cyamopsis tetragonoloba*); Lablab bean or Hyacinth bean (*Lablab purpureus*); Lentil (Lens esculenta); Pea (*Pisum* spp.) (includes field pea); Pigeon pea (*Cajanus cajan*)

[F] African nut-tree; almond; beechnut; Brazil nut; Brazilian pine; bunya; bur oak; butternut; Cajou nut; candlenut; cashew; chestnut; chinquapin; coconut; coquito nut; dika nut; ginkgo; Guiana chestnut; hazelnut (filbert); heartnut; hickory nut; Japanese horse-chestnut; macadamia nut; mongongo nut; monkey-pot; monkey puzzle nut; Okari nut; Pachira nut; peach palm nut; pecan; pequi; Pili nut; pine nut; pistachio; Sapucaia nut; tropical almond; walnut, black; walnut, English; yellowhorn; cultivars, varieties, and/or hybrids of these

[G] Make no more than 2 applications by air, the rest by ground.

RESULTS OF SUPERVISED RESIDUE TRIALS ON CROPS

The Meeting received information on supervised field trials for fludioxonil on the following crops or crop groups:

Crop	Table No.
Assorted tropical and sub-tropical Inedible Smooth Peel - Large	
Banana	3
Mango	4
Papaya	5
Legume Vegetables	
Beans with pods	6
Pulses	
Dry beans	7
Dry peas	8

Crop	Table No.
Root Vegetables	
Sugar beets	9
Tree nuts	
Almonds and Pecans	10
Animal feeds	
Bean forage	11
Almond hulls	12

Residue values from the trials conducted according to the critical GAP (or a suitable alternative GAP) have been used for the estimation of maximum residue levels, STMR, and HR (where applicable). Those results included in the evaluation as adequately supporting the GAP are underlined. Non quantifiable residues are shown as below the reported LOQ (e.g. < 0.02 mg/kg). Where multiple analyses were conducted on a single sample, the average value is reported. Where multiple samples were taken from a single plot, the individual and average values are reported. For all trials except citrus fruits (which had two treated samples), only a single composite treated sample was analysed.

Banana

			Pulp	0.0166, 0.0199 [0.018]
Sto. Domingo, Monterrey, Ecuador, 2016, Cavendish	Post-harvest/ Mature Commercial Harvest	20	Whole fruit	0.660, 1.01 [0.84]
			Pulp	0.0129, 0.0180 [0.015]
Los Rios, Valencia 2016, Ecuador, Valery	Post-harvest/ Mature Commercial Harvest	20	Whole fruit	1.29, 1.02 [1.2]
			Pulp	0.0186, <0.01 [<0.014]

Notes:

[A] A backpack sprayer was used to spray the hands of fruit for approximately 2 to 4 minutes to ensure thorough coverage of the fruit (simulating commercial processes).

[B] Hands of bananas were dipped into the treatment solution for approximately 30 seconds. Fruit were removed from the solution, placed on a tray, and allowed to air dry for several minutes up to one hour.

Mango

Table 4 Residues of fludioxonil (mg/kg) in mango following post-harvest application of fludioxonil in an SC-formulation (Pereira, 2020, LBS19053)

			42	16.04, 21.00 [19]	0.02, 0.02 [0.02]	3.76, 4.97 [4.4]

Notes:

[A] Dipped for about 120 seconds.

[B] After the post-harvest treatments (dip or spray), the fruits were sprayed with carnauba wax.

[C] Storage period = Days after post-harvest treatment. Samples were stored in a cold room prior to being sub-sampled into peel and pulp samples and frozen.

[D] The amount of residues in whole fruit was calculated as follows: [(weight of the pulp sample × residue found in the pulp sample) + (weight of peel sample × residue found in the peel sample)] / weight of the whole fruit sample. The weight of the whole fruit sample was calculated as follows: weight of the pulp sample + weight of peel sample + weight of seeds.

[E] The trials conducted in Juazeiro, Bahia, Brazil were treated in different facilities on different days and separate treatment mixtures were prepared at each site. As such the trials are considered independent for the purposes of estimating maximum residue levels.

Notes:

[A] Dipped for about 120 seconds.

[B] After the post-harvest treatments (dip or spray), the fruits were sprayed with carnauba wax.

[C] Storage period = Days after post-harvest treatment. Samples were stored in a cold room prior to being sub-sampled into peel and pulp samples and frozen.

[D] The amount of residues in whole fruit was calculated in the study report as follows: [(weight of the pulp sample × residue found in the pulp sample) + (weight of peel sample × residue found in the peel sample)] / weight of the whole fruit sample. The weight of the whole fruit sample was calculated as follows: weight of the pulp sample + weight of peel sample. Since the weight of the whole fruit sample did not take into account the weight of the seed, the residue values reported in the study were recalculated to include the weight of the seed (i.e. weight of the whole fruit sample = weight of the pulp sample + weight of peel sample + weight of seeds).

Fresh beans with pods

FATE OF RESIDUES IN STORAGE AND PROCESSING

Residues after processing

Sugar Beets

A processing trial on sugar beets was conducted in the United States in 2015 (Shepard, 2017, TK0044248). Fludioxonil, formulated as a SC (containing 235.9 g ai/L) was applied as a post-harvest spray to sugar beet roots at a rate of 4.7 g ai/1000 kg roots. The sugar beet roots were allowed to dry for about 2–3 hours prior to collection. The roots were quartered prior to placing samples in the bag to reduce the size of the beets for grinding purposes. The sugar beet samples were processed to generate raw juice, thick juice, raw sugar, refined sugar, molasses, wet pulp, ensiled pulp, dried pulp, pressed pulp, and press water using methods which are representative of commercial practice.

Sugar beets (~39 kg) were cleaned prior to processing and then sliced in a Hobart food chopper to form the cossettes. Cossettes were exposed to 88–92 °C water for 30–45 seconds and then diffused in 5 kettles in a 68–74 °C water bath for at least 9 minutes in each kettle. After diffusion, the raw juice was screened through a mesh sieve. Raw juice and wet pulp fractions were collected.

Diffused cossettes were then dewatered (pressed) in a filter bag and hydraulic press and pressed pulp fractions were collected. A portion of the pressed pulp was collected for ensiling. Dried beet pulp was produced by drying the remaining dewatered material in an oven at 54–71 °C until a final moisture content of 15 percent or less. Dried pump samples were collected.

In the first phosphatization step, raw juice from the dewatering process was screened through a mesh sieve and press water fractions were collected. Raw juice was mixed and heated to 79–85 °C and the pH was adjusted with calcium oxide solution to approximately 10.5. If the pH was above 11.2 it was lowered with 3M phosphoric acid. A precipitate/mud was formed and centrifugation was used to separate the mud and juice. In the second phosphatization step, the juice was again mixed and heated to 79–85 °C and the pH was reduced to 9.1–9.3 with 3M phosphoric acid and then centrifuged and vacuum filtered to separate the mud and clear/thin juice. The thin juice was mixed and heated to 79–85 °C, the pH was reduced to 8.8–9.0 with sodium bisulfite, and was evaporated under vacuum until the juice was 50–60 percent solids (thick juice). Temperature was maintained below 85 °C and after evaporation the thick juice was filtered using cotton and fractions of thick juice were collected.

The thick juice was evaporated under vacuum until a 70–80 percent solids juice (syrup) was achieved. A solution of white sugar was added to the juice to begin crystallization. The solution was allowed to cool and then raw sugar fractions were collected. Sugar and molasses were separated by centrifugation to remove all residual molasses from the crystallized sugar. After removing molasses, white sugar was dried (if necessary) in an oven at 54–71 °C until a final moisture content of approximately 1.0 percent. Sugar and molasses samples were collected.

Ensiled beet pulp was produced by placing vacuum sealed pressed pulp in a temperature controlled chamber set at 41–46 °C for 2 days. After, the pulp was removed and stored at ambient temperature for 12 days after which the ensiled beet pulp was collected.

All samples were stored frozen for a maximum of 131 days and then analysed for residues of fludioxonil using the validated method REM 133.06.

Table 19 Residues of fludioxonil (mg/kg) in sugar beet processed commodities (Shepard, 2017, TK0044248)

Location, year, variety SUGAR BEET ROOTS	N (int)	Rate (g ai/1000 kg roots)	Sample	Fludioxonil, mg/kg [median]	PF
St. Cloud, Minnesota, United States, 2015, SX1521N	1 (-)	4.7	Pre-processing sugar beet root	1.93, 1.23, 1.66 [1.7]	-
			Raw juice	0.24	0.15
			Thick juice	0.41	0.26
			Raw sugar	0.64	0.40
			Refined sugar	0.16	0.10
			Molasses	0.90	0.56
			Wet pulp	0.14	0.09
			Ensiled pulp	0.99	0.62
			Dried pulp	2.0	1.3
			Pressed pulp	1.3	0.81
			Press water	0.27	0.17

Almonds

A processing trial on almonds was conducted in the United States during the 2018 growing season (Baillargeon, 2020, TK0351660). Fludioxonil, formulated as a WG formulation (containing 25 percent fludioxonil) was applied as 4 foliar airblast applications at 1221–1230 g fludioxonil/ha, with an application interval of 14 days, totalling 4910 g fludioxonil/ha. Crop oil was added to the application mixtures. Samples of almond nutmeats were collected 15 days after the last application (DALA). Nutmeat was processed into roasted almonds and almond oil using methods which are representative of commercial practice.

Almond nutmeat samples (~22.7 kg) were ground to a homogenous consistency. The moisture content was determined for all samples using an electronic moisture balance. If the moisture was greater than 9.0 percent, samples were dried in an oven at 54–71 °C until a final moisture content of 3.0 to 9.0 percent was achieved. Nutmeats were cracked/broken into smaller pieces for feeding into the expeller.

Moisture content of the nutmeat material was adjusted to 12.0 percent by adding water and allowed to equilibrate for a minimum of 12 hours. Moisture adjusted nutmeat material was fed through an expeller to mechanically remove a majority of oil. Cold pressing produced crude oil and presscake (meal with residual oil). Crude oil was filtered and collected. Presscake (with residual oil) was discarded. For light roasting, whole nutmeats were dry roasted at a temperature of 129–149 °C for approximately 45 minutes in a roaster. After cooling, roasted almond fractions were collected.

All samples were stored frozen for a maximum of 10.4 months and then analysed for residues of fludioxonil using the validated method AG-597B.

Table 20 Residues of fludioxonil (mg/kg) in almond nutmeat processed commodities (Baillargeon, 2020, TK0351660)

Location, year, variety ALMOND NUTMEAT	N (int)	Rate (g ai/ha)	DALA	Sample	Fludioxonil, mg/kg [median]	PF
Lost Hills, California, United States, 2018, Monterey	4 (14, 14, 14)	1221 1230	15	Almond nutmeat (pre-processing)	0.082, 0.054, 0.062 [0.062]	-
		1230		Roasted almonds	0.053	0.80
		1230		Almond oil	0.096	1.5

APPRAISAL

Fludioxonil is a phenylpyrrole fungicide that was first evaluated for toxicology and residues by the JMPR in 2004. The Meeting derived an ADI of 0-0.4 mg/kg bw, decided that an ARfD is unnecessary and concluded that the residue definition for compliance with the MRL and for dietary risk assessment in plant commodities is *fludioxonil* and the residue definition for compliance with the MRL and for dietary risk assessment in animal commodities is the *sum of fludioxonil and its benzopyrrole metabolites, determined as 2,2-difluorobenzo[1,1]dioxole-4-carboxylic acid and expressed as fludioxonil*. The residue is fat-soluble.

Fludioxonil was listed at the Fifty-second Session of the CCPR for the evaluation of additional MRLs by the 2022 JMPR for banana, mango, papaya, beans and peas with pods, pulses, sugar beets, and tree nuts.

Additionally, new toxicology data (metabolism and toxicokinetics, genotoxicity, neurotoxicity, immunotoxicity and phototoxicity) for fludioxonil as well as genotoxicity studies for several of its metabolites were submitted to the current Meeting for follow up evaluation to the 2004 JMPR. As a result of the evaluation of these new data, the current Meeting agreed that exposure risks from the metabolites CGA 192155, SYN 551031, and CGA 339833 would be covered by the health-based guidance values (HBGVs) of the parent; while the exposure risks from the metabolites CGA 227731, CGA 308565/SYN 518579, CGA 265378, and CGA 308103 should be assessed using the Threshold of Toxicological Concern (TTC) approach.

Methods of analysis

Methods REM 133.06 and AG-597B, which were previously evaluated by the 2004, 2006, and 2012 JMPR, were used for the analysis of fludioxonil in banana, mango, papaya, beans with pods, pulses, sugar beets, and tree nuts. The Meeting received additional method validation and concurrent recovery data and both methods were demonstrated to have adequate performance for recovery of fludioxonil with an LOQ of 0.01 mg/kg in all matrices. Mean recoveries were within the acceptable range of 70–120 percent with RSDs of ≤ 20 percent.

The Meeting concluded that for the commodities considered by the Meeting, the methods used in the new residue trials were sufficiently validated and suitable to measure fludioxonil in plant commodities.

Stability of residues in stored analytical samples

The stability of fludioxonil residues in samples on frozen storage was evaluated by the 2004 and 2010 JMPR for a range of commodities. Although storage stability data are not available for any high protein content commodity, collectively the existing stability data for fludioxonil are acceptable to support the storage duration of samples in the trials considered by the current Meeting. Samples in the trials were stored frozen for periods less than the period of stability demonstrated in studies supplied to the 2004 and 2010 JMPR and were satisfactory.

Definition of the residue

The current Meeting considered the toxicological properties of the metabolites CGA 192155, SYN 551031, and CGA 339833 and concluded that they are covered by the HBGV for fludioxonil. When establishing the residues definition for dietary risk assessment, the Meeting considered their potential contribution to the dietary risk under the assumption them being covered by the parent HBGV and decided that CGA 192155, SYN 551031, and CGA 339833 would not be included.

The Meeting confirms its previous recommendation on the residue definition for fludioxonil.

Results of supervised residue trials on crops

The Meeting received information on supervised field trials on banana, mango, papaya, fresh beans with pods, dry edible beans, dry peas, sugar beets, almonds, and pecans.

Banana

The critical GAP for bananas is from the Republic of Colombia and is comprised of a single post-harvest spray application at 20 g ai/hL.

The Meeting received supervised residue trials conducted in Ecuador matching the critical GAP.

For estimation of maximum residue levels, residue levels of fludioxonil in bananas (whole fruit) ranked order were (n = 6): 0.58, 0.76, 0.82, 0.93, 1.1, and 1.2 mg/kg.

Residues in the edible portion (banana pulp) for dietary risk assessment in ranked order were (n = 6): <0.01 (2), <u><0.011</u>, <u>0.014</u>, 0.015, and 0.021 mg/kg.

The Meeting estimated an STMR value of 0.013 mg/kg (based on the pulp) and a maximum residue level (based on the mean + 4×SD, whole fruit) of 2 mg/kg (Po) for banana.

Mango

Mangoes were previously evaluated by the 2012 JMPR where a maximum residue level of 2 mg/kg and a STMR of 0.02 mg/kg were estimated based on the GAP from the Republic of South Africa, comprising a single post-harvest hot dip application at 52 °C at a maximum rate of 34.5 g ai/hL.

The Meeting received a new critical GAP for mangoes from Brazil comprising a single post-harvest spray or dip application at 120 g ai/hL.

Supervised residue trials were submitted to the Meeting that were conducted in Brazil matching the new critical GAP.

For estimation of maximum residue levels, residue levels of fludioxonil in mangoes (whole fruit, dip application) ranked order were (n = 4): 3.7 (2), 3.9, and 5.0 mg/kg.

Residues in the edible portion (mango pulp, dip application) for dietary risk assessment in ranked order were (n = 4): 0.01, 0.02, 0.04, and 0.05 mg/kg.

For estimation of maximum residue levels, residue levels of fludioxonil in mangoes (whole fruit, spray application) ranked order were (n = 4): 4.4, 4.5 (2), and 5.0 mg/kg.

Residues in the edible portion (mango pulp, spray application) for dietary risk assessment in ranked order were (n = 4): <0.01, 0.03, 0.04, and 0.06 mg/kg.

The Meeting noted that both treatments were applied at the same concentration (i.e., application rate) and considered the trials to be independent according to GAP.

Fludioxonil residues in mangoes (whole fruit, dip and spray applications) in ranked order were (n = 8): 3.7 (2), 3.9, 4.4, 4.5 (2), and 5.0 (2) mg/kg.

Fludioxonil residues in mango pulp (dip and spray applications) in ranked order were (n = 8): <0.01, 0.01, 0.02, 0.03, 0.04 (2), 0.05, and 0.06 mg/kg.

The Meeting estimated an STMR value of 0.04 mg/kg (based on the pulp) and a maximum residue level (based on the mean + 4×SD, whole fruit) of 7 mg/kg (Po) for mango. The latter replaces its previous recommended maximum residue level of 2 mg/kg for mango.

Papaya

The critical GAP for papayas is from Brazil and is comprised of a single post-harvest spray or dip application at 120 g ai/hL.

The Meeting received supervised residue trials conducted in Brazil matching the critical GAP.

For estimation of maximum residue levels, residue levels of fludioxonil in papayas (whole fruit, dip application) ranked order were (n = 4): 1.2, 1.5, 2.3, and 3.2 mg/kg.

Residues in the edible portion (papaya pulp, dip application) for dietary risk assessment in ranked order were (n = 4): 0.03, 0.06, 0.10, and 0.15 mg/kg.

For estimation of maximum residue levels, residue levels of fludioxonil in papayas (whole fruit, spray application) ranked order were (n = 4): 1.5, 1.7, 2.1, and 2.7 mg/kg.

Residues in the edible portion (papaya pulp, spray application) for dietary risk assessment in ranked order were (n = 4): 0.15 (2) and 0.16 (2) mg/kg.

The Meeting noted that both treatments were applied at the same concentration (i.e. application rate) which resulted in comparable residue levels in/on the fruit and decided to combine both datasets.

Fludioxonil residues in papayas (whole fruit, dip and spray applications) in ranked order were (n = 8): 1.2, 1.5 (2), 1.7, 2.1, 2.3, 2.7, and 3.2 mg/kg.

Fludioxonil residues in papaya pulp (dip and spray applications) in ranked order were (n = 8): 0.03, 0.06, 0.10, 0.15 (3), and 0.16 mg/kg.

The Meeting estimated an STMR value of 0.15 mg/kg (based on the pulp) and a maximum residue level (based on the mean + 4×SD, whole fruit) of 5 mg/kg (Po) for papaya.

Legume Vegetables

Subgroup of beans with pods and Subgroup of peas with pods

Beans with pods were previously evaluated by the 2013 JMPR where a maximum residue level of 0.6 mg/kg and a STMR of 0.02 mg/kg were estimated in Snap bean (young pods) and Beans, except broad bean and soya bean based on the GAP from the United States for snap beans (common beans) of 4 foliar applications × 250 g ai/ha, 7-day RTI, and 7-day PHI.

Peas with pods were previously evaluated by the 2004 JMPR where a maximum residue level of 0.3 mg/kg and a STMR of 0.04 mg/kg were estimated in Peas (pods and succulent=immature seeds) based residue data for beans with pods and the GAP from France for legume (pod and seed) of 250 g ai/ha, number of applications not specified, and a 14-day PHI.

Labels were provided for registrations in Canada on succulent beans (3 foliar applications × 250 g ai/ha, 7-day RTI, and 7-day PHI) and in Latvia on fresh beans and peas with pods (3 foliar applications ×

250 g ai/ha, 10-day RTI, and 14-day PHI). Based on the shorter RTI and PHI the Meeting decided that the GAP from Canada is the critical GAP.

The Meeting received three supervised residue trials conducted in Bulgaria, France and Italy approximating the Canadian GAP which is insufficient to support a recommendation. The Meeting agreed to consider the GAP from Latvia. The Meeting received eight supervised residue trials conducted in Bulgaria, Greece, Italy, Southern France and Spain matching the Latvian GAP.

Fludioxonil residues in beans green with pods in ranked order were (n = 8): <0.01, 0.01, 0.03, 0.05, 0.06, 0.07, 0.13, and 0.48 mg/kg.

The Meeting estimated a maximum residue level of 0.8 mg/kg and an STMR value of 0.055 mg/kg for the subgroup of beans with pods, except soya bean (succulent seeds in pods). The Meeting withdrew its previous recommendations of a maximum residue level 0.6 mg/kg for beans (*Phaseolus* spp.) immature pods and succulent seeds) and a maximum residue level of 0.6 m/kg for snap beans (young pods).

Residue trials for peas with pods were not available to the Meeting. Noting that beans with pods (*Phaseolus* spp.) is a representative crop for the subgroup of peas with pods, the Meeting decided to extrapolate its recommendation for the subgroup of beans with pods and estimated a maximum residue level of 0.8 mg/kg and an STMR value of 0.055 mg/kg for the subgroup of peas with pods. The Meeting withdrew its previous recommendation of a maximum residue level 0.3 mg/kg for peas (pods and succulent=immature seeds).

Pulses

Subgroup of dry beans (except soya beans)

Dry beans were previously evaluated by the 2013 JMPR where a maximum residue level of 0.5 mg/kg and a STMR of 0.04 mg/kg were estimated based on the GAP from the United States for dried beans (except cowpeas) of 4 foliar applications × 245 g ai/ha, 7-day RTI, and 7-day PHI.

The Meeting received a new GAP for dried shelled bean (except soya bean) from Canada consisting of 3 foliar applications × 244 g ai/ha, 7-day RTI, and 7-day PHI.

The Meeting received supervised residue trials for dry beans conducted in Canada matching the Canadian GAP. The Meeting also reassessed American dry bean residue data from the 2013 JMPR where 4 foliar applications were made at a rate of 245 g ai/ha, 6 to 8-day RTI and 5 to 8-day PHI. Residue decline data for dry peas indicate a half-life of fludioxonil of approximately 7.2 days. Based on the half-life, the Meeting decided that a first application (28 days before harvest) would not contribute significantly to residues at harvest. Therefore the Meeting determined that the dry bean trials from the 2013 JMPR sufficiently approximate the GAP from Canada and are suitable for making a recommendation.

Fludioxonil residues in dry beans in ranked order were (n = 13): <0.01, <0.011, 0.018, *0.02 (2)*, 0.023, 0.029, *0.04 (2)*, *0.06 (2)*, *0.12*, and *0.23* mg/kg.

The Meeting estimated a maximum residue level of 0.3 mg/kg and an STMR value of 0.029 mg/kg for the subgroup of dry beans (except soya beans). The Meeting withdrew its previous recommendation of a maximum residue level 0.5 mg/kg for beans (dry).

Subgroup of dry peas

Dry peas were previously evaluated by the 2004 JMPR where a maximum residue level of 0.07 mg/kg and a STMR of 0.02 mg/kg were estimated based on the GAP from Austria and Spain for pulse, dry seed of 2

foliar applications × 250 g ai/ha and a 14-day PHI. Lentils and chick-peas were previously evaluated by the 2018 JMPR where a maximum residue level of 0.3 mg/kg and an STMR value of 0.11 mg/kg were estimated based on the GAP from Canada of 3 foliar applications 244 g ai/ha, 7-day RTI, and 7-day PHI.

The Meeting received a new critical GAP for dried peas from Canada consisting of 3 foliar applications at 244 g ai/ha, 7-day RTI, and 7-day PHI.

The Meeting received the same supervised residue trials for dry peas conducted in Canada that were assessed by the 2018 JMPR for lentils and chick-peas, matching the Canadian GAP for dry peas.

Fludioxonil residues in dry peas in ranked order were (n = 7): 0.018, 0.046 (2), 0.11 (2), 0.13, and 0.17 mg/kg.

The Meeting estimated a maximum residue level of 0.3 mg/kg and an STMR value of 0.11 mg/kg for the subgroup of dry peas. The Meeting withdrew its previous recommendations of maximum residue levels of 0.07 mg/kg for peas (dry), 0.3 mg/kg for chick-pea (dry), and 0.3 mg/kg for lentil (dry).

Sugar beet

The critical GAP for sugar beets is from the United States and is comprised of a single post-harvest spray application at 4.5 g ai/1000 kg of roots.

The Meeting received supervised residue trials conducted in the United States matching the critical GAP.

Fludioxonil residues in sugar beet roots in ranked order were (n = 6): 0.64, 0.90, 0.96, 1.2, 1.7, and 1.9 mg/kg.

The Meeting estimated a maximum residue level (based on the mean + 4×SD) of 4 mg/kg (Po) and an STMR value of 1.1 mg/kg for sugar beet.

Tree nuts

Pistachios were previously evaluated by the 2004 JMPR where a maximum residue level of 0.2 mg/kg and a STMR of 0.05 mg/kg were estimated based on the GAP from the United States of 4 foliar applications × 250 g ai/ha and a 7-day PHI.

The Meeting received a GAP from the United States for numerous tree nuts consisting of 4 foliar applications at a rate of 247 g ai/ha/application, with a 14-day RTI, and a 14-day PHI. For pistachios, the GAP assessed by the 2004 JMPR remains the critical GAP for this commodity.

The Meeting received supervised residue trials for almonds and pecans conducted in the United States matching the United States GAP for tree nuts.

Fludioxonil residues in almond nutmeat in ranked order were (n = 5): ≤0.01 (3), 0.018, and 0.15 mg/kg.

Fludioxonil residues in pecan nutmeat in ranked order were (n = 5): <0.01 (5) mg/kg.

Since residues of fludioxonil were higher in almonds than in pecans, the Meeting agreed to use the almond dataset for the estimation of maximum residue levels and dietary risk assessment for tree nut commodities.

The Meeting estimated a maximum residue level of 0.3 mg/kg and an STMR value of 0.01 mg/kg for the group of tree nuts (except Canarium nut, Chilean hazelnut, and Pistachios).

Residues in animal feeds

Bean forage

Labels were provided for registrations in Canada on succulent beans (3 foliar applications × 250 g ai/ha, 7-day RTI, and 7-day PHI) and in Latvia on fresh beans with pods (3 foliar applications × 250 g ai/ha, 10-day RTI, and 14-day PHI). Based on the shorter RTI and PHI the Meeting decided that the GAP from Canada is the critical GAP.

The Meeting received three supervised residue trials conducted in Italy, France, and Bulgaria approximating the Canadian GAP which is insufficient to support a recommendation. The Meeting agreed to consider the GAP from Latvia.

The Meeting received eight supervised residue trials conducted in Italy, Spain, France, Bulgaria, and Greece matching the Latvian GAP.

Fludioxonil residues in beans, remaining plant, in ranked order were (n = 8): 0.40, 0.50, 2.3, 3.3, 4.2, 5.1, 7.8, and 11 mg/kg.

The Meeting estimated a highest residue of 11 mg/kg and a median value of 3.75 mg/kg for bean forage (as received).

Almond hulls

The critical GAP for almonds is from the United States consisting of 4 foliar applications at a rate of 247 g ai/ha, with a 14-day RTI, and 14-day PHI.

The Meeting received supervised residue trials for almonds conducted in the United States matching the United States GAP.

Fludioxonil residues in almond hulls in ranked order were (n = 5): 1.1, 1.7, 1.8, 3.3, and 7.6 mg/kg.

The Meeting estimated a maximum residue level of 20 mg/kg (dw) and a median value of 1.8 mg/kg for almond hulls (as received).

Fate of residues in processing

Processing data on sugar beet roots and almond nutmeat were provided. All data relevant for an estimation of maximum residue levels in processed commodities or for dietary exposure calculations are summarized in the following table.

Table 21 Processing factors and residue estimates for fludioxonil

Raw commodity	Residue in RAC, mg/kg		Processed commodity	Processing Factors	Residue in processed commodity, mg/kg	
	Max	STMR		Fludioxonil [best estimate]	MRL	STMR-P
Sugar beet roots	4	1.1	Refined sugar	0.10	--	0.11
			Molasses	0.56	--	0.62
			Ensiled pulp	0.62	--	0.68
			Dried pulp	1.3	--	1.4
Almond nutmeat	0.2	0.01	Roasted almonds	0.80	--	0.008
			Almond oil	1.5	0.3	0.015

Residues in animal commodities

Farm animal feeding studies

Farm animal feeding studies are reported in the evaluations of the 2004 JMPR (lactating dairy cow), 2013 JMPR (laying hen), and 2018 JMPR (lactating dairy cow).

Farm animal dietary burden

The Meeting has added feed items (bean forage and almond hulls) and their associated residues to the dietary burden calculations used by the 2018 Meeting. Dietary burden calculations are provided in Annex 6; the dietary burden estimates are summarized below.

Table 22 Estimated maximum dietary burdens of farm animals

Animal	Dietary burden estimates, ppm							
	Canada-United States		European Union		Australia		Japan	
	Maximum	Mean	Maximum	Mean	Maximum	Mean	Maximum	Mean
Beef cattle	11	8.7	22	12	23	10	0.10	0.10
Dairy cattle	3.9	3.2	26	12❷	38❶	9.9	0.65	0.65
Broiler poultry	0.04	0.04	1.5	0.79	0.03	0.03	0.02	0.02
Laying hen	0.04	0.04	1.9❸	0.87❹	0.03	0.03	0.02	0.02

Notes:

❶ Highest maximum beef or dairy cattle dietary burden suitable for MRL estimates for mammalian tissues and milk.

❷ Highest mean beef or dairy cattle dietary burden suitable for STMR estimates for mammalian tissues and milk.

❸ Highest maximum poultry dietary burden suitable for MRL estimates for poultry tissues and eggs.

❹ Highest mean poultry dietary burden suitable for STMR estimates for poultry tissues and eggs.

Animal commodity maximum residue levels

Cattle

For beef and dairy cattle, the Meeting estimated a maximum dietary burden of 38 ppm and a mean dietary burden of 12 ppm. The burdens calculated by the current meeting are substantially greater than those used by the 2018 meeting (23 ppm and 6.4 ppm, respectively). Based on the new dietary burden and the results of the dairy cattle feeding studies evaluated by the 2018 JMPR, the calculations used to estimate highest total residues for use in estimating maximum residue levels and STMR values in mammalian commodities are shown below.

Table 23 Maximum residue level and STMR in mammalian commodities

Fludioxonil feeding study	Feed level (ppm) for milk residues	Total Residues (mg/kg) in milk a	Feed level (ppm) for tissue residues	Total Residues a (mg/kg)			
				Muscle	Liver	Kidney	Fat
MRL beef or dairy cattle							
Feeding study b	20	0.030	20	<0.01	0.079	0.082	0.011
	100	0.15	100	0.012	0.35	0.29	0.033
Dietary burden and high residue	38	0.06	38	0.011	0.14	0.129	0.016
STMR beef or dairy cattle							
Feeding study b	20b	0.026	20	<0.01	0.055	0.062	0.01
Dietary burden and residue estimate	12	0.016	12	0.006	0.033	0.037	0.006

Notes:

[a] Total residues = fludioxonil and its benzopyrrole metabolites, determined as 2,2-difluorobenzo[1,1]dioxole-4-carboxylic acid and expressed as fludioxonil.

[b] Although the dairy cattle feeding study evaluated by the 2004 JMPR was conducted at a feeding level of 5.5 ppm, no quantifiable residues were observed in any matrices, as such it was decided to extrapolate from the feeding study evaluated by the 2018 JMPR where quantifiable residues were observed at a 20 ppm feeding level.

The Meeting confirmed its previous recommendation of a maximum residue level of 0.02 mg/kg for meat, based on fat (from mammals other than marine mammals) and mammalian fats (except milk fats).

The Meeting recommended a maximum residue level for milks at 0.07 mg/kg and edible offal (mammalian) at 0.15 mg/kg. The Meeting estimated STMRs of 0.006 mg/kg for muscle, 0.006 mg/kg for mammalian fat, 0.037 mg/kg for edible offal (mammalian), and 0.016 mg/kg in milks. These recommendations are intended to replace previous recommendations for these ruminant matrices.

Poultry

For poultry, the Meeting estimated a maximum dietary burden of 1.9 ppm and a mean dietary burden of 0.87 ppm which are the same as the dietary burdens estimated by the 2018 JMPR.

The Meeting therefore confirmed its previous recommendations.

RECOMMENDATIONS

On the basis of the data obtained from supervised residue trials the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI assessment.

Definition of the residue for compliance with the MRL and for dietary risk assessment for plant commodities: *fludioxonil*.

Definition of the residue for compliance with the MRL and for dietary risk assessment for animal commodities: *sum of fludioxonil and its benzopyrrole metabolites, determined as 2,2-difluoro-benzo[1,3]dioxole-4-carboxylic acid and expressed as fludioxonil*.

The residue is fat-soluble.

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The International Estimated Daily Intakes (IEDIs) of fludioxonil were calculated for the 17 GEMS/Food cluster diets using STMRs and STMR-Ps estimated by the JMPR in 2004, 2006, 2010, 2012, 2013, 2018 and current Meeting. The results are shown in Annex 3.

The ADI is 0–0.4 mg/kg bw and the calculated IEDIs were 1–6 percent of the maximum ADI. The Meeting concluded that the long-term intake of residues of fludioxonil from the uses considered by the JMPR is unlikely to present a public health concern

Acute dietary exposure

The 2004 JMPR decided that an ARfD for fludioxonil was unnecessary. The Meeting therefore concluded that the acute dietary exposure to residues of fludioxonil resulting from uses that have been considered by the JMPR is unlikely to present a public health concern.

Metabolites covered by the health-based guidance value (HBGV)

The Meeting concluded that metabolites CGA 192155, SYN 551031, and CGA 339833 are covered by the HBGV.

Residues of CGA 192155, SYN 551031, and CGA 339833 were not measured in any of the supervised field trials assessed by any of the previous Meetings or by the current Meeting. The Meeting estimated the dietary exposure to combined residues of fludioxonil, CGA 192155, SYN 551031, and CGA 339833 by applying conversion factors (based on the ratio of combined residues of fludioxonil, CGA 192155, SYN 551031, and CGA 339833 against residues of the parent) to the fludioxonil STMRs for those crops in which combined residue levels of these metabolites were significant when compared against the parent (i.e. ≥ 10 percent of the parent). The Meeting concluded that metabolites CGA 192155, SYN

551031, and CGA 339833 do not contribute significantly to the dietary exposure from fludioxonil (i.e. calculated IEDIs remained in the range of 1–6 percent of the HGBV) and are unlikely to present a public health concern.

Threshold of toxicological concern (TTC) consideration for metabolites

CGA 227731

The metabolite CGA 227731 could be assessed using the TTC approach (Cramer Class III threshold of 1.5 µg/kg bw per day).

Residues of CGA 227731 were not measured in any of the supervised field trials assessed by any of the previous Meetings or by the current Meeting but were observed in the soya bean seed treatment metabolism study and accounted for 1.9 percent of the TRR in forage (0.002 mg/kg) and 1.5 percent of the TRR in hay (<0.001 mg/kg). Residues of CGA 227731 were also observed in rotational wheat matrices accounting for 10.7 percent of the TRR in forage (0.006 mg/kg) and up to 22 percent of the TRR in straw (0.016 mg/kg). Residues of CGA 227731 were not found in any of the foliar metabolism studies conducted in plants (grapes, tomatoes, peaches, green onions, or head lettuce); seed treatment metabolism studies in potatoes, rice, wheat, or cotton; or in rotational lettuce, sugar beets, mustard greens, or turnips (2004 JMPR).

The Meeting concluded that no quantifiable residues of CGA 227731 are expected in soya bean forage and hay or rotational wheat forage, but that low concentrations of CGA 227731 might be expected in wheat straw grown in rotation with fludioxonil-treated crops.

Given that metabolite CGA 227731 was only present at insignificant levels in animal feed commodities, the Meeting agreed that dietary exposure to residues of CGA 227731 is expected to be below the TTC for Cramer Class III compounds of 1.5 µg/kg bw per day and is unlikely to present a public health concern. Should further uses be considered in the future, these conclusions may need to be re-evaluated.

CGA 308565/SYN 518579 tautomeric pair, CGA 265378 and CGA 308103

The CGA 308565/SYN 518579 tautomeric pair, CGA 265378 and CGA 308103 could be assessed using the TTC approach (Cramer Class III threshold of 1.5 µg/kg bw per day).

Residues of all components were not measured in any of the supervised field trials assessed by any of the previous Meetings or by the current Meeting. Based on metabolism studies previously evaluated by the 2004 JMPR, conversion factors to fludioxonil STMRs based on the ratio of each metabolite to parent were estimated. For post harvest uses and seed treatment uses, generally no residues of the metabolites were expected.

The Meeting estimated a dietary exposures to:

- CGA 308565/SYN 518579 metabolites of 0.0956 µg/kg bw/day;
- CGA 265378 of 0.236 µg/kg bw/day; and,
- CGA 308103 of 0.198 µg/kg bw/day.

The Meeting concluded that the estimated dietary exposure to residues of CGA 308565/SYN 518579 tautomeric pair, CGA 265378 and CGA 308103 from uses considered by the JMPR is below the TTC for Cramer Class III compounds and is unlikely to present a public health concern. Should further uses be considered in the future, these conclusions may need to be re-evaluated.

FLUINDAPYR (328)

First draft prepared by C.M. Mahieu, Centre for Nutrition, Prevention and Health Services (VPZ), National Institute for Public Health and the Environment (RIVM), The Netherlands

EXPLANATION

Fluindapyr (ISO name) is a new fungicide. The IUPAC name for fluindapyr is 3-(difluoromethyl)-N-(7-fluoro-1,1,3-trimethyl-2,3- dihydro-1H-inden-4-yl)-1-methyl-1H-pyrazole-4-carboxamide. Fluindapyr is a pyrazole carboxamide fungicide that is a Complex II succinate dehydrogenase inhibitor (SDHI) that inhibits production of succinate dehydrogenase, which is a functional part of the tricarboxylic acid cycle and is linked to the mitochondrial electron transport chain.

Fluindapyr was scheduled at the Fifty-second Session of the CCPR (2020) for evaluation as a new compound by the 2021 JMPR, which was postponed to the 2022 JMPR for toxicology and for residues.

The Meeting received information on identity, physical chemical properties, plant and animal metabolism, soil degradation, residue analysis, storage stability, use patterns, residues resulting from supervised trials on cereal grains (wheat, sorghum, maize, sweet corn) and tree nuts (pecan and almond), fate of residues during processing (wheat, sorghum, maize) and livestock feeding studies.

IDENTITY

Chemical name	Fluindapyr
IUPAC:	3-(difluoromethyl)-N-(7-fluoro-1,1,3-trimethyl-2,3-dihydro-1H-inden-4-yl)-1-methyl-1H-pyrazole-4-carboxamide
CAS:	3-(difluoromethyl)-N-(7-fluoro-2,3-dihydro-1,1,3-trimethyl-1H-inden-4-yl)-1-methyl-1H-Pyrazole-4-carboxamide
CAS Registry No:	1383809-87-7
CIPAC No:	not yet assigned
Synonyms and trade names	F9990, IR9792, F9944
Structural formula:		Structure is confirmed by UV-VIS, IR, ^{1}H-NMR, ^{13}C-NMR and HPLC-MS [Martinez, 2014p, 2013PCP-IFP0793]. Fluindapyr is a racemic mixture.
Molecular formula:	$C_{18}H_{20}F_3N_3O$
Molecular weight:	351.37 g/mole

Physical and chemical properties

Pure active ingredient (98.56 percent)

Parameter	Result	References	Guidelines/method
Appearance:	Purity: 98.56 percent Physical state: powdery solid Colour: light brown (but whiter than the technical active ingredient) Odour: odourless (20 °C)	[Martinez, 2014b, 2013PCP-IFP0782]	OPPTS 830.6302/ visual Munsell colour system, OPPTS 830.6303/ visual and OPPTS 830.6304/ olfactory determination
Vapour pressure:	Purity: 98.56 percent 2.85×10^{-8} Pa at 20 °C	[Martinez, 2014h, 2013PCP-IFP0795]	OPPTS 830.7950, EC Method A.4, and OECD 104/ gas saturation method
Melting point:	Purity: 98.56 percent 169.1 to 172.3 °C, without decomposition	[Martinez, 2014d, 2013PCP-IFP0787]	OECD 102, EC Method A.1, and OPPTS 830.7200/ Capillary/liquid bath
Henry's Law constant	Purity: 98.56 percent $6.13 \times 10^{-6} \times m^3 \times mol^{-1}$ at 20 °C	[Martinez, 2014h, 2013PCP-IFP0795]	OPPTS 830.7950 and OECD 104/ gas saturation method
Octanol/water partition coefficient:	Purity: 98.56 percent 4.12 at pH 7.7 and at 20°C	[Martinez, 2014i, 2013PCP-IFP0796]	OECD 107, EC Method A8, and OPPTS 830.7550 Shake flask method
Solubility in water at 20°C:	Purity: 98.56 percent 1.63 µg/mL in water at 20 ± 0.5 °C The solubility is not affected by the pH (tested at pH 4, 7 and 10).	[Martinez, 2014j, 2013PCP-IFP0798]	OECD 105, EC Method A6, CIPAC MT 157, and OPPTS 830.7840/ Shake flask method followed by column elution method
Solubility in organic solvents at 20 °C:	Purity: 98.56 percent 300-325 g/L in acetone 114-133 g/L in ethyl acetate 160-200 g/L in dichloromethane 0.31 g/L in n-heptane 80-100 g/L in methanol 20-25 g/L in toluene	[Gazzotti, 2015, 2015PCP-IFP1971]	CIPAC method MT 181 (solubility > 10 g/L), OECD 105, EC method A.6 (flask method for solubility <10 g/L), as well as OPPTS 830.7840 and OPPTS 830.7860
Density/Specific gravity/Relative density	Purity: 98.56 percent Density: 1.2735 g/mL Specific gravity: 1.2758 g/mL Relative density: 1.2735 at 20.09 °C (n=2) Was determined solvent mixture (1:5 of 2-propanol: water) and then converted to density in water.	[Martinez, 2014f, 2013PCP-IFP0780]	OECD 109, EC method A.3, CIPAC method MT 3.2, and OPPTS 830.7300, Pycnometer
Hydrolysis:	[^{14}C-5-Pyrazole]- and [^{14}C-U-Phenyl]-fluindapyr Radiochemical purity >95 percent Stable (no degradation) at pH 4, 7 and 9 over 5 days at 50 ± 0.5 ºC in the dark under sterile conditions at 0.45 mg ai/L. No degradation products were detected and the enantiomeric ratio remained unchanged.	[Russo, 2013, 2013EFT-IFP0692]	OECD 111, OPPTS 835.2110

Parameter	Result	References	Guidelines/method
	Hydrolytically stable at environmental conditions.		
Photolysis:	[^{14}C-5-Pyrazole] fluindapyr with radiochemical purity: >98 percent [^{14}C-U-Phenyl]-fluindapyr with radiochemical purity: >98 percent Photodegradation of fluindapyr was studied under simulated sunlight in sterile non-buffered water at 25± 1.0 ºC with 0.369 and 0.383 mg ai/L, for the [^{14}C-U-phenyl]-fluindapyr and the [^{14}C-pyrazole]-fluindapyr, respectively. Samples were taken after 1, 3, 6, 8, 10, 12 and 14 days and analysed by radio-TLC and LSC. Mass balances ranged from 91.7 to 100.7 percent. Degradation for fluindapyr equivalent to summer sunlight (55° North in June): U-Ph-^{14}C Pyr-^{14}C DT_{50} (years) 4.3 2.9 (arithmetic mean 3.5 years) Some minor degradation products were identified, all below 10 percent AR and the majority even below 5 percent AR. Two of the minor product were confirmed as 3-OH-fluindapyr and the pyrazole-amide. Photolysis of fluindapyr in water is water is insignificant. The distribution of the two enantiomers remained 1:1 throughout the entire irradiation duration.	[Hüben, 2017, 2015EFT-IFP2139]	OECD 316 and OPPTS 835.224, First tier: UV/VIS spectrum
Dissociation constant:	Could not be determined as fluindapyr is not capable of ionization.	[Martinez, 2014l, 2013PCP IFP0794]	OECD 112 and OPPTS 830.7370

Formulations

Fluindapyr has not been evaluated by JMPS and therefore no FAO specifications for technical and formulated fluindapyr have been published.

A suspension concentrate (SC) formulation, F9944-74, containing 42.4 percent (w/w) fluindapyr is commercially available in the United States of America.

List of reference compounds used in various study reports

The reference compounds used in the various study reports are listed in Table 1.

Table 1 List of reference compounds used in various study reports

Name & abbreviation	Chemical structure	Found in
Fluindapyr *(Code: 510142)* *IR9792/F9990* 3-(difluoromethyl)-N-(7-fluoro-1,1,3-trimethyl-indan-4-yl)-1-methyl-pyrazole-4-carboxamide *Parent*	 MW = 351 g/mol	Present in all primary (wheat, soybean, sugar beet, rice and grape) & rotational crops (lettuce, carrot and wheat) Present in all goat and hen matrices with highest residues in fat

METABOLISM AND ENVIRONMENTAL FATE

Plant metabolism

The meeting received metabolism studies for fluindapyr after foliar applications, conducted with crops representative of four different crop groups; fruit (grape), root crops (sugar beet), cereal/grass (wheat and rice), pulses and oilseeds (soya bean). Fluindapyr was applied using [phenyl-^{14}C] and [pyrazole-^{14}C] labelled fluindapyr. The structural formula for both radiolabels is given in Figure 1.

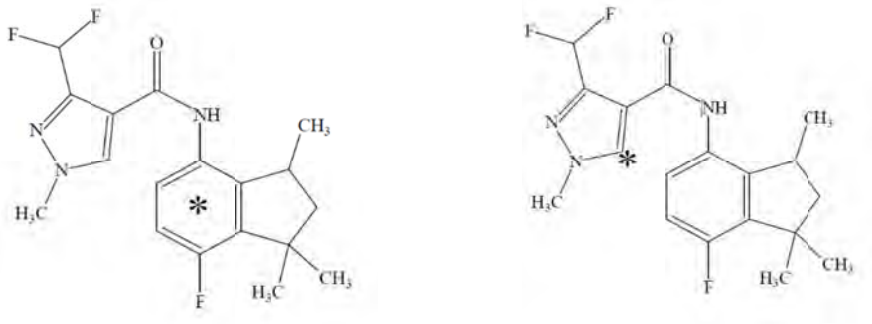

Figure 1 Position of radiolabels in fluindapyr used in plant metabolism studies with on the left the phenyl label and on the right the pyrazole label.

Foliar applications to fruits

A metabolism study using [phenyl-^{14}C] and [pyrazole-^{14}C] labelled fluindapyr was conducted outdoor in grapes (variety: Thompson seedless) after two applications of the test substance [Desai, 2017a, 2016MET-IFP2538] in Fresno CA, United States in 2016. Three established grape vines planted in 1960 were selected for the study: one untreated plot, one plot treated with phenyl-labelled fluindapyr, and one plot treated with pyrazole-labelled fluindapyr. Each plot contained one plant. A total of two applications of 237–313 g ai/ha each were conducted with [^{14}C]-labelled fluindapyr on grape vines. The first application was performed at growth stage BBCH 55 and the second application was performed at BBCH 85, resulting in an RTI of 123 days.

Fluindapyr was administered as an emulsifiable concentrate (EC) formulation by foliar spraying. Samples of mature crop (leaves and grapes) were harvested 14 days after the 2nd application. Samples were refrigerated until shipment. Grapes were kept refrigerated and leaves were frozen during shipment for analysis. All samples were processed within two weeks. At the time of processing, grape berries were rinsed with methanol, the rinse was collected, and the leaves and rinsed grapes were cryogenically homogenised, and the processed samples were kept frozen at -20 °C. All the processed samples were extracted within one month of processing. Initial sample analysis and metabolite profiling along with LC-MS characterisation/identification was performed within 6 months from harvest. Therefore, no additional extraction was conducted for storage stability evaluation.

Aliquots were taken for TRR determination by combustion. The TRR of grapes was obtained by summing radioactivity content in the grape rinse and combusted homogenized grapes.

Leaves and grapes were first extracted with acetonitrile/water (1:1, v/v). The extraction procedure was then repeated using methanol/water (1:1, v/v). All extracts were combined, assigned Ext-1 fraction and assayed by liquid scintillation counting (LSC). The remaining post extraction solid (PES) samples were combusted, followed by LSC to determine any residual ^{14}C-bound material. A further fraction of Ext-1 was evaporated to dryness and reconstituted in an aqueous solution. The concentrated Ext-1 fraction was then subjected to partitioning with dichloromethane. Subsamples of aqueous fractions remaining after dichloromethane separation of Phase I metabolites were concentrated and individually subjected to acid hydrolysis (1N HCl) under reflux at 100 °C for approximately 1 hour. All the fractions, solvent extract, concentrated extracts, and dichloromethane fractions were analysed by HPLC. Selected extracts and isolated metabolites were analysed by LC/RAM/ESI-MS and LC-MS/MS to obtain structural information of fluindapyr and metabolites. The available reference standards assayed were fluindapyr, pyrazole carboxamide, pyrazole carboxylic acid, N-DesMet-fluindapyr, dehydro-fluindapyr, 1-OH-Met-

fluindapyr (2 diastereomers), and 3-OH-Met-fluindapyr. In addition, 1-OH-Met-fluindapyr-Glu and 1-OH-Met-fluindapyr-Glu-sugar (M661/1-4) were identified by LC-MS/MS.

In leaves, the PES was greater than 0.05 mg/kg, and therefore, these fractions were further subjected to sequential enzyme (cellulase, alpha amylase, pectinase, protease), acid and base hydrolysis (both at 1N and 6N). All hydrolysis steps were conducted at 37 °C for 24 hours, except for the 6N HCl and 6N NaOH, which occurred at 100 °C for 1 hour. These fractions were quantified, but not further subjected to identification.

The enantiomeric composition of fluindapyr was determined by collection of the fluindapyr HPLC peak and further analysis by a chiral HPLC method.

The TRR, distribution of radioactivity and the identified metabolites are shown in Table 2 and Table 3. The TRR in grapes was low, while higher TRRs were detected in leaves. Rinsing of treated bunches dislodged 79 to 81 percent of TRR from the grapes. The extractable radioactivity of grapes and leaves for both labels (phenyl and pyrazole) was 99 percent TRR in grapes and 90–91 percent of the TRR in leaves. TRR in untreated control samples were ≤ 0.001 mg/kg.

The identification results of the organic/aqueous extracts (Ext-1) are shown in the table below. These extracts did not undergo any hydrolysis. The identification results of the extracts which were subjected to dichloromethane partitioning, after which the aqueous fractions were subjected to acid hydrolysis, are not shown, since these were parallel extractions and the identifications results are similar to the results in Ext-1. In the 'aqueous fraction after acid hydrolysis', some residues were retrieved, which would have originated from their conjugated counterparts, however, in the organic/aqueous extracts these metabolites were already present in their unconjugated form. The identification results of the organic/aqueous extracts are considered to better represent the original residue situation, since they did not undergo additional sample processing steps (i.e. partitioning and hydrolysis). Furthermore, high identification levels are already achieved with these organic/aqueous extracts.

Parent was the main component of the residue in grapes (63–65 percent TRR, 0.024–0.056 mg eq/kg) and leaves (38–54 percent TRR, 5.9–14 mg eq/kg). Further identified metabolites were 1-OH-Met-fluindapyr and its different conjugates (20 percent TRR, 0.017–0.07 mg eq/kg in grapes and 25–39 percent TRR, 6.0–6.4 mg eq/kg in leaves), and 3-OH-fluindapyr (12–15 percent TRR, 0.013–0.043 mg eq/kg in grapes and 9.3–12 percent TRR, 1.8–2.4 mg eq/kg in leaves), and in minor amounts N-DesMet-fluindapyr and dehydro-fluindapyr (0.1–0.3 percent TRR, 0.000–0.001 mg eq/kg in grapes and 0.019–0.064 mg eq/kg in leaves). In addition, in the extracts from the pyrazole-labelled leaves and grapes, pyrazole carboxylic acid and pyrazole carboxamide were detected at low levels (0.5–1.1 percent TRR, 0.002–0.003 mg eq/kg in grapes and 1.4–2.0 percent TRR, 0.35–0.53 mg eq/kg in leaves. Metabolite profiles from the phenyl and pyrazole labelled grape samples were similar with only minor differences in the magnitudes of their distributions.

The hydrolysis processes of the PES fractions of the leaves released small percentages of the TRR. Only the HPLC chromatograms are available as raw data in the study report (no quantitative information), showing the presence of 1-OH-Met-fluindapyr (2 diastereomers), 1-OH-Met-fluindapyr-Glu, fluindapyr, pyrazole carboxylic acid, and pyrazole carboxamide in these fractions.

Chiral analysis of fluindapyr in leaves showed no significant change in the enantiomeric composition, indicating non-selective metabolic biotransformation. However, in grapes, the parent dislodged by rinsing (79–81 percent of TRR found in grapes) showed an enantiomeric ratio approximately 50:50 while the parent found in grape extract has an *R/S* ratio of approximately 70:30 (see Table 4). No analysis of R/S isomerization for metabolites was performed.

Foliar application to root crops

The metabolic fate of fluindapyr following foliar application was studied in sugar beets [Tuffnail, 2017, 2013MET-IFP0758]. Sugar beet plants (variety: Pasteur) were grown outdoors in pots filled with sandy loam soil, in Essex, United Kingdom. A total of three applications of 113–149 g ai/ha each of either phenyl or pyrazole labelled fluindapyr were performed.

The first application was performed at BBCH 35-38, the second at BBCH 39–49 and third at BBCH 49, resulting in RTI's of 33 and 28 days, respectively. In addition, plants in two separate test plots were also treated at an exaggerated rate of once 646–648 g ai/ha at BBCH 39–49 for generating metabolites for identification purposes, if needed. Fluindapyr was administered as an emulsifiable concentrate (EC) formulation by foliar spraying. Samples of immature foliage were harvested at BBCH 39 (32 days after application 1 and 1 day prior to the second application), and mature samples (foliage and root) were harvested 30 days after the 3rd application. At maturity, leaves were separated from the roots, and roots were cleaned by gentle washing. Samples were stored frozen.

The samples were homogenised over dry ice, and the TRR was determined by combustion. The remaining samples were stored frozen. All samples were processed within 1 month, and subsequently extracted within 1 month. Initial analysis and metabolic profiling occurred within approximately 6 months after harvest. Further additional extractions were conducted *ca* 20 months (616 days) after harvest, and the metabolite profiles, generated during subsequent analysis, were compared with the initial analysis to

confirm that no significant degradation of the metabolites had taken place. The metabolic profiles of the major components were considered to be qualitatively similar. TRR levels in the experiment with the nominal use rate of 125 g ai/ha were deemed sufficient for qualitative and quantitative metabolite identification, therefore the samples from the exaggerated use rate were not analysed.

The homogenized samples were sequentially extracted with acetonitrile and acetonitrile/water (1:1 v/v). Aliquots of the resulting extracts were taken for radioactivity measurements (LSC) and for profiling using HPLC. The remaining radioactivity in the unextracted residue (PES) was determined by combustion and LSC. The concentrated acetonitrile/water extracts of mature foliage and root samples were partitioned twice with dichloromethane to separate parent and Phase I metabolites from the Phase II conjugated metabolites. Aliquots of each fraction were taken for LSC analysis. Following partitioning, a portion of the dichloromethane fraction was analysed by HPLC. Subsamples of aqueous fractions remaining after dichloromethane separation were subjected to acid hydrolysis (1N HCl) under reflux at 100 °C for approximately 1 hour, and then also analysed by LSC and HPLC. After the dichloromethane partitioning step, the aqueous root fractions contained high levels of sugars, therefore, they were subjected to a further clean-up. Aliquots were taken for LSC analysis, and chromatographic metabolite profiles generated using HPLC.

Aliquots of the concentrated acetonitrile/water extracts were treated with concentrated HCl to give solutions of approximately 1 M [H^+] concentration. Samples were incubated at ambient temperature for approximately 16 hours, and then incubated further at 60°C for 16 hours before being neutralised with NaOH (5 M). Aliquots were analysed by HPLC. Subsamples of phenyl and pyrazole concentrated foliage acetonitrile/water extracts were mixed with 5M NaOH to obtain an approximately 1 M basic solution. The samples were incubated at ambient temperature overnight before being neutralised by addition of concentrated HCl. Sample clean-up was performed, and aliquots of the supernatants were analysed by HPLC. The acetonitrile/water extract of phenyl and pyrazole foliage samples was reconstituted in 0.1 M acetate buffer, β-glucosidase enzyme was added and incubated at 37 °C for approximately 16 hours. Samples were then analysed by HPLC.

Selected leaf and root PES subsamples after extraction were subjected to enzyme hydrolysis. A PES subsample was suspended in 100 mM sodium acetate buffer (pH 5.0). Cellulase was added and incubated at 37 °C for approximately 24 hours. The enzyme hydrolysis procedure was repeated sequentially using amylase in 100 mM potassium phosphate buffer, pH 6.9 at approximately 22 °C, pectinase in 100 mM sodium acetate buffer, pH 4.0 at approximately 25 °C, and pronase in 100 mM phosphate buffer, pH 7.5 at approximately 37 °C. These fractions were quantified by LSC, but not further subjected to identification. After enzyme treatment further hydrolysis was performed on the remaining PES after the pronase treatment with EGTA in 50 mM sodium acetate buffer, pH 4.5 at approximately 80 °C for approximately 4 hours. The solid residue from this treatment (PES-2) was retained for further hydrolysis. The entire remaining PES-2 fraction was suspended in 1N HCl and agitated at 37 °C for approximately 24 hours. Aliquots of the acid hydrolysed aqueous fraction were taken for LSC evaluation of released radioactivity. The solid fraction after acid hydrolysis was individually suspended in 1N NaOH, and agitated at 37 °C for approximately 24 hours. of the base-hydrolysed aqueous fraction were taken for LSC.

Metabolite identities were confirmed by direct LC-MS/MS comparison with certified synthetic reference standards (fluindapyr and potential metabolites: N-DesMet-pyrazole carboxylic acid, pyrazole carboxamide, pyrazole carboxylic acid, 1-OH-Met-N-DesMet-fluindapyr, 1-COOH-fluindapyr, 1-OH-Met-fluindapyr (2 diastereomers), 2-Dehydro-fluindapyr, DesMet-fluindapyr-N-1-Gluc, 3-OH-fluindapyr, N-DesMet-fluindapyr, 2-OH-fluindapyr, 3-OH-fluindapyr, N-DesMet-3-COOH-fluindapyr, 3-COOH-fluindapyr, 3-

OH-Met-N-DesMet-fluindapyr). The enantiomeric ratio of fluindapyr was determined in the foliage samples.

The TRR, distribution of radioactivity and the identified metabolites in mature root and foliage are shown in Tables 5 to 7. The TRR in mature roots was relatively low (max. 0.122 mg eq/kg), with the TRR in immature foliage being higher, but with the highest TRR in mature foliage (maximum of 1.67 mg eq/kg). The TRR in control samples was below the LOQ of 0.01 mg/kg. The extractable radioactivity for all samples ranged from 90–93 percent TRR in both sugar beet roots and foliage. The remaining mature foliage and root PES samples contained residues > 0.05 mg eq/kg or >10 percent TRR, and were further investigated.

The identification results of the extracts which were subjected to dichloromethane partitioning, after which the aqueous fractions were subjected to acid hydrolysis are shown in Table 6 and Table 7. Immature foliage was not partitioned with dichloromethane, and therefore, no identification results are available for these type of extracts of immature foliage. The identification results of the organic/aqueous extracts are not shown here. These were parallel extractions and the identifications results of the organic/aqueous extracts are only shown in an appendix of the study report. This appendix has been checked and results are similar to the identification results shown here in Table 6 and Table 7. In the organic/aqueous extracts, in mature foliage, conjugated 1-OH-Met-fluindapyr has been specified as glucosyl conjugates and glucosylsulfate conjugates. In mature roots, no conjugated 1-OH-Met-fluindapyr has been detected in the acetonitrile extracts. The results of the acetonitrile extracts of the immature foliage are similar to the results of the extracts of mature foliage.

The β-glucosidase enzyme hydrolysis of extractable conjugated metabolites from the mature foliage samples from both labels was similar and showed minimal partial de-conjugation of the glucosylsulfate conjugate of 1-OH-Met-fluindapyr to liberate 1-OH-Met-fluindapyr. The results suggest a complex conjugation product. Therefore, the 1N HCl acid hydrolysis procedure was adopted for the hydrolysis of the conjugated residues remaining in the aqueous fractions after dichloromethane partitioning of the original extract. The acid hydrolysis of the conjugated metabolites in the concentrated acetonitrile/water extracts, at 60 °C gave a partial de-conjugation of the glucosylsulfate conjugate of 1-OH-Met-fluindapyr to the glucosyl conjugate and some liberation to 1-OH-Met-fluindapyr. After dichloromethane partitioning, the 1N HCl hydrolysis procedure of the conjugated metabolites performed at 100 °C gave full de-conjugation of the glucosylsulfate conjugate of 1-OH-Met-fluindapyr to the liberation of 1-OH-Met-fluindapyr.

Parent fluindapyr was a major component of the residue in sugar beet, both in mature roots (43–50 percent TRR, 0.036–0.062 mg eq/kg) and mature foliage (15–18 percent TRR, 0.25–0.30 mg eq/kg). The main component of the residue in mature foliage was 1-OH-Met-fluindapyr, both free and conjugated (62–66 percent TRR, 1.0–1.1 mg eq/kg). In sugar beet roots, this metabolite 1-OH-Met-fluindapyr was also retrieved (8.4–25 percent TRR, 0.007–0.031 mg eq/kg).

Levels of pyrazole carboxamide, pyrazole carboxylic acid and N-DesMet pyrazole carboxylic acid were low (each <5 percent TRR).

Further hydrolysis of the PES was performed on the phenyl-labelled root PES and on phenyl and pyrazole foliage PES samples, which showed very low amounts of radioactivity released. No further analysis was conducted.

Chiral analysis of fluindapyr showed no significant change in the enantiomeric composition, indicating non-selective metabolic biotransformation in sugar beet mature foliage. The chiral analysis results are presented in Table 8. No further analysis of R/S isomerization was performed.

Foliar application to cereals

Metabolism of fluindapyr following foliar application was investigated in wheat [Mainolfi & Garau, 2016, 2013MET-IFP0694]. Wheat plants (variety: San Carlo) were grown outdoors in pots with sandy loam soil in Italy. Two applications of 124–130 g ai/ha each of either phenyl or pyrazole labelled fluindapyr were

performed. The first application was performed at BBCH 31–33, the second at BBCH 65. Separate treatment pots received two exaggerated applications at a rate of 601–624 g ai/ha to be used to assist in the identification of specific metabolites, in case necessary (this treatment was not further analysed). Fluindapyr was administered as an emulsifiable concentrate (EC) formulation by foliar spraying. Harvesting took place at the following growth stages; immature whole plants at forage stage (BBCH 47–49; only 1 application has taken place yet, 3–4 days after application), immature whole plants at hay stage (BBCH 83; 21–22 DALA), and mature grain and straw (41–42 DALA) separately. Samples were stored at -20 °C until analysis. Samples were stored for a maximum period of 99 days (grain) before extraction, after which TLC analysis took place within max. 21 days.

Each RAC was thoroughly and finely ground to obtain a homogeneous sample and the TRR was determined by combustion of ground subsamples. Ground samples from each RAC were sequentially extracted with acetone/water mixtures four times. A fifth extraction was conducted on straw and grain with acetone/HCl (0.1 N 50:50, v/v). The extracts from forage, hay and straw were combined by matrix and sequentially partitioned with n-heptane (extract A) and ethyl acetate (extract B; remaining aqueous phase = C). The extracts from grain were evaporated and the solid residues were solubilized in methanol for analysis. All the organic extracts and aqueous phases were analysed by LSC to determine their radioactive content.

Bound residues (after the acetone extractions) from grain and straw were processed further to promote the release of the unextracted radioactivity. The solid residues were suspended in 0.5 N $NaOH/CH_3OH$ (50:50 v/v) and incubated for 2 hours at ambient temperature. The solid residues were subsequently suspended into 0.1 percent Tween 20 and incubated for 2 hours at ambient temperature. The solid residues were subsequently incubated with enzymes capable of degrading macromolecules from the matrices. Grain residue was suspended in 50 mM ammonium acetate buffer, pH 5, and sonicated for 5 minutes. An aliquot of the suspension was taken, β-amylase was added and the sample was incubated at 37 °C for 24 hours. Then, the grain residue was suspended in the buffer and sonicated as described above, prior to incubation with cellulase. The sample was incubated at 37 °C for 24 hours. Bound residue in straw was subjected to hydrolysis with cellulase, following the same procedure described above.

Aliquots of concentrated ethyl acetate (extract B) and aqueous extracts (phase C) from pyrazole or phenyl straw samples were subjected to enzymatic hydrolysis with β-glucosidase. The aliquots were evaporated to dryness. Enzyme was added to the obtained residues and suspended with sodium acetate 0.1 M (pH 4.8). The suspensions were incubated at 37 °C for 48 hours. The aqueous extract from the pyrazole straw sample after enzymatic hydrolysis was further subjected to chemical hydrolysis. Three aliquots were incubated with HCl at different acid strengths, 1N, 2N and 6N, for 1 hour at 80 °C. The samples were then neutralised by adding ammonia solution. In addition, aliquots of concentrated ethyl acetate (extract B) and aqueous phase (phase C) from pyrazole or phenyl samples (all RAC's) were subjected to acid hydrolysis with 6N HCl for 1 hour at 80 °C.

The extractable radioactivity from each RAC was analysed by TLC. Additionally, representative extracts from straw were analysed also by HPLC. Representative RAC extracts (extract A) of different commodities were analysed by chiral HPLC in order to evaluate the enantiomeric ratio of the unchanged fluindapyr. Reference standards were fluindapyr, pyrazole carboxylic acid, pyrazole carboxamide, 3-OH-fluindapyr, 1-OH-Met-fluindapyr, and 1-OH-Met-N-DesMet-fluindapyr. The identity of each metabolite was confirmed by comparison of the LC-MS data with an authentic reference standard, or in the case of conjugates with the reference standard of the corresponding aglycone.

The TRR and distribution of radioactivity is shown in Table 9. The TRR of grain was lower than the TRR obtained from the other wheat RACs. The highest TRR was observed in straw. The extractability was

at least 93 percent in forage and hay, while it was higher than 84 percent for straw. In grain, extractability was 66 percent with the phenyl-label and 77 percent with the pyrazole-label. Radioactivity in post-extraction solid residues from forage and hay was not further investigated, but the residual radioactivity in post-extraction solid residues from straw and grain required further characterization. Partitioning of extracts from forage, hay and straw showed that the water-soluble fractions contained relevant amounts of extractable radioactivity for all samples.

Identification and characterization results are shown in Table 10 and Table 11. The majority of the detected metabolites were found in both the phenyl-labeled and pyrazole-labeled samples. Parent fluindapyr was a major metabolite in all RACs (46–56 percent TRR, 0.0093–0.021 mg eq/kg in grain and 28–37 percent TRR, 0.46–4.3 mg eq/kg in forage, hay and straw). Unconjugated 3-OH-fluindapyr was present at 20–22 percent TRR (0.0042–0.0084 mg eq/kg) in grain and 4.5–14 percent TRR (0.56–1.8 mg eq/kg) in forage, hay and straw.

HPLC radio chromatograms of the ethyl acetate extract (B) and the aqueous phase (C) from pyrazole-labelled straw, chosen as representative, before and after enzymatic hydrolysis show that the metabolic profile was simplified by the hydrolysis with β-glucosidase, demonstrating that several glucosyl conjugated compounds are present in the extracts. In addition, the profile obtained from enzymatic hydrolysis was further simplified after the subsequent chemical hydrolysis by HCl. The peak for O-glucosyl-sulfate conjugate of 1-OH-Met-fluindapyr gradually disappeared while increasing the concentration of HCl from 1N up to 6N. Meanwhile, the peak corresponding to 1-OH-Met-fluindapyr gradually increased. Acid hydrolysis (6N HCl) of the ethyl acetate extract (B) and aqueous phase (C) from forage, hay and straw produced the complete conversion of all the conjugates to the two diastereomers of 1-OH-Met-fluindapyr. The two diastereomers of 1-OH-Met-N-DesMet-fluindapyr were found in residual aqueous phases (phase C) from forage, hay and straw after acid and enzymatic hydrolysis. Therefore, after enzymatic and chemical hydrolysis, four free aglycones were detected: the main two were identified as the diastereomers of 1-OH-Met-fluindapyr, the minor two as diastereomers of 1-OH-Met-N-DesMet-fluindapyr. Free and conjugated levels of 1-OH-Met-fluindapyr ranged from 35 to 60 percent TRR (0.64–7.1 mg eq/kg) in forage, hay and straw, with the largest part being conjugated, since free 1-OH-Met-fluindapyr was <1 percent TRR in all samples. This metabolite was not detected in grain. Glucosyl conjugated 1-OH-Met-N-DesMet-fluindapyr was present at 0.38–5.1 percent TRR (0.037–0.067 mg eq/kg) in forage, hay and straw, while it was not detected in grain.

The radioactivity levels in grain extracts were too low to be analysed by chiral HPLC. The starting enantiomeric ratio S:R was approximately 50:50 in the test formulations, however, a mean ratio of 34:66 was found in the forage, hay and straw RAC samples (see Table 12).

Foliar application to rice

A metabolism study using phenyl-^{14}C and pyrazole-^{14}C labelled fluindapyr was conducted in rice (variety: M-205) [Desai *et al*. 2017, 2015MET-IFP1891]. Rice plants were grown outdoors in boxes filled with sandy loam, in California, United States of America. Rice was seeded in May 2015. Two foliar applications of 114–122 g ai/ha each were performed at crop stage BBCH 33 and BBCH 75, corresponding with an RTI of 70 days. Fluindapyr was administered as an emulsifiable concentrate (EC) formulation. Samples of mature crop (dehulled grain and straw) were harvested 58 days after the 2nd application and frozen

(approximately at -20 °C) prior to shipment for analysis. All samples received were processed within two weeks. All the processed samples were extracted within one month and initial sample analysis was performed within 6 months (41 days) from harvest.

Combustion analysis of plant samples was performed using finely homogenised/ground straw and grain. Subsamples of rice samples were extracted three times with a solution of acetonitrile/water (1:1, v/v). Further extraction was repeated three additional times using methanol/water (1:1, v/v). All extracts were combined, assigned Ext-1 fraction, and analysed by LSC. A fraction of Ext-1 was also concentrated to dryness, reconstituted in aqueous solution and subjected to partitioning with dichloromethane. After dichloromethane partitioning, the separated aqueous fraction was subjected to acid hydrolysis (1N HCl) under reflux at 100 °C for approximately 1 hour. All the fractions were then concentrated and analysed by HPLC analysis. The remaining PES samples were air-dried and combusted, followed by LSC to determine residual ^{14}C-bound. The initial solvent extracts (Ext-1) were concentrated to remove organic solvent. Representative sample extracts were further analysed by chiral HPLC. Selected extracts and isolated metabolites were analysed by LC/RAM/ESI-MS and MS/MS. Metabolite reference standards were used for qualitative HPLC chromatographic analyses only. Reference standards were fluindapyr, pyrazole carboxylic acid, pyrazole carboxamide, N-DesMet-fluindapyr, dehdyro-fluindapyr, 1-OH-Met-fluindapyr (2 diastereomers), 3-OH-fluindapyr, fluindapyr-1-COOH (2 diastereomers).

The TRR and distribution of radioactivity are shown in Table 13. The TRR in rice grain was moderate (0.65 mg eq/kg and 0.78 mg eq/kg). Straw contained higher TRR levels of 1.83 mg eq/kg and 2.25 mg eq/kg for phenyl and pyrazole label respectively. Residues in control samples were <0.001 mg eq/kg. The data show ≥92 percent of the TRR was extracted with acetonitrile/water solvent mixture. The PES fractions from both phenyl- and pyrazole treatment constituted <10 percent TRR and <0.05 mg/kg, respectively. Therefore, the PES fractions from these samples were not subjected to further analysis.

The identification results of the organic/aqueous extracts (Ext-1) are shown in Table 14. These extracts did not undergo any hydrolysis. The identification results of the extracts which were subjected to dichloromethane partitioning, after which the aqueous fractions were subjected to acid hydrolysis, are not shown, since these were parallel extractions and the sum of the identifications results in the dichloromethane extract' and the 'aqueous fraction after acid hydrolysis' are similar to the results in Ext-1. In the 'aqueous fraction after acid hydrolysis', some residues were retrieved (parent, the two diastereomers of 1-OH-Met-fluindapyr, and 1-COOH-fluindapyr), which would have originated from their conjugated counterparts, however, in the organic/aqueous extracts these metabolites were already present in their unconjugated form. The identification results of the organic/aqueous extracts are considered to better represent the original residue situation, since they did not undergo additional sample processing steps (i.e. partitioning and hydrolysis). Furthermore, high identification levels are already achieved with these organic/aqueous extracts.

Metabolite profiles from the straw and mature grain samples of the phenyl and pyrazole labels were essentially similar with minor differences in the magnitudes of their distributions. Parent was the major residue in all samples, ranging from 53 to 57 percent TRR (0.37–1.2 mg eq/kg) in grain and straw. The two diastereomers of 1-OH-Met-fluindapyr, and 3-OH-fluindapyr were also present in large quantities, ranging from 17 to 23 percent TRR (0.11–0.43 mg eq/kg) and from 8.2 to 11 percent TRR (0.053–0.25 mg eq/kg) for each compound, respectively in rice grain and straw. Metabolites 1-COOH-fluindapyr, N-DesMet-fluindapyr and dehydro-fluindapyr accounted for <5 percent TRR (<0.1 mg eq/kg) in both matrices. In addition, in the extracts from the pyrazole-labelled grain and straw, pyrazole carboxylic acid was detected, indicating that breakage of the carboxamide bond in fluindapyr was a minor metabolic pathway.

Chiral analysis of fluindapyr in rice grain (husked rice) and straw indicated that a slight change in enantiomeric ratio (R:S) took place and was determined to be approximately 60:40. This is presented in Table 15.

Foliar application to soya bean

The metabolism of fluindapyr has been investigated in soya beans (variety: Mycogen 5N45122) after three foliar applications [Desai, 2016, 2013MET-IFP0730]. Soya bean seeds were sown in May 2013 in boxes and maintained outdoors in sandy loam soil in California, United States. Three applications of 117–129 g ai/ha each of either phenyl or pyrazole labelled fluindapyr were performed. The first application was performed at BBCH 15–16, the second at BBCH 55-60, and the third application at BBCH 79, corresponding with RTIs of 21 and 60 days. Separate treatment plots received once an exaggerated application at a rate of 667–676 g ai/ha at BBCH 55–60 to be used to assist in the identification of specific metabolites, in case necessary (this treatment was not further analysed). Fluindapyr was administered as an emulsifiable concentrate (EC) formulation by foliar spraying. Immature forage was sampled at 21 days after the first application (28 prior to the second application), hay was harvested after two applications, and mature seeds were collected 30 days after the third application. Harvested commodities were processed cryogenically. The TRR in each sample was determined via combustion. The remaining samples were stored frozen (approximately -20 °C). Samples were subsequently extracted within one month after processing, and initially analysed within 6 months from harvest.

Subsamples of soya bean samples were first extracted with a solution of 1:1 acetonitrile/water (v/w). The remaining solids were then re-blended with a solution of 1:1 acetonitrile/water (v/w). The extraction step was repeated once more with 1:1 acetonitrile/water. The extraction procedure was repeated three additional times using 1:1 methanol:water (v/w). All extracts were combined, assigned Ext-1 fraction, and assayed by LSC. Ext-1 fraction was concentrated and analysed by HPLC. A fraction of Ext-1 was also concentrated to dryness and reconstituted in aqueous solution. This was then subjected to partitioning with dichloromethane. After dichloromethane partitioning, the separated aqueous fraction was subjected to acid hydrolysis (1N HCl) under reflux at 100°C for approximately 1 hour. All the fractions were then concentrated separately for analysis by HPLC. The remaining PES samples were air-dried and combusted, followed by LSC to determine residual ^{14}C-bound. The initial solvent extracts (Ext-1) were concentrated to remove organic solvent.

The hay PES samples were subjected to sequential enzyme hydrolysis. A representative PES subsample was suspended in 100 mM sodium acetate buffer (pH ~5.0). Cellulase solution was prepared in 100 mM sodium acetate buffer. Fractions were then mixed with cellulase enzyme and incubated at 37 °C for about 24 hours. Aliquots were taken for LSC. The procedure was repeated for sequential enzyme hydrolysis with amylase, pectinase, and protease enzymes. The solid residues (PES-2) were transferred into a container for further hydrolysis. The bound residue samples remaining after sequential enzyme hydrolyses were subjected to further hydrolysis with 1N acid and 1N base. The entire remaining PES-2 fraction from each sample was suspended in 2× v/w of 1 N HCl. The mixture was sonicated for 15 minutes and stirred in a water bath at 37 °C for approximately 24 hours. A single aliquot of the aqueous fraction was taken for LSC evaluation of released radioactivity. The solid fraction after acid hydrolysis was individually suspended in 2 × v/w of 1 N NaOH and the mixture was vortex-mixed and stirred at ambient temperature for approximately 24 hours. A single aliquot of the aqueous fraction was taken for LSC.

Representative sample extracts were analysed by chiral HPL. Selected extracts and isolated metabolites were analysed by LC/MS with on-line UV and radio-detection and LC-MS/MS.

Reference standards were fluindapyr, pyrazole carboxylic acid, pyrazole carboxamide, N-DesMet-fluindapyr, dehydro-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr, 1-OH-Met-fluindapyr (2 diastereomers), 3-OH-fluindapyr, and DesMet-fluindapyr-N1-glycoside.

The TRR and distribution of radioactivity are shown in Table 16. The TRR in seeds was clearly lower than the TRR in forage and hay. Residues in control samples were <0.001 mg eq/kg.

The data showed ≥90 percent of the TRR was extracted with acetonitrile/water. Less than 10 percent of the TRR remained as bound residues. Based on the values ≥ 0.050 mg/kg in the PES from the two hay samples, these samples were subjected to enzyme, acid, and base hydrolysis. Sequential treatment of the PES fractions from mature hay samples released relatively insignificant amounts of TRR (less than 0.01 mg/kg in each fraction) from the PES fractions (see Table 17), suggesting natural incorporation. Since the amount of released radioactivity from various PES fractionations was less than 0.01 mg eq/kg, no further characterisation of these fractions was performed.

The identification results of the organic/aqueous extracts (Ext-1) are shown in Table 17. These extracts did not undergo any hydrolysis. The identification results of the extracts which were subjected to dichloromethane partitioning, after which the aqueous fractions were subjected to acid hydrolysis, are not shown, since these were parallel extractions and the sum of the identifications results in the dichloromethane extract' and the 'aqueous fraction after acid hydrolysis' are similar to the results in Ext-1. There is one small exception: pyrazole carboxylic acid was detected in the 'aqueous fraction after acid hydrolysis', while not observed in the organic/aqueous extracts and the 'dichloromethane extract'. This would imply that conjugated pyrazole carboxylic acid is present in low amounts. Interestingly, in the 'aqueous fraction after acid hydrolysis', some residues were retrieved (the two diastereomers of 1-OH-Met-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr and N-DesMet-fluindapyr-N-Ser), which probably have originated from their conjugated counterparts, and which in the organic/aqueous extracts were indeed present in their conjugated form. The identification results of the organic/aqueous extracts are considered to better represent the original residue situation, since they did not undergo additional sample processing steps (i.e. partitioning and hydrolysis). Furthermore, high identification levels are already achieved with these organic/aqueous extracts.

The identification results in Table 17 show that the metabolite profiles from the forage and hay samples for both labels were similar with only minor differences in the magnitudes of their distributions. Several metabolites have been observed, therefore, it can be concluded that fluindapyr has been rather intensively metabolised in soya bean plants. Parent was only present at 5.7–12 percent TRR (0.017–0.22 mg eq/kg) in forage and hay. Conjugated 1-OH-Met-fluindapyr, DesMet-fluindapyr, and 1-OH-Met-N-DesMet-fluindapyr were detected in larger quantities: 1-OH-Met-fluindapyr-conjugates ranged from 31–40 percent TRR (0.12–0.57 mg eq/kg), DesMet-fluindapyr-conjugates were present from 14–18 percent TRR (0.046–0.33 mg eq/kg) and 1-OH-Met-N-DesMet-fluindapyr-conjugates ranged from 9.5–12 percent TRR (0.034–0.17 mg eq/kg). In addition, N-DesMet-fluindapyr-N-Ser, 3-OH-Fluindapyr, N-DesMet-Fluindapyr and dehydro-fluindapyr were present in quantities < 5 percent TRR (< 0.1 mg eq/kg). Pyrazole carboxamide was only present in forage (1.1 percent TRR, 0.006 mg eq/kg).

No tabular results are shown for the soya bean seeds, since insufficient radioactivity was detected for characterisation and identification of metabolites in soya bean seed. In the phenyl-labelled soya bean seed samples, the profile contained 13 unknowns at levels of <0.001–0.001 mg eq/kg; and also in these samples after acid hydrolysis only unknowns were observed (maximum of 0.003 mg eq/kg). The pyrazole-labelled soya bean samples contained 13 unknowns at levels of 0.001–0.023 mg eq/kg, which

included 3 unknowns that were pyrazole carboxylic acid fragments. In addition, in the pyrazole-labelled soya bean sample, pyrazole carboxamide was identified at 6.7 percent TRR (0.006 mg eq/kg). In these samples after acid hydrolysis, similarly, only unknowns were retrieved (max. 0.013 mg eq/kg), in addition to pyrazole carboxamide at 0.032 mg eq/kg and pyrazole carboxylic acid at 0.003 mg eq/kg.

The chiral analysis results are presented in Table 18. The enantiomeric ratio R/S changed from approximately 50:50, as found in the test formulations, to 60:40 in hay and forage.

Overview of the metabolic pathway of fluindapyr in primary crops

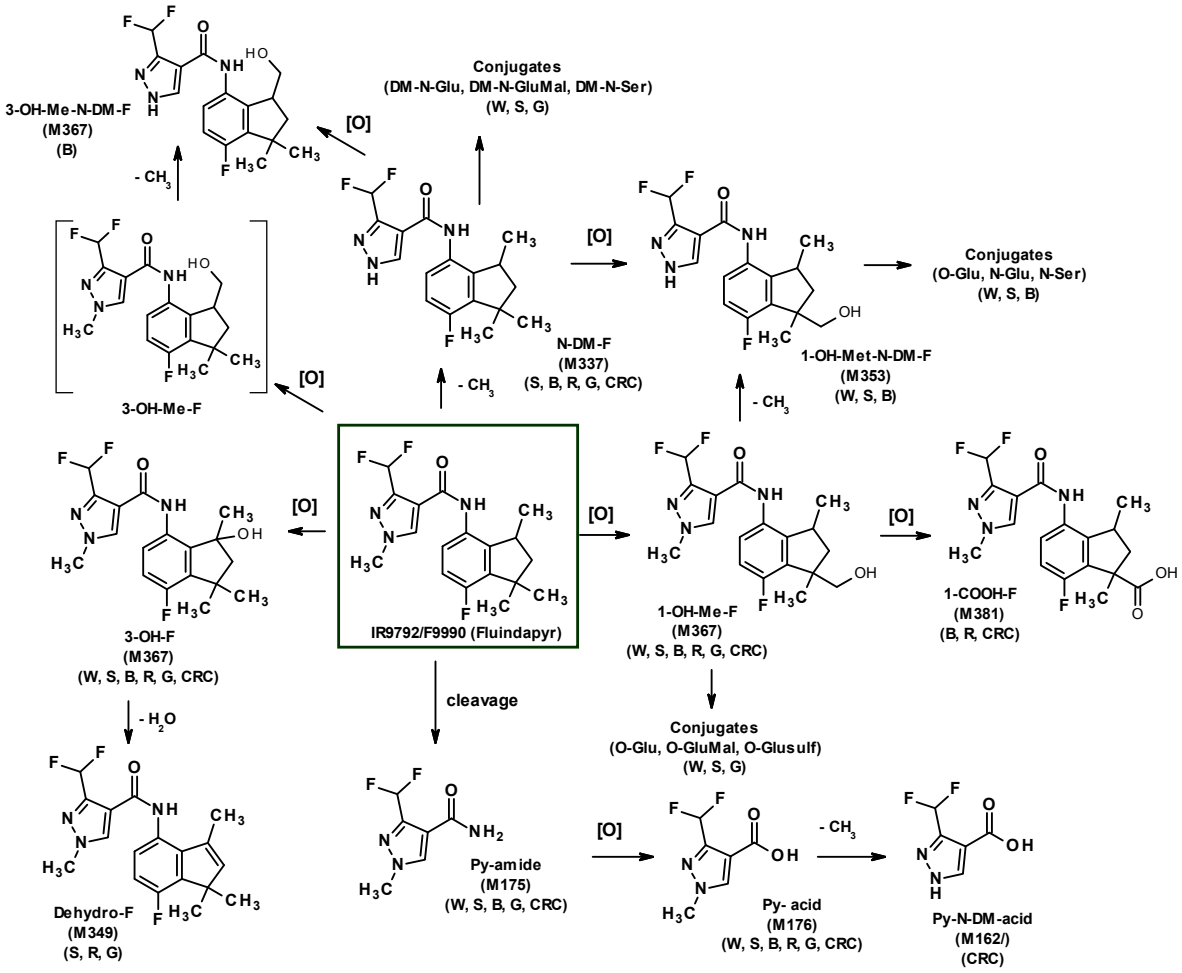
Plant metabolism studies have been presented covering foliar treatments to the crop categories of fruits (grape), root crops (sugar beet), cereal/grass (wheat and rice), pulses and oilseeds (soya bean).

The enantiomeric ratio R/S in some crops remained 50:50 (grape leaves and rinse, sugar beet foliage) however, in other crops a shift could be observed into a ratio of 60:40 or 70:30 (grape extract, wheat forage/hay/straw, rice grain/straw, soya bean hay/forage).

The major metabolic pathways of fluindapyr were hydroxylation, often followed by O-glycosylation, and oxidative-N-demethylation, both followed by conjugation, yielding the important

metabolites 1-OH-Met-fluindapyr (free and conjugated), 3-OH-fluindapyr, and 1-OH-Met-N-DesMet-fluindapyr (free and conjugated). Hydrolysis resulting in the parent breakage of the carboxamide bond constituted a relatively minor route.

In all crops most major pathways were observed, however, in some crops metabolism was more advanced (e.g. soya bean) than in other crops. See Figure 2, note that the figure below also includes the proposed metabolic pathways of the rotational crops, which are discussed in the section on the rotational crops after the section on environmental fate in soil. For better view an enlargement of the scheme can be found at the end of the evaluation.



F: fluidapyr; Me: methyl; DM: desmethyl; py: pyrazole; Glu: glucoside; GluMal: malonylglucoside; Ser: serine; Glusulf: glucosyl sulfate
M: Mol. Wt.

CRC: confined rotational crops (carrot, lettuce and wheat)

Figure 2 Proposed metabolic pathways of fluindapyr (F9990/IR9792) in primary and rotational crops

Environmental fate in soil

The Meeting received information on the environmental fate in soils. Information included studies on the route and rate of degradation of fluindapyr and its metabolites in aerobic soils under laboratory conditions and dissipation of fluindapyr under field conditions. The fate and behaviour of fluindapyr was investigated using ^{14}C-phenyl and ^{14}C-pyrazole-labeled fluindapyr. Furthermore, soil photolysis, soil

dissipation and confined and field rotational crop studies were provided. The anaerobic soils studies as well as the mobility studies (adsorption and desorption of the active substance and its soil metabolites) that were submitted, are not required according to the JMPR manual on the Submission and Evaluation of Pesticide Residues Data (2016). These studies were not further considered (see references submitted but not used).

Photodegradation on the soil surface

The photodegradation of fluindapyr was studied in a soil from Europe [Vanini & Pizzella, 2016, 2014EFT-IFP1406]. Soil characteristics are reported in Table xx.

Table 19 Soil characteristics for study 2014EFT-IFP106

Soil name	Stir-2

Disturbed bulk density (g/cm^3)	1.1
Dry Mass (%)	90.52

Notes:

[a] Classification according to United States Department of Agriculture (USDA).

The [^{14}C-pyrazole]-labelled fluindapyr or the [^{14}C-phenyl]-labelled fluindapyr was applied to a thin layer of soil. The soil layer was prepared by applying an aqueous slurry of soil to a stainless steel plate in such a way to form a soil layer of about 2 mm thick and of about an area of 12.5 cm^2.

A set of samples was allowed to air-dry, about 24 hours, to reach a soil moisture of about 75 percent of field capacity. A set of samples was completely dried out. ^{14}C-fluindapyr was applied to each unit at the nominal rate of 125 g a.i./ha. Half of the samples of the first set (named *Wet*) and all samples of the second set (named *Dry*) were placed in a stainless steel tray covered with a quartz lid, exposed to the Xenon lamp at a irradiance mean value of 708.5 W/m2 and maintained at a temperature of 20±2 °C. The other half of the samples of the first set were incubated under identical conditions but not irradiated (named *Dark*).

Duplicate incubation units were collected and analysed at the following sampling times after treatment: 0, 1, 2, 3, 6, 10 and 15 days (15 days of continuous irradiation corresponded to about 46 days of natural summer sunlight at latitude 30°N).

Soil was extracted with two different solvent mixtures and the extractable radioactivity was determined by Liquid Scintillation Counting (LSC). The radioactivity distribution in soil extracts was determined by Thin Layer Chromatography (TLC) analyses and the enantiomeric ratio of fluindayr by High Pressure Liquid Chromatography (HPLC) analyses of representative samples. The non-extractable radioactivity was determined by LSC, after oxidation of aliquots of soil residue by means of a biological oxidizer.

The soil extractable radioactivity ranged from 96 percent to 99 percent of Applied Radioactivity (AR) in *Dark* samples, from 94 percent to 98 percent AR in *Dry* samples and from 93 percent to 98 percent AR in *Wet* samples.

Fluindapyr progressively degraded in Wet and Dry samples, while in Dark samples no a evident decline was observed in 15 days of incubation. DT_{50} values were calculated assuming single first order (SFO) kinetics and using KinGUI version 1.1 software. The fit of the SFO model is based on visual assessment of goodness of fit and on Chi-squared error. Results are shown in Table 20.

Table 20 Degradation rate in irradiated soils for fluindapyr

	Dark controls soils				Irradiated dry soil				Irradiated wet soil			
	DT_{50} (days)	DT_{90} (days)	χ^2 (%)	r^2	DT_{50} (days)	DT_{90} (days)	χ^2 (%)	r^2	DT_{50} (days)	DT_{90} (days)	χ^2 (%)	r^2
[^{14}C-pyrazole] fluindapyr	318	1058	0.8	0.448	56	186	1.3	0.923	56	187	2.2	0.810
[^{14}C-phenyl] fluindapyr	281	933	0.9	0.430	65	217	1.2	0.907	52	172	2.2	0.831

The endpoint obtained from SFO equation were converted in equivalent days of natural summer sunlight and the results are listed in Table 21.

Table 21 Degradation rate in equivalent of natural summer light

Sample	endpoint	experimental days (mean of both labels)	equivalent days natural sunlight		
			sunlight 30°N	sunlight 40°N	sunlight 50°N
Dry	DT_{50}	61	188	183	193
	DT_{90}	202	624	608	640
Wet	DT_{50}	54	167	163	172
	DT_{90}	180	556	542	570

The route of degradation on the soil surface is similar for both the wet and dry samples and showed that the extracts contained the same main photo transformation products. Five or six photodegradation products were found. See Table 22. Two main compounds were identified; Co-chromatography identified one of the degradation products as 3-OH-fluindapyr (code 510152). On the basis of TLC, HPLC and LC-MS analyses, the second degradation compound was identified as pyrazole-carboxamide (code 510151). In Dark samples no degradation products were found.

The non-extractable radioactivity (bound residue) ranged from 0.77 percent to 4.6 percent AR. The Mass Balance was always higher than 96 percent AR.

HPLC analyses of representative soil extracts showed that the enantiomeric ratio S/R of unchanged ^{14}C-fluindapyr remained constant during the study and was found to be about 50 : 50.

Notes:

ND = not detected (detection limit = 0.88 percent).

NA = not applicable because of the labelling site.

- = Not analysed.

Overview of the metabolic pathway of fluindapyr after soil surface photolysis

Fluindapyr was only limited metabolised after soil surface photolysis with approximately 80 percent unchanged parent, two main degradation products could be identified, 4 minor, unidentified metabolites. The results indicates that some hydroxylation takes place resulting in 3-OH-fluindapyr (up to 9.7 percent AR) and that there is cleavage of the parent forming the pyrazole carboxamide (up to 7.3 percent AR) and finally some mineralization (formation of bound residues and CO_2), reaching maximums of 4.6 percent of the AR.

Aerobic degradation of fluindapyr in soil

Studies 1-4 In two studies (study 1 and 2) the route and the rate of degradation was studied in one European and oneUnited States soil [Mainolfi & Colombini, 2016a, 2013EFT-IFP0873; Mainolfi & Colombini, 2016b, 2013EFT-IFP0874] using both [^{14}C-phenyl]-fluindapyr and [^{14}C-pyrazole]-fluindapyr. In two additional studies (study 3 and 4) the route of degradation of fluindapyr was investigated in three European and three soils using only the [^{14}C-pyrazole]-labelled fluindapyr [Vanini, 2016a, 2013EFT-IFP0735; Vanini, 2016b, EFT-IFP0763]. Soil characteristics from the different soils are reported in Table 23.

In all four studies the soil samples (50 g dry weight) were maintained in the dark at a temperature of 20 ± 2 °C and the soil moisture was maintained at 60 percent of the Maximum Water Holding Capacity (MWHC) corresponding to a pF value of 2 (0.1 bar). After 7 days of acclimatization, [^{14}C-phenyl]-fluindapyr and [^{14}C-pyrazole]-fluindapyr were applied separately to the respective soil incubation units at 0.5 mg/kg, equivalent to a field application of 127–128 g ai/ha (1 × test solution) in all studies.

Each unit was then connected to 2N KOH and ethylene glycol traps to collect volatile radioactivity and incubated in the dark at 20 ± 2 °C for 123 days. Moistened CO_2-free air was passed through units to maintain aerobic conditions. The soil moisture content was adjusted by adding purified water during the study. For each soil, an untreated sample was set up and used as blank. Duplicate incubation units were collected and analysed at 0, 9, 19, 36, 61, 90 and 120 days in studies 1 and 2. In study 3 and 4 the European soil samples were taken at 0, 10, 24, 48, 91, 132, and 151 days for Stir-2 and Z-1 soils and at 0, 10, 34, 70, 98, and 125 days for Sp2.1 soil and for the three United States soils. Soil samples were stored at 4 °C for a maximum of three months after collection [Mainolfi & Colombini, 2016a, 2013EFT-IFP0873; Mainolfi & Colombini, 2016b, 2013EFT-IFP0874]. No storage data were reported in the other study reports [Vanini, 2016a, 2013EFT-IFP0735; Vanini, 2016b, EFT-IFP0763]. The experimental phase of both studies was performed within 9 months. The storage stability of fluindapyr and four of its metabolites was established by Skags, 2018 [Report X1509BK]. See section on storage stability.

Table 23 Soil characteristics for studies 2013EFT-IFP0873, 2013EFT-IFP0874, 2013EFT-IFP0735 and 2013EFT-IFP0763

[a] Classification according to United States Department of Agriculture (USDA).

[b] pH in 0.01 M $CaCl_2$.

Soils were extracted with acetone:water (9:1 v/v and 1:1 v/v) for all sample points, and with acetone:0.1N HCl (1:1 v/v) for all sample points except time 0. The extractable radioactivity was determined by LSC. Suitable aliquots of soil extracts were pooled, concentrated and analysed by TLC to quantify parent degradation and metabolite formation. Representative extract samples were analysed by LC-MS and compared to relevant reference compounds in order to identify the main degradation compounds. The unextracted radioactivity was determined by LSC, after oxidation of aliquots of soil residue using a biological oxidizer. The radioactivity content in the traps (volatiles) was determined by LSC, except at 0 day in all studies. Chiral High Performance Liquid Chromatography (HPLC) was used to confirm the enantiomeric ratio (S/R) of fluindapyr.

In study 1 and 2 the soils treated with an application rate of 1587-1599 g ai/ha (15 × test solution) were extracted only after 123 days of incubation. Each sample was extracted with acetone:water (9:1 v/v and 1:1 v/v) and pooled together. These extract samples were used as a source of metabolites for

characterisation/identification purposes as they have the same profile of radioactivity as the soil samples treated with the application rate of 125 g/ha.

The extractable radioactivity was higher than 90 percent of Applied Radioactivity (AR) in all samples. The unextracted radioactivity (bound residue) slightly increased during the study but did not exceed 5 percent AR. Volatile radioactivity did not exceed 4.3 percent AR, in either the KOH or ethylene glycol traps.

The mass balance ranged from an average of 93 percent to 104 percent AR and the individual mass balance values were within 90-110 percent AR throughout the studies.

In Sp-2.2 soil [Mainolfi&Columbini, 2016a, 2013EFT-IFP0873], the concentration of fluindapyr gradually decreased to averages of 71 percent AR at the end of the study (120 days) for the ^{14}C-phenyl and the ^{14}C-pyrazole labelled samples, respectively. In Iowa soil [Mainolfi & Columbini, 20156b, 2013EFT-IFP0874], the concentration of fluindapyr gradually decreased to averages of 66 percent AR at the end of the study (120 days) for both the ^{14}C-phenyl and the ^{14}C-pyrazole labelled samples. The same metabolic profile was observed for the ^{14}C-phenyl and the ^{14}C-pyrazole labels, indicating that no cleavage of the carboxamide bond occurred in the fluindapyr structure. The three main degradation compounds found during the study corresponded to 3-hydroxy-fluindapyr (code 510152), and the diastereomers *cis*-1-carboxy-fluindapyr (code 510170) and *trans*-1-carboxy-fluindapyr (code 510169). No other degradation compounds exceeded 3 percent AR at any sampling time. A similar pattern was observed in the studies only using ^{14}C-pyrazole labels [Vanini, 2016a, 2013EFT-IFP0735; Vanini, 2016b, EFT-IFP0763].

The concentration of all the three metabolites was still increasing at the end of the studies. The occurrence of fluindapyr and its metabolites in the eight tested soils are presented in Table 24.

Table 24 Distribution of radioactivity (percent of applied radioactivity) in 4 European and 4 United States soils after application of ^{14}C-phenyl or ^{14}C-pyrazole labelled fluindapyr (means of duplicate samples)

Soil/Study (label)	Compounds	percent of applied radioactivity per time interval

The rate of degradation of fluindapyr has been assessed using the FOCUS DEGKIN v2 Excel tool following FOCUS Kinetics guidance (2006). Single First-Order (SFO) kinetics adequately described the degradation in both radiolabels in the eight soils. The DT_{50} and DT_{90} values ranged from 141-353 and 469-1173 days, respectively. The individual results are summarized in Table 27.

Kinetic endpoints for aerobic degradation in soil

The rate of degradation of fluindapyr was calculated using kinetic modelling of the residue data for four soils in Europe [Mainolfi & Colombini, 2016a, 2013EFT-IFP0873; Vanini, 2016a, 2013EFT-IFP0735] and four soils in the United States [Mainolfi & Colombini, 2016b, 2013EFT-IFP0874; Vanini, 2016b, EFT-IFP0763]. The data were first fitted according to a single first order kinetic model (SFO) and secondly, if necessary, according to a bi-phasic kinetic model, First-Order Multi-Compartment kinetic model (FOMC).

The rate of degradation of fluindapyr has been assessed using the FOCUS DEGKIN v2 (June 2007) Excel tool following FOCUS Kinetics guidance (2006). The goodness of fit was assessed by visual inspection and an error criterion based on a chi-squared test. The findings are summarised in Table 27. Single First-Order (SFO) kinetics adequately described the degradation in both radiolabels in the eight soils.

The best fit DT_{50} and DT_{90} values ranged from 141-353 and 469-1173 days, respectively. When the data were combined, the geometric mean DT_{50} for fluindapyr is 265 days for the European soils, 187 days for the United States soils and 223 days for all soils together.

Overview of the metabolic pathway of fluindapyr in aerobic soil

Fluindapyr was metabolised in aerobic soil (depicted in Figure 3) either by hydroxylation resulting in 3-hydro-fluindapyr, or by carboxylation resulting in *cis*-1-carboxy-fluindapyr or *trans*-1-carboxy-fluindapyr. Mineralization (formation of bound residues and CO_2) was limited, reaching a maximum of almost 5 percent of the AR in one soil.

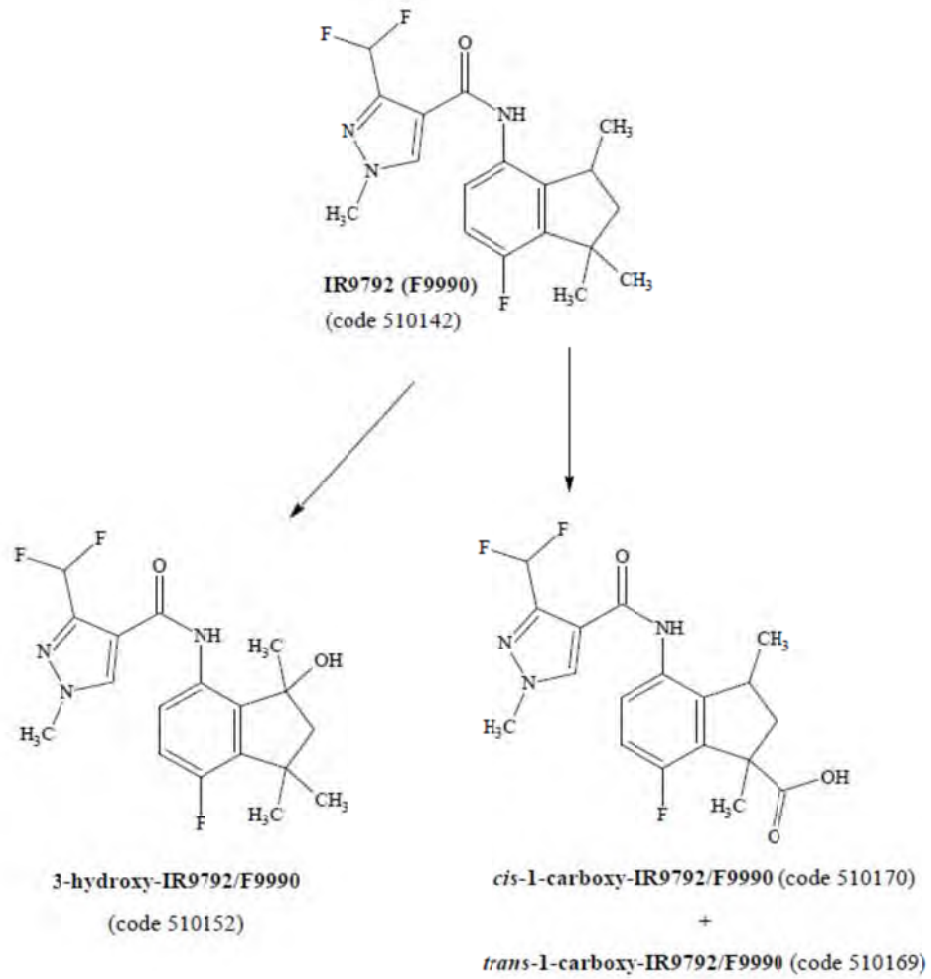

Figure 3 The proposed metabolic pathway for fluindapyr in aerobic soil

Aerobic degradation of metabolites in soil – laboratory studies with 3-OH-fluindapyr

The degradation of ^{14}C-3-hydroxy-fluindapyr under aerobic laboratory conditions was studied in three terrestrial soils from Europe [Vanini & Zerbinati, 2017, 2016EFT-IFP2696] and from the United States [Vanini, 2016c, 2015EFT-IFP2086]. Soil characteristics are reported in Table 28.

In both studies the soil samples (50 g dry weight) were maintained in the dark at a temperature of 20 ± 2 °C and the soil moisture was maintained at 60 percent of the Maximum Water Holding Capacity (MWHC) corresponding to a pF value of 2 (0.1 bar). After 7 days of acclimatization [^{14}C-pyrazole]-1-hydroxy fluindapyr was applied to the respective soil incubation units at 0.5 mg/kg, equivalent to a field application rate of 236–250 g ai/ha in all studies.

Each unit was then connected to 2N KOH traps to collect volatile radioactivity and incubated in the dark at 20 ± 2 °C for 123 days. Moistened CO_2-free air was passed through units to maintain aerobic conditions. The soil moisture content was adjusted by adding purified water during the study. For each soil, an untreated sample was set up and used as blank. Duplicate incubation units were collected and analysed at 0, 13, 31, 52, 81, and 117 days in the European soil studies and 0, 7, 25, 48, 81, and 123 day in the United States soils. No storage data were reported. The experimental phase of both studies was performed within 6 months. The storage stability of fluindapyr and four of its metabolites over a period of 2 years was established by Skags, 2018 [Report X1509BK]. See section on storage stability.

[a] Classification according to United States Department of Agriculture (USDA)

[b] pH in 0.01 M $CaCl_2$

Soils were extracted with acetone:water (7:3 v/v and 1:1 v/v)) for all sample points and with acetone:0.5N HCl (1:1 v/v) from 13 days [2016EFT-2696] and 7 days [2015EFT-IFP2086] onwards. The extractable radioactivity was determined by LSC. Suitable aliquots of soil extracts were pooled, concentrated and analysed by TLC to quantify parent degradation and metabolite formation. Representative extract samples were analysed by Liquid Chromatography - Mass Spectrometry (LC-MS) and compared to relevant reference compounds in order to identify the main degradation compounds. The unextracted radioactivity was determined by LSC, after oxidation of aliquots of soil residue using a biological oxidizer. The radioactivity content in the traps (volatiles) was determined by LSC, except at 0 day in all studies. Chiral High Performance Liquid Chromatography (HPLC) was used to confirm the enantiomeric ratio (S/R) of the metabolite in the United States soils [Vanini, 2016c, 2015EFT-IFP2086].

The extractable radioactivity ranged from 93-102 percent of Applied Radioactivity (AR) in all samples from both studies. The unextracted radioactivity (bound residue) slightly increased during the study but did not exceed 5.8 percent AR in both studies. Volatile radioactivity in the KOH solution trap was below detection limit in all samples from both studies.

The mass balance ranged from an average of 97 percent to 102 percent AR and the individual mass balance values were within 90–110 percent AR throughout the studies.

The chromatographic pattern of the European soil extracts showed a very slow degradation of 3-OH-fluindapyr. The unchanged 3-OH-fluindapyr decreased to 98 percent, 99 percent, and to 96 percent AR at the last sampling interval in SP-2.1, SP-2.2, and Stir-2 soils, respectively. No significant degradation compounds were detected in the extracts. The chromatographic pattern of the United States soil extracts also showed a very slow degradation of 3-hydroxy-fluindapyr and the formation of two or three minor degradation compounds depending on soil. None of them was increasing and the maximum amount reached was 4.2 percent AR. The unchanged 3-hydroxy-fluindapyr decreased to 89 percent, 87 percent, and to 92 percent AR at the last sampling interval in CA-SL, DU-L, and Iowa soils, respectively.

HPLC analyses of representative soil extracts showed that the enantiomeric ratio of unchanged ^{14}C-3-OH-fluindapyr remained constant during the study and was found to be about 50:50 in theUnited Statesstudy (ratios ranged from 0.97 to 1.01).

The occurrence of 3-OH-fluindapyr in the six tested soils are presented in Table 29.

Notes

n.a. = Not analysed.

ND = Not detected.

3-Hydroxy-fluindapyr very slowly degraded in the studies and the data fit well with the Single First-Order kinetic model (SFO) for each soil. The DT_{50} and DT_{90} values for 3-OH-fluindapyr were in higher than 1000 days in the European soils. The DT_{50} values were 970, 794, and 1302 days in the CA-SL, DU-L, and IOWA soils, respectively and the DT_{90} values 3222, 2639, and 4325 days, respectively. The results are summarized in Table 34.

Aerobic degradation of metabolites in soil – laboratory studies with cis-1-COOH-fluindapyr and trans-1-carboxy-fluindapy

The degradation of ^{14}C-*cis*-1-COOH-fluindapyr and ^{14}C-*trans*-1-COOH-fluindapyr under aerobic laboratory conditions was studied in three terrestrial soils from Europe [Mainolfi & Elmini, 2017, 2016EFT-IFP2510; Vanini, 2016d, 2016EFT-IFP2504]. Soil characteristics are reported in Table 30.

In both studies the soil samples (50 g dry weight) were maintained in the dark at a temperature of 20 ± 2 °C and the soil moisture was maintained at 60 percent of the Maximum Water Holding Capacity (MWHC) corresponding to a pF value of 2 (0.1 bar). After 7 days of acclimatization [^{14}C-pyrazole]-*cis*-1-COOH-fluindapyr or [^{14}C-pyrazole]-*trans*-1-COOH-fluindapyr was applied to the respective soil incubation units at 0.5 mg/kg, equivalent to a field application rate of 252 and 260 g ai/ha, respectively in both studies.

Each unit was then connected to 2N KOH traps to collect volatile radioactivity and incubated in the dark at 20 ± 2 °C for 117-120 days. Moistened CO_2-free air was passed through units to maintain

aerobic conditions. The soil moisture content was adjusted by adding purified water during the study. For each soil, an untreated sample was set up and used as blank. Duplicate incubation units were collected and analysed at 0, 10, 24, 48, 78, and 120 days in studies with ^{14}C-cis-1-COOH-fluindapyr and 0, 11, 24, 52, 81, and 117 day in the studies with ^{14}C-*trans*-1-COOH-fluindapyr. The experimental phase of both studies was performed within 6 months. The storage stability of fluindapyr and four of its metabolites over a period of 2 years was established by Skags, 2018 [Report X1509BK]. See section on storage stability.

Notes:

[a] Classification according to United States Department of Agriculture (USDA).

Soils were extracted with acetone:water (7:3 v/v and 1:1 v/v) for all sample points in both studies and with acetone:0.5N HCl (1:1 v/v) from 11 days onwards in study 2016EFT-IFP2504. In study 2016EFT-IFP2504 all samples were extracted twice with acetone:0.5N HCl (1:1 v/v). The extractable radioactivity was determined by LSC. Suitable aliquots of soil extracts were pooled, concentrated and analysed by TLC. The unextracted radioactivity was determined by LSC, after oxidation of aliquots of soil residue using a biological oxidizer. The radioactivity content in the traps (volatiles) was determined by LSC.

For the *cis*-metabolite, the extractable radioactivity ranged from 90.34 percent to 105.55 percent AR in SP-2.1 soil, from 90.38 percent to 101.58 percent AR in SP-2.2 soil and from 86.47 percent to 101.61 percent AR in Stir-2 soil. The extractable radioactivity ranged from 91.49 percent to 97.41 percent

AR in SP-2.1 soil, from 90.86 percent to 96.65 percent AR in SP-2.2 soil, and from 92.26 percent to 96.06 percent AR in Stir-2 soil with the *trans*-metabolite.

The non-extractable radioactivity (bound residue) slowly increased during the study to 2.21 percent, 4.00 percent and 9.03 percent AR in SP-2.1, SP-2.2 and Stir-2 soil respectively with the cis-metabolite. In the study with the trans-metabolite, the non-extractable radioactivity (bound residue) slowly increased to 4.09 percent, 4.44 percent, and 4.46 percent AR in SP-2.1, SP-2.2, and Stir-2 soil, respectively.

The radioactivity found in KOH traps reached 1.11 percent in SP-2.1 soil, 1.69 percent in SP-2.2 soil and 1.67 percent in Stir-2 soil with the *cis*-metabolite. The volatile radioactivity increased from 0.46 percent, 0.37 percent, and 0.23 percent AR at 52 days to 1.45 percent, 1.56 percent, and 0.92 percent AR in SP-2.1, SP-2.2, and Stir-2 soils, respectively with the *trans*-metabolite.

The ^{14}C-Mass Balance for each individual sample was always higher than 92 percent and 95 percent throughout the entire incubation duration for the cis and the trans metabolite, respectively in both studies and ranged from 93 percent to 106 percent AR and from 95 to 98 percent, respectively.

Twelve versus eight degradation products were found, always lower than 10 percent AR, in the studies with the *cis*- and *trans*-metabolite, respectively.

The occurrence of *cis*- and *trans*-1-COOH-fluindapyr in the three tested soils are presented in Table 31.

Notes:

[a] The mean percent AR of the unknowns were calculated by the reviewer.

The concentration of *cis*-1-COOH fluindapyr gradually decreased during incubation, according to a Single First-Order (SFO) kinetic in all soil, reaching 77 percent of AR in SP-2.1 soil, 65 percent of AR in SP-2.2 soil and 47 percent of AR in Stir-2 soil by the end of the incubation. ^{14}C-*trans*-1-COOH-fluindapyr also degraded slowly according to a Single First-Order (SFO) kinetic in all soils. Its amounts remaining at the last sampling interval were 67.93 percent, 60.07 percent, and 66.29 percent AR in SP-2.1, SP-2.2, and Stir-2 soils, respectively. The DT_{50lab} values for *cis*-1-COOH-fluindapyr ranged from 102–320 days. The DT_{50lab} values for *trans*-1-COOH-fluindapyr ranged from 170–223 days. The individual results and geometric means are summarized in Table 34.

Aerobic degradation of metabolites in soil–laboratory studies with pyrazole carboxamide

The rate of degradation of the photolytic soil metabolite pyrazole carboxamide (CSCC210616) was studied under aerobic conditions in 3 European and one United States soils [Simmonds & MacKenzie, 2009, NC/08/027]. Soil characteristics are reported in Table 32.

The soil samples (50 g dry weight) were maintained in the dark at a temperature of 20 ± 2 °C and the soil moisture was maintained at a moisture content equivalent to pF value of 2 (0.1 bar) for up to 119 days. After acclimatization [^{14}C-pyrazole]-pyrazole carboxamide was applied to the respective soil incubation units at an actual field application rate of 22 g ai/ha.

At intervals of 0, 3, 7, 14, 30, 60, 91 and 119 days after application duplicate flasks of each

soil were removed from the incubation system. Soil samples were extracted on the day that they were collected for analysis. Extracts were then stored refrigerated for a maximum of 10 days until processed. Concentrated extracts were stored frozen and initially analysed within 21 days of being generated. The longest storage period for extracts before the final HPLC analysis was 116 days. Comparison of chromatograms of the zero time and 3 day extracts of the North Dakota soil profiled following 116 days and 113 days storage confirmed that the test item pyrazole carboxamide (CSCC210616) and the metabolite CSAA798670 were stable throughout the respective storage periods.

Each soil sample was extracted three times with acetonitrile / water (1:1, v/v) at room temperature, including dilute formic acid in the final extraction. Extracted soil samples were air-dried, ground to a fine powder and the residual radioactivity quantified by combustion. Extracts from each soil sample were concentrated and analysed by reverse phase high performance liquid chromatography (HPLC). In addition, selected soil extracts were analysed by thin layer chromatography (TLC) and by mass spectrometry (LC-MS/MS) to provide confirmation of structural identity. At each sampling interval, the radioactivity in the trap solutions associated with each sample was quantified by liquid scintillation counting (LSC). Traps were also changed between sampling intervals and the radioactivity quantified by LSC.

Notes:

[a] Classification according to United States Department of Agriculture (USDA).

[b] Organic carbon percent calculated from organic matter percent assuming a conversion factor of 1.724.

The overall mean recovery values for each soil ranged from 95 percent to 97 percent AR. Recoveries for individual flasks ranged between 91 percent and 103 percent AR.

In all soils the extractable radioactivity decreased with time with a corresponding increase in

the unextracted radioactivity (maximum ca 35 percent in the 18 Acres sandy loam) and carbon dioxide (maximum ca 32 percent in the Gartenacker loam) after 119 days of incubation. The level of pyrazole carboxamide (CSCC210616) declined rapidly, reaching ≤ 6.0 percent AR in all soils by 14 days incubation. The results are shown in the Table 33.

Notes:

n.a. = Not analysed CSCD465008 = N-DesMet-pyrazole carboxamide acid; CSAA798670 = pyrazole carboxamide acid

Two metabolites, identified as CSAA798670 and CSCD465008, were observed in all soils, reaching maximum values of 65 percent AR in the Marsillargues clay and 78 percent in the Gartenacker loam soils respectively, after 14 days of incubation.

In all soils, aerobic degradation of [^{14}C]-pyrazole carboxamide led to the formation of $^{14}CO_2$ and non-extractable residues via two intermediate metabolites. The amide group was hydrolysed to form the acid metabolite CSAA798670 (pyrazole carboxamide acid), which then underwent demethylation to form N-DesMet-pyrazole carboxamide acid (CSCD465008). A proposed degradation pathway is depicted in Figure 4

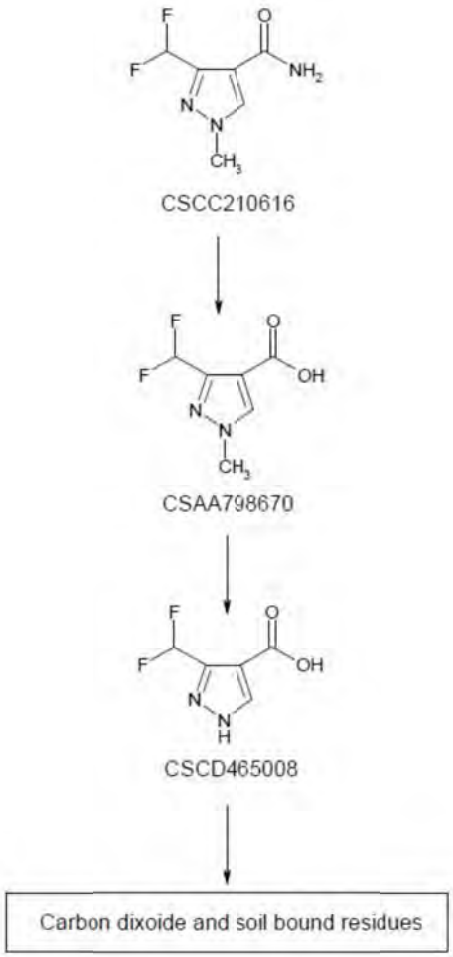

Figure 4 Aerobic degradation pathway of pyrazole carboxamide

DT_{50} and DT_{90} values for pyrazole carboxamide (CSCC210616) were determined following the recommendations of the FOCUS work group using a simple first order model (SFO). The results are shown in Table 34. Summary of DT_{50} and DT_{90} values of (photolytic) soil metabolites of fluindapyr in aerobic soils

Notes:

n.r. = Not reported.

[a] metabolite found in soil photolysis study, but not in aerobic soil degradation study.

Field dissipation studies in Europe

Study 1+2: Four field dissipation trials were carried out in Germany, United Kingdom, France and Italy in July 2015-August 2017 to study the dissipation and mobility of residues of fluindapyr and its metabolites in soil, following two applications of the a formulated product to bare soil [Gemroth, 2018, 2015-IFP1999 and 2015-IFP1999 Amendment no.1]. In order to assess the behaviour of fluindapyr and its metabolites 3 years after the last application, a second study was performed [Gemroth, 2020a, 2018-IFP4409].

Fluindapyr was sprayed twice, with a seven day interval, to bare soil at actual rates of 229–271 g ai/ha. Soil characteristics for the four soils are summarised in Table 35. Soil cores were taken immediately prior to the first spraying (-1DAA1), after the first application (0DAA2), prior to the second application (-1DAA2), after the second application (0DAA2) and at 1, 4–7, -12, 19–30, 88–1, 114–120, 143–146, 208–218, 358–373, 452–462, and 713–727 days after application. All soil cores were frozen at -18 °C or lower on the day of collection. The maximum storage interval from sampling to extraction was less than 730 days [Gemroth, 2018, 2015-IFP1999], which was within the 24 month period of storage stability demonstrated in study [Skaggs, 2018, 2015EFT-IFP1940]. In the extended study soil cores were taken 1080–1105 and 1232–1261 days after the last application [Gemroth, 2020a, 2018-IFP4409].

[a] Classification according to United States Department of Agriculture (USDA)

For residue analysis, the soil cores were cut into soil horizons (0–5 cm, 5–10 cm and 10–25 cm). The segmented soils were homogenized with dry ice and passed through a sieve with 3 mm mesh. Soils were extracted twice with acetone (trial GE01 and IT04) or with a mixture of acetone/water 51 (v/v) (trails United Kingdom02 and FR03). After drying by evaporation, residues from trials GE01 and IT04 were redissolved in methanol/water 8:2 (v/v/). For United Kingdom02 and FR03 methanol was added to the water phase to achieve methanol/water 8:2 (v/v). Soil samples were analysed for fluindapyr, 3-OH-fluindapyr, pyrazole carboxamide and *cis*- and *trans*-COOH-fluindapyr using LC-MS/MS with a reported LOQ of 0.01 for fluindapyr, 0.005 mg/kg for 3-OH-fluindapyr and pyrazole carboxamide and 0.003 and 0.002 mg/kg for *cis*- and *trans*-COOH-fluindapyr, respectively. The results were not corrected for recoveries.

The report included individual analytical results in terms of mg/kg soil, but no summarizing tables (mean of analytical results/sample). The results in terms of g/ha for the 0–5 cm, 5–10 cm and 10–25 cm soil layers were available for the four soils and are shown in Table 36.

Residues in control samples were generally below 0.3LOQ. The procedural recovery values for each analytical batch were within the acceptance criteria of 70–120 percent. The results were not correct for recoveries.

Parent was predominantly found in the 0-5 cm soil layer and less in 5-10 cm soil layer. Maximum levels of parent were found in the 0–10 cm soil layers on day 0–9, except FR (89 days) and ranged from 351 g/ha (Italian trial, day 0) to 522 g/ha (German trial, day 6). Parent declined to about 10 percent after approximately 700 days (French and Italian trials) and after approximately 1100 days in the trials from Germany and the United Kingdom.

Metabolite pyrazole carboxamide incidentally appeared at trace levels (1-6 g/ha) from day 1, but was not observed after 636 days.

Metabolite *cis*-1-COOH-fluindapyr and *trans*-1-COOH-fluindapyr generally appeared in trace levels (1–9 g /ha) at day 1 in all soil levels. Only in the French trial higher levels of *cis*-1-COOH-fluindapyr and *trans*-1-COOH-fluindapyr were observed; 11–45 g/ha from day 28–143, mainly in the top 0-5 cm layer.

Metabolite 3-OH-fluindapyr was observed in all soil samples (0–5 cm) and increased over time with a distribution into the second soil layer (5–10 cm) after approximately 200 days or more. Maximum levels of metabolite 3-OH-fluindapyr were reached after approximately 210–373 days and ranged from 42 to 113 g/ha.

Field dissipation studies in the United States

Study 3-6: Four field trials were carried out in the United States to study the dissipation and mobility of residues of fluindapyr and its metabolites in soil, following two applications of a formulated product to bare soil. The studies were performed in California [Schreier, 2017, 2014EFT-IFP1203], New York [Schreier, 2018a, EFT-IFP1205], Georgia [Schreier, 2018b, EFT-IFP1206], and Nebraska [Schreier, 2018c, EFT-IFP1331].

Fluindapyr was sprayed twice, with a seven day interval, to bare soil at actual rates of 215–359 g ai/ha, with one outlier at 535 g ai/ha in the Nebraska trial. The reported soil characteristics (ranges in the different soil levels 0–15 to 76–91 cm) are summarised in Table 37. Soil cores were taken prior to and immediately after each spraying as well as 7, 14–15, 21, 30–31, 56–60, 90–96, 120–122, 180–235, 240–301, 449–453, 538–551, 657–666, and 714–720 days after application. All soil core samples were frozen

at -18 °C or lower on the day of collection. The maximum storage interval from sampling to extraction was 760–873 days, which was within the 24 month period of storage stability demonstrated in study [Skaggs, 2018, 2015EFT-IFP1940].

Notes:

[a] Classification according to United States Department of Agriculture (USDA).

For residue analysis, the treated soil cores were segmented and composited by depth (0–15 cm), 15–30 cm, 30–46 cm, 46–61 cm, 61–76 cm, 76–91 cm) per subplot yielding 6 samples per subplot at each time interval except for Day 0. Residues of fluindapyr, *cis*-1-COOH-fluindapyr, *trans*-1-COOH-fluindapyr, 3-OH-fluindapyr, and pyrazole carboxamide were extracted from soil using acetone:water followed by acetone:0.5N HCl. The acetone was removed and the resulting sample diluted with methanol. The resulting solution was diluted as necessary and the residues were quantified by LC-MS/MS. The method had a limit of quantitation of 0.005 mg/kg for all analytes. The average concurrent method recoveries and relative standard deviation (n = 34/study report) for fluindapyr and its degradates in soil were within 70–110 percent with a mean RSD of 6.3–17, for fluindapyr, *cis*-1-COOH-fluindapyr, *trans*-1-COOH-fluindapyr, 3-OH-fluindapyr, and pyrazole carboxamide. All soil residues were corrected for percent moisture and presented on a dry weight basis. Residues in control samples were generally below 0.3LOQ. The results were not corrected for recoveries.

Residues of fluindapyr, *cis*-1-COOH-fluindapyr, *trans*-1-COOH-fluindapyr, 3-OH-fluindapyr, and pyrazole carboxamide were found mainly in the 0–15 cm soil layer. Trace residues of the parent and various degradates were occasionally found in the 15–31 cm layer. Residues below the 0–15 cm layer generally remained below the LOQ of 0.005 mg/kg, indicating minimal mobility in the soil. The results for the 0–15 cm soil layer are shown in Table 38.

Notes:

n.a. = Not analysed.

The average total fluindapyr (fluindapyr plus *cis*-1-COOH-fluindapyr, *trans*-1-COOH-fluindapyr, 3-OH-fluindapyr, and pyrazole carboxamide) residue at day 0 (0 days after the last application) in the 0–15 cm depth was 0.167–0.348 mg/kg following the second application. This value dropped to 120–183 ppb on day 7, except in the trial from New York where it increased to 0.353. The total residue dropped to 60–124 ppb by day 180-182 and 5-52 ppb by day 714-720.

At day 0, in the 0-15 cm layer, residues consisted almost entirely of parent fluindapyr. The degradates *cis*-1-COOH- fluindapyr, *trans*-1-COOH- fluindapyr, 3-OH-fluindapyr and pyrazole carboxamide contributed only little (1-5 percent) to the total fliunapyr equivalent residues in the trails from Georgia and California. In the New York trial degradate pyrazole carboxamide did not contribute to the total fluindapyr equivalent residues in this layer at day 0. In the Nebraska trial, the degradates *cis*-1-COOH-F9990, *trans*-1-COOH-F9990, and pyrazole carboxamide did not contribute to the total fluindapyr equivalent residues at day 0, but 3-OH-F9990 was 0.013 mg eq/kg. In the New York trial, 3-OH-fluindapyr was 0.008 mg eq/kg, on day 0 and *cis*-1-COOH-fluindapyr and *trans*-1-COOH-fluindapyr levels were 0.002 mg eq/kg and 0.004 mg eq/kg, respectively. On day 0, 3-OH-fluindapyr was 0.008 and 0.013 mg/kg in, except for the trial in California, where it did not contribute to the residue. On subsequent sampling days the cis-1-COOH-fluindapyr, trans-1-COOH- fluindapyr, 3-OH-fluindapyr, and pyrazole carboxamide residues remained below 10 percent of the total residue until day 14–59 in all trials except the trial in Georgia, where it remained below 15 percent of the total residue until day 180. The relative parent percentage of the total residue continued to drop until reaching approximately 45–67 percent of the total residue by day 452–540.

Residues of the soil degradates *cis*-1-COOH-fluindapyr and *trans*-1-COOH-fluindapyr were low with the individual diastereomers remaining at or below 0.002-0.018 mg eq/kg, or even below LOQ (Georgia trial) throughout the study.

Residues of 3-OH-fluindapyr were detected in the 0-15 com horizon starting after the first application in the Nebraska trial to one week after the first application. In the Californian trial. Residues remained low at 0.015–0.024 mg/kg or less throughout the study.

Residues of pyrazole carboxamide were either not detected or occasionally detected throughout the study, reaching a maximum average of 0.011 mg eq/kg on day 31. The results are also presented in Table 39.

Total fluindapyr residues	0.054	0.06	<LOQ	0.006	<LOQ	ND	0.005

Notes:

ND = Not detected; Note that all residues are expressed in fluindapyr equivalents: trans-1-COOH-fluindapyr ppb fluindapyr equivalents = (ppb trans-1-COOH-fluindapyr, dry weight) × (351.4/381.4), where 351.4 and 381.4 are the molecular weights of fluindapyr and trans-1-COOH-fluindapyr, respectively; cis-1-COOH-fluindapyr ppb fluindapyr equivalents = (ppb cis-1-COOH-fluindapyr, dry weight) × (351.4/381.4), where 351.4 and 381.4 are the molecular weights of fluindapyr and cis-1-COOH-fluindapyr, respectively; 3-OH-fluindapyr ppb fluindapyr equivalents = (ppb 3-OH-fluindapyr, dry weight) × (351.4/367.4), where 351.4 and 367.4 are the molecular weights of fluindapyr and 3-OH-fluindapyr, respectively; Pyrazole Carboxamide ppb fluindapyr equivalents = (ppb Pyrazole Carboxamide, dry weight) × (351.4/176.0), where 351.4 and 176.0 are the molecular weights of fluindapyr and Pyrazole Carboxamide, respectively; Total ppb fluindapyr equivalents = (ppb fluindapyr) + (trans-1-COOH-fluindapyr ppb fluindapyr equivalents) + (cis-1-COOH-fluindapyr ppb fluindapyr equivalent) + (3-OH-fluindapyr ppb fluindapyr equivalents) + (Pyrazole Carboxamide).

Kinetic endpoints for aerobic degradation in soil under field conditions

The dissipation and mobility of residues of fluindapyr and its metabolites under field conditions was determined in four European soils [Gemroth, 2018, 2015-IFP1999 and 2015-IFP1999 Amendment no.1, and the one year extension in Gemroth, 2020a, 2018-IFP4409]. The method and results are summarized above. The kinetic evaluation of these studies was described in Gemroth, 2020b [2018-EFT-IFP1999]. The rate of degradation of fluindapyr was assessed using the FOCUS DEGKIN v2 (June 2007) Excel tool and KinGUII (v2.1) following FOCUS Kinetics guidance (2006).

The data were first fitted according to a single first order kinetic model (SFO) and secondly, if necessary, according to a bi-phasic kinetic models, First-Order Multi-Compartment kinetic model (FOMC), Double-First-Order in Parallel (DFOP) or Hockey Stick (HS) kinetics models. The goodness of fit was assessed by visual inspection and an error criterion based on a chi-squared test. The findings are summarised in Table 40. The best fits for the European trials were obtained with the bi-phasic kinetic models.

The dissipation and mobility of residues of fluindapyr and its metabolites under field conditions was also determined in 4 United States soils in four different studies [Schreier, 2017, 2014EFT-IFP1203;

Schreier, 2018a, EFT-IFP1205; Schreier, 2018b, EFT-IFP1206; Schreier, 2018c, EFT-IFP131]. The residue values for the 0-15 cm depth at each sampling interval were used to calculate the total fluindapyr residue half-life (using first order rate kinetics), DT_{50}, DT_{75} and DT_{90}. For these calculations residues of *cis*-1-COOH-fluindapyr, *trans*-1-COOH-fluindapyr, 3-OH-fluindapyr, and pyrazole carboxamide were corrected for molecular weight to parent fluindapyr equivalents. All calculations were performed on a dry weight basis. The results of the kinetic evaluation are included in Table 40.

Notes:

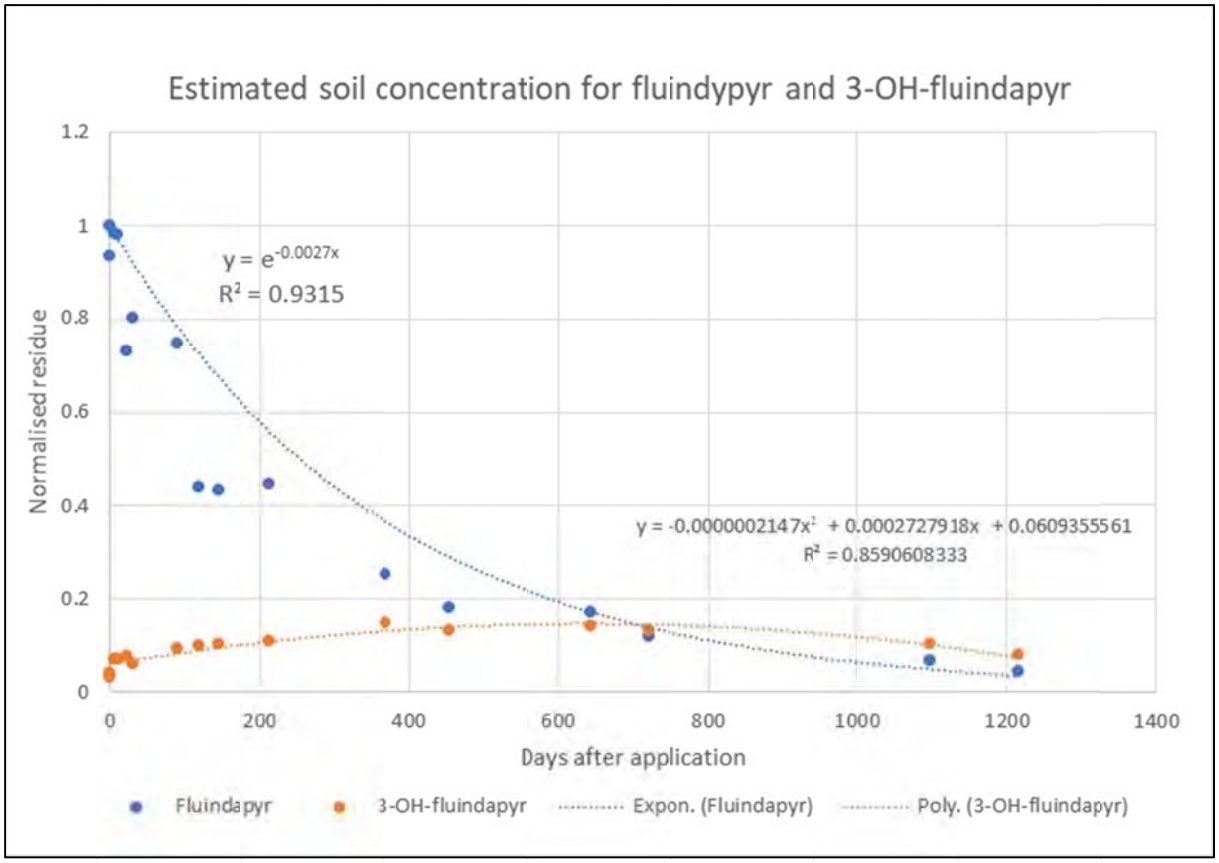
[a] Soil properties are for soils at depth of 0-10 and 0-15 cm for European and United States sites, respectively.

[b] Non-normalized field DT_{50}.

Note by the reviewer: The actual method description and calculation of the DT_{50}, DT_{75} and DT_{90} from the United States trials are not included in the reports (Schreier, 2017-2018c). The lack of this information does not hamper the assessment in the context of the JMPR.

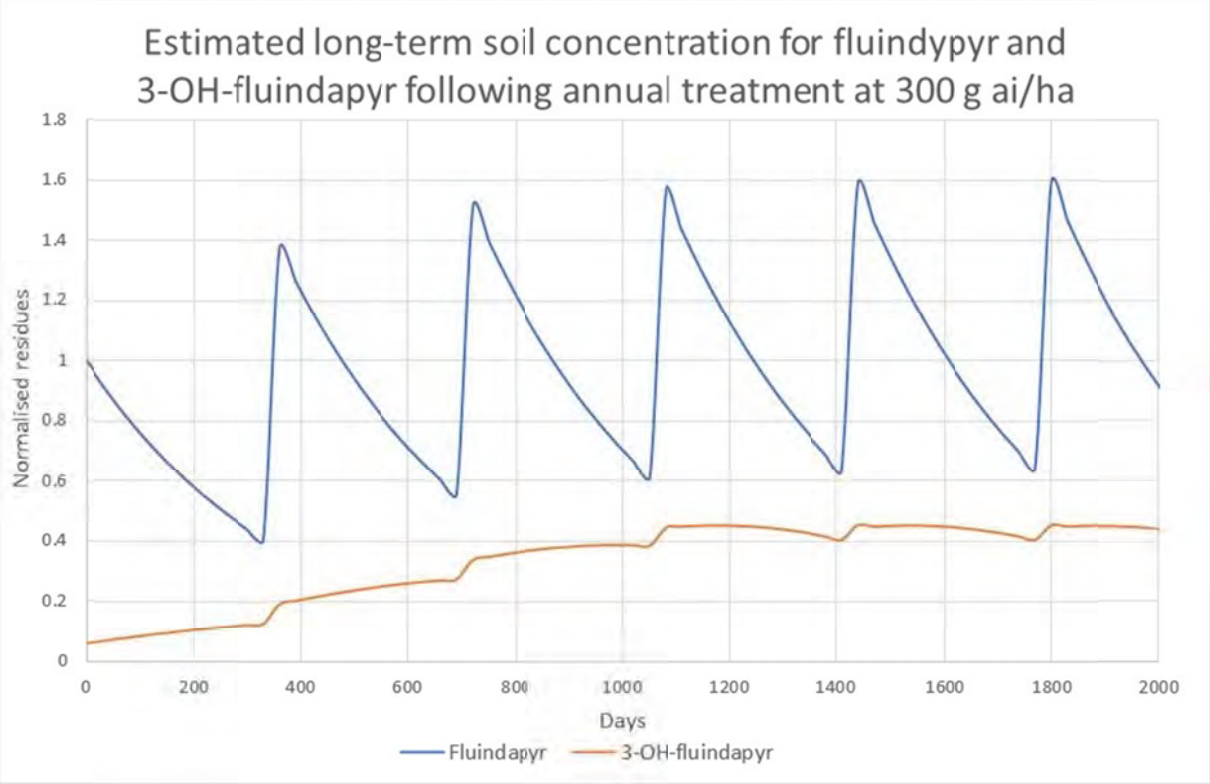
Estimated soil concentrations of fluindapyr and 3-OH-fluindapyr following single or subsequent annual application

In order to estimate potential soil residue plateau levels for fluindapyr and 3-OH-fluindapyr, the Meeting considered the field accumulation study results by Gemrot, 2018a,b and 2020a,b, since the interval investigated was sufficiently long. Residues for both analytes were initially expressed as kg ai/ha (0–25 cm soil layer) equivalents and have been normalised based on residues for fluindapyr at day zero of each plot. Regression considered the mean normalized concentration from each of the four plots in the study.



Based on the single application, a plateau of 15 percent of the dose rate for 3-OH-fluindapyr per ha was estimated, reached after approximately 700 days. Expressed in mg/kg soil, this plateau represents a concentration of 0.012 mg/kg soil (300 g/ha max. annual application rate, 25 cm soil layer, 1.5 g/cm³ soil density).

Due to the persistence of fluindapyr residues in soil, long term accumulation was taken into account by estimating plateau levels following annual application at the maximum seasonal rate:



Based on multiple annual applications, a plateau of 45 percent of the single maximum dose rate for fluindapyr per ha and year was estimated, reached approximately after 4 years. Expressed in mg/kg soil, this plateau represents a concentration of 0.036 mg/kg soil (300 g/ha max. annual application rate, 25cm soil layer, 1.5 g/cm³ soil density).

Environmental fate in water/sediment systems

The Meeting received information on the environmental fate in water/sediment systems. Studies on the environmental fate in water/sediments are not required for the envisaged uses, except for hydrolysis and photolysis in water. These studies were summarised in the physico-chemical properties section.

If the uses are to be extended to rice, the studies on the environmental fate in water/sediment systems will have to be evaluated (see references submitted but not used).

Rotational crops

Confined rotational crop studies

Study 1 and 2

Two confined rotational crop studies were conducted in Italy to provide information on the uptake and metabolism of fluindapyr in rotational crops [Mainolfi, 2017, 2013MET-IFP0693 and Vanini, 2017a, 2013MET-IFP0717]. Pots with bare sandy loam soil were treated dropwise with either phenyl-labelled fluindapyr or pyrazole-labelled fluindapyr at a dose rate of 360–387 g ai/ha. The treated soil was aged outdoors, for three time intervals prior to the sowing of each succeeding crop: 30, 120 and 300 days. Three different representative crops were used: lettuce (variety: Canasta), carrot (variety: Nantese F1) and wheat (variety: Bologna). From each plant-back interval (PBI), crop samples were harvested at maturity: lettuce, carrots (roots and leaves) and wheat (grain and straw). Samples of immature lettuce and wheat

forage and hay were also collected from each PBI. Carrot (roots and tops) and lettuce samples were gently rinsed with water in order to remove any soil adhering to the leaves. Hay samples were air dried to a moisture content of 10–20 percent. All plant materials were immediately frozen and stored at -20 °C prior to processing and analysis. Duplicate soil cores were removed from one of the treated pots at time of treatment and again at each crop harvest. The soil cores were immediately analysed or stored frozen at -20 °C. Sample preparation, extraction and analysis were carried out within 6 months of crop harvest, so further storage stability data were not required.

The crop samples were finely ground with dry ice. The ground crop material was analysed for total radioactivity by LSC after combustion. Extraction was carried out on the samples with TRR higher than 0.01 mg/kg. Each aliquot was homogenized with acetone-water (70:30 v/v), shaken and centrifuged [Extract I]. Shaking and centrifugation was repeated three times on each sample: twice with acetone-water (50:50 v/v) [Extract II and Extract III] and then once with acetone [Extract IV]. All extracts were analysed by LSC and stored at <7 °C. Suitable aliquots of extracts I to IV were pooled, concentrated and analysed by LSC and TLC. Suitable aliquots of the extracts were pooled, concentrated to remove the organic solvent, and the aqueous portion was extracted three times with n-heptane (1:2 v/v).

Reversed-phase HPLC was used to isolate the parent compound from aliquots of concentrated heptane phase for analysis by chiral HPLC. Further aliquots of the heptane phase were analysed by TLC, HPLC, and LC-MS for metabolite identification. For each RAC, a portion of the concentrated aqueous phase, after heptane extraction, was incubated with 6 N HCl for 1 hour at 80 °C. After hydrolysis, the samples were neutralized and analysed by HPLC and by LC-MS for metabolite profiling and identification. Reference compounds were 3-OH-fluindapyr, *cis*-1-COOH-fluindapyr, *trans*-1-COOH-fluindapyr, 1-OH-Met-fluindapyr (2 diastereomers), N-DesMet-fluindapyr, pyrazole carboxamide, pyrazole carboxylic acid and N-DesMet-pyrazole carboxylic acid.

Aliquots of selected samples of concentrated total extract and concentrated aqueous phase were subjected to enzymatic hydrolysis with β-glucosidase. The aliquots were dried and suspended in sodium acetate 0.1 M (pH 4.8) containing the enzyme and incubated at 37 °C for 48 hours under stirring. After incubation, samples were analysed by TLC.

After acetone extraction, the remaining solid residues from the RAC samples were air-dried at room temperature, and the radioactive content determined by LSC. The PES samples containing significant residues (≥0.05 mg/kg or 10 percent of TRR; i.e. grain and straw) were subjected to sequential base, some to surfactant, and enzymatic (β-amylase and cellulase) treatments to release and characterize the un-extractable radioactivity. The solid residues were suspended in 0.5 N NaOH - CH_3OH (1:1 v/v) and incubated for 2 hours at ambient temperature, under stirring (Extract Base). Subsequently, from some samples the solid residues were suspended in 0.1 percent Tween20 for 2 hours under stirring (Extract Surfactant). Grain residue was suspended in 50 mM ammonium acetate buffer, pH 5, and enzyme β-amylase was added. The sample was incubated at 37 °C for 24 hours under stirring (Extract Amylase). Subsequently, the solid residue was re-suspended in the buffer and incubated with cellulase at 37 °C for 24 hours, under stirring (Extract Cellulase). Straw residue was subjected to hydrolysis with cellulase, following the same procedure described above for grain residue (Extract Cellulase).

The soil samples were extracted by shaking with acetone. The soil residues were dried, then oxidized before determination of the radioactivity by LSC.

The TRR, distribution, and identification of radioactivity are shown in Tables 41 to Table 56. The TRR in carrot and lettuce samples showed a decline from the 30d PBI towards the 300d PBI for the phenyl-label, while no decline in TRR could be observed in the carrot and lettuce samples from the 30d PBI towards the 300d PBI for the pyrazole-label. Furthermore, for the phenyl-label, the TRR in wheat

forage and hay remained rather constant throughout the study, while a decline in TRR could be observed from the 120-day PBI to the 300-day PBI in wheat grain and straw. In the wheat RACs from the pyrazole-label, the TRR remained relatively constant throughout the study.

Extractable radioactivity from all different crop matrices was high and generally ranged from 83 to 99 percent TRR. Only the radioactivity in the PES of wheat straw and grain needed further investigation and was present mainly as cellulose ^{14}C-incorporated natural products and represented 6–10 percent TRR in straw, and 3–5 percent TRR in grain.

The residual water soluble fraction, remaining after the heptane extraction, was subjected to enzymatic hydrolysis using glucosidase, which resulted in partial hydrolysis of several glucoside conjugates. However, the chemical hydrolysis (6 N HCl) of the aqueous metabolite fraction (after heptane extraction) showed complete hydrolysis of the conjugated metabolites and further simplification of the chromatographic metabolite profile, thus allowing adequate quantification of individual aglycones.

The identified major residues (fluindapyr, 3-OH-fluindapyr, 1-COOH-fluindapyr, 1-OH-Met-fluindapyr, N-DesMet-fluindapyr, N-DesMet-pyrazole carboxylic acid, pyrazole carboxylic acid, pyrazole carboxamide) were common in all crops but their magnitude varied depending on the individual crop and matrix. Parent and 3-OH-fluindapyr were identified in the total acetone extracts and heptane extracts. On the other hand, pyrazole carboxamide, pyrazole carboxylic acid, N-DesMet-pyrazole carboxylic acid, 1-COOH-fluindapyr, 1-OH-Met-fluindapyr, and N-DesMet-fluindapyr were all identified as aglycones in the hydrolysed aqueous extracts. No quantitative results are available for the aqueous extracts before hydrolysis, therefore, it is not known how much of the respective metabolites were already present in their free form before the hydrolysis. A minor residual fraction in the TLC radio-profiles of almost all pooled acetone extracts of RACs was characterized as organo-soluble as it was completely extracted in the heptane phase after partitioning. Minor polar residues detected in the HPLC radio-profiles of the hydrolysed aqueous phases were characterized as water soluble as they remained in aqueous phase after partitioning with heptane. They could be present as sugar conjugates in the initial unhydrolysed extract.

Parent was the main component found in carrot roots ranging from 65 to 70 percent TRR (0.013–0.026 mg eq/kg) at the three different plant back intervals for the phenyl-label, while for the pyrazole-label parent was present at similar quantitative levels, but in a less pronounced percentage of the TRR (10–38 percent TRR, 0.011–0.031 mg eq/kg). Parent represented also less of the radioactive residue in immature and mature lettuce (2.8–20 percent TRR, 0.006–0.015 mg eq/kg) and wheat grain (6.1–15 percent TRR, 0.084–0.39 mg eq/kg).

In carrot root, the pyazole-label specific metabolite N-DesMet-pyrazole carboxylic acid (including its conjugates) was a major contributor to the TRR (28–65 percent TRR, 0.022–0.068 mg eq/kg), while 3-OH-fluindapyr, free and conjugated 1-COOH-fluindapyr, and free and conjugated 1-OH-Met-fluindapyr were present in quantities <0.01 mg eq/kg. The metabolite pyrazole carboxamide (including its conjugates) increased with longer PBIs in carrot root (from 6.6 percent TRR, 0.005 mg eq/kg at 30d PBI to 18 percent TRR, 0.018 mg eq/kg at 300d PBI).

For the phenyl-label, in mature and immature lettuce the free and conjugated metabolites 1-COOH-fluindapyr and 1-OH-Met-fluindapyr represented the majority of the radioactive residue, each ranging from 16 to 34 percent TRR (0.011–0.027 mg eq/kg), whereas these metabolites were clearly less present in the pyrazole-labeled studies. In the latter case, pyrazole-label specific free and conjugated N-DesMet-pyrazole carboxylic acid was present at high levels in lettuce (62–82 percent TRR, 0.12–0.21 mg eq/kg). Other detected metabolites in lettuce were 3-OH-fluindapyr (< 10 percent TRR, < 0.01 mg eq/kg), pyrazole carboxylic acid (≤ 12 percent TRR, ≤ 0.039 mg eq/kg), pyrazole carboxamide (≤ 13 percent TRR, ≤ 0.032 mg eq/kg), and N-DesMet-fluindapyr (< 5 percent TRR, < 0.01 mg eq/kg).

In wheat grain, 1-OH-Met-fluindapyr and its conjugates was the major contributor to the radioactive residue (12–52 percent TRR, 0.34–1.1 mg eq/kg), as well as free and conjugated pyrazole carboxylic acid (12–29 percent TRR, 0.34–0.83 mg eq/kg). 3-OH-fluindapyr was present at approximately 10 percent TRR, and free and conjugated 1-COOH-fluindapyr was detected at somewhat lower levels (2.7–7.0 percent TRR, 0.076–0.13 mg eq/kg). Also the label-specific metabolites N-DesMet-pyrazole carboxylic acid and pyrazole carboxamide were retrieved in wheat grain (1.7–16 percent TRR, 0.050–0.45 mg eq/kg; both increasing with longer PBIs; free and conjugated). N-DesMet-fluindapyr was observed at <5 percent TRR.

In feed commodities, the levels of parent varied from 0.24–11 percent TRR (0.004–0.013 mg eq/kg) in carrot tops to 13–32 percent TRR (0.050–0.14 mg eq/kg) in wheat forage. In feed crops, the (conjugated) metabolite 1-OH-Met-fluindapyr represented a major part of the radioactive residue in the phenyl-label, ranging from 11–36 percent TRR (0.061–0.13 mg eq/kg) in wheat forage to 17–46 percent TRR (0.49–1.6 mg eq/kg) in wheat straw. In the pyrazole-label, in particular free and conjugated pyrazole carboxylic acid was present in large quantities in cereal feed items (forage: 13–24 percent TRR, 0.050–0.12 mg eq/kg; straw: 9.1–28 percent TRR, 0.34–0.89 mg eq/kg), while in carrot tops free and conjugated N-DesMet-pyrazole carboxylic acid was more pronounced (52–58 percent TRR, 0.64–0.99 mg eq/kg). 3-OH-fluindapyr, pyrazole carboxamide (and its conjugates), N-DesMet-fluindapyr (and its conjugates), and 1-COOH-fluindapyr (and its conjugates) also contributed to the total radioactive residues, with levels depending on crop matrix and on PBI.

For the phenyl label, radioactivity found in soil after treatment ranged between 108-110 percent AR (Applied Radioactivity) and between 73 and 82 percent AR at crop harvest for the 30d PBI. Radioactivity recovered from soil at harvest from the 120d and 300d PBI gradually decreased, ranging between 61 and 71 percent AR and between 51 and 64 percent AR, respectively. For the pyrazole-label, radioactivity found in soil after treatment ranged between 81-86 percent AR (Applied Radioactivity), while radioactivity recovered from soil at crop harvest for the 30d PBI ranged between 69 and 91 percent AR. Radioactivity recovered from soil at harvest from the 120d and 300d PBI ranged between 67 and 90 percent AR and between 72 and 83 percent AR, respectively.

The chiral analysis results are presented in Table 57. A shift in the enantiomeric ratio *R/S* of 50/50 in the formulation to up to 23:77 after application can be observed in the rotational crop samples.

Study 3

A third confined rotational crop study was conducted in California, United States, with wheat (variety: Certified WB Patron) planted 30 and 120 days after a single bare-soil application of pyrazole-labelled fluindapyr [Desai, 2017b, 2015MET-IFP2064]. Only wheat has been investigated as rotational crop in this study, to verify the relatively high residue levels in rotational cereals obtained in the previous two confined rotational crop studies. The soil was treated with an actual application rats of 356 g ai/ha for the 30-day PBI and 360 g ai/ha for the 120-day PBI. Wheat seeds were planted into treated sandy loam soil in outdoor wooden boxes.

Forage samples were harvested at growth stage BBCH 17, hay at BBCH 85, and straw and grain at BBCH 89. Crops stored frozen (-20 °C) prior to shipment for analysis. Harvested commodities were processed cryogenically, after which they were combusted to determine the TRR. Processing of the samples occurred within maximally 8 days. Only data on the TRR were investigated, and further identification was considered not required.

The TRR of the samples is shown in Table 58. The TRR in hay and straw increased from the 30-day PBI to the 120-day PBI, while the TRR in forage and grain remained rather constant. Residues in control samples were < 0.01 mg/kg.

Table 58 Total Radioactive Residues (TRRs) in rotational wheat

Commodity	TRR (mg eq/kg)	
	30d PBI	120d PBI
Forage	0.22	0.21
Hay	0.67	1.2
Straw	0.67	1.2
Grain	0.064	0.10

Field rotational crop studies

Study 1

Field rotational crop studies were conducted in 2017 in Southern Europe (Italy and Spain) to provide information on the uptake of fluindapyr and its metabolites in rotational crops [Huaulmé, 2020a, 2017RES-IFP3569]. Representative crops from root and tuber vegetables (carrots/radish), small grain cereals (winter/spring wheat), leafy vegetables (lettuce), brassica vegetables (head cabbage), oilseeds crop group (soya beans), and fruits and fruiting vegetables (tomato) were planted into areas (bare soils) previously treated with a 100 g/L formulation of fluindapyr at interval of 30 (+/-3), 120 (+/-10), and 269 to 273 days (for targeted timing of 270 days) after the application. Fluindapyr was incorporated into the soil

at about 5 cm depth in trial 01-IT and at 5 mg/kg eq 10 cm depth in trial 02-SP with rotavator at actual dose rates of 215–226 g ai/ha (01-IT) and 204–231 g ai/ha (02-SP).

Soil samples (horizon approximately 0–20 cm depth) were collected just before the crops were sown or planted (on the same day). The characteristics of the soil are shown in Table 59. Succeeding crops (carrot/radish, wheat, lettuce, head cabbage, soya bean, and tomato) were sown or transplanted into the plots at PBI of approximately 30, 120 and 270 days. Samples of succeeding crops were harvested at their respective harvest time (Table 60). Commodities were collected from at least 12 plants or from 12 different areas of the plot. Samples for plants included for radish, leaves and roots separately, for cereal forage (whole plants), hay (whole plants), grain and straw, for lettuce, immature whole plants without roots and mature whole plants without roots, for head cabbage, immature whole plants without roots and mature whole plants without roots, for soya bean, forage, hay and seeds, and for tomato, fruits. The minimum weight was at least 1 kg per sample, except 0.3–0.5 kg soya bean hay, 0.5 kg straw and hay, 2 kg lettuce heads (mature), 2 kg tomato fruits, and 2 kg carrot roots and 2–4 kg head cabbage (mature).

Table 59 Soil characteristics

Trial	01-IT [a]		02-SP
	01-IT (Galliera, 40015, Italy)	01-IT (Poggio Renatico, 44028, Italy)*	Biar, 03410, Spain,

Notes:

PBI = Plant Back Interval; DAT = days after last application; DAS = Days after sowing.

[i] = Immature.

[m] = Mature.

Weather conditions did not generally alter the growth, development and maturity of the rotational crops at the trial sites. Samples were kept frozen (-18 °C) until extraction. Extraction for the analysis of fluindapyr and its metabolites occurred within a maximum of 361 and 421 days after the corresponding harvest for both trials, respectively. This storage period is covered by the storage stability studies for all crop commodities.

Soil samples were analysed using LC/MS-MS methods RA.14.07 (fluindapyr), RA.16.03 (3-OH-fluindapyr, 1-COOH-fluindapyr, and pyrazole carboxamide), and RA.18.11 (pyrazole carboxylic acid and N-DesMet-pyrazole carboxylic acid). The principle of the method was based on extraction using acetone or a mixture of acetone/water 5:1 (v/v). Residue were quantified with LC/MS-MS using ion transitions m/z 325 to 256 for fluindapyr, m/z 366 to 175 for 3-OH-fluindapyr, m/z 382 to 336 for both diastereomers of 1-COOH-fluindapyr, m/z 176 to 136 for pyrazole carboxamide, m/z 177/175 to 137 for pyrazole carboxylic acid and 163/161 to 123/141 for N-DesMet-pyrazole carboxylic acid. LOQs of the methods were 0.010 mg/kg for fluindapyr and for 3-OH-fluindapyr, 0.014 mg/kg for DesMet-F-N1-Gluc, 0.006 and 0.004 mg/kg for the two diastereomers of both 1-OH-Met-F and 1-COOH-fluindapyr (0.010 mg/kg combined), and 0.007 and 0.003 (combined 0.010 mg/kg) for the two stereo isomers of 1-OH-Met-N-DesMet-F, 0.010 mg/kg for pyrazole carboxamide, pyrazole carboxylic acid and N-desmethyl-pyrazole carboxylic acid.

The residues of fluindapyr found in soil were summarized in the table below.

Table 61 Residues of fluindapyr and its metabolites in soil after treatment to bare soil, expressed in mg/kg as such

Notes:

[a] Sum of diastereomers.

Samples of plant commodities were analysed for fluindapyr, 3-OH-fluindapyr and DesMet-fluindapyr-N1-Glucoside using the pre-hydrolysis method PTRL Europe Study ID P3770 [Stanislowski, 2016a, 2015RES-IFP2155], with an LOQ of 0.01 mg/kg for each compound. The same samples, were analysed for 1-OH-Met-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr, and 1-COOH-fluindapyr using the post-hydrolysis method RA.17.01 [Riccelli, 2017a, RA.17.01] with an LOQ of 0.01 mg/kg (sum of combined diastereomers) for each analyte. The post-hydrolysis method RA17.19 [Ricelli, 2017b, RA.17.19] was used to determine pyrazole carboxamide, pyrazole carboxylic acid and N-DesMet-pyrazole carboxylic acid with an LOQ of 0.01 mg/kg for each analyte.

A reduced method validation [Soddu, 2018, RA18.01, appendix to Huaulmé, 2020a, 2017RES-IFP3569] in carrot root and leaves and radish roots and leaves, cabbage, tomato fruit, soya bean forage and hay (n=3 at LOQ level and n=1 at 10 × LOQ) showed that recoveries for each matrix ranged between: 70-110 percent for fluindapyr, 3-OH-fluindapyr, DesMet-fluindapyr-N1-glucoside, pyrazole carboxamide, pyrazole carboxylic acid and N-DesMet-pyrazole-carboxylic acid, and for each diastereomer of 1-OH-Met-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr, and 1-COOH-fluindapyr. The results are summarized in the section on analytical methods. Procedural recoveries also ranged between 70-120 percent for parent fluindapyr and its metabolites (not included in the analytical section). Control samples had residues below 0.3LOQ.

Fluindapyr and its metabolites including their glucoside conjugates, expressed as the free aglycons, were not found (<0.01 mg/kg each) in lettuce, carrot or radish root (except one sample), carrot foliage, head cabbage, wheat grain, or soya bean seed) planted at approximately 30, 120 or 270 days after incorporation of the fluindapyr into the soil. Residues were observed in wheat straw, hay, forage, soya bean forage and hay, and incidentally in radish leaves and roots. The results are summarized in Table 62.

Table 62 Residues of fluindapyr and its metabolites, expressed as such in rotational crop samples of trials performed in Italy and Spain, respectively

Notes:

DMN-gluc=DesMet-N1-glucoside; 3-HF=3-OH-fluindapyr; 1-HMF=1-OH-Met-fluindapyr; 1-HDMF=1-OH-Met-N-DesMet-fluindapyr; 1-CF=1-COOH-fluindapyr; PC=pyrazole carboxamide; PCA = pyrazole carboxylic acid, NDPCA = N-DesMet-pyrazole carboxylic acid. All residues are expressed as such (not in parent equivalents).

[a] Sum of both diastereomers.

[b] One of the single diastereomers is above the respective LOQ, but are below LOQ when combined.

Study 2

Field rotational crop studies were conducted in 2017 in Northern Europe (Northern France and Hungary) to provide information on the uptake of fluindapyr and its metabolites in rotational crops [Huaulmé, 2020b, 2017RES-IFP3638]. Representative crops from root and tuber vegetables (radish), small grain cereals (winter/spring wheat), leafy vegetables (lettuce), brassica vegetables (head cabbage), oilseeds crop group (soya beans), and fruits and fruiting vegetables (tomato) were planted into areas (bare soils) previously treated with a 100 g/L formulation of fluindapyr at interval of 30 (+/-3), 120 (+/-10), and 269 to 273 days after the application. Fluindapyr was incorporated into the soil at about 5–10 cm depth in both

trial BPL17/69401/RC-01-FR and trial BPL/694/RC-02-HU with rotavator at actual dose rates of 204–226 g ai/ha (01-FR) and 203–232 g ai/ha (02-HU).

Soil samples (horizon approximately 0–20 cm depth) were collected just before the crops were sown or planted (on the same day). The characteristics of the soil are shown in Table 63. Succeeding crops (carrot/radish, wheat, lettuce, head cabbage, soya bean, and tomato) were sown or transplanted into the plots at PBI of approximately 30, 120 and 270 days. Samples of succeeding crops were harvested at their respective harvest time (Table 64). Commodities were collected from at least 12 plants or from 12 different areas of the plot. Samples for plants included for radish, leaves and roots separately, for cereal forage (whole plants), hay (whole plants), grain and straw, for lettuce, immature whole plants without roots and mature whole plants without roots, for head cabbage, immature whole plants without roots and mature whole plants without roots, for soya bean, forage, hay and seeds, and for tomato, fruits. The minimum weight was at least 1 kg per sample, except 0.3–0.5 kg soya bean hay, 0.5 kg straw and hay, 2 kg lettuce heads (mature), 2 kg tomato fruits, and 2–4 kg head cabbage (mature).

Table 63 Soil characteristics

Trial	BPL17/69401/RC-01-FR [a]		BPL/694/RC-02-HU
	01-FRA (Vauchrétien, 49320, France)	01-FRB (Saint Georges de Sept voies, 49350, France)	02-HU (Jászfényszaru, 5126, Hungary)

Notes:

PBI = Plant Back Interval; DAT = days after last application; DAS = Days after sowing.

[a] The trial site 01-FR was performed into two different test sites: one for wheat and the other for the remaining crops.

[b] deviation from protocol 30 days +/- 3 days and 207 +/- 15 days.

[i] = Immature.

[m] = Mature.

Weather conditions did not generally alter the growth, development and maturity of the rotational crops at the trial sites. Samples were kept frozen (-18 °C) until extraction. Extraction for the analysis of fluindapyr and its metabolites occurred within a maximum of 275 and 337 days after the corresponding harvest for both trials, respectively. This storage period is covered by the storage stability studies for all crop commodities.

Soil samples were analysed using LC/MS-MS methods RA.14.07 (fluindapyr), RA.16.03 (3-OH-fluindapyr, 1-COOH-fluindapyr, and pyrazole carboxamide), and RA.18.11 (pyrazole carboxylic acid and N-desmethyl-pyrazole carboxylic acid). The principle of the methods was based on extraction using acetone or a mixture of acetone/water 5:1 (v/v). Residue were quantified with LC/MS-MS using ion transitions m/z 325 to 256 for fluindapyr, m/z 366 to 175 for 3-OH-fluindapyr, m/z 382 to 336 for both diastereomers of 1-COOH-fluindapyr, m/z 176 to 136 for pyrazole carboxamide, m/z 177/175 to 137 for pyrazole carboxylic acid and 163/161 to 123/141 for N-DesMet-pyrazole carboxylic acid. Text can be removed after inclusion in the analytical section.

Response applicant: The LC/MS/MS method used to analyse test soil samples in 2017RES-IFP3569 is summarized in the document “2017RES-IFP3569_soil method_JMPR_08052022”.

LOQs of the methods were 0.010 mg/kg for fluindapyr, 0.005 mg/kg for 3-OH-fluindapyr, 0.003 and 0.002 mg/kg for the two diastereomers of 1-COOH-fluindapyr (0.005 mg/kg combined), 0.005 mg/kg for pyrazole carboxamide, pyrazole carboxylic acid and N-desmethyl-pyrazole carboxylic acid.

Table 65 Residues of fluindapyr and its metabolites, expressed as such, in soil after treatment to bare soil

Notes:

[a] Sum of diastereomers.

[b] One of the single diastereomers is above the respective LOQ, but are below LOQ when combined.

Samples of plant commodities were analysed for fluindapyr, 3-hydroxy-fluindapyr and desmethyl-fluindapyr-N1-Glucoside using the pre-hydrolysis method PTRL Europe Study ID P3770 [Stanislowski, 2016a, 2015RES-IFP2155], with an LOQ of 0.01 mg/kg for each compound. The same samples, were analysed for 1-OH-Met-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr, and 1-COOH-fluindapyr using the post-hydrolysis method RA.17.01 [Riccelli, 2017a, RA.17.01] with an LOQ of 0.01 mg/kg (sum of combined diastereomers) for each analyte. The post-hydrolysis method RA17.19 [Ricelli, 2017b, RA.17.19] was used to determine pyrazole carboxamide, pyrazole carboxylic acid and N-DesMet-pyrazole carboxylic acid. Except for DesMet-F-N1-Gluc, for which an LOQ of 0.014 mg/kg was established, for all other metabolites an LOQ of 0.01 mg/kg (combined for diastereomers) applied. Residues of the metabolites were expressed as such (not in parent equivalents).

A reduced method validation [Soddu, 2018, RA18.01, appendix to Huaulmé, 2020a, 2017RES-IFP3569] in carrot root and leaves and radish roots and leaves, cabbage, tomato fruit, soya bean forage and hay (n=3 at LOQ level and n=1 at 10 × LOQ) showed that recoveries for each matrix ranged between: 70–110 percent for fluindapyr, 3-OH-fluindapyr, DesMet-fluindapyr-N1-glucoside, pyrazole carboxamide, pyrazole carboxylic acid and N-desmethyl-pyrazole-carboxylic acid, and for each diastereomer of 1-OH-Met-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr, and 1-COOH-fluindapyr. The results are summarized in the section on analytical methods. Procedural recoveries also ranged between 70–120 percent for parent fluindapyr and its metabolites (not included in the analytical section). Control samples had residues below LOQ.

Fluindapyr and metabolites DesMet-N1-glucoside, 1-OH-Met-fluindapyr (apart from one finding), 3-OH-fluindapyr and 1-OH-Met-N-DesMet-fluindapyr, pyrazole carboxamide; were not observed in any of the matrices. Metabolite 1-COOH-fluindapyr was found in radish leaves at PBI 30 and 120 days, immature head cabbage (PBI 30 days) and soya bean forage and hay (all PBIs). Residues of 1-COOH-fluindapyr, pyrazole carboxylic acid, and N-DesMet-pyrazole carboxylic acid were observed in more plant matrices, predominantly soya bean forage and hay. The results are summarized in Table 66.

Table 66 Residues of fluindapyr and its metabolites, expressed as such, in mg/kg in rotational crop samples of trials performed in Northern France and Hungary, respectively

[c] Mean of three analyses.

[d] Mean of four analyses.

Study 3

Field rotational crop studies were conducted in 2015-2016 in the United States to provide information on the uptake of fluindapyr and its metabolites in rotational crops [Schreier, 2018, 2015RES-IFP1902]. Representative crops from root and tuber vegetables (radish), small grain cereals (wheat), leafy vegetables (mustard) were used. Nine untreated control plots and nine treated plots were established with soya beans as the primary crop at each trial site. At the appropriate timing, the treated plots received two applications of test substance formulated as a water soluble liquid. Each application was at an actual rate of 124–128 g ai/ha per application (168 to 224 L/ha). The first application was scheduled to occur 35±2 days prior to typical harvest of soya bean seed with the second application occurring 12 to 15 days following the first application (21±2 days prior to typical harvest of soya bean seed). For the Nebraska site (trial number 01) the soya bean seed was harvested with a combine which removed the seed but allowed the plant debris to return to the field. At the Georgia site location (Trial 02) both the soya bean seed and the soya bean straw were removed from the field. Following removal of the primary soya bean crop, the plot was planted with the follow-on rotational crop of mustard, radish, or wheat at target plant back intervals of 30, 60, and 210 days following the last application (DALA).

Soil was characterized as silt loam (Trail 01 from Nebraska) and loamy sand (Trial 02 from Georgia), but specifics were not reported. No soil samples were taken. Samples of succeeding crops were harvested at their respective normal commercial harvest time (Table 67). Commodities were collected from at least 12 plants or from 12 different areas of the plot and stored frozen within 3 hours of harvest. Samples for plants included for tops (0.5 kg) and roots (24 roots, minimum of 2 kg) separately for radish, for cereal forage (1 kg), hay (0.5 kg), grain (1 kg) and straw (0.5 kg), for mustard (2 kg).

Notes:

PBI = Plant Back Interval; DAT = days after last application; DAS = Days after sowing.

[a] Calculated by the reviewer based on the data provided in the report.

The farming practices or environmental conditions did not adversely impact the residue trials of wheat, mustard and radish. The crops were grown and maintained per typical agricultural practices for each geographical region. The crop varieties selected were typical for commercial production in each area. The actual temperature and rainfall were generally within normal parameters during the residue study period. The trials received irrigation as required during the trial period. The maximum storage interval of the rotational crop samples, from harvest to extraction for analysis, was 717 days (frozen, ~24 months) for the analysis of fluindapyr residues and its metabolites.

All samples were analysed for residues of fluindapyr and the metabolites, 3-hydroxy-fluindapyr, 1-hydroxymethyl-fluindapyr, and 1-carboxy-fluindapyr. Residues of fluindapyr and 3-hydroxy- fluindapyr in study samples were determined using PTRL Europe method P3770G [Stanislowski, 2016a, 2015RES-IFP2155]. Residues of 1-OH-Met-fluindapyr and 1-COOH-fluindapyr in study samples were determined using the Isagro method RA.17.01 [Riccelli, 2017a, 2017RESIFP3206]. For both methods, the limit of quantitation (LOQ) was 0.01 mg/kg (expressed as fluindapyr equivalents). Mean procedural recoveries and relative standard deviations (RSDs) for fluindapyr, 3-hydroxyfluindapyr, 1-hydroyxmethyl-fluindapyr and 1-carboxy-fluindapyr in all crop matrices, at each fortification level, were within the range of 70–120 percent for recoveries and a RSD of ≤ 20 percent. No apparent residues were detected in any of the control samples used for fortification recovery above the method LOQ (expressed as fluindapyr equivalents) for all analytes.

The results show that average residues of fluindapyr in radish (tops and roots), mustard leaves, and wheat (forage, hay, straw and grain) reached a maximum of 0.022 mg/kg for residues of fluindapyr (210 days, radish tops). Average residues of 3-OH-fluindapyr were <LOQ for all RACs at all plant back intervals. Average residues if 1-OH-Met-fluindapyr reached a maximum of 0.012 mg/kg (60 days, wheat straw) and the maximum average residues of 1-COOH-fluindapyr reached 0.054 mg/kg (210 days, radish tops). The results are summarized in Table 68.

Notes:

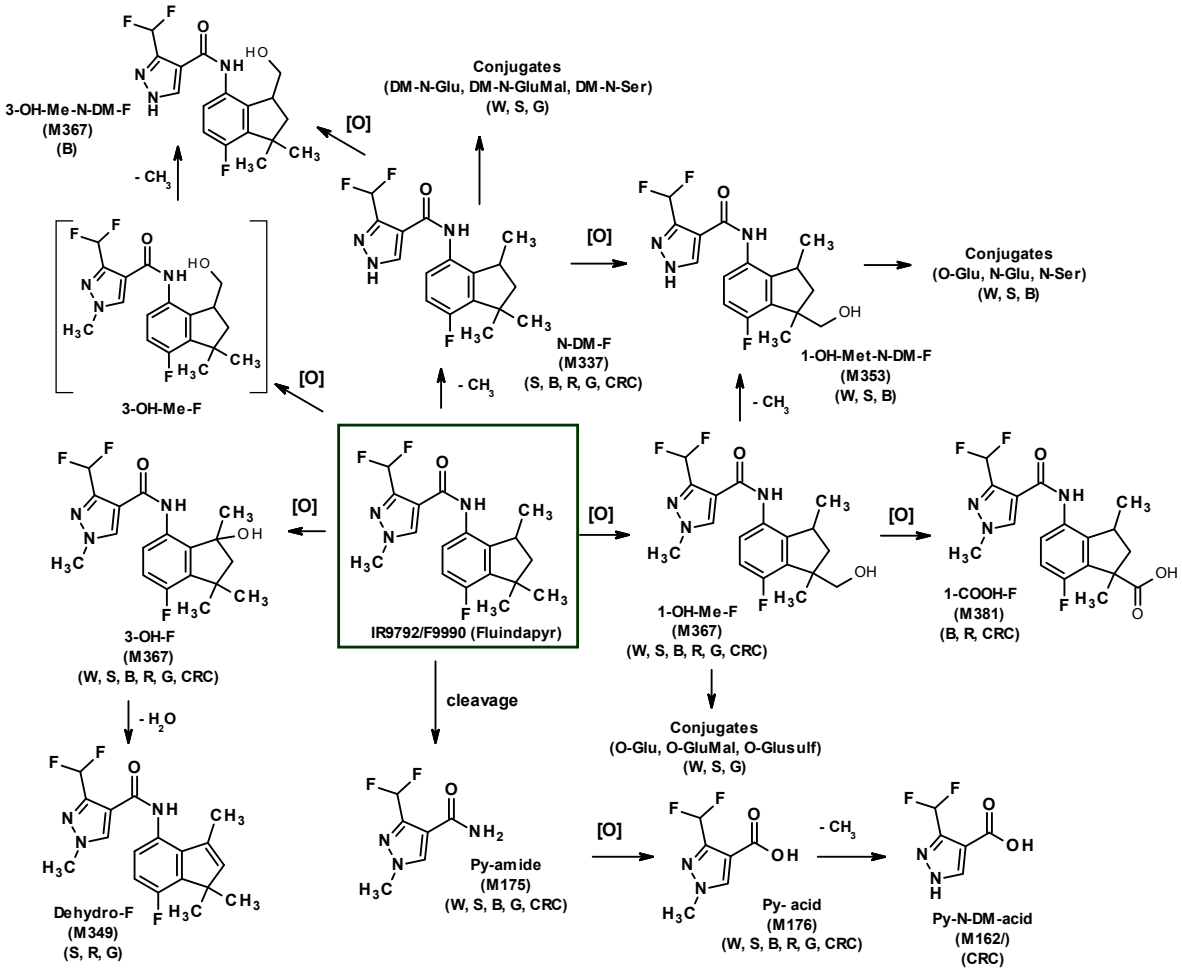
[a] Residues are means of two samples, expressed as parent equivalents.

[b] One of the duplicate samples had levels below LOQ, but combined the values are still above LOQ.

[c] One of the duplicate samples had levels above LOQ, but combined the values were below LOQ.

Overview of the metabolic pathway of fluindapyr in rotational crops

The proposed confined rotational crop metabolism (depicted in Figure 2 and again Figure 5) studies have been presented covering the crop categories root and tuber vegetables (carrots), leafy vegetables (lettuce), and cereal grains (wheat). Note that the figure below also includes the proposed metabolic pathways of the primary crops.



F: fluidapyr; Me: methyl; DM: desmethyl; py: pyrazole; Glu: glucoside; GluMal: malonylglucoside; Ser: serine; Glusulf: glucosyl sulfate
M: Mol. Wt.
Primary crops: W: wheat, S: soybean; B: sugarbeet; R: rice, G: grape
CRC: confined rotational crops (carrot, lettuce and wheat)

Figure 5 Metabolic pathway of fluindapyr in rotational crops

The enantiomeric ratio of the remaining fluindapyr slightly changed to 32/68 in both root and leaves, 42/58 in lettuce immature samples and 36/64 in lettuce mature samples. In wheat the S/R ratio was 36/64 in forage, 34/66 in hay and 27/73 in mature RACs (grain and straw). Generally a higher change in the enantiomeric ratio was observed in mature RACs than in the immature RACs. These conclusions are based on the confined rotational crop studies.

Parent was present in all commodities and the majority of the extractable metabolites were conjugated with the major (deconjugated) metabolites being 3-OH-fluindapyr, 1-COOH-fluindapyr, 1-OH-Met-fluindapyr, and N-DesMet-fluindapyr.

Based on the identified residues taken up from the soil by crops, and/or generated in the crops by further metabolism of those residues a metabolic pathway common to all rotated crops can be derived. The proposed metabolic pathway of rotational crops is similar to that in primary crops.

Metabolism in livestock

Lactating goats

The metabolism of fluindapyr was studied in lactating goats [Thomas, 2019a, 2015MET-IFP2176]. Two goats were orally dosed by capsule once daily for 7–8 consecutive days with either pyrazole-labelled fluindapyr or phenyl-labelled fluindapyr at 7.3 or 7.5 mg/kg feed/day, respectively. This is corresponding to 0.35 or 0.23 mg/kg bw/day, respectively. The actual dose received by the treated goats was based on the mean daily feed consumption of the treated goats over at least 3 days of acclimation (i.e. 1.9–2.0 kg feed/day). Goats were 7–9 years old, and body weights were 72 and 52 kg at the start of the study, and 81 kg and 48 kg at sacrifice, for the goats receiving phenyl-labelled and pyrazole-labelled fluindapyr respectively.

Goats were milked twice daily at regular intervals (in the morning prior to dosing and late afternoon). Milk was separated into aqueous and milk fat fractions for analysis. Urine and feces were collected twice daily. All goats were euthanized approximately 6 hours after the last dose. Select tissue samples were collected from each goat: liver, kidneys, loin and flank muscle, subcutaneous, renal and omental fat.

Milk was separated into cream and skimmed milk by centrifugation. Tissue samples and excreta were homogenized. All samples were stored frozen at about -20 °C until analysis. Initial sample analysis and metabolite profiling, along with LC-MS characterization/identification, were performed within 6 months of sample collection. Some samples (primarily liver, bile, urine, and feces) were re-extracted and/or re-analysed up to 15 months after collection for the confirmation of metabolite identification (qualitative analysis). In some cases, the metabolite profiles generated during the subsequent analyses were compared with the initial analyses to confirm that the profiles were qualitatively similar and no significant degradation of metabolites had taken place. Total radioactive residues (TRR) were determined by liquid scintillation counting (LSC).

Skimmed milk was extracted three times with ethyl acetate. All extracts were combined and analysed by LSC and LC-MS/MS. Composite fat samples (renal, omental, subcutaneous) and composite cream samples from several collection days were extracted by homogenization with hexane. After centrifugation, the hexane phase was separated and the remaining residue was extracted three times with acetonitrile. The hexane phase was extracted three times with acetonitrile as well, and all acetonitrile phases were combined and analysed by LSC and LC-MS/MS. Liver and kidney were extracted three times with acetonitrile followed by two extractions with an acetonitrile/water mixture (50:50; v/v). All extracts were combined and analysed by LSC and LC-MS/MS. Alternatively, three extractions with an acetone/water mixture (90:10; v/v) were conducted, followed by 2 extractions with acetone/water mixture (50:50; v/v). All acetone/water extracts were combined and analysed by LSC and LC-MS/MS. Composite muscle samples (loin and flank) were extracted three times with acetonitrile followed by two extractions with an acetonitrile/water mixture (50:50; v/v). All extracts were combined and analysed by LSC. The remainder was re-extracted three times with ethyl acetate. The combined ethyl acetate phases were concentrated and residues were determined by LSC and LC-MS/MS.

Liver extracts from the extraction process performed with acetone/water mixtures (see above) were lyophilized and re-suspended in acetate buffer at pH 5.0. Bile samples were diluted in acetate buffer at pH 5.0. Liver and bile samples were treated with β-glucuronidase by incubation for approximately 24 hours at 37 °C. Afterwards, the incubation was continued for an additional 21 hours with fresh β-glucuronidase. After incubation the whole samples were subjected to a C-18 SPE column clean-up. All fractions containing radioactivity were combined and residues were determined by LC-MS/MS.

Reference standards used were fluindapyr, 5'-OH-fluindapyr, 1-OH-Met-fluindapyr, 3-OH-Met-N-DesMet-fluindapyr, 3-OH-Met-fluindapyr, 3-OH-fluindapyr, 2-dehydro-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr, 3-COOH-N-DesMet-fluindapyr, 2-OH-fluindapyr, 1-COOH-fluindapyr, 1-COOH-N-DesMet-fluindapyr, N-DesMet-fluindapyr, and DesMet-N-OH-fluindapyr.

The ratio of the two chiral isomers of the intact fluindapyr was determined in body fat and cream. Samples were extracted according to the same extraction procedure as mentioned above. The combined acetonitrile extracts were further processed to isolate the fluindapyr fractions on an HPLC. The combined fractions were partitioned into hexane. The hexane phase was analysed by a chiral HPLC method.

The overall recovery was approximately 76 percent of the total administered phenyl-labelled dose, while 94 percent was recovered of the total administered pyrazole-labelled dose. Total radioactivity recovered in the excreta (urine and faeces) accounted for 65–81 percent of the total dose. After sacrifice, 11–13 percent of the dose remained unextracted in the gastrointestinal (GI) tract. For the phenyl-label, 0.017 percent was recovered in milk and 0.34 percent in tissues at necropsy, with the highest amount in liver (0.27 percent). For the pyrazole-label, 0.088 percent of the total dose was found in milk, while 0.20 percent was recovered from tissues at necropsy, with 0.16 percent in liver.

The total residue levels determined in milk, both fat (cream) and aqueous fraction (skimmed milk), versus sampling times (AM and PM) are given in Table 69. The concentration in milk reached the maximum concentration by day 2 or day 3. Residues were higher in cream compared to skimmed milk. The concentrations in the PM samples (collected in the afternoon after capsule administration) were higher than the concentration in the AM sample collected just prior to administration of the next capsule.

The TRR, distribution, and identification of radioactivity are shown in Table 70 to Table 72. The highest TRR was observed in liver, followed by kidney. The TRRs in the different fat (renal, omental, subcutaneous) and muscle (loin, flank) samples were comparable, and these were pooled for further analysis. Extractability was at least 78 percent. Comparable radioactivity was extracted from liver and kidney using the two different extraction procedures (with acetone or acetonitrile). The PES from all matrices was found to contain <10 percent TRR or a low residue level, therefore, no further characterization of bound residue was necessary.

Fluindapyr was extensively metabolized, and no big differences between the metabolic profiles were observed between the phenyl and pyrazole label. Parent was the predominant compound with regard to the percent TRR in cream (0.045–0.057 mg/kg, 75-93 percent TRR), fat (0.024–0.042 mg/kg, 74–75 percent TRR), and muscle (0.004–0.006 mg/kg, 32–39 percent TRR), while it ranged from not detected to 8.4 percent TRR in the other samples. Glucuronidated metabolites were identified in kidney and liver; The primary metabolites identified in the liver were 1-OH-Met-fluindapyr and its glucuronides (up to 52 percent TRR and 0.13 mg eq/kg), 1-COOH-fluindapyr plus glucuronides (up to 27 percent TRR and 0.075 mg eq/kg), and 1-OH-Met-N-DesMet-fluindapyr plus glucuronides (up to 8.9 percent TRR and 0.025 mg eq/kg). In the kidney, 1-OH-Met-fluindapyr (up to 57 percent TRR and 0.059 mg eq/kg), and 1-OH-Met-N-DesMet-fluindapyr plus their glucuronides (up to 24 percent TRR and 0.029 mg eq/kg), were major metabolites with a notable concentration of 1-COOH-fluindapyr plus glucuronides (up to 11 percent TRR and 0.011 mg.kg eq). No individual metabolite in the remaining edible tissues (skimmed milk, cream,

fat, or muscle) exceeded 0.01 mg eq/kg in concentration. In skimmed milk, 1-OH-Met-fluindapyr and di-hydroxylated species represented a large part of the residue in terms of percent TRR (16 percent to 43 percent TRR), however, their individual concentrations were very low, ranging between <0.001 and 0.005 mg eq/kg. In muscle, 1-OH-Met-fluindapyr, found at the very low concentration of max. 0.006 mg eq/kg, represented the main metabolite in terms of TRR (up to 41 percent TRR).

The acid and enzymatic hydrolysis experiments, which were performed on selected samples, confirmed the identity of the glucuronidated metabolites. Chiral analysis of fluindapyr isolated from fat and cream, which showed high levels of unchanged parent compound compared to other tissues, showed that the S/R enantiomeric ratio changed from about 50/50, as observed in the dosing formulations, to 34/66 and 35/65 in milk and fat with the respective labels.

Laying hens

The metabolism and excretion of [phenyl-^{14}C]-fluindapyr or [^{14}C-5-pyrazole]-fluindapyr was investigated in laying hens [Thomas., 2019b, 2015MET-IFP2135]. The study consisted of a preliminary phase using 4 hens per label to determine the tissue collection time points for the main study phase after one single dose of 0.74–0.82 mg/kg body weight. In the main study ten hens per label group were used and 4 in the control group. Hens were 29–31 weeks of age and weighed between 1629 and 2135 g at the time of dosing. In both the preliminary and main test the test compound was orally administered using gelatine

capsules containing the ^{14}C-labeled compound mixed with cellulose at a cumulative dose of 4.95–6.42 mg/kg body weight (mean daily dose of 0.64–0.66 mg/kg bw). Based on the daily feed consumption, the dose level corresponded to *ca.* 10 ppm (mg ai/kg dry feed/day). The hens received 9 consecutive doses at 24-hour intervals in the morning and were sacrificed *ca.* 6 hours after the last dose. This time point was selected based on the fluindapyr-equivalent concentration levels in whole blood, where maximum concentrations were observed between 0.5 and 1 hours after dosing, being 0.31 and 0.35 µg/g for the phenyl and pyrazole label, respectively. By 12 hours post dose, the mean concentration in blood was ≤ 0.01 µg/g for both groups.

The eggs were collected twice daily; egg whites and yolks were combined for analysis. Following the last dose, the treated and control hens were sacrificed and muscle tissue (2 locations), fat tissue (3 locations), skin with adhering fat, partially formed shelled eggs, liver, and gastrointestinal tract with contents were collected. Total radioactive residue was measured in all eggs, tissues, and excreta by LSC (after combustion, depending on sample). All matrices were exhaustively extracted by organic solvent-water mixtures and the radioactivity remaining in post-extraction solids was quantified by LSC after combustion. The extracts were analysed by HPLC with radiometric and mass spectrometry detection to determine the metabolite distribution and nature of the incurred residue. Unchanged parent compound was isolated from representative extracts and analysed by chiral HPLC to determine the enantiomeric composition.

The overall recovery was 96.6 percent of the total administered dose. Until sacrifice, 93.2–95.7 percent of the total administered radioactivity (TAR) was excreted and only a very low amount of 0.113–0.117 percent TAR was quantified in the eggs. At the sacrifice, 6 hours after the 9th dose, the residue in the edible organs and tissues was very low and accounted for 0.146–0.158 percent TAR.

The TRR in the laid eggs ranged from 0.0073–0.0142 mg eq/kg (Day 1 AM) to 0.045–0.047 mg eq/kg (Day 8 AM). A gradual increase was observed until Day 6 when a residue plateau of ca. 0.05 mg eq/kg with both labels was reached.

The highest TRR in edible tissues was measured in the liver (0.107–0.117 mg eq/kg, 0.043 percent TAR) followed in decreasing order by those measured in fat (0.079–0.104 mg eq/kg, 0–0.043 percent TAR) and skin (0.044–0.057 mg eq/kg, 0.024–0.037 percent TAR). The lowest TRR was measured in muscle (0.010–0.013 mg eq/kg, 0.012–0.016 percent TAR). The TRR and the percent of total administered dose quantified in each tissue is summarized in Table 73.

Table 73 Distribution of total administered dose

Because the concentration of radioactivity in each tissue exceeded 0.01 ppm following dosing of both [phenyl-^{14}C]-fluindapyr and [^{14}C-5-pyrazole]-fluindapyr, sub-samples from each tissue type were extracted to characterize the nature of the radioactive residues, obtain metabolite profiles, and identify their molecular structure, where possible.

Fat and skin samples were extracted by homogenization with hexane. After centrifugation, the hexane phase was separated and the remaining residue was extracted three times with acetonitrile. The hexane phase was extracted three times with acetonitrile as well, and all acetonitrile phases were combined and analysed by LSC and LC-MS/MS.

Pooled shelled eggs were extracted by homogenization with hexane. After centrifugation, the hexane phase was separated and the remaining residue was extracted an approximate equivalent volume of acetone:DI water (9:1, [v/v]). This was repeated two times followed by 2 times with acetone:DI water (1:1, [v/v]). For the first extraction, the volume of each supernatant fraction was measured individually before pooling and the radio-concentration determined by LSC. All acetone:DI water extractions were pooled and evaporated in a rotary evaporator at room temperature. The remaining aqueous fraction was extracted 3 times with ethyl acetate. Ethyl acetate extracts and residual aqueous phase were quantified by LSC and residues identified by LC-MS/MS.

Liver samples were equally extracted as egg samples (see above). In addition, the aqueous fraction of liver samples contained a significant amount of radioactivity and was concentrated by evaporation with ACN, diluted, separated by solid phase extraction, concentrated and analysed by HPLC.

Muscle samples from the breast and thigh were pooled; approximate equal masses from each location were used in the pools. A portion of muscle was extracted by homogenization with of ACN. The extraction was repeated 2 additional times with ACN and 2 times with ACN:DI water (1:1, [v/v]) as the solvent. Radio-concentration was determined by LSC (first extraction only). All ACN and ACN:DI water (1:1, [v/v]) extractions were pooled and concentrated and the radioconcentration determined by LSC. The concentrated extracts were re-extracted from the aqueous phase with ethyl acetate, 3 times. The combined ethyl acetate phases were concentrated and residues were determined by LSC and LC-MS/MS.

Reference standards used were fluindapyr, 5'-OH-fluindapyr, 1-OH-Met-fluindapyr, 3-OH-Met-N-DesMet-fluindapyr, 3-OH-Met-fluindapyr, 3-OH-fluindapyr, 2-dehydro-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr, 3-COOH-N-DesMet-fluindapyr, 2-OH-fluindapyr, 1-COOH-fluindapyr, 1-COOH-N-DesMet-fluindapyr, N-DesMet-fluindapyr, and DesMet-N-OH-fluindapyr.

The ratio of the two chiral isomers of the intact fluindapyr was determined in hen fat and skin. Samples were extracted according to the same extraction procedure as mentioned above. The combined acetonitrile extracts were further processed to isolate the fluindapyr fractions on an HPLC. The combined fractions were partitioned into hexane. The hexane phase was analysed by a chiral HPLC method.

Radioactive residues were efficiently extracted from eggs, edible organ and tissues (>89 percent of the TRR) prior to HPLC analysis. The PES were found to contain <10 percent TRR and ≤ 0.01 mg/kg; therefore, no additional work was conducted on the post-extraction residue. The distribution of radioactivity in eggs and edible tissues is presented in Table 74.

Notes:

[a] At necropsy.

The parent compound, fluindapyr was the major residue identified in skin, fat, egg, and muscle extracts, ranging from 30.8 percent (egg) to 93.5 percent (skin) TRR. In liver, it represented only about 5 percent TRR. The concentration of fluindapyr was 0.041 mg eq/kg and 0.050 mg eq/kg in skin, 0.073 mg eq/kg and 0.090 mg eq/kg in fat, 0.028 mg eq/kg and 0.018 mg eq/kg in egg, 0.006 mg eq/kg and 0.005 mg eq/kg in liver, and 0.005 mg eq/kg and 0.005 mg eq/kg in muscle for Group 4 (phenyl label) and Group 5 (pyrazole label), respectively.

The N-DesMet-fluindapyr metabolite was the residue of greatest concentration in the liver and represented up to 62 percent of the TRR and 0.067 mg eq/kg. A minor fraction of N-DesMet-fluindapyr was present as sulfate conjugate (< 2 percent of TRR). The N-DesMet-fluindapyr metabolite was detected at much lower levels in the egg. (up to 0.004 mg eq/kg and 6.8 percent TRR), in fat (up to 0.002 mg eq/kg and 2.0 percent TRR), in skin (up to 0.001 mg eq/kg and 1.6 percent TRR), and in muscle (<0.001 mg eq/kg and 4.5 percent of TRR). The 2 diastereomers of 1-OH-Met-IR9792/F9990 and the corresponding conjugates 1-SO_4-Met-fluindapyr represented significant fractions of TRR in liver, at 22.2 percent TRR and 0.026 mg eq/kg, in egg, at 31.8 percent TRR and 0.019 mg eq/kg, and in fat, at 10.6 percent TRR and 0.010 mg eq/kg, and in muscle, at 14.5 percent TRR and 0.002 mg eq/kg. The 1-OH-Met-fluindapyr was a minor metabolite in skin, at 0.004 mg eq/kg and 9.8 percent TRR. The 1-COOH-fluindapyr

metabolite reached 12.1 percent TRR and 0.001 ppm in muscle and 7.2 percent TRR and 0.008 mg eq/kg in liver. The 2 diastereomers of 1-OH-Met-N-DesMet-fluindapyr and/or the corresponding conjugates 1 SO_4-Met-N-DesMet-fluindapyr reached 8.5 percent of TRR and 0.010 mg eq/kg in liver and 4 percent of TRR and <0.001 mg eq/kg in muscle.

Several minor metabolites, generally representing less than 10 percent TRR and always found at concentrations lower than 0.01 mg eq/kg, were identified/characterized in edible tissues from hen. Among them, 2-OH-fluindapyr, 5'-OH-fluindapyr, 3-OH-fluindapyr, and 3-OH-Met-fluindapyr were identified and in both phenyl and pyrazole extracts. A glycine conjugate of pyrazole carboxylic acid was detected at a trace level of 0.001 mg eq/kg (11.4 percent TRR) in muscle.

The metabolic profile of fluindapyr in eggs and the edible tissues of hens is presented in Table 75 and Table 76.

Chiral analysis of fluindapyr isolated from fat and skin, which showed the higher level of unchanged parent compound compared to other tissues, showed that the S/R enantiomeric ratio changed from about 50/50, as observed in the dosing formulations, to 20/80 (to 18:82 in fat (phenyl and pyrazole group) and to 23:77 in the skin (pyrazole group only)).

Table 75 Distribution of parent compound and metabolites in the extracts of eggs, fat and skin of hens following oral administration of [phenyl-^{14}C]-fluindapyr or [^{14}C-5-pyrazole]-fluindapyr for 9 consecutive days at 10 ppm ai in feed

Overview of the metabolic pathway of fluindapyr in livestock

In goats the primary metabolic pathways for fluindapyr involve oxidation to form alcohols (a.o. 1-OH-Met-fluindapyr (diastereomers M24 and M26), 2-OH-fluindapyr (M27), Di-OH-fluindapyr) and carboxylic acids (1-COOH-fluindapyr (diastereomers M23 and M25)). A less pronounced metabolic pathway is N-demethylation of the parent to form N-DesMet-fluindapyr (M33) or further demethylation of the alcohols to form 1-OH-Met-DesMet-fluindapyr. The primary site of oxidation is at the 1-Met-fluindapyr position. The alcohols and carboxylic acids can also undergo extensive glucuronide conjugation. No sulfate conjugates were detected.

A shift of R/S-ratio of enantiomers was recognized for parent fluindapyr from a 50:50 ratio in the applied compound to a 35:65 ratio for S:R in body fat and cream (milk fat), indicating a higher metabolism rate for the S-enantiomer.

The primary metabolic pathways for fluindapyr in hens also involve N-demethylation (N-DesMet-fluindapyr (M33)) and oxidation to form alcohols (1-OH-Met-fluindapyr (diastereomers M24 and M26), 2-OH-fluindapyr (M27), and 5'-OH-fluindapyr (M35)). The 1-OH-Met-fluindapyr alcohols are further oxidized to form carboxylic acids (1-COOH-fluindapyr (diastereomers M23 and M25)). The 1-OH-Met-fluindapyr alcohols also undergo sulfation to form 1-SO_4-Met-fluindapyr sulfates (M41 and M42). These can

subsequently undergo demethylation to form 1-SO_4-Met-N-DesMet-fluindapyr (diastereomers M39 and M40).

Apart from the more extensive glucuronide conjugations in goat and sulfation steps in hens, the primary metabolic steps prior to glucuronidation or sulfation are similar for goat and hen.

The metabolic pathways of fluindapyr in goats and hens are depicted in Figure 6 and Figure 7. A combined overview of the metabolic pathways of fluindapyr (F9990/IR9792) in goat and hen is presented at the end of the evaluation (landscape required).

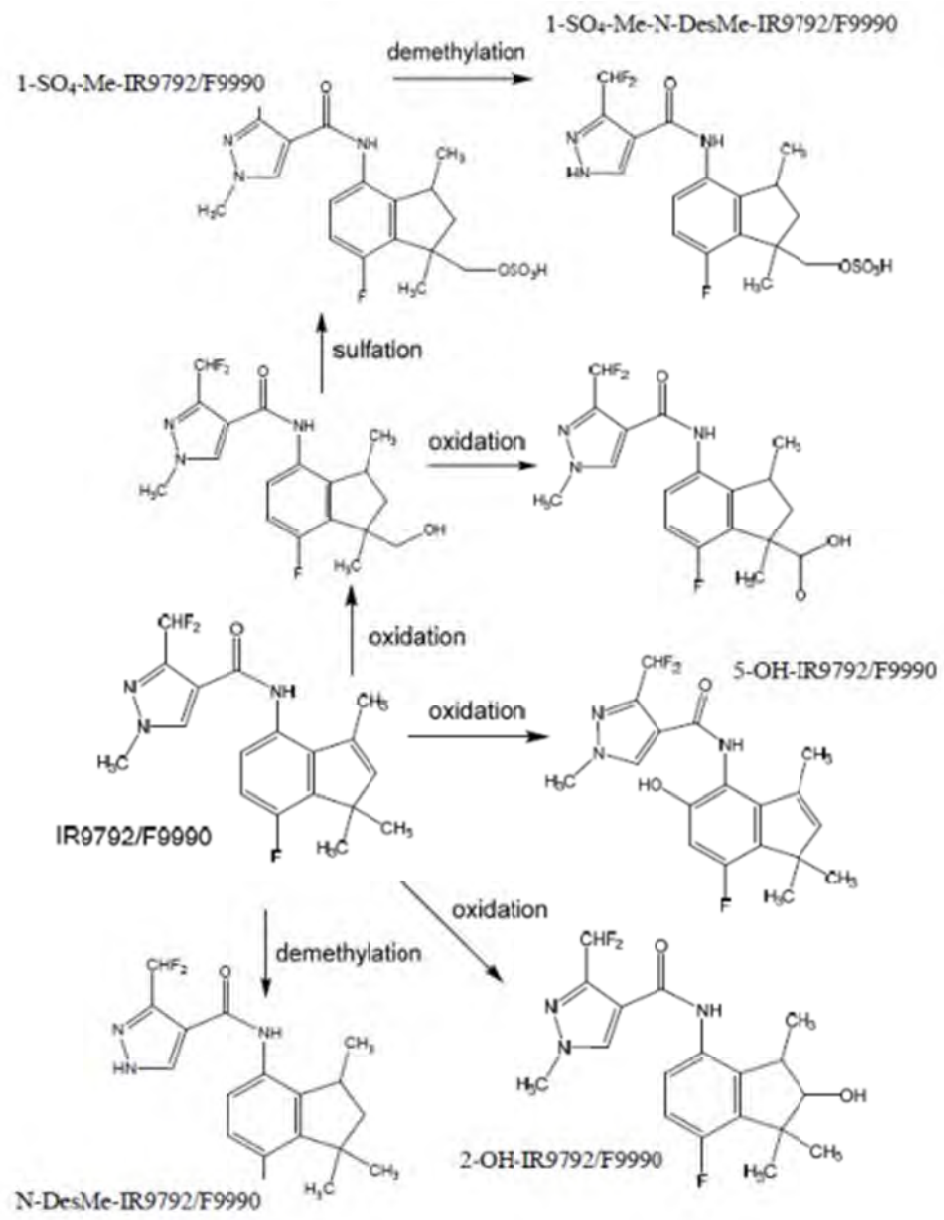

Figure 7 Proposed metabolic pathways of fluindapyr in hens

RESIDUE ANALYSIS

The Meeting received information on enforcement/monitoring methods for the determination of fluindapyr and its metabolites in plant and animal commodities. In addition the Meeting received information on analytical methods for the determination of fluindapyr and its metabolites as used in the various study reports (supervised residue trials, storage stability studies, processing studies, feeding studies). The analytical residue methods have been evaluated according to the guidance provided by OECD (Series on Pesticides number 39) as indicated on page 25 of the FAO manual 2009.

Radiovalidation for plant commodities

The extraction efficiency of the residue analytical methods PTRL P 3770 G and Isagro RA17.01 for fluindapyr and its metabolites was determined using radiolabelled samples from wheat and soya bean [Mainolfi&Garau, 2017, 2017RES-IFP3209]. Method PTRL P3770 is used for determination of parent fluindapyr, 3-OH-fluindapyr and DesMet-fluindapyr-N1-Glu. Method Isagro RA.17.01 is used for determination of 1-OH-Met-fluindapyr, 1-OH-Met-N-DesMet-fluinpdayr, 1-COOH-fluindapyr, Pyrazole carboxylica acid, N-DesMet-pyrazole carboxylic-acid and pyrazole amide.

Radiolabelled samples were obtained from a wheat metabolism study [Mainolfi & Garau, 2016, 2013MET-IFP0694], soya bean metabolism study [Desai, 2016,2013MET-IFP0730] and two confined rotational crop metabolism studies [Mainolfi & Colombini, 2017, 2013MET-IFP0693; Vanini, 2013MET-IFP0717]. In these studies pyrazole-^{14}C- of phenyl-^{14}C-labelled fluindapyr was applied. The characteristics of the studies are summarized in the table below.

Table 77 Study characteristics of the studies used providing the radiolabelled samples

Study	Study type	Method used in study	Treatment and timing	Crop samples	PHI	Analyte
2013MET-IFP0694	PCM	MEF.13.14	2 × 125-130 g ai/ha or 2 ×601-625 g ai/ha at BBCH 31-33 and BBCH 65	Wheat forage	18-22	fluindapyr 3-OH-fluindapyr 1-OH-Met-fluindapyr 1-OH-Met-N-DesMet-fluindapyr

				Wheat grain	n.a.	Pyr-acid N-DesMet-Pyr-acid Pyr-amide

Notes:

PCM = primary crop metabolism; CRCM = confined rotational crop metabolism; n.a. = not applicable because it is a rotational crop study.

The crop samples were collected during the in-life part of the relevant crop metabolism studies, homogenized and stored frozen. Wheat and soybean RACs were exhaustively extracted and analysed according to the methods of the metabolism studies. These RACs were also extracted and analysed by the residue analytical methods to check the extraction efficiency of the residues as reported for PTRL P 3770 G and Isagro RA.17.01. An overview of the extraction schemes and of the various relevant metabolites analysed with the different methods is given in Table 78 and Table 79.

Table 78 Extraction schemes of the various methods

Study	Method	Extraction	Partitioning	Samples
2013MET-IFP0694	MEF.13.14	Ultra-Turrax Forage and straw I: acetone:water 70:30 v/v II: acetone:water 50:50 v/v III: acetone:water 50:50 v/v IV: acetone V (straw only): hydrolysis by acetone/HCl (0.1N) 50:50 v/v → neutralized with 0.5 N HN_3 Grain I-III + step V, evaporated and solubilized in methanol	Extracts combined and evaporated. Aqueous phase extracted twice with n-heptane (A extract) and twice with ethyl acetate (B-extract incubated with HCl and C -aqueous phase) also incubated with HCl.	14 g wheat forage 13 g wheat straw 10 g wheat grain
2013MET-IFP0730	XBL 13027	Ultra-Turrax 3 × acetone:water 1-1 (v/v) 3 × methanol:water 1-1 (v/v/)	No partitioning, pooled extract (extract A) are evaporated and re-dissolved with CH_3OH-H_2O 1-1 (v/v) – Extract B	9 g soya bean hay
2013MET-IFP0693 and 2013MET-IFP0717	MEF.13.08 and MEF.13.09	Ultra-Turrax I: acetone:water 70:30 v/v II: acetone:water 50:50 v/v III: acetone:water 50:50 v/v IV: acetone	Extracts combined and evaporated. Aqueous phase extracted three times with n-heptane (extract A). 12 N HCl was added to the aqueous phase (extract B) for hydrolysis and neutralize with NH_3. Dried and resolved in methanol (extract C)	40-50 g wheat forage 20 g wheat straw 20-24 g wheat grain
	PTRL P 3770 G	Addition of water, same amount of acetonitrile, vigorous shaking 1 minute, centrifugation 5 minutes at 4000 rpm	Extract A	5 g wheat forage 2.5 g wheat straw 5 g wheat grain 2.5 g soya bean hay
	Isagro RA.17.01	Addition of water (shake), same amount of acetonitrile (shake), hydrolysis with HCl 4 N (80° C, 2 hrs) neutralization with 10 N NAOH, dilution with acetone and water followed by centrifugation	Extract A Cleanup on CHEMELUT cartridge (Extract B) Evaporation to dryness followed by redissolution with acetone-water 50-60 (v/v)	1 g wheat forage 1 g wheat straw 1 g wheat grain

Table 79 Overview of relevant metabolites covered by the different methods

Relevant residue	Residue method	Metabolism method	RACs
Fluindapyr	PTRL P 3770 G	MEF.13.14	wheat straw, wheat grain and wheat forage
3-OH-fluindapyr			
DesMet-fluindapyr -N1-Glu		XBL 13027	soybean hay
1-OH-Met-fluindapyr	Isagro RA.17.01	MEF.13.14	wheat straw and wheat forage
1-OH-Met-N-DesMet-fluindapyr			
1-COOH-fluindapyr		MEF.13.08	wheat straw, wheat grain and wheat forage
Pyr-acid		MEF.13.09	wheat straw, wheat grain and wheat forage
N-DesMet-Pyr-acid			
Pyr-amide			

All the extracts were assayed for radioactivity content by LSC and radio-chromatographic profiles were obtained by TLC or HPLC. The amounts of the residues obtained by residues and metabolism analytical methods were determined and the extraction efficiency as percentage of recovery (percentR) was calculated. The results of the radio-validation were reported in Table 80 and Table 81.

PTRL P 3770 G residue analytical method efficiently extracted fluindapyr, 3-OH-fluindapyr

and DesMet-fluindapyr-N1-Glu residues from crop matrices. Recovery was in the range 105 percent to 113 percent for fluindapyr, 81.7 to 110 percent for 3-OH-fluindapyr and amounted to 72.9 percent for DesMet-fluindapyr-N1-Glu.

Isagro RA.17.01 residue analytical method efficiently extracted 1-OH-Met-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr, 1-COOH-fluindapyr, N-DesMet-Pyr-acid, Pyr-acid and Pyr-amide.

Recovery was in the range 79.0 to 86.7 percent for 1-OH-Met-fluindapyr, 95.0 to 95.3 percent for 1-OH-Met-N-DesMet-fluindapyr, 88.1 to 112 percent for 1-COOH-fluindapyr, 73.2 to 79 percent for N-DesMet-Pyr-acid, 73.4 to 85.5 percent for Pyr-acid and 72.2 to 81.4 percent for Pyr-amide.

Table 80 Radiovalidation of residue analytical method PTRL P 3770 G

Compound	RACs	Residue method (mg/kg) [a]		Metabolism method (mg/kg) [a]		percent R

Notes:

[a] Data are expressed as mg/kg of fluindapyr equivalents per kg of plant material weight.

The analytical methods used in the supervised trials use the following extraction methods:

- Method PTRL P 3770 G uses water & same amount of acetonitrile and 5 g (wheat forage or grain) or 2.5 g (wheat straw or soya bean hay) samples, shaking vigorously for 1 minute, centrifuge for 5 minutes at 4000 rpm.
- Method Isagro RA.17.01 uses water (shaking for 30 minutes), same amount of acetonitrile (shaking for 30 minutes) to extract 1 g of samples (wheat forage straw and grain), hydrolysis with HCl 4 N (80° C, 2 hours), neutralization with 10 N NaOH, dilution with acetone and water followed by centrifugation and clean-up on CHEMELUT cartridge, after drying re-dissolution with acetone-water 50–60 (v/v)

The extraction efficiency for these methods is shown to be sufficient.

Radiovalidation for animal commodities

A radiovalidation study was carried out to determine the extraction efficiency of SynTech Analytical Method 133SRUS16R0208 as a data collection method for determination of residues of fluindapyr, N-DesMet-fluindapyr, 1-OH-Met-fluindapyr, fluindapyr-1-carboxylate and 1-OH-Met-N-DesMet-fluindapyr in livestock matrices [Ray, 2018, 2016RES-IFP2944]. ^{14}C-labeled goat liver, muscle, milk-aqueous, milk-fat and ^{14}C-labeled hen fat and egg samples were obtained from two metabolism studies [Thomas, 2019a and 2019b, 2015MET-IFP2176 and 2015MET-IFP2135].

Extractions used in metabolism studies performed at Charles River Laboratories (CRL)

In the goat metabolism study aqueous milk samples were extracted 3 times with equivalent volumes of EtOAc, extracts were combined and concentrated and analysed by LSC and LC-MS/MS. Subsamples of other samples were extracted by polytron homogenization (Brinkmann Homogenizer).

Samples of goat fat, milk fat and hen fat were homogenized using a 2-fold volume of hexane; after shaking, sonification and centrifugation, supernatant was separated from PES. PES was extracted 3 times with acetonitrile; The radio-concentration in hexane and combined acetonitrile supernatants was determined by LSC. The hexane fractions were extracted 3 times with acetonitrile in equal volumes and the radioactivity of the combined extracts was determined by LSC. All acetonitrile fractions and extracts were combined, concentrated and analysed by LSC and LC-MS/MS.

Subsamples of goat liver and kidney were homogenized with equivalent volumes of acetonitrile; after sonification. shaking, and centrifugation, supernatant was separated from PES and PES was extracted another 2 times with acetonitrile and 2 times with acetonitrile/water (1:1, v/v/). All extractions were pooled and concentrated and radio-concentration determined by LSC.

Another set of subsamples of goat liver and kidney were homogenized with equivalent volumes of acetonitrile:water (9:1, v/v); after sonification. shaking, and centrifugation, supernatant was separated from PES and PES was extracted another 2 times with acetonitrile:water (9:1, v/v) and 2 times with acetone/water (1:1, v/v/). All acetone:water extractions were pooled and concentrated and radio-concentration determined by LSC. Subsequent liver and kidney extractions used the acetone:water methods.

Samples of goat muscle were homogenized with equivalent volumes of acetonitrile; after shaking, sonification, and centrifugation, supernatant was separated from PES and PES was extracted another 2 times with acetonitrile and 2 times with acetonitrile:water (1:1, v/v). All acetonitrile and acetonitrile:water extractions were pooled and concentrated and radio-concentration determined by LSC and LC-MS/MS.

Samples of eggs were homogenized using a 2-fold volume of hexane; after shaking, sonification and centrifugation, supernatant was separated from PES. PES was extracted with acetone:water (9:1, v/v) and 2 additional times with acetone:water (1:1, v/v); All acetone:water extracts were combined, concentrated. The remaining aqueous fraction was extracted 3 times with ethyl acetate. Ethyl acetate extracts and residual aqueous phase were quantified by LSC. The ethyl acetate fractions were pooled and concentrated under a steady stream of nitrogen and injected into HPLC for metabolite profiling and identification.

Hydrolysis of the glucuronides in goat liver and kidney samples was performed by addition of 10 N HCl and overnight incubation at 70 °C. Samples were neutralized using ammonium hydroxide and followed by SPE column clean-up. Fractions containing radioactivity were pooled, concentrated, and analysed by LSC and LC-MS/MS.

Enzyme hydrolysis of goat liver samples was performed on acetone:water extracts of liver by addition of β-glucuronidase. After SPE-clean-up the fractions containing radioactivity were concentrated and analysed by LC-MS/MS.

Extractions used in radio-validation study by Symbiotic Research LLC (Method 133SRUS16R0208)

For the radio-validation study subsamples (4 g) of ^{14}C-labeled goat liver and muscle and hen egg were weighed in triplicates into HDPE bottles (125 mL) and 50 mL of acetonitrile was added to each. The samples were shaken and centrifuged and the supernatants transferred to a graduated cylinder.

Acetonitrile:water (7:3) was added to the solids and the samples mixed and centrifuged again. The supernatants were combined and diluted acetonitrile.

Subsamples of (4 g) ^{14}C-labeled hen fat and goat milk fat were weighed in triplicates into HDPE bottles (125 mL) and 100 mL of acetonitrile:hexane (1:1) added to each. The samples were blended and the phases allowed to separate.

A subsample (4 g) of ^{14}C-labeled goat aqueous milk was weighed in triplicate into HDPE bottles (125 mL) and 40 mL of acetonitrile was added to each. The samples were shaken and centrifuged and the supernatants diluted to 50 mL with acetonitrile. Further extraction steps were followed depending on the analyte/matrix as detailed below.

In the radio-validation study the individual supernatants for each sample were radio-assayed by a liquid scintillation counter (Beckman LS6500) in triplicate. The samples were combusted in the previous goat and hen metabolism studies and the total radioactive residues (TRR) were determined.

For the current radio-validation a HPLC system was used to profile the sample extract and for profiling of the metabolites as described in the previous goat and hen metabolism studies. The HPLC system was also used as a means of comparing reference standard to ^{14}C-components by comparison of retention times.

For determination of fluindapyr and N-DesMet-fluindapyr, 4 mL methanol/water (1:3) was added to the 1 mL extract of each of the matrices (except fat and milk fat) before injection on the LC-MS/MS.

For determination of fluindapyr and N-DesMet-fluindapyr in milk fat and fat, water was added to the acetonitrile layer, mixed and cleaned up with SPE, dried, re-dissolved in MeOH/water (1:3) and injected onto the LC-MS/MS.

For determination of 1-OH-Met-fluindapyr, 1-COOH-fluindapyr and 1-OH-Met-N-DesMet-fluindapyr in goat liver, hen fat and eggs 4 NHL was added to the acetonitrile layer, mixed, incubated (60 min at 80 °C). After SPE clean-up, and drying, the samples were re-dissolved in MeOH/water (1:4) and injected onto the LC-MS/MS.

Comparison of the profiles of the extracted ^{14}C-labeled goat and hen samples showed that the retention times for the reference standards are shorter compared to the results of CRL, as different HPLC systems were used. Goat milk (aqueous and fat) profiles were similar using both methods. Parent fluindapyr is the only analyte of concern in milk and is only observed in the milk fat. The goat muscle profiles were similar across both methods with parent also being the only major analyte. The profiles for goat liver show parent and two major clusters of several peaks. These peaks were better resolved by Symbiotic Research LC system and consisted of the major metabolites 1-OH-Met-fluindayr and 1-COOH-fluindapyr. While 1-OH-Met-N-DesMet-fluindapyr was not considered a major metabolite in the goat liver, it was included in the analytical method due to the presence of liver as a representative matrix for kidney in the validation. The hen egg extracts show similar profiles between both methods with the parent and 1-OH-Met-fluindapyr being the major analytes observed. The hen fat profiles essentially exhibit one major peak for parent for both methods. Overall, similar profile patterns are exhibited for each extracted sample for CRL and Symbiotic Research. This demonstrates that the extraction used for data collection is capable of extracting the residues of concern from livestock matrices.

Table 82 Extraction efficiency and accountability of radioactivity

Matrix	Component	TRR by combustion or LSC (ppm) [a]	RR in sample extract by LSC (ppm) [b]	Extraction efficiency (%) [c]	HPLC/LSC (ppm) [a]	Determined by 133SRUS16R0208 (ppm) [d]	Accountability 133SRUS16R0208 [e]

Notes:

F= fluindapyr; n.d. = not detected; n.a. = not analysed.

[a] Goat samples transferred from goat metabolism study [Thomas, 2019a, 2015MET-IFP2176] and hen samples transferred from hen metabolism study [Thomas, 2019b, 2015MET-IFP2135]; the total radioactive residues (TRR) were determined by combustion analysis of ^{14}C-labeled samples in both metabolism studies.

[b] LSC (ppm) values were determined by Symbiotic Research after extractions in current radio-validation study.

[c] Method extraction efficiency = (LSC results ÷ TRR values) × 100 percent.

[d] Averaged from triplicate analysis of ^{14}C-labeled samples using Analytical Method 133SRUS16R0208 LC-MS/MS analysis.

[e] Method accountability = (result from LC-MS/MS analysis ÷ results from HPLC beta ram detection/LSC) × 100 percent.

[f] Data from CRL Study [Thomas, 2019a, 2015MET-IFP2176] for Group 3: Day 7 (same sample sent to Symbiotic Research).

[g] Data from CRL Study [Thomas, 2019a, 2015MET-IFP2176] for Group 3: Days 3,5,6 (Day 7 sample sent to Symbiotic Research).

[h] Data from CRL Study [Thomas, 2019a, 2015MET-IFP2176] Group 3 (same sample sent to Symbiotic Research).

[i] Data from CRL Study [Thomas, 2019a, 2015MET-IFP2176] for Group 3 Acetone Extract, sum of metabolites and their glucuronides (same sample sent to Symbiotic Research).

[j] Data from CRL Study [Thomas, 2019b, 2015MET-IFP2135] Group 5, Necropsy (Day 8 sample sent Symbiotic Research).

[k] Data from CRL Study [Thomas, 2019b, 2015MET-IFP2135] Group 5 (same sample sent to Symbiotic Research).

[l] Expressed as sum of both isomers.

The method extraction efficiencies were determined to be: goat milk-aqueous (92 percent), goat milk-fat (84 percent), goat muscle (100 percent), goat liver (99 percent), hen egg (94 percent) and hen fat (83 percent). The full method accountability was variable due to the low absolute value of radioactivity present in some of the matrices and ranged from 23 percent to 1400 percent as determined by triplicate analyses of the goat and hen samples. The results demonstrate that the analytical method used for livestock residue analysis and tolerance enforcement is capable of extracting and analysing the analytes 1-OH-Met-F and 1-OH-Met-N-DesMet-F. The results do not demonstrate that the method used in the

dietary feedings studies is capable of extracting the main analyte of concern, being parent fluindapyr and 1-COOH-fluindapyr.

The analytical methods used in the dietary feeding studies [Brungardt, 2018, 2016RES-IFP2942 and Brungardt&Dixon 2018, 2016RES-IFP2943] use the following extraction methods:

- 133SRUS16R0208 [Moore& Shephard, 2018, as Appendix 3 of both feeding studies] Samples of muscle, liver, and egg were first extracted by blending with acetonitrile followed by extraction with acetonitrile/water (7:3). Extracts were pooled and diluted with acetonitrile. For analysis of fluindapyr and N-DesMet-fluindapyr a 1 mL sample was diluted with 4 mL of methanol/water (1:3), mixed and injected on LC-MS/MS. For analysis of 1-OH-Met-fluindapyr and 1-OH-Met-N-DesMet-fluindapyr, a 1 mL sample was mixed with 2.5 mL of 4 N HCL and incubated (80°C, 60 min). The samples were cleaned-up by SPE, concentrated and reconstituted in methanol/water (1:4) for injection on LC-MS/MS.
- Samples of fat were extracted with acetonitrile/hexane (1:1) and the phases were separated. For analysis of fluindapyr and N-DesMet-fluindapyr, part of the acetonitrile layer was mixed with water, cleaned-up by SPE, concentrated and reconstituted in methanol/water (1:4) for injection on LC-MS/MS.
- For analysis of 1-OH-Met-fluindapyr and 1-OH-Met-N-DesMet-fluindapyr, part of the acetonitrile layer mixed with 4 N HCL and incubated (80°C, 60 min), and subsequently cleaned-up, concentrated, reconstituted in methanol/water (1:4) for injection on LC-MS/MS.

Analytical methods for enforcement in plant commodities

Four methods are provided for the analysis of fluindapyr and/or metabolites in crops. The method selected for enforcement will depend on the compounds that are being analysed.

The first QuEChERS-based method [Stanislowski, 2016a, 2015RES-IFP2155] consists of a solvent/water extraction followed by analysis with LC-MS/MS. This method is to be used for analysis of fluindapyr plus metabolites 3-OH-fluindapyr and fluindapyr-DesMet-N-glucoside. An ILV of this study was conducted [Sahvorost, 2018a, 2017AMT-IFP3871] to qualify this procedure as an enforcement method.

While this method was validated for the metabolites 1-OH-Met-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr, and 1-COOH-fluindapyr, corresponding radio-validation experiments demonstrated that the method was not suitable for the analysis of incurred residues and could only be used for the analysis of spiked residues. The validation data is included here to support the crop storage stability [Soddu, 2020, 2016RES-IFP2653] that was performed using this method.

A separate LC-MS/MS method [Riccelli, 2017a, 2017RES-IFP3206] was developed to analyse for fluindapyr metabolites 1-OH-Met-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr, and 1-COOH-fluindapyr and should be used to analyse for incurred residues of these compounds. This method consists of solvent/water extraction followed by acid hydrolysis to hydrolyse sugar conjugates and allow for analysis of the metabolite aglycones.

An independent method validation of this procedure was conducted in [Sahvorost, 2018b, 2017AMT-IFP3872]. The acid hydrolysis method was further validated [Sahvorost, 2018b, 2017AMT-IFP3872] to include the common pyrazole metabolites pyrazole carboxamide, pyrazole carboxylic acid, and desmethyl-pyrazole carboxylic acid. A chiral method is also presented [Stanislowski, 2016b, 2016RES-IFP2666] to analyse the individual enantiomers of fluindapyr in crop matrices. Finally, a QuEChERS-based method [Soddu&Sicbaldi, 2014c, 2014-RES-IFP1239] is presented for the analysis of

fluindapyr in wheat matrices to support a storage stability study performed on wheat [Soddu, 2017, 2014RES-IFP1459].

LC-MS/MS method P3770G (fluindapyr, 3-OH-fluindapyr and fluindapyr-DesMet-N-glucoside)

A QuEChERS-based residue analytical method (including hydrolytic deconjugation) was developed and validated for determination of fluindapyr, and its metabolites 3-OH-fluindapyr, 1-OH-Met-fluindapyr (present in plants as a glucoside conjugate), 1-OH-Met-N-DesMet-fluindapyr (present in plant as a glucoside conjugate), 1-COOH-fluindapyr (presumably present as a glucoside conjugate) and the conjugate fluindapyr-N-DesMet-glucoside (stable to hydrolysis) in various crop materials, using LC-MS/MS for quantification and confirmation. The method was validated for sugar beet leaves (high water content), sugar beet root (high water and carbohydrate content), grapes (high acid content), soya bean seeds (high oil content), dry beans (high protein and starch content), and wheat straw (dry and difficult matrix) [Stanislowski, 2016a, 2015RES-IFP2155].

Initially parent fluindapyr and its metabolites/conjugates are extracted from various crop materials (sample size 5.0 g, except straw: 2.5 g) with a mixture of acetonitrile and water (about 1/1 v/v) by shaking vigorously for 1 min, followed by centrifugation. This extraction solvent composition is based on the initial extraction procedure of the European QuEChERS (EN 15662:2009-2) multi-residue method.

Before hydrolysis and phase separation (determination of fluindapyr, 3-OH-fluindapyr, and fluindapyr-N-DesMet-glucoside)

A small aliquot of the raw extract supernatant (acetonitrile/water about 1/1 v/v) is diluted with acetonitrile/water (1/1, v/v, containing 0.1 percent formic acid) for subsequent LC-MS/MS determination of fluindapyr, 3-OH-fluindapyr, and fluindapyr-N-desmethyl-glucoside, monitoring daughter ions for quantification and confirmation for all three analytes. The transitions are listed in Table 83.

After hydrolysis and phase separation (determination of 1-OH-Met-fluindapyr, l-OH-Met-N-DesMet-fluindapyr, and 1-COOH-fluindapyr)

In a second branch of the method, the raw extract with homogenized crop sample material still present is acidified with 10N HCl_{aq}, vortexed and hydrolysed at about 60° C for 1 hour. Then 10 N $NaOH_{aq}$ is added and the pH adjusted to slightly acidic (pH 4–6). The contents of the QuEChERS dispersive SPE (dSPE) citrate (buffer/salt) extraction tubes are added and the mixture is shaken vigorously for 1 min, followed by separation of the acetonitrile and water/salt phases supported by centrifugation.

For all matrices except straw and other dry, difficult matrices, a small aliquot of the hydrolysed upper acetonitrile extract is taken and diluted with acetonitrile/water (1/1, v/v, 0.1 percent formic acid) for subsequent LC-MS/MS determination of the deconjugated (by hydrolysis) metabolites 1-OH-Met-fluindapyr, l-OH-Met-N-DesMet-fluindapyr, and 1-COOH-fluindapyr, monitoring daughter ions for quantitation and confirmation for all three analytes. For straw a larger aliquot of the acetonitrile extracts obtained after hydrolysis and salt-induced phase separation is cleaned-up by liquid/liquid partition based on SPE for final LC-MS/MS determination of the deconjugated (by hydrolysis) metabolites 1-OH-Met-fluindapyr, l-OH-Met-N-DesMet-fluindapyr, and 1-COOH-fluindapyr. The transitions are listed in Table 83.

Table 83 Ion transitions

Analyte	MS/MS transition	
	Quantification	Confirmation
Fluindapyr	m/z 352 → 332	m/z 352 → 312
3-OH-fluindapyr	m/z 366 → 175	m/z 366 → 91
Fluindapyr-N-DesMet-glucoside	m/z 500 → 338	m/z 500 → 242

1-OH-Met-fluindapyr	m/z 368 → 310	m/z 368 → 330
1-OH-Met-N-DesMet-fluindapyr	m/z 352 → 312	m/z 352 → 332
1-COOH-fluindapyr	m/z 382 → 336	m/z 382 → 296 and m/z 382 → 281

The limit of quantitation (LOQ) was 0.010 mg/kg for all analytes, expressed as fluindapyr equivalents. The molecular weight (MW) ratios of the analytes in relation to the MW of parent fluindapyr resulted in individual LOQs for the analytes as listed below (Table 84):

Table 84 Overview of diastereomer ratio, molecular weights, LOQ and conversion factors

Analyte	Diastereomer ratio	Molecular Weight	LOQ (F-eq.)	LOQ (analyte)	Conversion Factor
Fluindapyr	n.a.	351.37	0.010	0.0100	1.000
3-OH-fluindapyr	n.a.	367.37	0.010	0.0105	1.046
Fluindapyr-N-DesMet-glucoside	n.a.	499.49	0.010	0.0142	1.422
1-OH-Met-N-DesMet-fluindapyr	1.28:1	353.35	0.010 (a+b) 0.0069 (a) 0.0031 (b)	0.010	1.046
1-OH-Met-fluindapyr	2.2:1	367.35	0.010 (a+b) 0.0056 (a) 0.0044 (b)	0.0109	1.006
1-COOH-fluindapyr	1.72:1	381.36	0.010 (a+b) 0.0063 (a) 0.037 (b)	0.0105	1.085

Notes:

n.a. = Not applicable

Calibration diagrams/functions obtained from injections of calibration solutions in matrix with at least 5 different concentrations were used to evaluate the diluted extracts. Matrix matched controls ranged from 0.0125 ng/mL (lowest in straw) to 0.50 ng/mL. Calibration functions were calculated and plotted by regression analysis. Regression coefficients (r) were > 0.99. In all cases linear regression was employed using the LC-MS/MS evaluation software, with one exception. For 3-OH-fluindapyr in soya bean the 366 m/z → 91 m/z mass transitions was evaluated using a slightly quadratic response/calibration curve. The validation results are summarized in Table 86.

A reduced validation for the analytes in dry crop matrices (soya bean seeds, dry bean, and wheat straw) was performed to prove that addition of water before fortification (full validation) has no impact on recovery results compared to addition of water after fortification (reduced validation) [Stanislowski, 2016a, 2015RES-IFP2155]. The reduced validation recovery results ranged from 70 to 107 percent with RSDs ranging from 0 to 10 percent per fortification level (n=3/fortification level) in the various matrices. Since the results are similar, they are not included in the tables below.

The method allows the determination and confirmation of all analytes with limits of quantification (LOQ) of 0.01 mg/kg, expressed as parent equivalents. No detectable analyte residues in any of the blank control samples were observed. A signal observed in the blank chromatogram of fluindapyr-*N*-DesMet-glucoside in soya bean at the retention time expected for the analyte was present at approximately 35 percent of the peak observed for the LOQ fortified sample. It was presumably caused by matrix interference and was not present in the confirmatory mass transition.

The analytical method P3770G [Stanislowski, 2016a, 2015RES-IFP2155] was subjected to independent validation for the determination of fluindapyr and metabolites 3-OH-fluindapyr, and

fluindapyr-N-glucoside in/on wheat straw (difficult matrix), wheat forage (high water content), wheat grain (high starch content), soybean seed (high oil content), grape (high acid content) and dry bean (high protein content) [Sahvorost, 2018a, 2017AMT-IFTP3871]. A sample aliquot was extracted once by shaking with water and acetonitrile. After centrifugation, the raw extract was diluted in acetonitrile/water (1/1, v/v) containing 0.1 percent formic acid prior LC-MS/MS analysis. The limit of quantification (LOQ) is 0.010 mg/kg for each analyte/matrix expressed as parent equivalents. Validation results are shown in Table 86 to Table 91.

LC-MS/MS method RA.17.01 (1-OH-Met-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr and 1-COOH-fluindapyr)

During the assessment of the extraction efficiency it was determined that for metabolites 1-OH-Met-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr and 1-COOH-fluindapyr alteration of the original method P3770 G was required. An adjusted method was developed and validated for 1-OH-Met-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr and 1-COOH-fluindapyr and their isomers in various wheat matrices [Ricelli, 2017a, 2017RES-IFP3206]. Samples were retrieved from different sources and included wheat dry gluten (high protein), grapes (high acid), oil seed rape (OSR) crude oil (high oil content), OSR straw (difficult matrices), OSR whole plant (high water content), wheat grain (high starch content) and wheat straw.

For this method water is added to the crop samples (1 g) and shaken for 30 minutes followed by addition of acetonitrile (10 mL) and shaking for 30 minutes (except for wheat straw where both acetonitrile and water are added at the same time and for dry gluten (high protein) where first acetonitrile is added followed by water). After addition of 37 percent hydrochloric acid (7 mL) samples are hydrolysed in a water bath at 80 °C for 2 hours, after cooling and pH adjustment (pH 4–5) with 10N NaOH (8 mL), acetone (25 mL) and water (20 mL) are added with mixing and sonification for 5 minutes, followed by centrifugation for 10 minutes at 4000 rpm. The sample is cleaned-up with a Chem Elute Cartridge (first 20 min soak) and elution with ethyl acetate (25 mL). The elution is and evaporated to dryness at 40 °C, reconstituted in 40:60, v/v, acetone/water (5 mL) with sonication and analysed by LC-MS/MS in positive ion mode (negative for 1-OH-Met-N-DesMet-fluindapyr) using a Phenomenex Kinetex 2.6µ C18 column (50 × 4.6 mm, 5 µm particle size), a SecurityGuard Ultra Cartridge UHPLC C18 guard column and gradient elution with mobile phases of 10mM ammonium acetate and 0.2 percent formic acid in water, and 0.2 percent formic acid in methanol. Calibration was performed using matrix matched external reference standards. The ion transitions monitored for quantification are included in Table 83.

Specificity and linearity was established. The limit of quantification for the method for all analytes in the tested matrices was 0.01 mg/kg (sum of diastereomers). The limit of quantification for the individual diastereomers is given in Table 84. Matrix effects for all analytes were found to be significant. Therefore matrix matched standards were used for all determinations. The stability of the calibration solutions and the final extracts was determined. The recovery findings of the individual diastereomers are included in Table 89, Table 90, and Table 91.

An independent method validation (ILV) for determination of 1-OH-Met-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr and 1-COOH-fluindapyr was performed [Sahvorost, 2018b, 2017AMT-IFP3872]. Similar as in the primary method validation [Ricelli, 2017a, 2017RES-IFP3206] a sample aliquot was extracted by shaking with water and acetonitrile. After addition of concentrated hydrochloric acid, the raw extract was hydrolysed in a water bath at 80 °C for 2 hours with sonication. After cooling, neutralization with 10N sodium hydroxide solution, addition of acetone and water, sonication and centrifugation, the clean-up steps were carried out using a ChemElute cartridge. After evaporation, the remaining residues were reconstituted in acetone/water (40/60, v/v), mixed and sonicated prior to LC-MS/MS analysis. Matrix matched standards were used in the calibration ranges as indicated Table 85. The validation results for

the individual diastereomers are included in Table 89, Table 90, and Table 91. The recovery findings of the sum of the diastereomers were reported, but not included in the tables.

Table 85 Calibration ranges of matrix matched standards

Analyte	Calibration range (ng/mL)	Calibration range (mg/kg)
1-OH-Met-fluindapyr, diastereomer a	0.0225-1.12	0.0015-0.07
1-OH-Met-fluindapyr, diastereomer b	0.0175-0.877	0.0013-0.06
1-OH-Met-N-DesMet-fluindapyr, diastereomer a	0.0275-1.38	0.0021-0.09
1-OH-Met-N-DesMet-fluindapyr, diastereomer b	0.0125-0.625	0.0009-0.04
1-COOH-fluindapyr, diastereomer a	0.0253-1.26	0.0019-0.08
1-COOH-fluindapyr, diastereomer b	0.0147-0.735	0.0011-0.05

LC-MS/MS multi-residue method QuEChERS for determination of fluindapyr (RA.14.04)

[QuEChERS, 2007] is a multi-residue method of the Official Collection of Test Methods. The method describes the analytical procedures for the determination of pesticide residues in foods of plant origin with a low fat content such as fruits, vegetables, cereals and cereal products, herbs, spices, tea and tobacco using GC-MS and/or LC-MS/MS following acetonitrile extraction and clean-up by dispersive SPE. The method was validated for determination of fluindapyr in wheat grain, forage, hay and straw [Soddu&Sicbaldi, 2014c, 201RES-IFP1239].

The principle of the method is based on extraction in test tubes containing, anhydrous magnesium sulfate, sodium chloride, sodium citrate tribasic dihydrate, or sodium citrate dibasic sesquihydrate. A further purification is carried out in test tubes containing anhydrous magnesium citrate, PSA or C18. The mean recoveries of the tested levels (LOQ of 0.01 mg/kg (n=7) and 10 × LOQ at 0.1 m/kg (n=5)) were within 70–120 percent range, with percentRSD ranging from 1.2–7.9 per fortification level and for each matrix. The results are not included in the tables below.

Matrix effects were investigated for wheat grain, forage, grain, and wheat straw [Soddu&Sicbaldi, 2014b, 201RES-IFP1238] by comparing peak areas of solvent standard solution with peak areas of matrix matched standard solutions. Significant matrix effects (>20 percent) were observed for wheat hay (-24 to -26 percent) and wheat straw (-27 to -28 percent). For wheat grain and wheat forage, the matrix effects were reduced to -14 to -16 percent and -12 to -15 percent, respectively.

The stability of fluindapyr in wheat forage, grain, hay and straw extracts for two weeks under controlled storage conditions was determined [Soddu&Sicbaldi, 2014a, 2014RES-IFP1236]. Two spiking levels (LOQ and 10× LOQ) were tested. The mean recoveries were 75-80 percent in wheat grain (14 days), 86-99 percent in wheat forage (15 days), 72 percent in wheat hay (15 days) and 73-75 percent in wheat straw (16 days). In addition, the stability of fluindapyr in standard calibration solutions was determined [Soddu&Sicbaldi, 2014d, 2014RES-IFP1240]. Concentrations of 0.001, 0.005 and 0.01 mg/L were tested over a period of 0–90 days. Uncorrected recoveries ranged from 75–106 percent. Recoveries corrected for recovery in fresh solution ranged from 76–117 percent.

Enantioselective (chiral) RP-HPLC-MS/MS method (P 3928 G) for determination of fluindapyr

A QuEChERS-based residue analytical method for the enantio-selective (chiral) determination of fluindapyr in various crop materials was developed and validated, with a target limit of quantitation (LOQ) of 0.010 mg/kg, using chiral reversed-phase (RP-)HPLC/MS/MS for quantitation and confirmation [Stanislowski, 2016bb, 2016RES-IFP2666].

The analytical method was validated for oilseed rape plant (high water content), grape (high acid content), wheat grain (dry, high starch content), oilseed rape seeds (high oil content), dry bean (high protein content) and straw (difficult matrix), obtained locally or from a related field study. The analytical method is derived from the QuEChERS (EN 156621) multi-residue method. Fluindapyr residues were extracted from various crop materials (sample size 5.0 g, except straw:2.5 g) with a mixture of acetonitrile and water (about 1/1, v/v) by shaking vigorously for 1 minute. After addition of $MgSO_4$, NaCl and buffering citrate salts (pH 5–5.5), the mixture is shaken intensively and centrifuged for phase separation. After freezing out fat (only for oilseed rape matrix), an aliquot of the organic extract was cleaned-up by dispersive SPE with PSA and $MgSO_4$. An aliquot of the raw extract supernatant was further diluted with acetonitrile/water (1/1, v/v, containing 0.1 percent formic acid) for subsequent chiral RP-HPLC/MS/MS determination of the two enantiomers of fluindapyr, monitoring daughter ions for quantitation and confirmation for both enantiomers.

Chiral separation was achieved on a Daicel Chiralcel OX-3 (250 mm × 4.6 mm i.d., 3 µm particle size) column, operated at 25 °C with a mobile phase consisting of aqueous 20 mM ammonium hydrogen carbonate (pH 9 adjusted with ammonia) and acetonitrile (containing 0.1 percent water).

For method validation, homogenized plant/crop samples were fortified (5 replicates per matrix and fortification level) at LOQ (0.01 mg/kg) and at 0.10 mg/kg, or 0.005 and 0.05 mg/kg per enantiomer. In addition, unfortified samples were used as blank controls. Residues in all blank control specimens were below 30 percent of the LOQ (<0.003 mg/kg). The average recoveries (n=5 per fortification level, per enantiomer, per matrix), for the two parent-daughter ion transitions monitored ranged from 95 percent to 110 percent with relative standard deviations (RSD) ≤10 percent and were within the acceptable range of 70-110 percent, with RSD ≤20 percent. The results are not included in the tables below.

Note by the reviewer:

LC-MS/MS method P3370G is considered

- valid (full validation (n=5) for the determination of fluindapyr, 3-OH-fluindapyr, fluindapyr-DesMet-N-glucoside in the range 0.01-0.1 mg/kg in sugar beet leaves (high water content), sugar beet root (high starch content), grapes (high acid content), almond, pecan and soya bean seeds (high oil content), dry beans (high protein content), and wheat grain (high starch content), wheat forage (high water content) wheat straw and (dry and difficult matrix) .
- valid (reduced validation (n=3) for the determination of fluindapyr, 3-OH-fluindapyr, fluindapyr-DesMet-N-glucoside in the range 0.01-0.1 mg/kg in maize and sorghum forage and stover, maize grain, wheat hay, and reduced validation at 0.01 mg/kg in cabbage, carrot roots and leaves and radish roots and leaves, soya bean hay and forage.
- Limited recovery experiments (n=1-2) suggest validity of method P3370G for the determination of fluindapyr, 3-OH-fluindapyr, fluindapyr-DesMet-N-glucoside in the range 0.01-0.1 mg/kg in maize AGF, flour, forage, grits, meal, oil and starch, as well as I mustard greens, peakon nutmeat, sorghum AGF and flour, sweet corn K+CWHR, forage, and stover. In addition, limited recovery experiments with fluindapyr were available at higher levels in almond hulls (5.0 and 15 mg/kg), maize forage (7.8 mg/kg), maize stover (0.2-2.0 mg/kg), sorghum forage (0.25-16.0 mg/kg), grain (0.25-8.0 mg/kg), stover (0.40-2.0 mg/kg) and AGF (1.0-26.0 mg/kg), sweet corn forage (1.0-10.0 mg/kg) and stover (1.0-20.8 mg/kg), wheat forage (1.0-20 mg/kg), wheat grain (1.0 mg/kg), wheat hay (1.0-20 mg/kg), and wheat straw (1.0-20 mg/kg). Similarly, incidental limited recoveries were available for some metabolites.

LC-MS/MS method RA.17.01 is considered

- valid (full validation (n=5) for the determination of the (sum of) diastereomers 1-OH-Met-fluindapyr in almond and pecan nutmeat (high oil content), almond hulls, dry beans (high protein content), grapes (high acid content), soya bean seed (high protein content), sugar beet roots (high starch content) and sugar beet leaves and wheat forage (both high water content), wheat straw, wheat grain and dry gluten (high starch)
- valid (full validation (n=5) for the determination of 1-OH-Met-N-DesMet-fluindapyr and 1-COOH-fluindapyr in the range 0.01-0.1 mg/kg (sum) in dry beans and soya bean seeds (high protein content), grapes (high water content), oil seed rape (OSR) crude oil (high oil content content), OSR whole plant (high water content), OSR straw, grapes (high acid content), sugar beet leaves (high water content) and roots (high starch content), wheat forage (high water content), wheat grain (high starch content), wheat dry gluten (high protein content), wheat hay and wheat straw.
- valid (reduced validation (n=3) for the determination of the (sum of) diastereomers 1-OH-Met-fluindapyr was available for concentration level 0.01 mg/kg (sum) in cabbage immature, carrot roots and leaves, maize grain, maize forage (also 0.1 mg/kg), radish leaves, radish roots, sorghum forage, sorghum grain and stover (both also 0.1 mg/kg), soya bean forage and hay, tomato and wheat hay.
- valid (reduced validation (n=3) for the determination of the (sum of) diastereomers 1-OH-Met-N-DesMet-fluindapyr and 1-COOH-fluindapyr was available for concentration level 0.01 mg/kg (sum) in in cabbage immature, carrot roots and leaves, radish roots and leaves, soya bean forage and hay, and tomato.
- Limited recovery experiments (n=1-2) suggest validity of method RA.17.01 for the determination of the (sum of) diastereomers 1-OH-Met-fluindapyr in the range 0.01-0.1 mg/kg in almond nutmeat, almond hulls, maize AGF, maize flour, maize grits, maize meal, oil, starch and stover, mustard greens sorghum AGF and flour, sweet corm K+CWHR, forage, stover
- Limited recovery experiments (n=1-2) suggest validity of method RA.17.01 for the determination of the (sum of) diastereomers 1-COOH-fluindapyr in the range 0.01-0.1 mg/kg in mustard greens and wheat hay.

Notes:

[a] At least one control (untreated field sample) per trial was analysed for each matrix.

[a] One value of 147 percent was excluded. If included (n=5), mean = 111 percent and RSD = 18 percent.

[b] One value of 148 percent was excluded. If included (n=5), mean = 111 percent and RSD = 19 percent

[c] This fortification was conducted within the 2015 field corn study entitled "Magnitude and Decline of Residues of F9944 and Metabolites in/on Field Corn and Processed Fractions Following Applications of F9944-6" (Thorn 2018) that was run simultaneously with this study.

Notes:

[a] second attempt

[b] considered an outlier

LC-MS/MS method RA.17.19 for determination of pyrazole carboxamide, pyrazole carboxylic acid and N-desmethyl-pyrazole carboxylic acid

An analytical method was developed and validated for the determination of pyrazole carboxamide, pyrazole carboxylic acid and N-desmethyl-pyrazole-caborboxylic acid in plant matrices [Ricelli, 2017b, 2017AMT-IFP3922]. A full validation was performed for wheat grain (high starch content), lettuce (high water content), soya bean seed (high oil content), dry bean (high protein content), strawberry (high acid content), wheat straw (difficult matrix). This method is an extension of method RA.17.01.

Samples of each matrix (1.0 g) were extracted with water (5 mL) and acetonitrile (10 mL) added one after the other. For high protein matrices (dry bean) acetonitrile was added prior to water and for wheat straw, water and acetonitrile were added simultaneously. HCl was added to 4N HCl and left to hydrolysed at 80 °C for 2 hours with sonication. NaOH was added to neutralize (pH 4). Acetone (5 mL) and water (20 mL) were added and mixed subsequently. After sonication and centrifugation samples were cleaned-up by ChemElute cartridge (20 minutes soaking and elution with ethyl acetate). After evaporation the residue was reconstituted in acetone/water (40/60 v/v), stirred and sonicated. Where applicable matrix matched standards where added and analysed by LC-MS/MS.

The limit of quantitation (LOQ) was 0.010 mg/kg for all analytes. The molecular weight (MW) ratios of the analytes in relation to the MW of parent fluindapyr as listed below can be used to calculate LOQs expressed as parent equivalents where needed.

Table 92 Overview of molecular weights, LOQ and conversion factors

Analyte	Transition (m/z) [a]	Molecular Weight	LOQ (analyte)	Conversion Factor
Fluindapyr	-	351.37	0.010	1.000
Pyrazole carboxylic acid	177 → 137 (+) 175 → 91 (-) 175 → 111 (-)	176.12	0.010	1.995
Pyrazole carboxamide	176 → 136 (+) 176 → 156 (+)	175.14	0.010	2.006
N-desmethyl-pyrazole carboxylic acid	163 → 123 (+) at H 3 161 → 141 (-)	162.10	0.010	2.168

Notes:

[a] Positive (+) or negative (-) polarity.

An independent method validation was carried out within a rotational crop field trial [Skaggs, 2019, 2018RES-IFP4200]. Field samples from radish tops, radish roots, mustard greens, wheat forage, wheat hay, wheat grain and wheat straw were collected, extracted and analysed for pyrazole carboxamide, pyrazole carboxylic acid and N-desmethyl-pyrazole-caborboxylic acid.

The metabolites were extracted by solvent:water, followed by addition of hydrochloric acid and subsequent hydrolysis with 4N HCl at 75 °C for 2 hours. After adjustment of pH (to approximately 4) with NaOH and dilution, analysis was performed using LC-MS/MS with primary and confirmatory mass transition. Since in the primary study matrix effects were found to be significant, matrix matched standards were included in the method to correct for potential matrix effect.

In addition, validation studies were carried out for determination of pyrazole carboxamide in almond nutmeat [Skaggs, 2019a, 2018RES-FNF4542] and soya bean seeds, hulls, meal, and refined oil [Skaggs, 2019b, 2018RES-IFP4183]. The results are summarized in Table 93, Table 94 and Table 95 for pyrazole carboxamide, pyrazole carboxylic acid and N-DesMet-pyrazole carboxylic acid.

Analytical methods for enforcement in animal commodities

The Meeting received the description and validation for an analytical method for the determination of fluindapyr, and its metabolites N-DesMet-fluindapyr, 1-OH-Met-fluindapyr, 1-COOH-fluindapyr and 1-OH-Met-N-DesMet-fluindapyr in animal commodities. These studies are summarized in the section analytical methods used in study reports on animal commodities. No validation results for existing multi-residue methods were submitted.

Analytical methods used in study reports in plant commodities

Field residue trials on field corn [Webber, 2018a, 2015RES-FNF1900, Webber, 2018b, 2016RES-FNF2453] were performed using the analytical methods PTRL Method P3770G for determination of fluindapyr, 3-OH-fluindapyr and fluindapyr-N-DesMet-glucoside and method RA.17.01 for determination of 1-OH-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr and 1-COOH-fluindapyr. The same applies for the field residue trials on sorghum [Webber, 2018d, 2015RES-FNF1901, Webber, 2018e, 2016RES-FNF2455] and wheat [Webber, 2018f, 2016RES-FNF2456, Peterek, 2018, 2015RES-IFP1968, Ricelli, 2018, 2015RESIFP1950] and tree nuts [Webber, 2017a, 2016RES-FNF2450 and Webber, 2017b, 2016RES-FNF2451].

Analytical methods used in study reports in animal commodities

The Meeting received the description and validation for an analytical method, Method 133SRUS16R0208, for the determination of fluindapyr, and its metabolites N-DesMet-fluindapyr, 1-OH-Met-fluindapyr, 1-COOH-fluindapyr and 1-OH-Met-N-DesMet-fluindapyr in animal commodities.

HPLC-MS/MS Method 133SRUS16R0208 for the determination of fluindapyr, N-DesMet-fluindapyr, 1-OH-Met-fluindapyr, 1-COOH-fluindapyr and 1-OH-Met-N-DesMet-fluindapyr

HPLC-MS/MS Method 133SRUS16R0208 determines fluindapyr, N-DesMet-fluindapyr, 1-OH-Met-fluindapyr, 1-COOH-fluindapyr and 1-OH-Met-N-DesMet-fluindapyr in animal commodities. The method was used in the animal feeding studies [Brungardt, 2018, 2016RES-IFP2942 and Brungardt&Dixon, 2018, 2016RES-IFP2943] and storage stability study [Moore&Shepherd, 2018, 2016RES-IFP2945]. The development and validation of the method is described in Moore&Shepherd [2018, 2016RES-IFP2941].

Residues of fluindapyr and its metabolites were extracted from muscle, liver, and kidney by blending first with acetonitrile (2 ×). The extract was centrifuged. The samples were blended a second time with acetonitrile/water (7:3, v/v), centrifuged, and the extracts pooled. The extracts were brought up to a final volume of 100 mL with acetonitrile. For analysis of fluindapyr, a 1 mL aliquot was diluted with 4 mL of methanol/water (1:3, v/v), mixed well, and injected on LC-MS/MS. For analysis of fluindapyr-1-COOH, 1-OH-Met-fluindapyr, and 1-OH-Met-N-DesMet-fluindapyr, the extract was mixed with 4 N HCL and allowed to hydrolyse (at 80 °C for 60 minutes). After cooling, the sample was processed through an Oasis HLB cartridge and the analytes were eluted with acetonitrile/water (7:3, v/v). The sample were concentrated to dryness and reconstituted in 1 mL of methanol/water (1:4, v/v) for injection on LC-MS/MS.

Residues of fluindapyr were extracted from milk by shaking with acetonitrile. The extract was centrifuged. The extracts were brought up to a final volume of 50 mL with acetonitrile. A 1 mL aliquot was diluted with 4 mL of methanol/water (1:3, v/v), mixed well, and injected on LC-MS/MS.

Residues of fluindapyr and its metabolites were extracted from fat by blending with acetonitrile/hexane (1:1, v/v). After phase separation the procedure was split for analyses of the various analytes. For analysis of fluindapyr, a 0.5 mL aliquot of the acetonitrile layer was diluted and mixed with 2.5 mL of water. The sample was then processed through an Oasis HLB cartridge and the analytes were eluted with acetonitrile/water (7:3, v/v). The sample was concentrated to dryness and reconstituted in 1 mL of methanol/water (1:4, v/v) for injection on LC-MS/MS. For analysis of 1-OH-Met-fluindapyr, a 0.5 mL aliquot of the acetonitrile layer was mixed with 2.5 mL of 4 N HCL and allowed to hydrolyse (80 °C for 60 minutes). After cooling down, the sample was processed through an Oasis HLB cartridge and the analytes were eluted with acetonitrile/water (7:3, v/v). The sample was concentrated to dryness and reconstituted in 1 mL of methanol/water (1:4, v/v) for injection on LC-MS/MS.

Samples were analysed by LC-MS/MS at different primary transitions for quantitation and confirmation as summarized in Table 96. The linearity of detector response for fluindapyr and its metabolites was evaluated using matrix-matched standard solutions. The reported LOQ for each analyte was 0.01 mg/kg in all tissues and 0.005 mg/kg in milk. Validation results are shown in Table 97

Table 96 Ion transitions

Analyte	Ion transition (quantitation)	Ion transition (confirmation)
Fluindapyr	352 → 332	352 → 256
N-DesMet-fluindapyr	338 → 262	338 → 242
1-OH-Met-fluindapyr	368 → 310	368 → 330
1-OH-Met-N-DesMet-fluindapyr	354 → 296	354 → 145
Fluindapyr-1-COOH	382 → 336	382 → 296

An independent laboratory validation (ILV) was performed for residues in several animal matrices [Sahvorost, 2018c, 2017AMT-IFP3873]: fluindapyr in bovine, muscle, cow milk, bovine fat, bovine liver and poultry eggs; N-DesMet-fluindapyr in bovine liver and poultry eggs; diastereomers of 1-OH-Met-fluindapyr in bovine fat and liver and poultry eggs; diatereomers of 1-OH-Met-N-DesMet-fluindapyr in bovine liver and poultry eggs, and diastereomers of 1-carboxy-fluindapyr in bovine liver. Linearity was demonstrated by determination of matrix matched standards at 6 concentration levels covering the range from no more than 20 percent of the LOQ and at least +20 percent of the highest analyte concentration. The calibration curves obtained for both mass transitions were linear with the target correlation coefficients $r \geq 0.995$. Linear regression was performed with 1/× weighting. Validation results are shown in Table 97 to Table 101.

Note by the reviewer:

HPLC-MS/MS method 133SRUS16R0208 is considered

- valid (full validation) for the determination of fluindapyr, N-DesMet-fluindapyr, 1-OH-Met-fluindapyr (sum of both diastereomers), 1-OH-Met-N-DesMet-fluindapyr (sum of both diastereomers) in the range 0.01–0.1 mg/kg in bovine muscle, bovine fat, bovine liver, bovine kidney, poultry muscle (breast & thigh), poultry fat, poultry liver and eggs and in the range 0.005-0.05 mg/kg in milk.
- Valid (full validation) for the determination of 1-COOH-fluindapyr (sum of both diastereomers) in the range 0.01–0.1 mg/kg in bovine liver and bovine kidney.

Analytical methods used in study reports on soil

The Meeting received the description and validation for an analytical methods for the determination of fluindapyr, 3-OH-fluindapyr, 1-COOH-fluindapyr (sum of diastereomers), and pyrazole carboxamide in soil.

LC-MS/MS method (fluindapyr, 3-OH-fluindapyr, 1-COOH-fluindapyr (both isomers), and pyrazole carboxamide)

The LC-MS/MS method that is part of a terrestrial field dissipation study [Schreier, 2017, 2014EFT-IFP1203] determines fluindapyr, cis-1-COOH-fluindapyr, trans-1-COOH-fluindapyr, 3-OH-fluindapyr, and pyrazole carboxamide and was validated in two representative soils, one from Nebraska and one from New York [Sahvorost, 2018d, 2017AMT-IFP3870].

Soil samples (5 g) were extracted twice using acetone:water (9:1, v/v), followed by a single extraction utilizing acetone:0.5 N HCl (1:1, v/v). The resulting solution was concentrated under nitrogen to remove the acetone and diluted with methanol. Following methanol dilution the sample was analysed for fluindapyr, cis-1-COOH-fluindapyr, trans-1-COOH-fluindapyr, 3-OH-fluindapyr, and pyrazole carboxamide content using a validated LC-MS/MS method. The samples are analysed by high performance liquid chromatography with tandem mass specific detection (LC-MS/MS) in positive polarity mode (negative for 3 hydroxy-fluindapyr), using a Phenomenex Kinetex C18 100A column (50 × 4.6 mm, 2.6 µm particle size) and gradient elution with mobile phases of 10mM ammonium acetate and 0.2 percent formic acid in water, and 0.2 percent formic acid in methanol. Calibration was performed using external reference standards. Detection was at m/z 352 to 332 (quantitation) and 257 (confirmation) for fluindapyr; at m/z 366 to 175 or 131 for 3-OH-fluindapyr; at m/z 382 to 336 or 296 for the 1-COOH-fluindapyr diastereomers, and at m/z 176 to 136 and 156 for pyrazole carboxamide. The method had a limit of quantitation (LOQ) of 0.005 mg/kg for fluindapyr, the combined diastereomers of 1-COOH-fluindapyr, 3-OH-fluindapyr, and pyrazole carboxamide.

The method was independently validated [Sahvorost, 2018d, 2017AMT-IFP3870]. In brief, the soil samples were extracted three times with acetone/water (90/10, v/v), acetone/water (50/50, v/v) and acetone/0.5 N HCl (50/50, v/v) using a sonicator and/or a reciprocal shaker. After centrifugation and

evaporating off the acetone, the remaining water part was diluted with methanol for HPLC-MS/MS analysis. Quantification was performed by use of HPLC-MS/MS detection. Two mass transitions for each analyte were evaluated in order to demonstrate that the method achieves a high level of specificity. No significant interference above 20 percent of LOQ was detected in any of the reagent blanks or the control sample extracts of each soil type, so that a high level of selectivity was demonstrated.

Matrix effects on the detection of fluindapyr, 3-OH-fluindapyr, 1-COOH-fluindapyr, and pyrazole carboxamide in final extracts of both types of soil were found to be insignificant (< ±20 percent), except 3-hydroxy-IR9792/F9990 in silt loam soil from New York. However, matrix-matched standards were used for quantification. Linearity of the response was demonstrated with six (6) matrix matched calibration standards (corresponding with 0.002–0.20 mg/kg (fluindapyr, 3-OH-fliundpayr and pyrazole carboxamide) and 0.0013–0.13 mg/kg and 0.0007–0.07 mg/kg for both diastereomer a and b from 1-COOH-fluindapyr, respectively). The calibration curves obtained for both mass transitions were linear with correlation coefficients ($r \geq 0.995$). Linear regression was performed with 1/x-weighting.

The validation results (primary transitions) for the determination of each of the analytes in soil from both reports are summarised in Table 102

Note by the reviewer: The LC-MS/MS method for the determination of fluindapyr, 3-OH-fluindapyr, 1-COOH-fluindapyr (both diastereomers), and pyrazole carboxamide in soil is considered valid in the range 0.005-0.5 mg/kg for each analyte.

Table 102 Validation results for fluindapyr and its metabolites with HPLC-MS/MS method from the original study (OS) [Schreier, 2017, 2014EFT-IFP1203] and the independent laboratory validation (ILV) [Sahvorost, 2018d, 2017AMT-IFP3870]

STABILITY OF [PESTICIDES RESIDUES IN STORED ANALYTICAL SAMPLES

The Meeting received information on the storage stability of parent, 3-OH-fluindapyr, fluindapyr-glucoside, 1-OH-Met-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr, and 1-COOH-fluindapyr in wheat matrices (grain, forage, hay and straw, dry gluten), oilseed rape (seed and whole plant) and grapes. Storage stability of fluindapyr, N-DesMet-fluindapyr, 1-OH-Met-fluindapyr, 1-COOH-fluindapyr and 1-OH-Met-N-DesMet-fluindapyr in animal tissues (muscle, fat, liver, kidney), egg, and milk were also received, as well as data on the storage stability of parent, 3-OH-fluindapyr, 1-COOH-fluindapyr diastereomers, and 3-(difluoromethyl)- l-methyl-1H-pyrazole-4-carboxamide in different soils.

Storage stability of spiked residues in plant commodities

Storage stability was investigated by **spiking** oil seed rape (OSR) whole plant (high water), wheat dry gluten (high protein), wheat grain (high starch), grapes (high acid), and OSR seed (high oil) with 0.10 mg/kg of parent, 3-OH-fluindapyr, DesMet-fluindapyr-1N-glucoside, 1-OH-Met-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr, and 1-COOH-fluindapyr [Soddu, 2020, 2016RES-IFP2653]. Samples were stored for 36 months at -20 ºC and were analysed in duplicate at various intervals.

The analytes were quantified by LC-MS/MS method based on method P3770G [2015RES-IFP2155]. The LOQ was 0.01 mg/kg.

In a second study, wheat matrices (grain, forage, straw and hay) were spiked with 0.1 mg/kg fluindapyr [Soddu, 2017, 2014 RES-IFP1459]. Samples were stored for 36 months at -20 ± ºC and were analysed in duplicate at various intervals. The analytical method was based on a QuEChERS-extraction method RA14.04 as validated in report 2014RES-IFP1239. The LOQ of the method was 0.01 mg/kg.

Storage stability results (not corrected for concurrent recovery) and concurrent recoveries for parent fluindapyr and its metabolites are shown in Table 103 to Table 106.

Note by the reviewer:

- The analytical methods used in both studies are valid for the purpose of these studies (commodity type and concentration level of the analytes).
- The results from the storage stability investigations demonstrated that parent fluindapyr, and metabolites 3-OH-fluindapyr, DesMet-fluindapyr-1N-glucoside, 1-OH-Met-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr, and 1-COOH-fluindapyr are stable over a period of 3 years in matrices covering high water, high protein, high starch, high acid, and high oil contents.

Notes:

[a] Mean recovery over fortification based on two or three samples.

[b] The percent remaining is indicated as the percentage of the initial, which is calculated by dividing the mean recovery of stored samples at each interval by the mean recovery at day 0. The values are calculated by the reviewer and not corrected with the concurrent fresh recoveries.

Storage stability of spiked residues in animal commodities

The Meeting received storage stability studies for fluindapyr in animal tissues, milk, and eggs.

The storage stability of fluindapyr and its metabolites N-DesMet-fluindapyr, 1-OH-Met-fluindapyr, 1-COOH-fluindapyr, and 1-OH-Met-N-DesMet-fluindapyr was evaluated in representative animal matrices.

The stability of fluindapyr and its metabolites metabolites N-DesMet-fluindapyr, 1-OH-Met-fluindapyr, 1-COOH-fluindapyr, and 1-OH-Met-N-DesMet-fluindapyr was evaluated in liver (hen). The stability of all analytes except 1-COOH-fluindapyr was evaluated in eggs. The stability of all analytes except N-DesMet-fluindapyr was evaluated in kidney (cow). The stability of fluindapyr and 1-OH-Met-fluindapyr was evaluated in fat (cow). The stability of fluindapyr only was evaluated in milk and muscle (hen). Storage conditions and duration were chosen to closely mimic those utilized for storage of residue samples during the fluindapyr cattle and poultry feeding studies [Brundgardt, 2018, 2016RES-IFP2942 and Brungardt& Dixon, 2018, 2016RES-IFP2943].

Samples were prepared by fortifying homogenized control matrices with the analytes of interest for that matrix at 10× the method LOQ. Samples were removed from frozen storage and analysed at intervals of 2 months in milk, kidney, muscle, and egg, and at intervals of 2 and 3 months in liver. Control and fresh fortification recovery samples were analysed at each of these time points as well as at Day 0.

Samples were analysed for fluindapyr and its metabolites using HPLC-MS/MS Method 133SRUS16R0208 with an LOQ of 0.01 mg/kg for each analyte. Average recoveries for these fresh spikes fortified on the day of extraction were within 70 percent to 120 percent. Control samples had residues below 0.3LOQ.

The results are summarised in Table 107. The results provided are the results of two (2 and 3 months data) or three (day 0) replicate samples.

Notes by the reviewer:

- The analytical method used is considered valid for the purpose of this study (commodity type and concentration level of the analytes).
- The results from the storage stability investigations demonstrated that:
    - fluindapyr was stable in all animal matrices (bovine muscle (55 days), fat (77 days), kidney (62 days), and liver (91 days)), eggs (64 days) and milk (55 days);
    - N-DesMet-fluindapyr was stable in bovine liver (91 days), bovine kidney and eggs (64 days);
    - 1-OH-Met-fluindapyr was stable in bovine fat (70 days), bovine kidney (62 days), bovine liver (58 days) and eggs (64 days);
    - 1-OH-N-DesMet-fluindapyr was stable in bovine liver (58/91 days), bovine kidney (62 days) and eggs (64 days);
    - 1-COOH-fluindapyr was stable in bovine kidney (62 days) and liver (91 days).

Table 107 Storage stability of 0.10 mg/kg fluindapyr and its metabolites, in liver, kidney, muscle, fat, milk and eggs stored at -20 °C using method 133SRUS16R0208

Notes:

[a] Normalized Recovery is indicated as the percentage of the initial, which is calculated by dividing the mean recovery of stored samples at each interval by the mean recovery at day 0 = (Average recovery / average recovery at day 0) × 100 percent. The values are not corrected for the concurrent recoveries.

[b] Mean of 2 or 3 samples.

Storage stability of spiked residues in soils

Storage stability of fluindapyr and its soil degradates, 3-OH-fluindapyr, 1-COOH-fluindapyr diastereomers, and 3-(difluoromethyl)-l-methyl-1H-pyrazole-4-carboxamide during frozen storage was investigated in two United States soils (Nebraska and New York) [Skaggs, 2018, 2015EFT-IFP1940]. Both unfortified and fortified samples of soil were kept in cold storage (-20 °C ± l 0 °C) and in dark conditions for a period of approximately two years. Beginning at 0-day, a total of seven time intervals (0-day, 3, 6, 9, 12, 18, and 24 months) were analysed for the presence of fluindapyr and its metabolites.

The method for soil was validated at a limit of quantitation (LOQ) of 0.005 mg/kg for all analytes. The method validation results included in this report are the same as presented in terrestrial field dissipation study [Schreier, 2017, 2014EFT-IFP1203] used for development and validation of the analytical method. The method consisted of a series of three solvent: water extractions followed by a solvent reconstitution. Analysis was performed using HPLC-MS/MS with primary and confirmatory mass transitions. Individual recoveries were 70–120 percent for all analytes at every stability interval, with one exception. Spike "Replicate l" for 3-OH-fluindapyr in New York soil recovered at 69 percent. Mean recoveries of the stability fortifications for all analytes were 70–120 percent at every stability interval. The percentRSD for all analytes was ≤ 20 percent at every stability interval.

Control samples at each timepoint had residues below 0.2LOQ. The recoveries of the residues after storage (uncorrected for concurrent recoveries) and concurrent recoveries are shown in Table 108.

Note by the reviewer:

The method is considered fit for the purpose of this study.

The results demonstrate that fluindapyr, 3-OH-fluindapyr, 1-COOH-fluindapyr diastereomers, and 3-(difluoromethyl)-l-methyl-1H-pyrazole-4-carboxamide are stable in soil when stored at -20 °C or lower for a period of at least 24 months.

Table 108 Storage stability at -20 °C of fluindapyr, 3-OH-fluindapyr, 1-COOH-fluindapyr diastereomers, and 3-(difluoromethyl)-l-methyl-1H-pyrazole-4-carboxamide in soil spiked with 0.1 mg/kg of each analyte

USE PATTERN

The meeting received labels from the United States for a 480 g/L formulation to be applied as foliar application either by ground or aerial application. See Table 109.

Table 109 Registered pre-harvest uses of fluindapyr

Crop	Country	F/G	Form	Application				PHI, days
				Method	Rate g ai/ha	Spray conc, g ai/hL	Number (RTI)	
Cereal grains, except rice [a]	United States	F	480 g/L SC [b]	Foliar (ground or aerial)	90-150 (max total seasonal rate 300)	Ground: 96-156 [c] Aerial: 480-780	1-2 (10 days)	7 (forage) 14 (hay) 30 (grain/straw)
Grain sorghum	United States	F	480 g/L SC [b]	Foliar (ground or aerial)	90-150 (max total seasonal rate	Ground: 96-156 [c] Aerial: 313-	1-2 (10 days)	7 (forage) 30 (stover/grain)

Crop	Country	F/G	Form	Application				PHI, days
					300)	540		
Maize (field corn, popcorn)	United States	F	480 g/L SC [b][d]	Foliar (ground or aerial)	90-150 (max total seasonal rate 300)	Ground: 96-156 [c] Aerial: 480-780	1-2 (10-14 days)	7 (forage) 30 (stover/grain)
Corn (sweet corn)	United States	F	480 g/L SC [b][d][e]	Foliar (ground or aerial)	90-150 (max total seasonal rate 300)	Ground: 96-156 [c] Aerial: 480-780	1-2 (10-14 days)	14
Tree nuts [f]	United States	F	480 g/L SC [b]	Foliar (ground or aerial) [g]	123-168 (max total seasonal rate 506)	Ground: 131-180 [c] Aerial: 131-180	1-3 (7-14 days)	30
Almonds	United States	F	480 g/L SC [b]	Foliar (ground or aerial) [g]	123-168 (max total seasonal rate 506) [h]	Ground: 131-180 [c] Aerial: 131-180	1-3 (7-14 days)	30

Notes:

F= field; G = Greenhouse; RTI = ReTreatment Interval; PHI: Post Harvest Interval.

[a] Barley, Buckwheat, Millet, pearl, Millet, proso, Oats, Rye, Teosinte, Triticale, Wheat (spring and winter).

[b] An adjuvant may be used, unless specified in the crop use directions.

[c] Sufficient water volume to ensure thorough coverage as a foliar application for good disease control. Ground, air-blast, or aerial equipment may be used, so long as adequate spray coverage is achieved, unless prohibited in crop directions for use. For ground application, apply a minimum of 93.5 L/ha (10 gallons/acre) of spray solution. For aerial application, apply a minimum of 93.5 L/ha (10 gallons/acre) of spray solution for tree nut crops, and a minimum of 18.7 L/ha (2 gallons/acre) of spray solution for all other crops.

[d] Do not use an adjuvant after the V8 stage and prior to the VT stage of the corn. An adjuvant may be used in all other growth stages. V8 is when 8th trifoliate leave is unfolded=BBCH18; VT = tassel fully emerged and separated=BBCH59-61.

[e] Do not apply to sweet corn by mechanically pressurized handgun.

[f] African nut-tree, Almond, Beechnut, Brazil nut, Brazilian pine, Bunya, Bur oak, Butternut, Cajou nut, Candlenut, Cashew, Chestnut, Chinquapin, Coconut, Coquito nut, Dika nut, Ginkgo, Guiana chestnut, Hazelnut, Heartnut, Hickory nut, Japanese horse-chestnut, Macadamia nut, Mongongo nut, Monkey-pot, Monkey puzzle nut, Okari nut, Pachira nut, Peach palm nut, Pecan, Pequi, Pili nut, Pine nut, Pistachio, Sapucaia nut, Tropical almond, Walnut, black, Walnut, English, Yellowhorn, cultivars, varieties, and/or hybrids of these.

[g] Do not apply by handheld sprayer.

[h] Do not apply on almond until after petal fall.

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received supervised trial data on wheat, sorghum, field corn, sweet corn and tree nuts.

Cereal grains

Wheat–Unite States trials

Supervised residue trials were conducted in the United States in 2016 to measure the magnitude of fluindapyr residues in/on wheat agricultural commodities following two foliar applications of a fluindapyr SC formulation [Webber, 2018e, 2016RES-FNF2456]. At each site one plot (T2) received two foliar applications at an application rate of 147–157 g ai/ha, with an interval of 6–11 days for forage and hay samples with the last application made at BBCH 21–61. At the second plot (T3) application rates ranged from 146-160 g ai/ha each, with application interval of 7–14 days for the generation of grain and straw

sample with the last applications made at BBCH 54-87. Treated plot (T2) received applications targeted at 17±2 days and 7±1 days prior to forage collection. Treated plot (T3) received applications targeted at 40±2 days and 30±2 days prior to grain harvest.

The wheat (forage, hay, grain, and straw) samples were harvested at proper times to yield commercially representative samples. At each of the sampling events, one composite sample from the untreated plot (control) and two independently collected composite samples from the treated plot, were collected randomly from at least 12 separate areas within the plots so that each sample yielded a minimum of 1 kilogram of forage and grain and 0.5 kilogram of hay and straw. The wheat forage samples were harvested at 7–8 days after the last application and the hay samples were collected from the same plots at 14–15 days after the last treatment. The grain and straw samples were harvested 26–31 days after the last application. Decline samples were collected at two trial locations. At these locations samples were collected at 0, 3, 7±1, 10±1 and 14±1 days after last application for treated forage and 7±1, 10±1, 14±2, 21±2, and 28±2 days after last application for treated hay and 20±2, 25±2, 30±2, 35±2, and 40±2 days after the last application for treated grain and straw.

Wheat raw agricultural commodity samples were maintained frozen after collection through analysis for up to 610 days. Frozen RAC samples were transferred from the field facility to the analytical laboratory in Norwell, MA, for preparation/homogenization and analysis. Samples were prepared by chopping and homogenizing the entire field sample, then removing a subsample for analysis. Samples were maintained frozen from receipt at the analytical facility until extraction for analysis.

Analytical methods used were PTRL Method P3770G for fluindapyr and 3-OH-fluindapyr and method RA.17.01 for determination of 1-OH-Met-fluindapyr, both with an LOQ of 0.010 mg/kg (metabolites expressed as parent equivalents). The analytical method for 1-OH-Met-F-O-glucoside (RA.17.01) utilizes acid hydrolysis so that this conjugate would be hydrolysed to the aglycone 1-OH-Met-F

The efficiency of the analytical method was determined at the time of analysis with each set of samples by fortifying subsamples of the control matrix with fluindapyr and the metabolites 3-OH-fluindapyr and 3-OH-Met-fluindapyr. The fortified samples were processed according to the analytical method and analysing them similar to a field-treated sample. Control matrices were fortified at levels ranging from the LOQ (0.01 mg/kg) to 20.0 mg/kg for forage, 20.0 mg/kg for hay, 1.0 mg/kg for grain, and 20.0 mg/kg for straw. Fortified control samples were included in each analysis set for method verification.

Laboratory fortification samples were analysed concurrently with each analytical set to demonstrate method performance. The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from wheat forage were 100 ± 8 percent (n = 9), 101 ± 7 percent (n = 8) and 83 ± 12 percent (n = 9), respectively. Recoveries from wheat hay were 104 ± 11 percent (n = 9), 100 ± 6 percent (n = 8) and 78 ± 12 percent (n = 8), respectively.

The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from wheat grain were 100 ± 8 percent (n = 8), 100 ± 7 percent (n = 8) and 82 ± 18 percent (n = 10), respectively.

The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from wheat straw were 98 ± 12 percent (n = 9), 105 ± 8 percent (n = 8) and 83 ± 22 percent (n = 10), respectively.

Wheat–European trials

Supervised residue trials were conducted in Northern (United Kingdom and Germany) and Southern (Italy and France) Europe in 2015 to measure the magnitude of fluindapyr residues in/on wheat agricultural commodities following two foliar applications of a fluindapyr EC formulation [Peterek, 2018, 2015RES-IFP1968 and Ricelli, 2018, 2015RES-IFP1950]. At each site one plot was left untreated (U) and one plot received two foliar applications (T1) at an application rate of 138-160 g ai/ha, with an interval of 13–15 days [Peterek, 2018, 2015RES-IFP1968] and 9–15 days [Ricelli, 2018, 2015RES-IFP1950] with the last application made at BBCH 69. In harvest + processing phase trials a third plot was included (T2) which was applied with the same timing as plot T1, but the target dose was 5 × the normal dose 689–794 g ai/ha.

For harvest trials, straw (at least 0,5 kg) and grain (at least 1 kg) were taken in plots U and T1 at normal commercial harvest. After sampling, the specimens for analysis were all stored in a freezer within 8 hours after collection. Specimen storage was done in the requested frozen conditions. For harvest + processing phase trials, at least 50 kg of grain were taken in plot U and T2, and were sent at ambient temperature to the processing site.

For decline trials, whole plants (≥1 kg) were sampled just before application 2 and also at 0, 7 (±1), 14 (±1) and 28 (±2) days after application 2; ears and rest of plants (≥1 kg) were taken at 35 (±2) days after application 2; straw (≥0.5 kg) and grain (≥1 kg) were sampled at normal commercial harvest.

Treated raw and processed crop commodity specimens for this study were frozen upon collection, shipped frozen, and stored frozen for less than 814 days (27 months) [Peterek, 2018, 2015RES-IFP1968] and less than 687 days (23 months) [Ricelli, 2018, 2015RES-IFP1950] between sample collection and analysis (<-18 °C at the analytical facility).

Analytical methods used were PTRL Method P3770G for fluindapyr, 3-OH-fluindapyr, and fluindapyr-N-desmethyl-glucoside and method RA.17.01 for determination of 1-OH-fluindapyr, 1-OH-Met-N-desmethyl-fluindapyr and 1-COOH-fluindapyr, all with an LOQ of 0.010 mg/kg (metabolites expressed as parent equivalents). The analytical method RA.17.01 utilizes acid hydrolysis so that the conjugates would be hydrolysed to their respective aglycones. Acceptance for concurrent recovery control was met with average recoveries ranging from 70 percent to 110 percent and relative standard deviations (RSD) ≤ 20 percent, respectively ≤ 15 percent for higher fortification levels.

The results on wheat grain are summarized in Table 110. The results on wheat forage, hay and straw are summarized in the section on feed commodities (Table 116 to Table 119).

Notes:

RTI = Retreatment Interval; DALA = Days After Last Application; 3-OH-F = 3-OH-fluindapyr ; 1-OH-Met-F = 1-OH-Met-fluindapyr; ^ no adjuvant used; NIS: Adjuvant Non-Ionic Surfactant; COC: Adjuvant Crop Oil Concentrate.

[a] Residues are expressed as parent equivalents.

[b] 0.010 mg/kg 1-OH-Met-N-desMet-fluindapyr (sum of diastereomers) was measured, but level was not included in the total calculation.

[c] 0.011 mg/kg 1-OH-Met-N-desMet-fluindapyr (sum of diastereomers) was measured, but level was not included in the total calculation.

[d] 0.034 mg/kg 1-OH-Met-N-desMet-fluindapyr (sum of diastereomers) was measured, but level was not included in the total calculation.

[e] Total residues is the sum of fluindapyr and 1-OH-Met-fluindapyr, expressed as parent equivalents.

[P] Used for processing study.

Sorghum

Supervised residue trials were conducted in the United States and Canada in 2015 (3) and 2016 (six in the United States only) to measure the magnitude of fluindapyr residues in/on sorghum agricultural commodities following two foliar applications of a fluindapyr SC formulation [Webber, 2018d, 2015RES-FNF1901 and Webber, 2018e, 2016RES-FNF2455]. The two foliar applications were made at an application rate of 148–159 g ai/ha each, with application interval of 9–12 days. At one site (PMS-15-02-04-01) exaggerated doses (747–770 hg ai/ha) were for processing purposes.

The sorghum (forage, grain, stover) samples were harvested at proper times to yield commercially representative samples. At each of the sampling events, one composite sample from the untreated plot (control) and two independently collected composite samples from the treated plot, were collected randomly from at least 12 separate areas within the plots so that each sample yielded a minimum of 1 kilogram of forage and grain and 0.5 kilogram of stover. Bulk samples for processing were at least 250 kg. The sorghum forage samples were harvested at 6–7 days after the last application and the grain and stover samples were harvested 45 days after the last application (2015 trials) and 28–30 days (2016 trials). Decline samples were collected at two trial locations. At these locations samples were collected at 3, 7, 10 and 13/14 days after last application for forage and 30/31, 34/35, 45, 54/55 and 60/61 days for grain and stover.

Sorghum raw agricultural commodity samples were maintained frozen after collection through analysis for up to 819 (2015 trials) and 498 (2016 trials) days. Frozen RAC samples were transferred from the field facility to the analytical laboratory in Norwell, MA, for preparation/homogenization and analysis. Samples were prepared by chopping and homogenizing the entire field sample, then removing a subsample for analysis. Samples were maintained frozen from receipt at the analytical facility until extraction for analysis.

Analytical methods used were PTRL Method P3770G for fluindapyr and 3-OH-fluindapyr and method RA.17.01 for determination of 1-OH-Met-fluindapyr, both with an LOQ of 0.010 mg/kg (metabolites expressed as parent equivalents). The analytical method RA.17.01 utilizes acid hydrolysis so that the 1-OH-Met-fluindapyr-glucoside would be hydrolysed to the aglycone1-OH-Met-fluindapyr.

The efficiency of the analytical method was determined at the time of analysis with each set of samples by fortifying subsamples of the control matrix with fluindapyr and the metabolites 3-OH-fluindapyr and 3-OH-Met-fluindapyr. The fortified samples were processed according to the analytical method and analysing them similar to a field-treated sample. Control matrices were fortified at levels ranging from the LOQ (0.01 mg/kg) to 16.0 mg/kg for forage, 8.0 mg/kg for grain, and 2.0 mg/kg for stover, 26.0 mg/kg for aspirated grain fractions, and 3.0 mg/kg for flour.

Laboratory fortification samples were analysed concurrently with each analytical set to demonstrate method performance. The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from sorghum forage were 102 ±16 percent (n = 6), 101 ± 11 percent (n = 5) and 98 ± 9 percent (n = 5), respectively [Webber, 2018d, 2015RES-FNF1901]. The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from sorghum forage were 99 ± 18 percent (n = 8), 96 ± 17 percent (n = 7) and 100 ± 13 percent (n = 7), respectively [Webber, 2018e, 2016RES-FNF2455].

The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from sorghum grain were 100 ± 25 percent (n = 6), 88 ± 14 percent (n = 5) and 84 ± 9 percent (n = 5), respectively [Webber, 2018d, 2015RES-FNF1901]. The overall mean

laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from sorghum grain were 105 ± 23 percent (n = 8), 92 ±12 percent (n = 7) and 87 ± 11 percent (n = 7), respectively [Webber, 2018e, 2016RES-FNF2455].

The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from sorghum stover were 109 ± 13 percent (n = 6), 93 ±

10 percent (n = 6) and 80 ± 9 percent (n = 5), respectively [Webber, 2018d, 2015RES-FNF1901]. The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from sorghum stover were 108 ± 11 percent (n = 8), 99 ± 11 percent (n = 8) and 82 ± 6 percent (n = 7), respectively [Webber, 2018e, 2016RES-FNF2455].

The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from sorghum aspirated grain fractions were 107 ±

17 percent (n = 4), 104 ± 4 percent (n = 3) and 77 ± 8 percent (n = 3), respectively [Webber, 2018d, 2015RES-FNF1901].

The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from sorghum flour were 100 ± 31 percent (n = 3), 106 ± 30 percent (n = 3) and 82 ± 13 percent (n = 3), respectively [Webber, 2018d, 2015RES-FNF1901].

The results on sorghum grain are summarized in Table 111.

Notes:

RTI = Retreatment Interval; DALA = Days After Last Application; 3-OH-F = 3-OH-fluindapyr ; 1-OH-Met-F = 1-OH-Met-fluindapyr; ^ no adjuvant used; NIS: Adjuvant Non-Ionic Surfactant; COC: Adjuvant Crop Oil Concentrate.

[a] Residues are expressed as parent equivalents.

[b] Total residues is the sum of fluindapyr and 1-OH-Met-fluindapyr, expressed as parent equivalents.

[P] Used for processing.

Maize cereals

Two studies with three [Webber, 2018a, 2015RES-FNF1900] and 18 [Webber, 2018b, 2016RES-FNF2453] field trials were conducted in the United States in 2015 and 2016 to measure the magnitude of fluindapyr residues in/on field corn raw agricultural commodities following two foliar application of fluindapyr SC formulation.

The two foliar applications were made at an application rate of 148–169 g ai/ha each, with application interval of 10–11 days. Additional plots [Webber, 2018a, 2015RES-FNF1900] were treated with exaggerated dose levels (5×) for the purpose of processing (see section on processing).

The field corn (forage, grain, stover) samples were harvested at proper times to yield commercially representative samples. At each of the sampling events, one composite sample from the untreated plot (control) and two independently collected composite samples from the treated plot, were collected randomly from at least 12 separate areas within the plots so that each sample yielded a minimum of 1 kilogram of forage, 1 kilogram of grain, and 0.5 kilogram of stover. Bulk grain samples reached the minimum of 240 kg per sample. The field corn raw agricultural commodity of forage was harvested at 6-7 DALA. The field corn raw agricultural commodities of grain and stover were harvested at 45 DALA.

Decline samples were collected at two trial locations (PSM-15-02-03, trial 02 and 03). At these locations samples were collected at a target of 0, 3, 7, 10, and 14 days after last application for forage and 30, 35, 45, 55, and 60 days after last application for grain and stover.

Treated raw crop commodity specimens for the 2015 study were frozen upon collection, shipped frozen, and stored frozen for less than 816 days (27 months) between sampling and analysis (<-20 °C at the analytical facility). In the 2016 study treated raw crop commodity samples were frozen upon collection, shipped frozen, and stored frozen for less than 483 days (16 months) between sampling and analysis (<-20 °C at the analytical facility).

Analytical methods used were PTRL Method P3770G for fluindapyr and 3-OH-fluindapyr and method RA.17.01 for determination of 1-OH-Met-fluindapyr, both with an LOQ of 0.010 mg/kg (metabolites expressed as parent equivalents). The analytical method RA.17.01 utilizes acid hydrolysis so that the 1-OH-Met-fluindapyr-glucoside would be hydrolysed to the aglycone1-OH-Met-fluindapyr.

The efficiency of the analytical method was determined at the time of analysis with each set of samples by fortifying subsamples of the control matrix with fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr. The fortified samples were processed according to the analytical method and analysing them similar to a field-treated sample. Control matrices were fortified at levels ranging from the LOQ (0.01 mg/kg) to 15.5 mg/kg for forage, 0.1 mg/kg for grain, 2.0 mg/kg for stover, 1.0 mg/kg for aspirated grain fractions, and 0.1 mg/kg for all processed commodities. Laboratory fortification samples were analysed concurrently with each analytical set to demonstrate method performance.

The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 3-OH-Met-fluindapyr from field corn grain were 100 ± 4 percent (n = 4), 96 ± 9 percent (n = 4) and 77 ± 7 percent (n = 4), respectively [Webber, 2018a, 2015RES-FNF1900] and 94 ± 7 percent (n = 6), 95 ±3 percent (n = 6) and 85 ± 16 percent (n = 6), respectively in the second study [Webber, 2018b, 2016RES-FNF2453].

The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from field corn aspirated grain fractions were 112 ± 12 percent (n = 3), 119 ± 6 percent (n = 3) and 78 ± 8 percent (n = 3), respectively.

The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from field corn starch were 130 percent (n = 2), 117 percent (n = 2) and 77 percent (n = 2), respectively.

The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from field corn refined oil (wet milling) were 93 percent (n = 2), 100 percent (n = 2) and 82 percent (n = 2), respectively.

The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from field corn grits were 89 percent (n = 2), 74 percent (n = 2) and 77 percent (n = 2), respectively.

The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from field corn flour were 98 percent (n = 2), 94 percent (n = 2) and 84 percent (n = 2), respectively.

The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from field corn germ were 94 percent (n = 2), 109 percent (n = 2) and 74 percent (n = 2), respectively.

The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from field corn meal were 98 percent (n = 2), 90 percent (n = 2) and 73 percent (n = 2), respectively.

The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from field corn refined oil (dry milling) were 124 percent (n = 2), 106 percent (n = 2) and 84 percent (n = 2), respectively.

The results on grain are summarized in Table 112.

Notes:

RTI = Retreatment Interval; DALA = Days After Last Application; 3-OH-F = 3-OH-fluindapyr ; 1-OH-Met-F = 1-OH-Met-fluindapyr; ^ no adjuvant used; NIS: Adjuvant Non-Ionic Surfactant; COC: Adjuvant Crop Oil Concentrate.

[a] Residues are expressed as parent equivalents. Since all results were <0.01 mg/kg in both duplicates, only the mean is included in the table.

[b] Total residues is the sum of fluindapyr and 1-OH-Met-fluindapyr, expressed as parent equivalents.

Sweet corns

Supervised residue trials were conducted in the United States in 2015 and 2016 to measure the magnitude of fluindapyr residues in/on sweet corn raw agricultural commodities following two foliar applications of a fluindapyr SC formulation [Webber, 2018c, 2016RES-FNF2454]. The two foliar applications were made at an application rate of 148–156 g ai/ha each, with application interval of 10–11 days.

The sweet corn (Kernel + Cobs With Husks Removed = K+CWHR, forage, stover) samples were harvested at proper times to yield commercially representative samples. At each of the sampling events, one composite sample from the untreated plot (control) and two independently collected composite samples from the treated plot, were collected randomly from at least 12 separate areas within the plots so that each sample yielded a minimum of 1 kilogram of K+CWHR, 1 kilogram of forage, and 0.5 kilogram of stover. The sweet corn raw agricultural commodities of K+CWHR, forage, and stover were harvested at 12–16 days after the second application to the treated plot. Decline samples were collected at one trial location (Trial 06). At these locations samples were collected at a target of 3, 7, 14, 21, and 28 days after last application for K+CWHR, forage and stover.

Sweet corn raw agricultural commodity samples were maintained frozen after collection through analysis for up to 564 days. Frozen RAC samples were transferred from the field facility to the analytical laboratory in Norwell, MA, for preparation/homogenization and analysis. Samples were prepared by chopping and homogenizing the entire field sample, then removing a subsample for analysis. Samples were maintained frozen from receipt at the analytical facility until extraction for analysis.

Analytical methods used were PTRL Method P3770G for fluindapyr and 3-OH-fluindapyr and method RA.17.01 for determination of 1-OH-Met-fluindapyr, both with an LOQ of 0.010 mg/kg (metabolites expressed as parent equivalents). The analytical method RA.17.01 utilizes acid hydrolysis so that the 1-OH-Met-fluindapyr-glucoside would be hydrolysed to the aglycone1-OH-Met-fluindapyr.

The efficiency of the analytical method was determined at the time of analysis with each set of samples by fortifying subsamples of the control matrix with fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr. The fortified samples were processed according to the analytical method and analysing them similar to a field-treated sample. Control matrices were fortified at levels ranging from the LOQ (0.01 mg/kg) to 1.0 mg/kg for K+CWHR, 10.0 mg/kg for forage, and 20.8 mg/kg for stover. Fortified control samples were included in each analysis set for method verification. The

methodology was shown to be robust for the analysis of sweet corn K+CWHR, forage, and stover in this study.

Laboratory fortification samples were analysed concurrently with each analytical set to demonstrate method performance. The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from sweet corn K+CWHR were 97 ± 11 percent (n = 4), 95 ± 5 percent (n = 4) and 82 ± 7 percent (n = 4), respectively.

The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from sweet corn forage were 102 ± 11 percent (n = 5), 104 ±3 percent (n = 4) and 90 ± 12 percent (n = 4), respectively.

The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from sweet corn stover were 101 ± 13 percent (n = 5), 102 ± 3 percent (n = 4) and 93 ± 10 percent (n = 4), respectively.

The results on K+CWHR are summarized in Table 113.

Tree nuts

Almond

Supervised residue trials were conducted in the United States in 2016 to measure the magnitude of fluindapyr residues in/on almond agricultural commodities following three foliar applications of a fluindapyr SC formulation [Webber, 2017a, 2016RES-FNF2450]. At each site two plots received three foliar applications at an application rate of 156–192 g ai/ha, with an interval of 7 to 8 days with the last application made at BBCH75–85. At one plot (T2) 443-528 L water/ha was used and the second plot (T3) 1730–1991 L/ha water was used.

The almond (nutmeat and hulls) samples were harvested at maturity to yield commercially representative samples. At each of the sampling events, one composite sample from the untreated plot (control) and two independently collected composite samples from the treated plot, were collected randomly from at least 4 different trees within the plots so that each sample yielded a minimum of 1 kilogram of nutmeat and hulls. The samples were harvested at 29–31 days after the last application. Decline samples were collected at one trial locations on days 15, 23, 30, 37, and 44 after the last application.

Samples were maintained frozen after collection through analysis for up to 379 (nutmeat) and 384 (hulls) days. Frozen RAC samples were transferred from the field facility to the analytical laboratory in Norwell, MA, for preparation/homogenization and analysis. Samples were prepared by chopping and

homogenizing the entire field sample, then removing a subsample for analysis. Samples were maintained frozen from receipt at the analytical facility until extraction for analysis.

Analytical methods used were PTRL Method P3770G for fluindapyr and 3-OH-fluindapyr and method RA.17.01 for determination of 1-OH-Met-fluindapyr, both with an LOQ of 0.010 mg/kg (metabolites expressed as parent equivalents). The analytical method RA.17.01 utilizes acid hydrolysis so that the 1-OH-Met-fluindapyr-glucoside would be hydrolysed to the aglycone1-OH-Met-fluindapyr.

The efficiency of the analytical method was determined at the time of analysis with each set of samples by fortifying subsamples of the control matrix with fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr. The fortified samples were processed according to the analytical method and analysing them similar to a field-treated sample. Control matrices were fortified at levels ranging from 1/5 LOQ (0.002 mg/kg) to 10 × LOQ (0.1 mg/kg). The overall mean method validation recoveries and RSDs for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from almond nutmeat were 99 ± 11 percent (n = 10), 82 ± 7 percent (n = 10) and 92 ± 6 percent (n = 10), respectively.

Laboratory fortification samples were analysed concurrently with each analytical set to demonstrate method performance. The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from almond nutmeat were 107 ± 18 percent (n = 4), 86 ± 15 (n = 4) and 91 ± 7 percent (n = 4), respectively.

The results on almond nutmeat are summarized in Table 114.

Pecan

Supervised residue trials were conducted in the United States in 2016 to measure the magnitude of fluindapyr residues in/on pecan agricultural commodities following three foliar applications of a fluindapyr SC formulation [Webber, 2017b, 2016RES-FNF2451]. At each site two plots received three foliar applications at an application rate of 165–177 g ai/ha, with an interval of 7 days with the last application made at BBCH78–85 (chuck split stage). At one plot (T2) 450–555 L water/ha was used and the second plot (T3) 1583–1994 L/ha water was used.

The pecan nutmeat samples were harvested at maturity to yield commercially representative samples. At each of the sampling events, one composite sample from the untreated plot (control) and two independently collected composite samples from the treated plot, were collected randomly from at least 4 different trees within the plots so that each sample yielded a minimum of 1 kilogram of nutmeat. The

samples were harvested at 30 days after the last application. Decline samples were collected at one trial locations on days 16, 23, 30, 37, and 44 after the last application.

Samples were maintained frozen after collection through analysis for up to 272 days. Frozen RAC samples were transferred from the field facility to the analytical laboratory in Norwell, MA, for preparation/homogenization and analysis. Samples were prepared by chopping and homogenizing the entire field sample, then removing a subsample for analysis. Samples were maintained frozen from receipt at the analytical facility until extraction for analysis.

Analytical methods used were PTRL Method P3770G for fluindapyr and 3-OH-fluindapyr and method RA.17.01 for determination of 1-OH-Met-fluindapyr, both with an LOQ of 0.010 mg/kg (metabolites expressed as parent equivalents). The analytical method RA.17.01 utilizes acid hydrolysis so that the 1-OH-Met-fluindapyr-glucoside would be hydrolysed to the aglycone1-OH-Met-fluindapyr.

The efficiency of the analytical method was determined at the time of analysis with each set of samples by fortifying subsamples of the control matrix with fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr. The fortified samples were processed according to the analytical method and analysing them similar to a field-treated sample. Control matrices were fortified at levels ranging from 1/5 LOQ (0.002 mg/kg) to 10 × LOQ (0.1 mg/kg). The overall mean method validation recoveries and RSDs for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from pecan nutmeat were 92 ± 4 percent (n = 10), 97 ± 2 percent (n = 10) and 88 ± 5 percent (n = 10), respectively.

Laboratory fortification samples were analysed concurrently with each analytical set to demonstrate method performance. The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from pecan nutmeat were 102 percent (n = 4), 102 percent (n = 4) and 74 percent (n = 4), respectively.

The results on pecan nutmeat are summarized in Table 115.

Notes:

RTI = Retreatment Interval; DALA = Days After Last Application; 3-OH-F = 3-OH-fluindapyr ; 1-OH-Met-F = 1-OH-Met-fluindapyr; ^ no adjuvant used; NIS: Adjuvant Non-Ionic Surfactant; COC: Adjuvant Crop Oil Concentrate; n.r. = not reported.

[a] Residues are expressed as parent equivalents.

[b] Total residues is the sum of fluindapyr and 1-OH-Met-fluindapyr, expressed as parent equivalents.

Animal Feed

Wheat forage, hay and straw–United States trials

Supervised residue trials were conducted in the United States in 2016 to measure the magnitude of fluindapyr residues in/on wheat agricultural commodities following two foliar applications of a fluindapyr SC formulation [Webber, 2018e, 2016RES-FNF2456]. The details of the study are described in the section on food commodities (wheat grain).

The wheat (forage, hay, and straw) samples were harvested at proper times to yield commercially representative samples. At each of the sampling events, one composite sample from the untreated plot (control) and two independently collected composite samples from the treated plot, were collected randomly from at least 12 separate areas within the plots so that each sample yielded a minimum of 1 kilogram of forage and at least 0.5 kilogram of hay or straw. The wheat forage samples were harvested at 7–8 days after the last application and the hay samples were collected from the same plots at 14–15 days after the last treatment. The straw samples were harvested 26-31 days after the last application. Decline samples were collected at two trial locations. At these locations samples were collected at 0, 3, 7±1, 10±1 and 14±1 days after last application for treated forage and 7±1, 10±1, 14±2, 21±2, and 28±2 days after last application for treated hay and 20±2, 25±2, 30±2, 35±2, and 40±2 days after the last application for treated grain and straw.

Analytical methods used were PTRL Method P3770G for fluindapyr and 3-OH-fluindapyr and method RA.17.01 for determination of 1-OH-fluindapyr, both with an LOQ of 0.010 mg/kg (metabolites expressed as parent equivalents). The analytical method RA.17.01 utilizes acid hydrolysis so that the 1-OH-Met-fluindapyr-glucoside would be hydrolysed to the aglycone1-OH-Met-fluindapyr.

The efficiency of the analytical method was determined at the time of analysis with each set of samples by fortifying subsamples of the control matrix with fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr. The fortified samples were processed according to the analytical method and analysing them similar to a field-treated sample. Control matrices were fortified at levels ranging from the LOQ (0.01 mg/kg) to 20.0 mg/kg for forage, hay and straw and 1.0 mg/kg for grain. Fortified control samples were included in each analysis set for method verification.

Laboratory fortification samples were analysed concurrently with each analytical set to demonstrate method performance. The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from wheat forage were 100 ± 8 percent (n = 9), 101 ± 7 percent (n = 8) and 83 ± 12 percent (n = 9), respectively. Recoveries from wheat hay were 104 ± 11 percent (n = 9), 100 ± 6 percent (n = 8) and 78 ± 12 percent (n = 8), respectively.

The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from wheat grain were 100 ± 8 percent (n = 8), 100 ±

7 percent (n = 8) and 82 ± 18 percent (n = 10), respectively.

The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from wheat straw were 98 ± 12 percent (n = 9), 105 ±

8 percent (n = 8) and 83 ± 22 percent (n = 10), respectively.

Wheat forage, hay and straw–European trials

Supervised residue trials were conducted in Northern (United Kingdom and Germany) and Southern (Italy and France) Europe in 2015 to measure the magnitude of fluindapyr residues in/on wheat agricultural commodities following two foliar applications of a fluindapyr EC formulation [Peterek, 2018, 2015RES-IFP1968 and Ricelli, 2018, 2015RES-IFP1950]. The details of the study are described in the section n food commodities (wheat grain).

For harvest trials, straw samples (at least 0,5 kg) were taken in plots U and T1 at normal commercial harvest. After sampling, the specimens for analysis were all stored in a freezer within 8 hours after collection. Specimen storage was done in the requested frozen conditions. For decline trials, whole plants (≥1 kg) were sampled just before application 2 and also at 0, 7 (±1), 14 (±1) and 28 (±2) days after

application 2; ears and rest of plants (≥1 kg) were taken at 35 (±2) days after application 2; straw (≥ 0.5 kg) and grain (≥1 kg) were sampled at normal commercial harvest (DALA 40–47 days).

Analytical methods used were PTRL Method P3770G for fluindapyr, 3-OH-fluindapyr, and fluindapyr-N-desmethyl-glucoside and method RA.17.01 for determination of 1-OH-fluindapyr, 1-OH-Me-N-desmethyl-fluindapyr and 1-COOH-fluindapyr, all with an LOQ of 0.010 mg/kg (metabolites expressed as parent equivalents). The analytical method RA.17.01 utilizes acid hydrolysis so that the conjugated metabolites would be hydrolysed to their respective aglycones. Acceptance for concurrent recovery control was met with average recoveries ranging from 70 percent to 110 percent and relative standard deviations (RSD) ≤ 20 percent, respectively ≤ 15 percent for higher fortification levels.

The results on wheat forage, hay, whole plants, ears, rest of plants, and straw are summarized in Table 116 to Table 119.

Notes:

RTI = Retreatment Interval; DALA = Days After Last Application; 3-OH-F = 3-OH-fluindapyr ; 1-OH-Met-F = 1-OH-Met-fluindapyr; ^ no adjuvant used; NIS: Adjuvant Non-Ionic Surfactant; COC: Adjuvant Crop Oil Concentrate.

[a] Residues are expressed as parent equivalents and total residues represent the sum of fluindapyr and 1-OH-Met-fluindapyr, expressed as parent equivalents.

[b] Also levels of 0.11 mg/kg 1-OH-Met-N-desMet-fluindapyr (sum of diastereomers) and 0.025 mg/kg 1-COOH-fluindapyr (sum of diastereomers) were recorded, but not included in the total residue calculations.

[c] Also levels of 0.16 mg/kg 1-OH-Met-N-desMet-fluindapyr (sum of diastereomers) and 0.030 mg/kg 1-COOH-fluindapyr (sum of diastereomers) were recorded, but not included in the total residue calculations.

[d] Also levels of 0.12 mg/kg 1-OH-Met-N-desMet-fluindapyr (sum of diastereomers) and 0.023 mg/kg 1-COOH-fluindapyr (sum of diastereomers) were recorded, but not included in the total residue calculations.

[e] Also levels of 0.15 mg/kg 1-OH-Met-N-desMet-fluindapyr (sum of diastereomers) and 0.059 mg/kg 1-COOH-fluindapyr (sum of diastereomers) were recorded, but not included in the total residue calculations.

[f] Also levels of 0.13 mg/kg 1-OH-Met-N-desMet-fluindapyr (sum of diastereomers) and 0.016 mg/kg 1-COOH-fluindapyr (sum of diastereomers) were recorded, but not included in the total residue calculations.

[g] Also levels of 0.44 mg/kg 1-OH-Met-N-desMet-fluindapyr (sum of diastereomers) and 0.043 mg/kg 1-COOH-fluindapyr (sum of diastereomers) were recorded, but not included in the total residue calculations.

[h] Also levels of 0.39 mg/kg 1-OH-Met-N-desMet-fluindapyr (sum of diastereomers) and 0.042 mg/kg 1-COOH-fluindapyr (sum of diastereomers) were recorded, but not included in the total residue calculations.

[i] Also levels of 0.24 mg/kg 1-OH-Met-N-desMet-fluindapyr (sum of diastereomers) and 0.018 mg/kg 1-COOH-fluindapyr (sum of diastereomers) were recorded, but not included in the total residue calculations.

Sorghum forage and stover

Supervised residue trials were conducted in the United States and Canada in 2015 (3) and 2016 (6 in United States only) to measure the magnitude of fluindapyr residues in/on sorghum agricultural commodities following two foliar applications of a fluindapyr SC formulation [Webber, 2018d, 2015RES-FNF1901 and Webber, 2018e, 2016RES-FNF2455]. The details of the study are described in the section n food commodities (sorghum grain).

The sorghum forage samples were harvested at 6–7 days after the last application and stover samples were harvested 45 days after the last application (2015 trials) and 28–30 days (2016 trials). At each of the sampling events, one composite sample from the untreated plot (control) and two independently collected composite samples from the treated plot, were collected randomly from at least 12 separate areas within the plots so that each sample yielded a minimum of 1 kilogram of forage and 0.5 kilogram of stover. Decline samples were collected at two trial locations. At these locations samples were collected at 3, 7, 10 and 13/14 days after last application for forage and 30/31, 34/35, 45, 54/55 and 60/61 days for stover.

Analytical methods used were PTRL Method P3770G for fluindapyr and 3-OH-fluindapyr and method RA.17.01 for determination of 1-OH-fluindapyr, both with an LOQ of 0.010 mg/kg (metabolites expressed as parent equivalents). The analytical method RA.17.01 utilizes acid hydrolysis so that the 1-OH-Met-fluindapyr-glucoside would be hydrolysed to the aglycone1-OH-Met-fluindapyr.

The efficiency of the analytical method was determined at the time of analysis with each set of samples by fortifying subsamples of the control matrix with fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr. The fortified samples were processed according to the analytical method and analysing them similar to a field-treated sample. Control matrices were fortified at levels ranging from the LOQ (0.01 mg/kg) to 16.0 mg/kg for forage and 2.0 mg/kg for stover.

Laboratory fortification samples were analysed concurrently with each analytical set to demonstrate method performance. The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from sorghum forage were 102 ±16 percent (n = 6), 101 ± 11 percent (n = 5) and 98 ± 9 percent (n = 5), respectively [Webber, 2018d, 2015RES-FNF1901]. The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from sorghum forage were 99 ± 18 percent (n = 8), 96 ± 17 percent (n = 7) and 100 ± 13 percent (n = 7), respectively [Webber, 2018e, 2016RES-FNF2455].

The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from sorghum stover were 109 ± 13 percent (n = 6), 93 ± 10 percent (n = 6) and 80 ± 9 percent (n = 5), respectively [Webber, 2018d, 2015RES-FNF1901]. The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from sorghum stover were 108 ± 11 percent (n = 8), 99 ± 11 percent (n = 8) and 82 ± 6 percent (n = 7), respectively [Webber, 2018e, 2016RES-FNF2455].

The results on sorghum forage and sorghum stover are summarized in Table 120 and Table 121.

Notes:

RTI = Retreatment Interval; DALA = Days After Last Application; 3-OH-F = 3-OH-fluindapyr ; 1-OH-Met-F = 1-OH-Met-fluindapyr; ^ no adjuvant used; NIS: Adjuvant Non-Ionic Surfactant; COC: Adjuvant Crop Oil Concentrate.

[a] Residues are expressed as parent equivalents.

[b] Total residues is the sum of fluindapyr and 1-OH-Met-fluindapyr, expressed as parent equivalents.

Maize forage and stover

Two studies with three [Webber, 2018a, 2015RES-FNF1900] and 18 [Webber, 2018b, 2016RES-FNF2453] field trials were conducted in the United States in 2015 and 2016 to measure the magnitude of fluindapyr residues in/on field corn raw agricultural commodities following two foliar applications of a fluindapyr SC formulation. More details of the study are described in the section on food commodities (maize cereals).

The field corn (forage and stover) samples were harvested at proper times to yield commercially representative samples. At each of the sampling events, one composite sample from the untreated plot (control) and two independently collected composite samples from the treated plot, were collected randomly from at least 12 separate areas within the plots so that each sample yielded a minimum of 1 kilogram of forage and 0.5 kilogram of stover. The field corn raw agricultural commodity of forage was harvested at 6-7 DALA. The field corn raw agricultural commodity stover was harvested at 45 DALA.

Decline samples were collected at two trial locations (PSM-15-02-03, trial 02 and 03). At these locations samples were collected at a target of 0, 3, 7, 10, and 14 days after last application for forage and 30, 35, 45, 55, and 60 days after last application for stover.

Analytical methods used were PTRL Method P3770G for fluindapyr and 3-OH-fluindapyr and method RA.17.01 for determination of 1-OH-fluindapyr, both with an LOQ of 0.010 mg/kg (metabolites expressed as parent equivalents). The analytical method RA.17.01 utilizes acid hydrolysis so that the 1-OH-Met-fluindapyr-glucoside would be hydrolysed to the aglycone1-OH-Met-fluindapyr.

The efficiency of the analytical method was determined at the time of analysis with each set of samples by fortifying subsamples of the control matrix with fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr. The fortified samples were processed according to the analytical method and analysing them similar to a field-treated sample. Control matrices were fortified at levels ranging from the LOQ (0.01 mg/kg) to 15.5 mg/kg for forage, and 2.0 mg/kg for stover.

Laboratory fortification samples were analysed concurrently with each analytical set to demonstrate method performance and the overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from field corn forage were 86 ± 11 percent (n = 6), 94 ± 10 percent (n = 4) and 77 ± 5 percent (n = 5), respectively [Webber, 2018a, 2015RES-FNF1900] and 101 ± 5 percent (n = 7), 101 ± 6 percent (n = 6) and 79 ± 8 percent (n = 7), respectively in the second study [Webber, 2018b, 2016RES-FNF2453].

The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from field corn stover were 110 ± 8 percent (n = 6), 90 ± 4 percent (n = 6) and 78 ± 6 percent (n = 5), respectively [Webber, 2018a, 2015RES-FNF1900] and 99 ± 13 percent (n = 10), 94 ± 7 percent (n = 10) and 83 ± 12 percent (n = 9), respectively in the second study [Webber, 2018b, 2016RES-FNF2453].

The results on field corn forage and field corn stover are summarized in Table 122 and Table 123.

Notes:

RTI = Retreatment Interval; DALA = Days After Last Application; 3-OH-F = 3-OH-fluindapyr ; 1-OH-Met-F = 1-OH-Met-fluindapyr; ^ no adjuvant used; NIS: Adjuvant Non-Ionic Surfactant; COC: Adjuvant Crop Oil Concentrate.

[a] Residues are expressed as parent equivalents.

[b] Total residues is the sum of fluindapyr and 1-OH-Met-fluindapyr, expressed as parent equivalents.

Sweet corn forage and stover

Supervised residue trials were conducted in the United States in 2015 and 2016 to measure the magnitude of fluindapyr residues in/on sweet corn raw agricultural commodities following two foliar application of fluindapyr SC formulation [Webber, 2018c, 2016RES-FNF2454]. More details of the study are described in the section on food commodities (maize cereals).

The sweet corn (Kernel + Cobs With Husks Removed = K+CWHR, forage, stover) samples were harvested at proper times to yield commercially representative samples. At each of the sampling events, one composite sample from the untreated plot (control) and two independently collected composite samples from the treated plot, were collected randomly from at least 12 separate areas within the plots so

that each sample yielded a minimum of 1 kilogram of K+CWHR, 1 kilogram of forage, and 0.5 kilogram of stover. The sweet corn raw agricultural commodities of K+CWHR, forage, and stover were harvested at 12–16 days after the second application to the treated plot. Decline samples were collected at one trial location (Trial 06). At these locations samples were collected at a target of 3, 7, 14, 21, and 28 days after last application for K+CWHR, forage and stover.

Analytical methods used were PTRL Method P3770G for fluindapyr and 3-OH-fluindapyr and method RA.17.01 for determination of 1-OH-fluindapyr, both with an LOQ of 0.010 mg/kg (metabolites expressed as parent equivalents). The analytical method RA.17.01 utilizes acid hydrolysis so that the 1-OH-Met-fluindapyr-glucoside would be hydrolysed to the aglycone 1-OH-Met-fluindapyr. The efficiency of the analytical method was determined at the time of analysis with each set of samples by fortifying subsamples of the control matrix with fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr. The fortified samples were processed according to the analytical method and analysing them similar to a field-treated sample. Control matrices were fortified at levels ranging from the LOQ (0.01 mg/kg) to 1.0 mg/kg for K+CWHR, 10.0 mg/kg for forage, and 20.8 mg/kg for stover. Fortified control samples were included in each analysis set for method verification.

Laboratory fortification samples were analysed concurrently with each analytical set to demonstrate method performance. The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from sweet corn forage were 102 ± 11 percent (n = 5), 104 ±3 percent (n = 4) and 90 ± 12 percent (n = 4), respectively.

The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from sweet corn stover were 101 ± 13 percent (n = 5), 102 ± 3 percent (n = 4) and 93 ± 10 percent (n = 4), respectively.

The results on sweet corn forage and sweet corn stover are summarized in Table 124 and Table 125.

Almond hulls

Supervised residue trials were conducted in the United States in 2016 to measure the magnitude of fluindapyr residues in/on almond agricultural commodities following three foliar applications of a fluindapyr SC formulation [Webber, 2017a, 2016RES-FNF2450]. More details of the study are described in the section on food commodities (tree nuts).

The almond (nutmeat and hulls) samples were harvested at maturity to yield commercially representative samples. At each of the sampling events, one composite sample from the untreated plot (control) and two independently collected composite samples from the treated plot, were collected randomly from at least 4 different trees within the plots so that each sample yielded a minimum of 1 kilogram of hulls. The samples were harvested at 29–31 days after the last application. Decline samples were collected at one trial locations on days 15, 23, 30, 37, and 44 after the last application.

Analytical methods used were PTRL Method P3770G for fluindapyr and 3-OH-fluindapyr and method RA.17.01 for determination of 1-OH-fluindapyr, both with an LOQ of 0.010 mg/kg (metabolites expressed as parent equivalents). The analytical method RA.17.01 utilizes acid hydrolysis so that the 1-OH-Met-fluindapyr-glucoside would be hydrolysed to the aglycone 1-OH-Met-fluindapyr. The efficiency of the analytical method was determined at the time of analysis with each set of samples by fortifying subsamples of the control matrix with fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr. The fortified samples were processed according to the analytical method and analysing them similar to a field-treated sample. Control matrices were fortified at levels ranging from 1/5 LOQ (0.002 mg/kg) to 10 × LOQ (0.1 mg/kg). The overall mean method validation recoveries and RSDs for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from almond hulls were 96 ± 11 percent (n = 10), 77 ± 8 percent (n = 10) and 93 ± 6 percent (n = 10), respectively.

Laboratory fortification samples were analysed concurrently with each analytical set to demonstrate method performance. The overall mean laboratory fortification recoveries for fluindapyr and

the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from almond hulls were 103 ± 6 percent (n = 7), 102 ± 7 percent (n = 5) and 93 ± 10 percent (n = 5), respectively.

The results on almond hulls are summarized in Table 126.

Table 126 Residues of fluindapyr in almond hulls after three foliar treatments with a suspension concentrate

FATE OF RESIDUES IN PROCESSING

Nature of residues processing study

The behaviour of fluindapyr was studied under conditions simulating pasteurisation, baking/brewing/boiling and sterilisation [Vanini & Zerbinati, 2017, 2016RES-IFP3051]. The phenyl- or pyrazole radiolabelled [^{14}C]-fluindapyr was used for this study at approximately 0.5 µg/mL.

Duplicate solutions were prepared in 0.1 M sterile citrate buffers at pH 4, 5 and 6. The buffer solutions were incubated in the dark for 20 minutes at 90 °C (pH 4), 60 minutes at 100 °C (pH 5) or 20 minutes at 120 °C (pH 6). During the test, the temperature was maintained within ± 2 °C of each required temperatures. At the end of each test the samples were cooled at room temperature and analysed by Liquid Scintillation Counting (LSC) to determine the Total Radioactive Residue (TRR) and by High Performance Liquid Chromatography (HPLC) to establish the amount of unchanged ^{14}C-fluindapyr and its degradation products. The enantiomeric ratio of fluindapyr was also determined using chiral HPLC.

The TRR ranged from 93 percent to 98 percent of applied radioactivity (AR), corresponding to 0.45 and 0.47 mg/L (Table 127). According to the HPLC analyses performed before and after each test, the amount of fluindapyr and its enantiomeric ratio remained constant (50:50) in each test. The results showed that fluindapyr was stable under simulated conditions of processing operations and no additional residues were found.

Table 127 Recovery and identification of radioactivity in 0.5 mg/L ^{14}C-fluindapyr solutions under pasteurisation, baking/brewing/boiling and sterilization simulating conditions

	Pyrazole label		Phenyl label	
Conditions	mg/L	Percent TRR	mg/L	Percent TRR
pH 4 (90 °C, 20 min) (pasteurisation)	0.470/0.450	97.32/93.12	0.453/0.450	95.58/94.97
pH 5 (100 °C, 60 min) (baking/brewing/boiling)	0.474/0.472	97.88/97.53	0.460/0.460	94.94/95.04
pH 6 (120 °C, 20 min) (sterilisation)	0.458/0.458	93.93/93.83	0.463/0.463	95.42/93.97

Supervised processing studies

Wheat

Study 1 + 2

Two processing studies were conducted as part of the residue trial studies to measure the magnitude of fluindapyr residues in/on wheat processed commodities, one at two locations (the United Kingdom and Germany, GB01 and DE03) in Northern Europe [Peterek, 2018, 2015RES-IFP1968] and one at two locations (Italy and France) in Southern Europe [Riccelli, 2017, 2015RES-IFP1950]. Since the study protocols were identical the study results were combined. Two foliar applications of fluindapyr at an exaggerated rate of 689 to 794 g ai/ha and a retreatment interval of 13–19 days for processing purposes. The last application was made at BBCH 69 in both studies.

The wheat grain samples were harvested at proper times to yield commercially representative samples. Bulk samples for processing weighed >50 kg and were harvested 40 to 48 days after the last application.

Grain conditioning

Upon the arrival of the bulk grain specimens from trials, aliquots of grain specimens were taken and cleaned, then the water content of each specimen (10–15 kg) was measured and by adding water for approx. 5 hours the water content was increased to about 17 percent, resulting in final grain weights of 10.00–15 kg. The water content in the treated batch of GB01 did not need any adjustment.

Generation of wheat flour (whole meal)

For bran and flour processing wheat grains (3000–3022 gram) were used for the generation of whole meal flour. The grain was ground through a mill consisting of break rolls and then reduction rolls and screened. After the break stage, coarse bran (543–684 gram) and grinding flour (675–984 gram) were recovered. After the reduction stage, fine bran (1011–1476 gram) and reduction flour (191–295 gram) were recovered. Coarse bran and fine bran together with the grinding flour and reduction flour was combined to whole-meal flour (2957–2993 gram), and samples were taken (sample: *wheat whole meal flour*). The yield from RAC to whole meal was 99–106 percent.

Generation of white flour

Approximately 7 kg of wheat grains (6894–7671 gram) were placed through a mill consisting of break rolls and the reduction rolls and screened. After the break stage, coarse bran (1282–1784 gram) and milling flour (1755–2510gram) were recovered. After the reduction stage, fine bran (2411–3465 gram) and reduction flour (431–968 gram) were recovered. Coarse bran and fine bran were combined to obtain total bran (3914–4941 gram), and a sample was taken (sample: *wheat bran*). Milling flour (1755–2510 gram) and reduction flour (431–968 gram) were combined to obtain white flour (2442–3059 gram) and samples were taken (sample: *wheat white flour*). The yield from RAC to white flour was 33–44 percent.

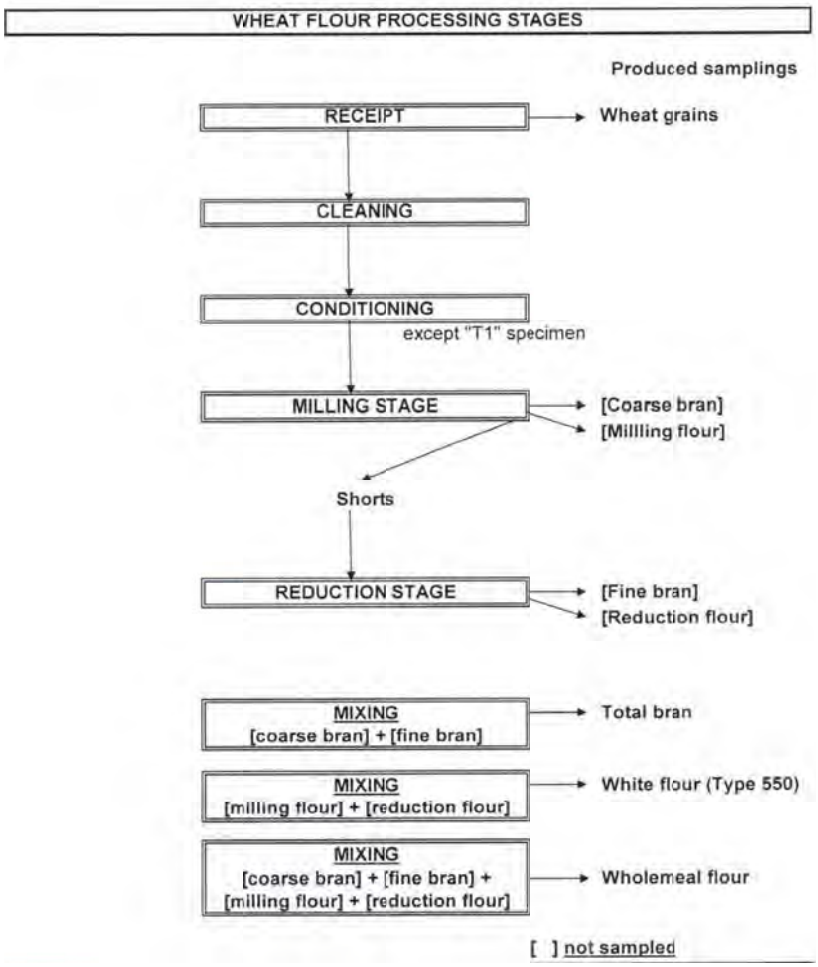

Figure 8 Flow chart of wheat flour processing

Whole meal bread processing

For whole-meal bread processing, whole-meal flour obtained before was kneaded together with prepared yeast and water. Five minutes before the kneading, salt was added. The dough was left to rise for 45 minutes, divided in smaller portions of 350 gram. The divided portions were covered and held at ambient temperature for another 15 minutes. Each portion was then shaped into a baguette, covered and kept at ambient temperature for 2 hours. The baguettes were then notched with a knife and baked in an oven at 250 °C for 30 minutes. Whole-meal bread sub-specimens were taken and stored in a freezer.

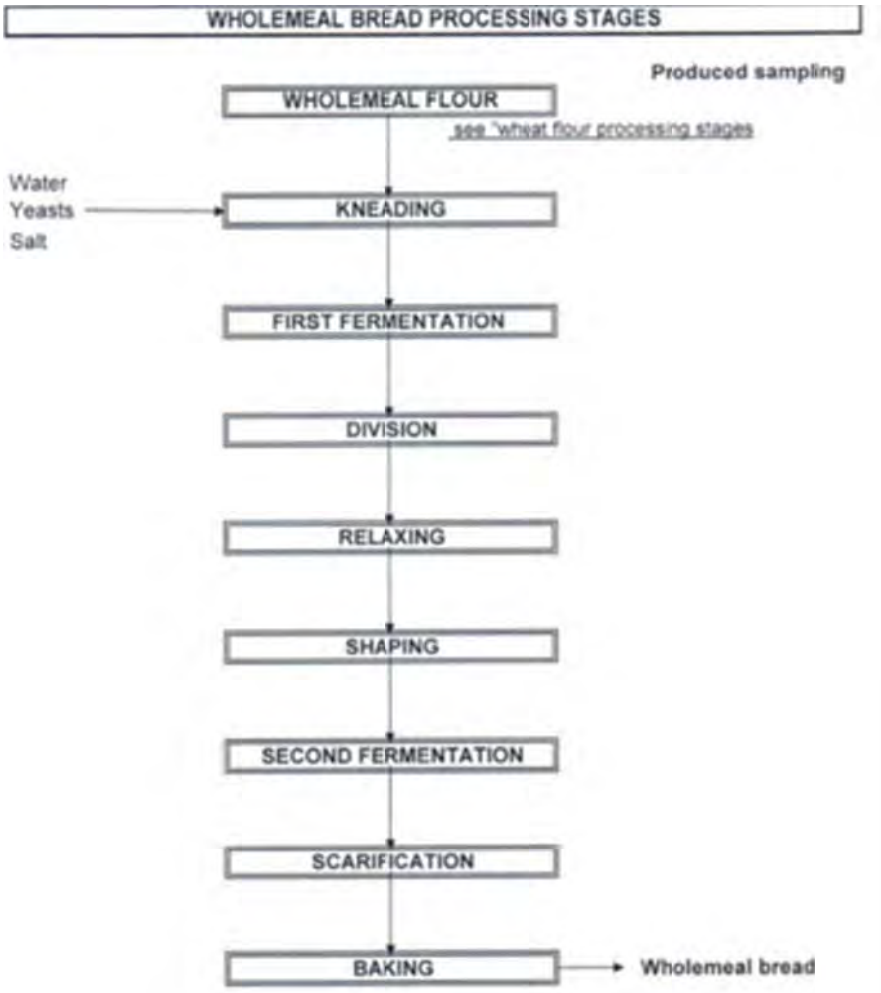

Figure 9 Flow chart of wholemeal bread processing

Gluten and starch of wheat flour separation processing

For gluten and starch of wheat flour separation processing, dough of white flour (2323–3141 gram) was prepared from 2000 gram white flour and 1200 gram (NE study) and 900–904 gram (SE study) water and after a rest, was washed with water to separate milk (30141–30944 gram, NE study; 20910–21332 gram, SE study) and wet gluten (472–809 gram, NE study; 402–517 gram, SE study). Wet gluten was dried in an oven at 50 °C and after settling of starch milk in a cold room, the wet starch (3046–3586 gram, NE study; 1480–2266 gram, SE study) was dried in an oven at 50 °C.

Dry gluten (150–233 gram, NE study; 129–164 gram SE study) and dry starch (1167–1345 gram, NE study; 582–897 gram NE study) were ground separately with a mill and mixed (1/1). Samples of gluten feed meal were taken (sample: *gluten feed meal*) and stored in a freezer.

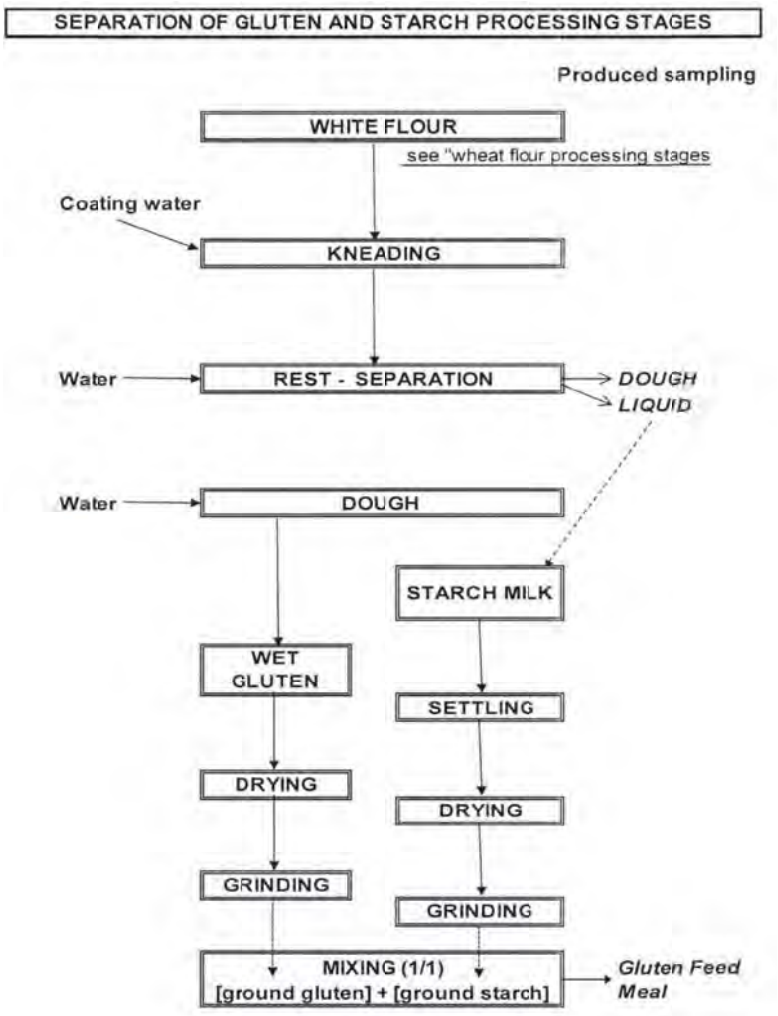

Figure 10 Flow chart of separation of gluten and starch processing

Germ extraction processing

For the germ extraction processing 1.5 kg of cleaned gains were steeped for at least one day in a container with a similar quantity of water. After straining a portion of grains was set down on absorbing paper. The germ was removed from wheat grain with a cutter. Samples of germs were taken (sample: *germ*) and stored in a freezer. The yield from RAC to germ is 5.8–10 percent.

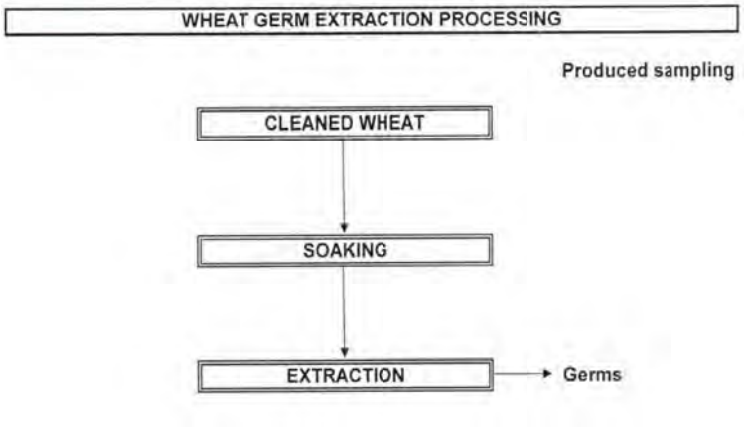

Figure 11 Flow chart of wheat germ extraction processing

Treated raw and processed crop commodity specimens for this study were frozen upon collection, shipped frozen, and stored frozen for less than 814 days (27 months in NE study) and less than 687 days (23 months in SE study) between sampling and analysis (<-18 °C at the analytical facility).

Analytical methods used were PTRL Method P3770G for fluindapyr, 3-OH-fluindapyr, and fluindapyr-N-DesMet-glucoside and method RA.17.01 for determination of 1-OH-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr and 1-COOH-fluindapyr, all with an LOQ of 0.010 mg/kg (metabolites expressed as parent equivalents). The analytical method RA.17.01 utilizes acid hydrolysis so that the conjugates would be hydrolysed to their respective aglycones.

Acceptance for concurrent recovery control was met with average recoveries ranging from 70 percent to 110 percent and relative standard deviations (RSD) ≤ 20 percent, respectively ≤ 15 percent for higher fortification levels. Exception: Only for whole meal flour and white flour the individual recoveries (expressed as sum of diastereomers) ranged between 45 percent and 79 percent. However, average recoveries at LOQ and at higher fortification level were always >50 percent. Specific details are still to be included in the section on analytical methods! No residues of F-N-DesMet-glucoside or 1-COOH-fluindapyr were observed in the RAC or either of the processed commodities. Metabolite 1-OH-Met-N-DesMet-fluindapyr was observed in RAC and processed commodities in one trial at levels of 0.012–0.014 mg/kg in the study by Peterek, 2018.

Processing factors were derived for wheat grain processed commodities. A concentration of residues was observed in total bran. Residues were diluted in all other commodities. Trial data, residues and processing factors for each type of commodity are summarised in Table 128.

Table 128 Fluindapyr residues and processing factors in wheat grain and processed commodities [Peterek, 2018, 2015RES-IFP1968 and Riccelli, 2017, 2015RES-IFP1950]

Notes:

DALT = Days After Last Treatment; RAC = Raw Agricultural Commodity; RTI = Retreatment Interval; n.a. = not anlyzed

[a] Expressed as parent fluindapyr.

[b] PF: Processing Factor = Residue level in processed commodity (mg/kg) ÷ Residue level in unprocessed commodity (mg/kg).

[c] Total is based on parent + 1-OH-Met-fluindapyr, not including 3-OH-fluindapyr.

Sorghum

A processing trial was conducted in the United States as part of the residues trial to measure the magnitude of fluindapyr residues in/on sorghum processed commodities [Webber, 2018d, 2015RES-FNF1901]. Two foliar applications of fluindapyr at an exaggerated rate of 747 and 770 g ai/ha and a retreatment interval of 11 days for processing purposes.

The sorghum grain samples were harvested at proper times to yield commercially representative samples. Bulk samples for processing weighed approximately 250 kg and were harvested 45 days after the last application.

Drying

Samples were weighed and the moisture content of the samples determined with an electronic moisture analyser. Since the moisture content was greater than 13.0 percent, both the control and the treated samples were dried at 43–57 °C in an oven until the moisture content was 10.0–13.0 percent.

Generation of aspirated grain fractions

To generate aspirated grain fractions, each seed sample was placed in a dust generation room containing a holding bin, two bucket conveyors, and a screw conveyor. As the samples were moved in the system, aspiration was used to remove light impurities (grain dust). Each batch was moved for 120 minutes. Light impurities were classified using the following sieves: 2360 micron (8 mesh); 2000 micron (10 mesh); 1180 micron (16 mesh); 850 micron (20 mesh); and 425 micron (40 mesh). After classification of each sample, the material through the 2360 micron sieve was recombined to produce one aspirated grain fraction (AGF). For both samples, the material that passed through the 425 micron screen was not greater than half the weight of the total material passing through the 2360 micron screen, so the AGF was recombined in a way that 50 percent of the final AGF fraction was comprised of material passing through the 425 micron screen. A representative sample was removed and the ash content was determined.

Generation of sorghum flour

A representative sample of generated grain sorghum (23 kg) was cleaned by aspiration and screening. Light impurities (907 gram) were removed from the grain sorghum by aspiration in an aspirator. After aspiration, the samples were screened in a screen cleaner to separate large foreign particles (screenings (680 gram)) from the cleaned grain sorghum sample (21 kg). A sample of cleaned grain sorghum (4.5 kg) was ground in a pin mill. Ground material was screened with a rotating sifter equipped with a 62 mesh sieve. Material passing through the screen was grain sorghum flour (3.0 kg). Requested grain sorghum flour fractions were collected and placed into frozen storage. After correction to fractionation, the yield from sorghum grain to flour was 66 percent.

Sorghum raw and processed commodity samples were maintained frozen after collection through analysis for up to 762 days (grain), 572 days (aspirated grain fractions) and 574 days (flour) at the analytical laboratory Samples were maintained frozen from receipt at the analytical facility until extraction for analysis.

Analytical methods used were PTRL Method P3770G for fluindapyr and 3-OH-fluindapyr and method RA.17.01 for determination of 1-OH-fluindapyr, both with an LOQ of 0.010 mg/kg (metabolites expressed as parent equivalents). The analytical method RA.17.01 utilizes acid hydrolysis so that the 1-OH-Met-fluindapyr-glucoside would be hydrolysed to the aglycone 1-OH-Met-fluindapyr. The efficiency of the analytical method was determined at the time of analysis with each set of samples by fortifying subsamples of the control matrix with fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr. The fortified samples were processed according to the analytical method and analysing them similar to a field-treated sample. Control matrices were fortified at levels ranging from the LOQ (0.01 mg/kg) to 26.0 mg/kg for aspirated grain fractions, and 3.0 mg/kg for flour.

The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from sorghum grain were 100 ± 25 percent (n = 6), 88 ± 14 percent (n = 5) and 84 ± 9 percent (n = 5), respectively. The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr and 1-OH-Met-fluindapyr from sorghum aspirated grain fractions were 107 ± 17 percent (n = 4), 104 ± 4 percent (n = 3) and 77 ± 8 percent (n = 3), respectively. The overall mean laboratory fortification recoveries for fluindapyr and the metabolites 3-OH-fluindapyr

and 1-OH-Met-fluindapyr from sorghum flour were 100 ± 31 percent (n = 3), 106 ± 30 percent (n = 3) and 82 ± 13 percent (n = 3), respectively.

Processing factors were derived for field corn/maize grain processed commodities. A concentration of residues was observed in aspirated grain fractions and refined bleached deodorized oil, more predominant in the wet milled oil. Residues were diluted in all other commodities. Trial data, residues and processing factors for each type of commodity are summarised in Table 129.

Notes:

DALT = Days After Last Treatment; RAC = Raw Agricultural Commodity; RTI = Retreatment Interval.

[a] Expressed as parent fluindapyr.

[b] PF: Processing Factor = Residue level in processed commodity (mg/kg) ÷ Residue level in unprocessed commodity (mg/kg).

[c] Total is based on parent + 1-OH-Met-fluindapyr, not including 3-OH-fluindapyr.

Maize

A processing trial was conducted in the United States as part of the residues trials to measure the magnitude of fluindapyr residues in/on maize processed commodities [Webber, 2018a, 2015RES-FNF1900]. Two foliar applications of fluindapyr at an exaggerated rate of 747 and 728 g ai/ha, respectively, with application intervals of 11 days. Samples of maize grain were collected 45 days after the final application at commercial maturity. Grain was processed according to simulated commercial procedures into grits, meal, flour, starch and oil (wet and dry milled). Throughout the study one representative sample of untreated control and two (duplicate) samples of treated processed commodities were taken.

Generation of Aspirated Grain Fraction (AGF)

To generate aspirated grain fractions, the maize grain sample (241 kg) was dried and the dried maize (192 kg) was placed in a dust generation room containing a holding bin, two bucket conveyors, and a screw conveyor. As the samples were moved in the system (120 minutes), aspiration was used to remove light impurities (grain dust) weighing 3.9 kg. Light impurities (501.4 gram) were classified using different sieves and the material through the 2360 micron sieve was recombined to produce one aspirated grain fraction (AGF). A representative sample was removed and the ash content (1.88 percent) was determined.

Dry milling process

After drying, the sample for production of processed fractions (190 kg) was cleaned resulting in batches of cleaned maize grain weighing 167 kg. For the dry milling process, maize grain (92 kg) was moisture conditioned to 21.0 percent and tempered for approximately two hours (steeping with 12 kg water added). The samples were fed into a mill to crack the kernels. Corn stock from the mill was dried and screened to separate bran (4.6 kg), germ (11.8 kg), and large grits (63 kg) from the grits (8.6 kg), meal (8.4 kg), and flour (2.3 kg) and samples were taken (sample: *meal*; sample: *grits*; sample: *flour*). The two germ fractions were combined and dried at 54–71 °C to a final moisture content of 14.0–16.0 percent. Samples of grits, meal, flour, and germ were collected and placed into frozen storage for analysis. Germ material was heated at 71–79 °C for 10 minutes and flaked in a flaking roll. The flaked kernels were placed in stainless steel batch extractors and submerged in hexane at 49–60 °C. After 30 minutes, the miscella (crude oil and hexane) was drained. Hexane was added and the cycle repeated 2 additional times. The miscella was passed through a laboratory vacuum evaporator to separate the crude oil and hexane. The crude oil was heated to 91–96 °C to complete the hexane removal, filtered and collected for refining. The free fatty acid of the crude oil was determined and an appropriate amount of sodium hydroxide was added to neutralize the oil. Neutralized refined oil and soapstock were separated by centrifugation. The refined oil was decanted and heated to 40–50 °C and activated bleaching earth was added. The temperature was increased to 85–100 °C and held for 10–15 minutes. After reducing the temperature to 58–68 °C and breaking the vacuum, the bleached oil was filtered. The bleached oil (405 gram) was steam bathed at 220–230 °C for 28–32 minutes under vacuum. The oil was cooled and citric acid was added. A sample of the refined oil (sample: *refined bleached, deodorized oil, dry milled*) was collected and placed in frozen storage for analysis. The yield of cleaned corn to refined, bleached, deodorized oil via dry milling process was 0.4 percent.

A flowchart of the field corn dry milling process is given below.

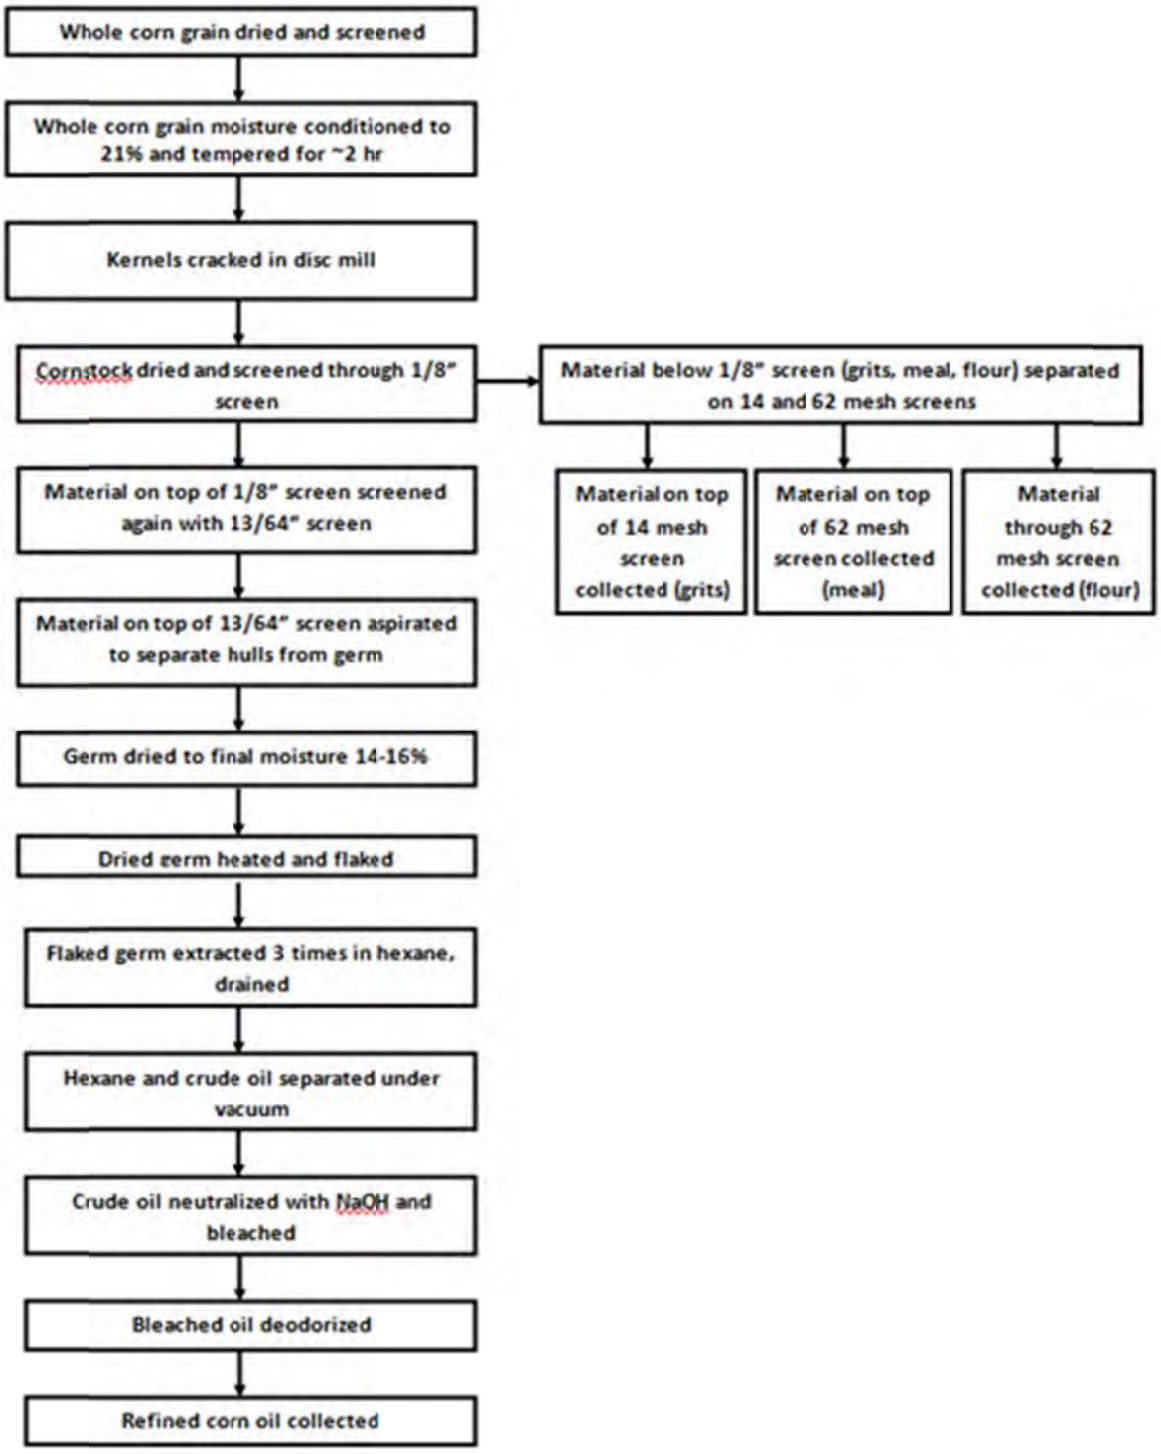

Figure 12 Flow chart of field corn dry milled processing

Wet Milling Process

A sample of cleaned field corn grain (75 kg) was steeped in water (125 kg) containing 0.1–0.2 percent sulfur dioxide for 22–48 hours at 49–54 °C. After the water was drained, steeped whole corn (116 kg) was passed through a disc mill. Most of the germ and hull was separated by a hydroclone. Germ and hulls were dried at 74–91 °C to a final moisture of 5–10 percent. After drying, the germ and hulls were

separated by aspiration and screening, and samples were taken (sample: *germ*). Corn stock (without germ and hulls) was screened with a 50 µm screen. Material on top of the screen (bran) was discarded. Process water passing through the screen was separated into starch and gluten by centrifugation. Starch (50.7 kg) was dried in an oven at 54–71 °C until a moisture content of <15 percent. Starch samples were collected (sample: *starch*) and placed in frozen storage for analysis. Germ samples (3.6 kg) were moisture conditioned to 14–16 percent, heated to 88–104 °C, flaked in a flaking roll, and pressed in an expeller to liberate part of the crude oil (354 gram). The presscake was placed in a stainless steel extractor and submerged in hexane at 49–60 °C. After 30 minutes, the miscella was drained. Hexane was added and the cycle was repeated an additional 2 times. Following the final draining, the miscella was passed through a laboratory evaporator to separate the crude oil from hexane. The crude oil (792 gram) was heated to 91–96 °C to remove the remaining hexane and combined with the crude oil from expelling. The combined crude oil (1087 gram) was neutralized, bleached and deodorized, using the same process as dry milling above. A sample of refined oil (sample: *refined bleached deodorized oil, wet milled*) was collected and placed in frozen storage for analysis. The yield of cleaned corn to refined, bleached, deodorized oil via the wet milling process was *ca* 1.3 percent.

A flowchart of the field corn dry milling process is given below.

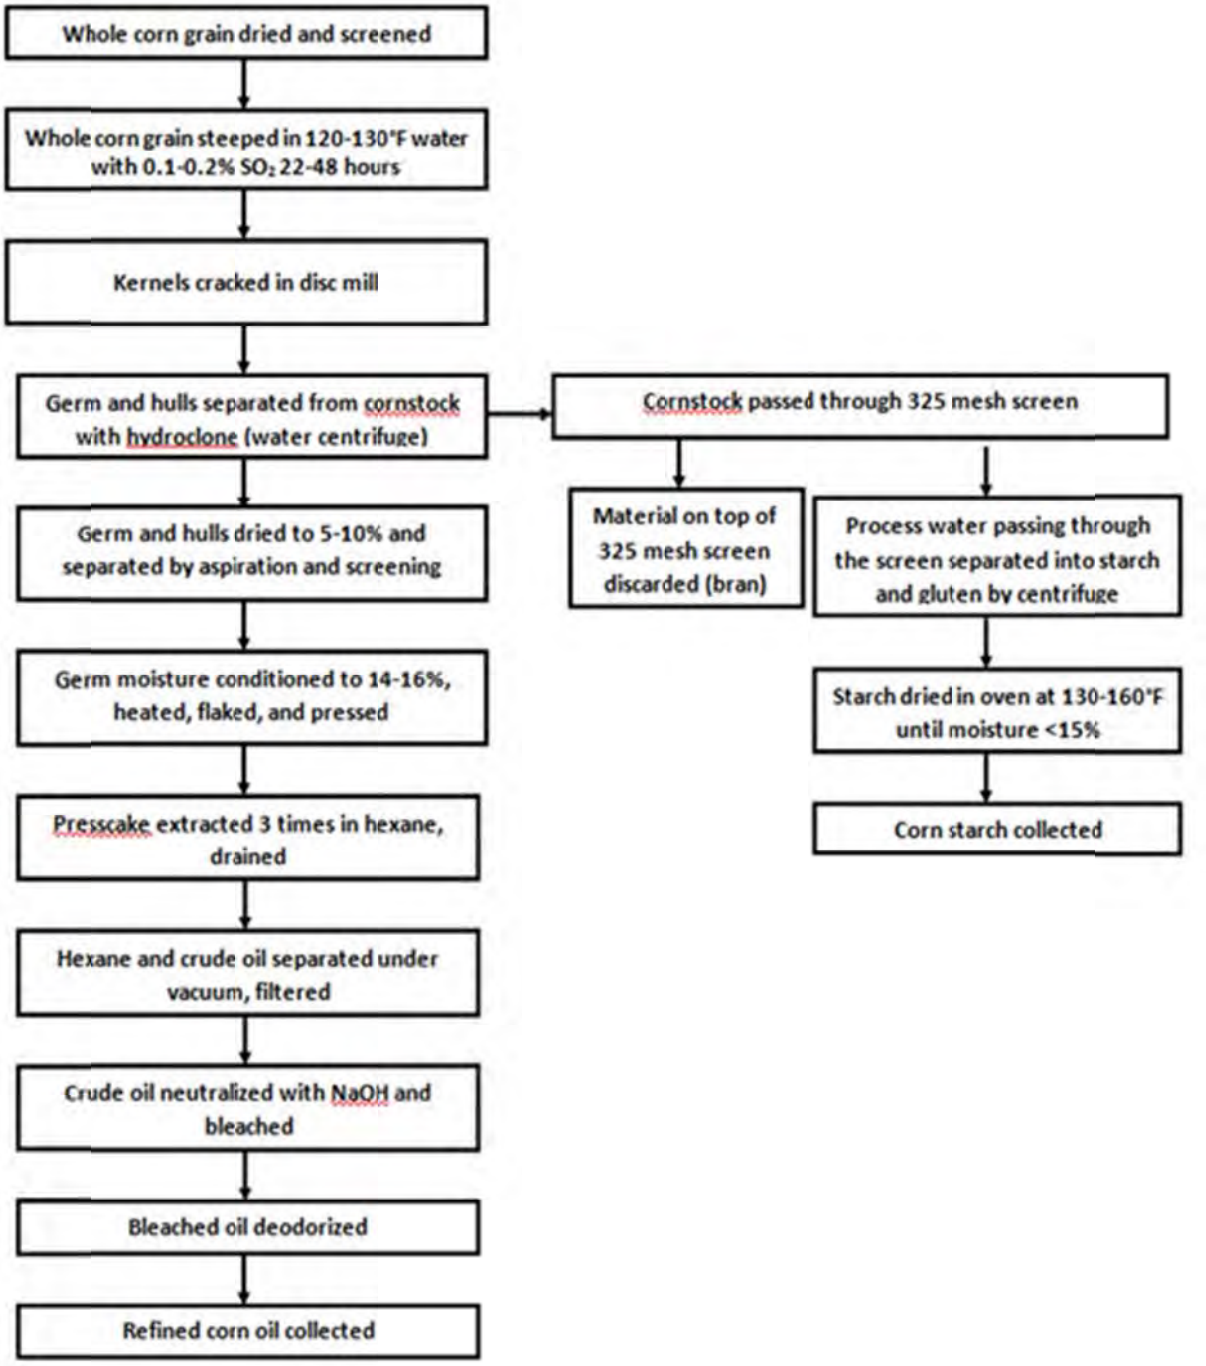

Figure 13 Flow chart of field corn wet milled processing

Samples were stored frozen (<-4 °C) for a maximum of 790 days (*ca* 26 months) prior to analysis. All samples were analysed for residues of fluindapyr, 3-OH-fluindapyr, and 1-OH-fluindapyr using the analytical method P 3770G and RA.17.01 (see section on analytical methods). The analytical method RA.17.01 utilizes acid hydrolysis so that the 1-OH-Met-fluindapyr-glucoside would be hydrolysed to the aglycone 1-OH-Met-fluindapyr. The results are shown in Table 130.

Processing factors were derived for field corn/maize grain processed commodities. A concentration of residues was observed in aspirated grain fractions and refined bleached deodorized oil,

more predominant in the wet milled oil. Residues were diluted in all other commodities. Trial data, residues and processing factors for each type of commodity are summarised in Table 130.

Farm animal feeding studies

Animal feeding study in lactating dairy cows

A residue feeding study in dairy cattle was conducted in the United States in 2015/2016 [Brungardt, 2018, 2016RES-IFP2942] to measure the residues of fluindapyr found in milk and tissues. Lactating Holstein (*Bos taurus*) dairy cows (three animals per group) were orally dosed with fluindapyr via capsule for 28 consecutive days at levels of 5.09, 15.25, and 48.06 mg/kg in feed, corresponding to 0.17, 0.50, and 1.55 mg/kg bw/day. One group remained as control group and the highest dose group an additional three animals were dosed for use in a depuration phase. Animals were observed several times daily for any clinical signs of toxicity or ill health. Bodyweights were determined at intervals and concentrate food/hay consumption was monitored daily.

The cows weighed on average 380–614 kg at the beginning of the study and 378–954 kg at the end of the experiment and had an average daily milk production of 19–26 kg/day during the experiment. The milk production was not adversely affected.

Milk samples were collected twice daily (morning and evening) on study days -1, 1, 2, 4, 7, 10, 14, 17, 21, 24 and 28. Additionally, a portion of the study day 2, 14 and 28 milk samples from a single control, and three of the highest dose group animals were separated into skim milk and cream, and each was analysed. On study day 29, within 24 hours of the last dose, one of the control, all of the low

dose group, all of the mid dose group, and three of the high dose group cows were sacrificed and liver, kidney, composite muscle, subcutaneous fat, mesenterial fat and perirenal fat were collected for analysis. The remaining cows entered into the depuration phase of the study where milk and tissues were analysed throughout a 21-day period following the cessation of the last dose. Milk samples from the five cows (two control and three high dose group cows; depuration group) in the depuration phase were collected on study day 35. On study day 36, one cow from the high dose group was sacrificed and the tissues (liver, kidney, composite muscle, mesenterial fat, perirenal fat and subcutaneous fat) were collected. Milk samples from the remaining four cows (two control and two high dose group cows) were collected on study day 42, then on study day 43 one cow from the high dose group was sacrificed and the tissues were collected. Milk was again collected from the remaining three cows (two control and one high dose group cow) on study day 49. On study day 50, one control cow and the remaining cow from the high dose group were sacrificed and the tissues were collected. The remaining control cow was not sacrificed.

After collection and processing, all milk and tissue samples were stored frozen at an average storage temperature of ≤-18 °C during the storage period. The milk samples in this study were extracted within 52 days of collection. Cream and skimmed milk samples were extracted within 35 days of collection. The liver, kidney, muscle and fat samples were extracted within 35, 55, 27 and 50 days of collection, respectively.

Analytical method SRLS133SRUS16R0208 as validated in study 2016RES-IFP2941 (see section on analytical methods) was used. The method uses an additional hydrolysis step before analysis of fluindapyr-1-COOH, 1-OH-Met-fluindapyr, and 1-OH-Met-N-DesMet-fluindapyr to separate the conjugates from the aglycone version of the metabolites. Milk, skim milk, cream and muscle were analysed for parent compound fluindapyr only. Fat samples were analysed for fluindapyr and its metabolite 1-OH-Met-fluindapyr. Liver and kidney samples were analysed for the parent compound fluindapyr and its metabolites 1-OH-Met-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr and fluindapyr-1-COOH. The reported residue values were calculated in parent equivalents and were not corrected for recoveries. Residues were quantitated by high performance liquid chromatography/electrospray ionization/tandem mass spectrometry (ESI LC-MS/MS). The limit of quantitation (LOQ) for fluindapyr in milk, skim milk and cream

was 0.005 mg/kg. The LOQ for all metabolites was 0.010 mg/kg in all relevant matrices. Average concurrent fresh recoveries in liver, kidney, muscle, fat, milk, cream and skim milk were within the range of 70–110 percent for fluindapyr and its metabolites at 0.01–0.4 mg/kg in tissues and 0.005 and 0.05 mg/kg in milk. Control samples had residues below 0.2LOQ.

Analytical results in milk and tissue samples are shown in Table 131 and Table 132.

In milk, the maximum average fluindapyr residue from the high dose group (1.55 mg/kg bw/day) was 0.0093 mg/kg. Milk samples from the medium dose group did not contain quantifiable residues (LOQ=0.005 mg/kg), and no milk samples from the low dose group were therefore analysed. No detectable residues of fluindapyr were found in skim milk samples from the high dose group. Residues were found in all cream samples from the high dose group, with group means ranging from 0.0105 to 0.020 mg/kg. In the six animals of the high dose group, the mean residue levels of fluindapyr in milk reached a plateau at day 4 and declined rapidly during the depuration phase.

For the medium dose group, average residue levels of fluindapyr in milk remained below the LOQ throughout the dosing period.

Notes:

LOQ = 0.005 mg/kg.

[a] Expressed as fluindapyr.

[b] Mean average of 6 cows, except for the depuration group, which lasted 3, 2 or 1 cows.

Quantifiable residues of fluindapyr were found in liver and fat tissues from the high and medium dose groups. Mean residues of fluindapyr found in fat samples ranged from 0.0324 to 0.0406 mg/kg in

the high dose group; mean residues in the medium dose group were <LOQ (0.010 mg/kg). Mean fluindapyr residues in liver samples from the high and medium dose groups were 0.0454 mg/kg and 0.0165 mg/kg, respectively. No quantifiable residues of fluindapyr were found in any of the low dose group tissues or in the kidney or muscle tissues from the medium and high dose groups, or in the fat samples from the medium dose group.

Quantifiable residues of 1-OH-Met-fluindapyr were found in the high, medium and low dose group samples of tissues. The highest mean residues were found in the perirenal fat at 0.0486, 0.0138 and 0.0118 mg/kg for the high, medium and low dose groups, respectively.

Liver and kidney samples were also analysed for 1-hydroxymethyl-N-desmethyl-fluindapyr and fluindapyr-1-COOH. Quantifiable 1-OH-Met-N-DesMet-fluindapyr residues were detected in all three dose groups; the highest mean residue of 0.259 mg/kg being found in kidney at the high dose group. fluindapyr-1-COOH was not quantifiable in the low dose group samples, but was detected at a maximum of 0.0291 mg/kg in kidney from the high dose group.

Fluindapyr and its metabolite residues were all below the LOQ by the first sampling interval of the depuration phase (day 35). No quantifiable residues of parent (>LOQ) were found in any of the milk, liver, kidney, muscle of fat samples during the depuration phase. No detectable 1-OH-Met-fluindapyr residues were found in any of the samples from the depuration phase (liver, kidney, fat). No quantifiable residues of 1-OH-N-DesMet-fluindapyr or fluindapyr-1-COOH were found in any kidney or liver samples from the depuration phase.

Levels of parent compound in skim milk (not detectable on day 2–28) and cream (0.011–0.020 mg/kg day 2–16) of animals given the highest feeding level indicate that parent compound has a tendency to concentrate in fat. The concentration of parent in fat compared to muscle was >3, also indicating a tendency to concentrate in fat. A similar profile was seen for 1-OH-Met-fluindapyr in muscle (not detectable) and fat tissues (0.015–0.049 mg/kg) at day 28. All residues levels declined rapidly and were <LOQ on day 7 of the depuration period.

Table 132 Fluindapyr related residues in cow tissues for 05.09, 15.25 and 48.06 ppm groups

Notes:

F-1-COOH = fluindapyr carboxylate; 1-OH-Met-N-DesMet-F = 1-OH-Met-DesMet-fluindapyr; 1-OH-Met-F= 1-OH-Met-fluindapyr

[a] Expressed as parent equivalents.

[b] Mean values are calculated by the reviewer. Where values were <LOQ, 0.01 mg/kg was used for the calculations.

[c] Total residues is the sum of fluindapyr and metabolites F-COOH, 1-OH-Met-DesMet-F, and 1-OH-Met-F expressed as parent equivalents and are used for HR and STMR estimation.

[d] Fluindapyr plus 1-OH-Met-fluindapyr expressed as parent equivalents is used for MRL estimation.

Animal feeding study in laying hens

A residue feeding study in laying hens was conducted in the United States in 2015/2016 [Brungardt & Dixon, 2018, 2016RES-IFP2943] to measure the residues of fluindapyr found in eggs and tissues.

Sixty ISA Brown laying hens (*Gallus gallus domesticus*; 12 hens each for the control, low, and mid dose groups and twenty-four hens for the high dose group) were used in the study. Each group of hens was subdivided into subgroups of four hens each. All hens were dosed orally, via capsule, for 36 consecutive days with fluindapyr at actual dose rates of 2.064, 6.231, and 20.596 ppm in feed, corresponding with 0.108, 0.328, and 1.102 mg ai/kg bw/day.

Animals were observed twice daily for any clinical signs of toxicity or ill health. Bodyweights were determined at intervals and group feed consumption was calculated weekly for each group.

The birds weighed on 1562–2345 gram on study day 1 and between 1585 and 2447 gram on study day 36. Egg production appeared to be consistent throughout the study and did not appear to be affected by treatment with the test substance. Average egg production values were comparable in the test and control groups throughout the study.

Eggs for residue analysis were collected beginning on study day -1 and continuing through the dosing period and depuration phase. Egg samples (pooled AM and PM) were collected from all dose subgroups on Study Days -1, 1, 3, 7, 10, 14, 17, 21, 28, 32, and 35. Additionally, on study days 2, 9, 16 and 27 eggs were collected from the hens in the control and high dose subgroups that were not utilized in the depuration period of the study. Whole eggs were separated for analysis into egg yolk and egg white fractions. On Study Day 36, within approximately 6 hours of the last dose, one of the control subgroups (subgroup A), all of the low dose group (subgroups A, B and C), all of the mid dose group (subgroups A, B and C), and three subgroups of the high dose group hens (subgroups A, B and C) were sacrificed. Liver, muscle and fat were collected from each hen and pooled by subgroup for analysis.

The remaining hens (two control subgroups (B and F) and three high dose subgroups (D, E and F)) entered into the 11-day depuration phase of the study following the last dose. Egg samples (pooled AM and PM) for residue analysis were collected from each subgroup (remaining at that time) on study days 39, 42 and 46 of the depuration period. On study day 40, the hens from subgroup D of the high dose group were sacrificed and the tissues (liver, muscle and fat) were collected. On study day 43, the hens from

subgroup E of the high dose group were sacrificed and the tissues were collected. On study day 47, the hens from subgroup F of the control group and subgroup F of the high dose group were sacrificed and the tissues were collected. The remaining control hens (subgroup B) were not sacrificed.

Samples were stored at ca. -18 °C until they were extracted. Whole egg samples were extracted within 36 days of collection, while egg white and yolk samples were extracted within 40 days of collection. Samples of liver, muscle, and fat were extracted within 76, 51, and 52 days after collection, respectively. Freezer storage stability data demonstrated that residues of fluindapyr and metabolites are stable in fortified samples of eggs at -18 °C for up to 64 days. Freezer storage stability for fortified samples of liver, muscle, and fat were demonstrated for up to 91, 55, and 70 days, respectively.

Analytical method SRLS133SRUS16R0208 as validated in study 2016RES-IFP2941 (see section on analytical methods) was used. The method uses an additional hydrolysis step before analysis of the unconjugated metabolites. Eggs, egg whites, egg yolks, and liver samples were analysed for the parent compound fluindapyr and metabolites N-DesMet-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr and 1-OH-Met-fluindapyr. Fat samples were analysed for fluindapyr and 1-OH-Met-fluindapyr, and muscle samples were analysed for fluindapyr alone. The reported residue values were calculated in parent equivalents and were not corrected for recoveries. Residues were quantitated by high performance liquid chromatography/electrospray ionization/tandem mass spectrometry (ESI LC-MS/MS). The LOQ for parent and all metabolites was 0.010 mg/kg in all relevant matrices. Average concurrent fresh recoveries in eggs and relevant poultry tissues were within the range of 70–110 percent for fluindapyr and its metabolites. Control samples had residues below 0.2LOQ.

Analytical results in eggs and tissue samples are shown in Table 133 and Table 134.

Residues of fluindapyr reached a plateau in eggs (group 4, 20.6 mg/kg dose group) after approximately 7 days. Residues of fluindapyr in egg whites were <LOQ at all sampling intervals, while average fluindapyr residues in egg yolks reached a maximum of 0.040 mg/kg (day 9). Residues in eggs were predominately parent fluindapyr with average residues of metabolites N-DesMet-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr, and 1-OH-Met-fluindapyr at or below the LOQ at all sampling intervals.

Table 133 Average residues in eggs dosed with fluindapyr for 28 days at 48.06 mg/kg in feed

Dose mg/kg	Matrix	Sampling day	Average residues, mg/kg

Notes:

N-DesMet-F = N-desmethyl-fluindapyr; 1-OH-Met-N-DesMet-F = 1-hydroxymethyl-N-desmethyl-fluindapyr; 1-OH-Met-fluindapyr = 1-hydroxymethyl-fluindapyr.

[a] Sum of diastereomers.

[b] Total fluindapyr residue is the sum of the residues of fluindapyr and metabolites N-DesMet-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr, and 1-OH-Met-fluindapyr expressed in parent equivalents and is used for HR and STMR estimation.

[c] Total fluindapyr residues for calculation of MRL consisting of parent fluindapyr + 1-OH-Met-fluindapyr expressed as parents equivalents.

[d] Samples at days 39, 42, and 46 were collected 4, 6, and 10 days after cessation of dosing, respectively, with n = 3, 2 and 1, respectively.

In muscle, average residues of fluindapyr were 0.012 mg/kg in group 4 (20.6 mg/kg dose) while fluindapyr residues were <LOQ in group 3 (6.23 mg/kg dose) and group 2 (2.06 mg/kg dose).

In liver, average residues of fluindapyr were 0.029 mg/kg, 0.012 mg/kg, and <0.010 mg/kg in groups 4, 3, and 2, respectively. Average residues of N-DesMet-fluindapyr were 0.174 mg/kg, 0.070 mg/kg, and 0.022 mg/kg in groups 4, 3, and 2, respectively. Average residues of 1-OH-Met-N-DesMet-fluindapyr were 0.0271 mg/kg in group 4 and <0.010 mg/kg in groups 2 and 3. Average residues of 1-OH-Met-fluindapyr were 0.178 mg/kg, 0.041 mg/kg, and 0.030 mg/kg in groups 4, 3, and 2, respectively. Total average residues (parent plus metabolites) in liver were 0.409 mg/kg, 0.167 mg/kg, and 0.060 mg/kg in groups 4, 3, and 2, respectively.

In fat, average residues of fluindapyr were 0.080 mg/kg, 0.029 mg/kg, and <0.010 mg/kg in groups 4, 3, and 2, respectively. Average residues of 1-OH-Met-fluindapyr were 0.064 mg/kg, 0.025 mg/kg, and <0.010 mg/kg in groups 4, 3, and 2, respectively. Total average residues (parent plus metabolites) in fat were 0.167 mg/kg, 0.054 mg/kg, and 0.015 mg/kg in groups 4, 3, and 2, respectively.

Following cessation of dosing residues rapidly declined. In all matrices, all residues were <LOQ by 4 days after the last dose.

Table 134 Fluindapyr related residues in tissues from poultry fed 2.06, 6.23, or 20.6 ppm fluindapyr

Notes:

N-DesMet-F = N-desmethyl-fluindapyr; 1-OH-Met-DesMet-F = 1-hydroxymethyl-N-desmethyl-fluindapyr; 1-OH-Met-fluindapyr = 1-hydroxymethyl-fluindapyr.

[a] Expressed in fluindapyr equivalents.

[b] Sum of diastereomers.

[b] Mean values are calculated by the reviewer. Where values were <LOQ, 0.01 mg/kg was used for the calculations.

[c] Total fluindapyr residue is the sum of the residues of fluindapyr and metabolites N-DesMet-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr, and 1-OH-Met-fluindapyr expressed in parent equivalents and is used for HR and STMR estimation.

[d] Fluindapyr plus 1-OH-Met-fluindapyr expressed in parent equivalents is used for MRL estimation.

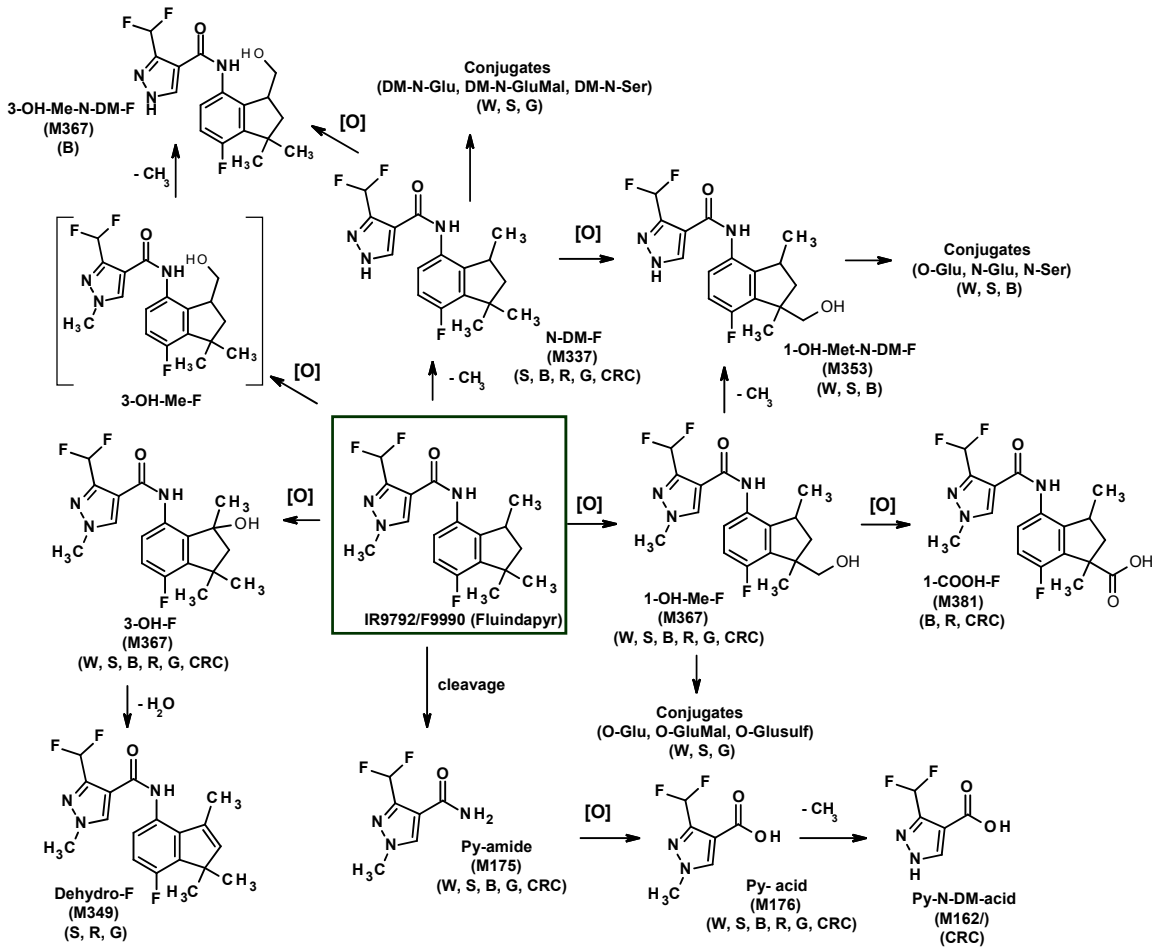
NATIONAL RESIDUE DEFINITION

Fluindapyr is registered in the United States with the following residue definitions:

Commodity	Enforcement (US EPA)	Risk assessment (US EPA)
Primary Crop	Fluindapyr	Sum of fluindapyr (F) plus 3-OH-F, 1-OH-Met-F, 1-OH-Met-F-O-glucoside, DesMet-F-N-glucoside, 1-OH-Met-DesMet-F, and 1-COOH-F
Ruminant meat, fat, milk	Fluindapyr	Sum of fluindapyr plus 1-OH-Met-F, 1-COOH-F, and 1-OH-Met-DM-F
Ruminant edible offal	Sum of fluindapyr and 1-OH-Met-fluindapyr	
Poultry meat, fat, eggs	Fluindapyr	Sum of fluindapyr plus 1-OH-Met-F, 1-OH-Met-DM-F, and DesMet-F
Poultry edible offal	Sum of fluindapyr and 1-OH-Met-fluindapyr	

Notes:

EPA Document ID EPA-HQ-OPP-2018-0551-0020 "Fluindapyr: Human Health Risk Assessment for Section 3 Registration and Tolerance Requests for a New Active Ingredient Proposed for a Use on Cereal Grains Crop Group 15 except Rice; Forage, Fodder and Straw of Cereal Grains Crop Group 16; Nut, Tree, Group 14-12; Soybean; Ornamentals; and Turf."



F: fluindapyr; Me: methyl; DM: desmethyl; py: pyrazole; Glu: glucoside; GluMal: malonylglucoside; Ser: serine; Glusulf: glucosyl sulfate
M: Mol. Wt.
Primary crops: W: wheat, S: soybean; B: sugarbeet; R: rice, G: grape
CRC: confined rotational crops (carrot, lettuce and wheat)

APPRAISAL

Fluindapyr (ISO common name) is a broad spectrum fungicide, which belongs to the succinate dehydrogenase inhibitors (SDHI) class of compounds. The mode of action is inhibition of the energy production process in pathogenic fungi.

Fluindapyr was scheduled at the Fifty-first Session of the CCPR for evaluation as a new compound by the 2021 JMPR and rescheduled for evaluation by the 2022 JMPR. The Meeting received information on identity, physical chemical properties, plant and animal metabolism, soil degradation, residue analysis, storage stability, use patterns, residues resulting from supervised trials on wheat, sorghum, maize, rice, almonds and pecan nuts, fate of residues during processing, and livestock feeding studies.

The IUPAC name for fluindapyr is 3-(difluoromethyl)-N-(7-fluoro-1,1,3-trimethyl-2,3-dihydro-1H-inden-4-yl)-1-methyl-1H-pyrazole-4-carboxamide.

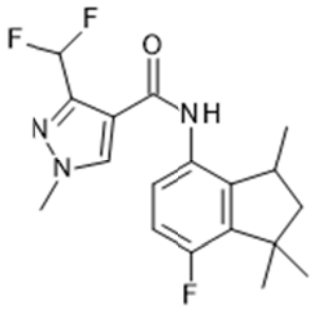

Table 135 Abbreviations used for relevant compounds referred to in the appraisal

Code	Name and Matrix	Structure
1-OH-Met-fluindapyr (Code: 510153) 1-Hydroxymethyl-fluindapyr 1-OH-Met-F M24, M26 in animal studies	3-(difluoromethyl)-N-[7-fluoro-1-(hydroxymethyl)-1,3-dimethyl- 2,3-dihydro-1H-inden-4-yl]-1-methyl-1H-pyrazole-4-carboxamide MW = 367 g/mol Found in: goat (various tissues), hen (all tissues), rat, primary crops (grape, sugar beet, wheat, rice) and rotational (carrot, lettuce, wheat) crops	1-OH-Met-fluindapyr-Glu 1-Hydroxymethyl-fluindapyr glucoside (plant) 1-Hydroxymethyl-fluindapyr gluc-mal (plant) 1-Hydroxymethyl-fluindapyr glucuronide (animals) M13, M15 in animal studies	3-(difluoromethyl)-N-(7-fluoro-1-(hydroxymethyl)-1,3-dimethyl-2,3-dihydro-1H-inden-4-yl)-1-methyl-1H-pyrazole-4-carboxamide gluc MW-Glu= 529 g/mol MW-Glu-Mal = 615 g/mol MW-Glucuronide = 544 g/mol Found in: goat liver, primary crops (grapes fruit and leaves), wheat (forage, hay, straw), soya bean (forage and hay)	  
Code	Name and Matrix	Structure
3-OH-fluindapyr (Code:510152) 3-Hydroxy-fluindapyr M34 in animal studies	3-(difluoromethyl)-N-(7-fluoro-3-hydroxy-1,1,3-trimethyl-2,3-dihydro-1H-inden-4-yl)-1-methyl-1H-pyrazole-4-carboxamide MW = 367 g/mol Found in: some goat tissues, primary crops (grape fruit and leaves, wheat matrices, rice, and limited in sugar beet and rice) and rotational crops	1-COOH-fluindapyr (Code: 510216) 1-Carboxy-fluindapyr M23, M25 in animal studies Diastereoisomer ratio = 1.72:1	4-(3-(difluoromethyl)-1-methyl-1H-pyrazole-4-carboxamido)-7-fluoro-1,3-dimethyl-2,3-dihydro-1H-indene-1-carboxylic acid MW = 381 g/mol Found in: goat liver and kidney and hen liver and muscle and rat metabolite. Limited amounts in primary crops (sugar beet roots and rice grain and straw) and rotational crops	1-OH-Met-N-DesMet-fluindapyr (Code: 510215) 1-Hydroxymethyl-N-Desmethyl-fluindapyr M18, M19 in animal studies Diastereoisomer ratio = 2.2:1	3-(difluoromethyl)-N-[7-fluoro-1-(hydroxymethyl)-1,3-dimethyl-2,3-dihydro-1H-inden-4-yl]-1H-pyrazole-4-carboxamide MW = 353 g/mol Found in limited amounts in goat muscle and milk and in very limited amounts in primary crops (sugar beet roots and leaves, forage, hay and wheat forage, hay and straw after hydrolysis, indicating that it is the glucosyl conjugate)	1-OH-Met-N-DesMet-fluindapyr-gluc (Code: N/A) 1-hydroxymethyl-N-desmethyl-fluindapyr glucoside (plant) 1-hydroxymethyl N-desmethyl-fluindapyr-glucuronide (animal) M10 and M11 in animal metabolism studies	3-(difluoromethyl)-N-(7-fluoro-1-(hydroxymethyl)-1,3-dimethyl-2,3-dihydro-1H-inden-4-yl)-1H-pyrazole-4-carboxamide gluc MW-N-Ser-conjugate = 440 g/mol MW-N-Glu-conjugate = 515 g/mol Found in: goat liver and kidney and in limited amounts in wheat forage and hay and in soya bean and hay.	 N-DesMet-fluindapyr (Code: 510220) N-Desmethyl-fluindapyr M33 in animal studies	3-(difluoromethyl)-N-(7-fluoro-1,1,3-trimethyl-2,3-dihydro-1H-inden-4-yl)-1H-pyrazole-4-carboxamide MW=337 g/mol Found in: very limited amounts in primary crops, rotational crops, and some goat tissues (fat, muscle, and cream), and all hen matrices.	
Code	Name and Matrix	Structure
N-DesMet-fluindapyr-glu (Code: N/A) N-Desmethyl-fluindapyr-glucuronide M6 and M7 in animal studies	3-(difluoromethyl)-N-(7-fluoro-1,1,3-trimethyl-2,3-dihydro-1H-inden-4-yl)-1H-pyrazole-4-carboxamide glucuronide MW = 513 g/mol Found in very limited amounts in goat kidney	Pyrazole carboxylic acid (Code: 510147)	3-(difluoromethyl)-1-methyl-1H-pyrazole-4-carboxylic acid MW = 176 g/mol Found in very limited amounts in wheat feed matrices, grape fruit and leaves and rice grain and straw.	Pyrazole carboxamide (Code: 510151)	3- (difluoromethyl)- 1-methyl-1H-pyrazole-4-carboxamide MW = 175 g/mol Found in very limited amounts in wheat feed matrices, soya bean forage, sugar beet foliage and grape fruit and leaves.	N-DesMet-pyrazole carboxylic acid (Code: 510219)	3- (difluoromethyl)- 1H-pyrazole-4- carboxylic acid MW = 162 g/mol Found in very limited amounts in sugar beet root and in some rotational crops	N-DesMet-fluindapyr-N-ser (Code: N/A)	1-(2-amino-3-hydroxy-propanoyl)-3-(difluoromethyl)-N-(7-fluoro-1,1,3-trimethyl-indan-4-yl)pyrazole-4-carboxamide MW = 424 g/mol Found in soya bean forage and hay	
Code	Name and Matrix	Structure
N-DesMet-fluindapyr-N1-Glu (Code: 510171) and DesMet-fluindapyr-N1-Glu-Mal (Code: N/A)	3-(difluoromethyl)-N-(7-fluoro-1,1,3-trimethyl-2,3-dihydro-1H-inden-4-yl)-1H-pyrazole-4-carboxamide N1-Glu and Glu-Mal MW = 499 g/mol (glu) MW = 585 g/mol (glu-mal) Found in limited amounts in soya bean forage and hay	2-OH-fluindapyr (Code: 510321) 2-Hydroxy-fluindapyr M27 in animal metabolism studies	3-(difluoromethyl)-N-(7-fluoro-2-hydroxy-1,1,3-trimethyl-2,3-dihydro-1H-inden-4-yl)-1-methyl-1H-pyrazole-4-carboxamide MW = 367 g/mol Found in limited amounts in all goat and hen tissues	1-COOH-fluindapyr-glu (Code: N/A) 1-Carboxy-fluindapyr-glucuronide M14 in animal metabolism studies	4-(3-(difluoromethyl)-1-methyl-1H-pyrazole-4-carboxamido)-7-fluoro-1,3-dimethyl-2,3-dihydro-1H-indene-1-carboxylic acid glucuronide MW = 557 g/mol Found in goat liver and trace in kidney	1-OH-Met-dehydro-fluindapyr (Code: N/A) 1-hydroxymethyl-dehydro-fluindapyr M20 in animal metabolism studies	3-(difluoromethyl)-N-(7-fluoro-1-(hydroxymethyl)-1,3-dimethyl-1H-inden-4-yl)-1-methyl-1H-pyrazole-4-carboxamide MW = 365 g/mol Found in skimmed milk	
Code	Name and Matrix	Structure
Di-OH-fluindapyr (Code: N/A) Dihydroxy-fluindapyr M4 and M8 in animal metabolism studies	Chemical name: N/A MW = 383 g/mol Found in skimmed milk and goat muscle.	Tri-OH-dehydro-fluindapyr (Code: N/A) Trihydroxy-dehydro fluindapyr M2 and M3 in animal metabolism studies	Chemical name: N/A MW = 397 g/mol Found in skimmed milk.	1-OH-Met-N-DesMet-dehydro-fluindapyr (Code: N/A) 1-hydroxymethyl-N-desmethyl-dehydro-fluindapyr M12 in animal metabolism studies	3-(difluoromethyl)-N-(7-fluoro-1-(hydroxymethyl)-1,3-dimethyl-1H-inden-4-yl)-1H-pyrazole-4-carboxamide MW = 351 g/mol Found in skimmed milk and very limited amounts in goat muscle.	1-SO_4-Met-N-DesMet-fluindapyr (Code: N/A) M39 and M40 in hen metabolism study	[4-[[3-(difluoromethyl)-1H-pyrazole-4-carbonyl]amino]-7-fluoro-1,3-dimethyl-indan-1-yl]methyl hydrogen sulfate MW = 433 g/mol Found in hen liver	1-SO_4-Met-fluindapyr (Code: N/A) M41 and M42 in hen metabolism study	[4-[[3-(difluoromethyl)-1-methyl-pyrazole-4-carbonyl]amino]-7-fluoro-1,3-dimethyl-indan-1-yl]methyl hydrogen sulfate Found in hen liver	5′-OH-fluindapyr (Code: 510217) 5′-Hydroxy-fluindapyr M35 in hen metabolism study	3-(difluoromethyl)-N-(7-fluoro-5-hydroxy-1,1,3-trimethyl-2,3-dihydro-1H-inden-4-yl)-1-methyl-1H-pyrazole-4-carboxamide MW = 367 g/mol Found in at limited amounts in various hen tissues and eggs	
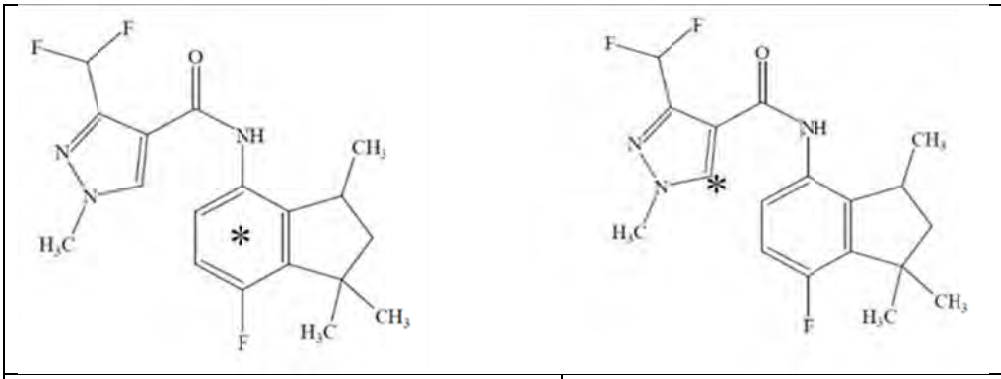
Physical and chemical properties

Fluindapyr is not volatile (2.89×10^{-5} Pa at 20 °C), relatively insoluble in water (1.63 mg/L), but appears to be more soluble in organic solvents (up to 325 g/L in acetone). It is hydrolytically stable at environmental conditions. Photolysis is not a significant route of degradation in water. The octanol/water partition coefficient log P_{ow} of 4.12 suggests a potential to partition into fat.

Plant metabolism

The Meeting received outdoor metabolism studies for fluindapyr after foliar applications, conducted with crops representative of four different groups: fruit (grape), root crops (sugar beet), cereal/grass (wheat and rice), pulses and oilseeds (soya bean). Fluindapyr was applied using [phenyl-^{14}C] and [pyrazole-^{14}C] labelled fluindapyr, as shown below. The results for both labels are presented as phenyl/pyrazole, unless indicated otherwise.



Phenyl label	Pyrazole label

Grape

Phenyl or pyrazole labelled fluindapyr was applied as an EC formulation to grapes (variety: Thompson seedless), with two foliar spray applications at fruit development (BBCH stage 55 and 85, corresponding with an RTI of 123 days) at a rate of 237–313 g ai/ha per application. Each outdoor plot contained one plant.

At 14 days after the second application, total radioactive residues (TRR) were 0.089/0.36 mg eq/kg in grapes and 16/26 mg eq/kg in grape leaves. A fruit surface wash with methanol released 79/81 percent TRR, indicating that fluindapyr residues remained mainly on the surface of the grapes. Leaves and grapes were extracted with acetonitrile/water, followed by extraction with methanol/water. Part of the extract was partitioned against dichloromethane and subjected to hydrolysis with HCl, which did not release much more of unconjugated forms. Both conjugated and unconjugated forms could be identified before hydrolysis. The surface wash with methanol and extraction released most of the radioactivity for both labels in fruit (>98.8 percent TRR) and in leaf (>90 percent TRR) samples.

Approximately 99 percent TRR could be identified in grape fruit and 88/92 percent TRR in grape leaveswith both labels. Parent fluindapyr accounted for 63/65 percent TRR (0.056/0.24 mg/kg) in grapes and 38/54 percent TRR (5.9/14 mg/kg) in grape leaves. 1-OH-Met-fluindapyr and its conjugates accounted for 20 percent TRR (0.017/0.07 mg eq/kg) in grapes and 39/25 percent TRR (6.0/6.4 mg eq/kg) in grape leaves. A second metabolite found at significant concentrations was 3-OH-fluindapyr at levels of 15/12 percent TRR (0.013/0.04 mg eq/kg) in grapes and 12–9.3 percent TRR (1.8/2.4 mg eq/kg) in grape

leaves. Minor metabolites were found in fruit and leaves, but none exceeded 0.2 percent TRR (< 0.001–0.064 mg eq/kg).

Chiral analysis of fluindapyr in leaves showed no significant change in the enantiomeric composition, indicating non-selective metabolic biotransformation. However, in grapes, fluindapyr present in the rinsing (79–81 percent of TRR) showed an enantiomeric ratio approximately 50:50 while in the extract this ratio was approximately 70:30.

Sugar beets

Phenyl or pyrazole labelled fluindapyr was applied as an EC formulation to sugar beet plants, with three foliar spray applications at root development (BBCH stage 35/38, 39/49, and 49, corresponding with RTI of 33 and 28 days between the subsequent applications) at a rate of 113–149 g ai/ha per application.

At 30 days after the last application (DALA), total radioactive residues were 0.084/0.122 mg eq/kg in mature sugar beet roots and 1.67/1.64 mg eq/kg in mature sugar beet foliage. Extraction with dichlormethane/water released most of the radioactivity for both labels in roots (90/92 percent TRR) and in foliage (92/93 percent TRR) samples. The aqueous fraction was subjected to acid hydrolysis to release the unconjugated forms of the conjugated metabolites. Exhaustive extraction with enzymes and acid/base released another 4.0–5.7 percent TRR.

Approximately 89/86 percent TRR could be identified in sugar beet root and 90/88 percent TRR in mature foliage with both labels.

Parent fluindapyr accounted for 43/50 percent TRR (0.036/0.062 mg/kg) in sugar beet roots and 18/15 percent TRR (1.5/1.4 mg/kg) in mature foliage. The 1-OH-Met-fluindapyr diastereomer 2 could not be distinguished from 1-COOH-fluindapyr, diastereomer 2, with the phenyl label and together accounted for 26 percent TRR (0.022 mg eq/kg) in mature sugar beet root, where an addition 8.4 percent TRR (0.007 mg eq/kg) accounted for the remaining 1-OH-Met-fluindapyr diastereomers in mature roots. 1-OH-Met-fluindapyr diastereomers in sugar beet foliage accounted for 66/62 percent TRR (1.1/1.0 mg eq/kg). The diastereomer 1 of COOH-fluindapyr accounted for 4.1/2.1 percent TRR (0.003 mg eq/kg) in sugar beet root. Metabolite 1-OH-Met-N-DesMet-fluindapyr accounted for 1.2/0.4 percent TRR and 1.8/1.7 percent TRR in sugar beet root and foliage, respectively, accounting for 0.001 mg eq/kg in roots and 0.029/0.028 mg eq/kg in foliage. Two other metabolites 3-OH-fluindapyr and N-DesMet-fluindapyr, either single or combined, were found, but below 10 percent TRR with only 3-OH-fluindapy observed at levels above 0.01 mg eq/kg(2.0/1.3 percent TRR, 0.034/0.022 mg eq/kg) in sugar beet foliage. Finally, 3-OH-N-DesMet-fluindapyr was observed at low levels (0.24/0.64 percent TRR, 0.004/0.010 mg eq/kg) in sugar beet foliage.

Chiral analysis of fluindapyr showed no significant change in the enantiomeric composition.

Wheat

Phenyl or pyrazole labelled fluindapyr was applied as an EC formulation to wheat plants, with two foliar spray applications at BBCH stage 31–33 and BBCH 65 (RTI 28 days) at a rate of 124–130 g ai/ha per application. Plants were harvested at BBCH47-49 (immature whole plants/forage stage and 3–4 days after the first application), BBCH 83 (21–22 DALA; immature whole plants/hay stage), mature grain and straw (41–42 DALA).

At 41–42 DALA, TRR were 0.020/0.038 mg eq/kg in wheat grain and 15/13 mg eq/kg in wheat straw. Total residues in wheat forage (3–4 days after the first application) and in wheat hay (21–22 DALA) were 1.2/2.2 and 5.5/7.4 mg eq/kg, respectively. Samples were extracted four times with acetone/water. Straw and grain were extracted a fifth time with acetone/HCl. Extracts from forage, hay

and straw were sequentially partioned with n-hexane and ethyl acetate. Most of the radioactivity for both labels was released in samples of grain (66/77 percent TRR), forage (99/97 percent TRR), hay (103/93 percent TRR), and straw (90/84 percent TRR). Exhaustive extraction with enzymes and acid/base released another 22/13 percent TRR in grain and 6.4/7.3 percent TRR in straw.

In wheat grain, 66/78 percent TRR could be identified, whereas 99/97 percent TRR, 103/93 percent TRR, and 90/85 percent TRR was identified in wheat forage, hay and straw, respectively.

Parent fluindapyr accounted for 46/56 percent TRR (0.0093/0.021 mg/kg) in wheat grain and for 37/31 percent TRR (0.46/0.66 mg/kg) in wheat forage, 31/28 percent TRR (1.7/2.1 mg/kg) in wheat hay, and 29/28 percent TRR (4.3/3.7 mg/kg) in wheat straw.

The 3-OH-fluindapyr metabolite accounted for 20/22 percent TRR (0.0042/0.0084 mg eq/kg) in wheat grain, 4.5/5.5 percent TRR (0.056/0.12 mg eq/kg) in wheat forage, 10/11 percent TRR (0.57/0.79 mg eq/kg) in wheat hay, and 12/14 percent TRR (1.8 mg eq/kg) in wheat straw.

Metabolite 1-OH-Met-fluindapyr (free and glucosyl and glucosyl sulpfate conjugates) was not identified in grain, but found to be a major metabolite in wheat forage, hay and straw, ranging from 35-60 percent TRR with both labels (0.64-7.1 mg eq/kg). Metabolite 1-OH-Met-N-DesMet-fluindapyr as glucosyl conjugate was found at low levels in forage, hay and straw (0.38–5.1 percent TRR, 0.029–0.066 mg eq/kg) as were the pyrazole label specific metabolites pyrazole carboxylic acid and carboxamide with 2.9–3.8 percent TRR (0.082–0.42 mg eq/kg) and 0.40–2.9 percent TRR (0.0087–0.38 mg eq/kg), respectively.

Chiral analysis of fluindapyr showed an R:S change of 50:50 in the test formulations to a mean ratio of 66:34 in the forage, hay and straw samples. The radioactivity levels in grain extracts were too low to be analysed by chiral HPLC.

Rice

Phenyl or pyrazole labelled fluindapyr was applied as an EC formulation to rice plants, with two foliar spray applications at BBCH stage 33 and BBCH 75 (corresponding with an RTI of 70 days) at a rate of 114–122 g ai/ha per application. Samples of husked grain and straw were harvested at 58 DALA.

Total radioactive residues were 0.78/0.65 mg eq/kg in rice grain and 1.8/2.2 mg eq/kg in rice straw. Samples were extracted 3 times with acetonitrile/water followed by extraction with methanol/water. Part of the extract was partitioned with dichloromethane and the aqueous fraction subjected to hydrolysis with HCl. Similar identification results were found in the paralel extracts of dichlorometane and the aqueous fraction after acid hydrolysis. Extraction released most of the radioactivity for both labels in samples of rice grain and straw (93–98 percent TRR).

In husked rice grain and rice straw 94/91 percent TRR and 95/96 percent TRR could be identified, respectively. Fluindapyr accounted for 53/57 percent TRR (0.41/0.37 mg/kg) in husked rice grain and 55/56 percent TRR (1.0/1.2 mg/kg) in rice straw.

Metabolite 1-OH-Met-fluindapyr accounted for 22/17 percent TRR (0.17/0.11 mg eq/kg) and 23/19 percent TRR (0.43/0.21 mg eq/kg) in rice grain and rice straw, respectively.

The 3-OH-fluindapyr metabolite accounted for 9.1/8.2 percent TRR (0.072/0.053 mg eq/kg eq) in rice grain and for 11/11 percent TRR (0.20/0.25 mg eq/kg) in rice straw. Metabolite 1-COOH-fluindapyr was found at 4.2/4.0 percent TRR (0.033/0.026 mg eq/kg) in rice grains and 3.7/4.4 percent TRR (0.068/0.099 mg eq/kg) in rice straw. Low levels of N-DesMet-fluindapyr and dehydro-fluindapyr were found in rice grain (0.4–1.0 percent TRR) and rice straw (0.9–1.1 percent TRR), ranging from 0.003–0.006 mg eq/kg in rice grains to 0.016–0.025 mg eq/kg in rice straw.

Chiral analysis of fluindapyr in rice grain and straw indicated that a slight change in the original (50:50) enantiomeric ratio (R:S) took place and was determined to be approximately 60:40.

Soya bean

Phenyl or pyrazole labelled fluindapyr was applied as an EC formulation to soya bean plants, with three foliar spray applications at BBCH stage 15–16, BBCH 55-60, and BBCH 79 (corresponding with RTIs of 21 and 60 days, respectively) at a rate of 117–129 g ai/ha per application. Two additional plots were also treated at a higher rate of 667–676 g ai/ha for generation additional metabolised for identification purposes, if needed. Plants were grown in outdoor pots and samples of immature forage were taken at 21 days after the first application (28 prior to the second application), hay was harvested after two applications, and mature seeds were collected 30 DALA.

Total radioactive residues were 0.013/0.090 mg eq/kg in soya bean seed, and 0.30/0.51 mg eq/kg in soya bean forage and 1.8/1.6 mg eq/kg in soya bean hay. Samples were extracted 3 times with acetonitrile/water followed by extraction with methanol/water. Part of the extract was partitioned with dichloromethane and the aqueous fraction subjected to hydrolysis with HCl. Similar identification results were found in the paralel extracts of dichlorometane and the aqueous fraction after acid hydrolysis, Extraction with dichloromethane/water released most of the radioactivity for both labels in samples of soya bean seed, forage and hay (92–98 percent TRR). Exhaustive (enzyme and acid/base) extraction released another 2–3 percent TRR in soya bean hay.

Insufficient radioactivity was detected for characterisation and identification of metabolites in soya bean seed.

Fluindapyr accounted for 5.7/5.9 percent TRR and 12 percent TRR (0.017/0.031 mg/kg and 0.22/0.19 mg/kg) in soya bean forage and hay, respectively. Free and conjugated 1-OH-Met-fluindapyr accounted for 31–40 percent TRR (0.12/0.47 mg eq/kg) in both RACs. Free and conjugated 1-OH-Met-N-DesMet-fluindapyr represented 9.5–12 percent TRR (0.034–0.17 mg eq/kg) in both matrices. The sum of DesMet-fluindapyr-N1-conjugates ranged from 14 to 18 percent TRR (0.046–0.33 mg eq/kg) in forage and hay. Metabolites found at lower concentrations were N-DesMet-fluindapyr-N-Ser (3.5–4.0 percent TRR, 0.012–0.062 mg eq/kg), 3-OH-fluindapyr (2.4–4 percent TRR, 0.012–0.077 mg eq/kg), N-DesMet-fluindapyr (1.0–4.6 percent TRR, 0.013–0.025 mg eq/kg)), dehydro-fluindapyr (0.046–0.13 percent TRR, 0–0.001 mg eq/kg), and pyrazole carboxamide (1.1 percent TRR (0.006 mg eq/kg) in forage only).

Chiral analysis of fluindapyr in soya bean hay and forage samples indicated that a slight change in enantiomeric ratio (R:S) took place and was determined to be approximately 60:40.

Summary of plant metabolism

Plant metabolism studies have been presented covering foliar treatments in grape, sugar beet, wheat, rice, pulses and soya bean. The application rates used in the metabolism studies with crops covering the current uses on cereals (wheat, sorghum, maize and rice) are slightly lower and RTIs are longer. However, exaggerated application rates were also used, showing similar distribution patterns.

The enantiomeric ratio R:S in some crops remained 50:50 (grape leaves and rinse, sugar beet foliage), however, in other crops a shift could be observed into a ratio ranging from 60:40 to 70:30 (grape, wheat forage/hay/straw, rice grain/straw, soya bean hay/forage).

The metabolic pathways of fluindapyr where similar in the crops investigated, mainly through hydroxylation and oxidative-N-demethylation, both followed by conjugation. Parent fluindapyr was a major residue (43–65 percent TRR) in grapes, sugar beet root, wheat grain, and rice grain. Major identified metabolites were 1-OH-Met-fluindapyr (free and conjugated) accounting for 17 to 66 percent TRR in food

and feed commodities, except wheat grain, 3-OH-fluindapyr accounting for 10 to 22 percent TRR in grapes and leaves and wheat grain, hay and straw, rice straw and 8.2 to 9.1 percent TRR in rice grain, and 1-OH-Met-N-DesMet-fluindapyr (free and conjugated) accounting for 12 percent TRR in soya bean forage only and DesMet-fluindapyr-conjugates accounting for 14–18 percent TRR in soya bean forage and hay only.

Environmental fate

The Meeting received information on hydrolytic stability, photochemical degradation in water and soil, aerobic soil metabolism, and soil degradation field studies for fluindapyr.

Hydrolysis

Radiolabelled fluindapyr, incubated in the dark in sterile aqueous buffered solutions at pH 4, 7, and 9 for 5 days at 50 °C remained stable. No degradation products were detected and the enantiomeric ratio remained unchanged. The results indicate that fluindapyr is hydrolytically stable at environmental conditions.

Photochemical degradation

In an aqueous photolysis study, [^{14}C- phenyl]-fluindapyr and [^{14}C-pyrazole]-fluindapyr was incubated in sterile non-buffered water under simulated sunlight at 25 ± 1.0 ºC, equivalent to summer sunlight (55 °North in June). The DT_{50} of fluindapyr was calculated to be 4.3 and 2.9 years, with only minor degradation products identified. Two of the minor products were confirmed as 3-OH-fluindapyr and the pyrazole-amide. The distribution of the two enantiomers remained 50:50 throughout the entire irradiation duration.

In a soil photodegradation study [^{14}C-pyrazole]- or [^{14}C-phenyl]-labelled fluindapyr slowly degraded in the irradiated samples, with an associated increase of 3-OH-fluindapyr (up to 9.7 percent AR) and pyrazole-carboxamide (up to 7 percent AR after 15 days). The estimated photolysis DT_{50} in clay loam soil was 54–61 experimental days, equivalent to 163–183 natural sunlight days at 50 °N.

In summary, the Meeting concluded that photodegradation contributes to some extent to the overall degradation of fluindapyr in soil, but photolysis of fluindapyr in water is insignificant.

Aerobic soil metabolism (laboratory studies)

The biotransformation of [^{14}C-phenyl]- or [^{14}C-pyrazole]-fluindapyr in soil was investigated in four European and four United States soils under laboratory conditions. The equivalent of 127–128 g fluindapyr/ha was mixed with soil and incubated under aerobic conditions in the dark at 20 °C for 120–151 days.

The estimated DT_{50} for fluindapyr ranged from 141to 353 days in the various soils with both labels, with a geometric mean of 223 days. Three degradation products were identified above 5 percent AR; 3-OH-fluindapyr (max 15 percent AR at DAT-120), and *cis*-1-COOH-fluindapyr (max 13 percent AR at DAT-151) and *trans*-1-COOH-fluindapyr (max 11 percent AR at DAT-151). The enantiomeric ratio remained constant during the studies (ca. 50:50).

The aerobic degradation of the three soil metabolites 3-OH-fluindapyr, *cis*-1-COOH-fluindapyr and *trans*-1-COOH-fluindapyr and the photolytic soil metabolite pyrazole carboxamide was investigated under laboratory conditions for up to approximately 120 days in different soils from Europe orUnited Statesin four studies.

The laboratory DT_{50} values for 3-OH-fluindapyr were >1000 days in three European soils and ranged from 794 to 1302 days in three United States soils. The laboratory DT_{50} values for *cis*- and *trans*-1-

COOH-fluindapyr ranged from 102 to 320 days in three United States soils, and ranged from 1.7 to 4.1 days in two European and two United States soils for pyrazole carboxamide

Soil degradation (field studies)

The field dissipation of fluindapyr has been studied in Europe and the United States. Quantifiable residues of fluindapyr were detected predominantly in the upper 15 cm of the soils, with incidental findings in the following 10–25/15–30 cm layers. The DT_{50} for total residues ranged from 30 to 168 days, with a geometric DT_{50} of 91 days.

Residues in succeeding or rotational crop

The Meeting received information on the metabolism of fluindapyr in wheat, carrot, and lettuce grown as confined rotational crops, and in a range of representative field crops grown in fluindapyr treated soil.

Confined rotational crop studies

In two confined rotational crop studies in Italy, soil was treated with either [^{14}C-phenyl]- or [^{14}C-pyrazole]-labelled fluindapyr at 360/387 g ai/ha (covering the current registered uses at a maximum seasonal rate of 300 g ai/ha) and planted with lettuce, carrots and wheat at plant-back intervals at 30 days, 120, and 300 days. The TRR in the different RACs were highest when using the pyrazole label declining from 0.037 (PBI 30 days) to 0.019 mg eq/kg (PBI 300 days) in carrot root (phenyl label) and increasing from 0.081 (PBI 30) to 0.11 (PBI 300) mg eq/kg (pyrazole label) in first to last rotation. Similar patterns was observed in carrot tops, with a decline from 0.18 to 0.075 mg eq/kg (phenyl) and increase from 1.1 to 1.7 mg eq/kg (pyrazole label); in immature lettuce, from 0.070 mg eq/kg to 0.046 mg eq/kg (phenyl) and 0.22 mg eq/kg to 0.25 mg eq/kg (pyrazole) and mature lettuce 0.081 to 0.044 mg eq/kg (phenyl) and 0.23 to 0.34 mg eq/kg (pyrazole).

Residues in wheat matrices were generally higher, remaining constant over the three rotations and the patterns between the two labels were similar: 1.5 to 0.73 mg eq/kg (phenyl) and 2.9 to 2.8 mg eq/kg (pyrazole) in wheat grain, 0.35 to 0.36 mg eq/kg (phenyl) and 0.54 to 0.37 mg eq/kg (pyrazole) in wheat forage; 0.82 to 0.62 mg eq/kg (phenyl) and 1.5 to1.7 mg eq/kg (pyrazole) in rotated wheat hay; 2.0 to 1.3 mg eq/kg (phenyl) and 3.8 to 3.2 mg eq/kg (pyrazole) in wheat straw.

Extractated radioactivity from all different crop matrices was high and generally ranged from 83 to 99 percent TRR. Only the radioactivity in the PES of wheat straw and grain needed further investigation and was present mainly as cellulose ^{14}C-incorporated natural products, representing 6–10 percent TRR in straw and 3–5 percent TRR in grain.

The identified residues (fluindapyr, 3-OH-fluindapyr, 1-COOH-fluindapyr (and its conjugates), 1-OH-Met-fluindapyr (and its conjugates), N-DesMet-fluindapyr (and its conjugates), N-DesMet-pyrazole carboxylic acid, pyrazole carboxylic acid, pyrazole carboxamide) were common in all crops but their magnitude varied depending on the individual crop, matrix and label.

In commodities relevant for human consumption and considering the phenyl label study, fluindapyr was one of the main components found, accounting for 2.8–20 percent TRR (0.006–0.015 mg eq/kg) in immature lettuce, 6.1–15 percent TRR (0.084–0.39 mg eq/kg) in wheat grain and up to 65–70 percent TRR (0.013–0.026 mg eq/kg) in carrots.

Metabolite 3-OH-fluindapyr accounted for 9.8–25 percent TRR (0.004-0.005 mg eq/kg) in carrot roots, 7.3-8.5 percent TRR (0.003-0.007 mg eq/kg) in (im)mature lettuce, and 11 percent TRR (0.092-0.17 mg eq/kg) in wheat grain.

Free and conjugated 1-OH-Met-fluindapyr accounted for 8.2–9.4 percent TRR (0.002–0.004 mg eq/kg) in first two rotations only in carrot roots, 23–34 percent TRR (0.011–0.027 mg eq/kg) in (im)mature lettuce, and 47–52 percent TRR (0.42–0.78 mg eq/kg) in wheat grain.

Free and conjugated 1-COOH-fluindapyr accounted for 9.5–9.6 percent TRR (0.003–0.004 mg eq/kg) in carrot roots, 16–34 percent TRR (0.012–0.018 mg eq/kg) in (im)mature lettuce, and 5.9–10.0 percent TRR (0.082–0.11 mg eq/kg) in wheat grain.

The pyrazole specific metabolites included (conjugates of) N-DesMet-pyrazole carboxylic acid, pyrazole carboxylic acid and pyrazole carboxamide. Free and conjugated N-DesMet-pyrazole carboxylic acid increased in time and represented the majority of the radioactivity in carrot roots, with 48–65 percent TRR (0.022–0.065 mg eq/kg) and in (im)mature lettuce with 62–82 percent TRR (0.12–0.21 mg eq/kg). In wheat grain, N-DesMet-pyrazole carboxylic acid accounted for 3–10 percent TRR 0.087–0.31 mg eq/kg), pyrazole carboxylic acid for 12–29 percent TRR (0.27–0.69 mg eq/kg) and pyrazole carboxamide for 1.7–16 percent TRR (0.050–0.45 mg eq/kg). Pyrazole carboxylic acid and pyrazole carboxamide were below 10 percent TRR in the other commodities, except in carrot roots at PBI 120 and 300 days (14–18 percent TRR) and in (im)mature lettuce at PBI 120 and 300 days (11–13 percent TRR).

In feed commodities, the levels of parent varied from 0.24–11 percent TRR (0.004–0.013 mg eq/kg) in carrot tops to 13–32 percent TRR (0.050–0.14 mg eq/kg) in wheat forage. The (conjugated) metabolite 1-OH-Met-fluindapyr represented a major part of the radioactive residue in the phenyl-label, ranging from 11–36 percent TRR (0.061–0.13 mg eq/kg) in wheat forage to 17–46 percent TRR (0.49–1.6 mg eq/kg) in wheat straw. In the pyrazole-label, free and conjugated pyrazole carboxylic acid was present in forage (13–24 percent TRR, 0.050–0.12 mg eq/kg) and straw (9.1–28 percent TRR, 0.34–0.89 mg eq/kg), while in carrot tops free and conjugated N-DesMet-pyrazole carboxylic acid was more pronounced (52–58 percent TRR, 0.64–0.99 mg eq/kg). 3-OH-fluindapyr, and free and conjugated pyrazole carboxamide, N-DesMet-fluindapyr, and 1-COOH-fluindapyr also contributed to the total radioactive residues, with levels depending on crop matrix and on PBI.

A third confined rotational crop study was performed using a single bare soil application of 356–360 g ai/ha and wheat as a rotational crop planted at PBI 30 and 120 days. This study confirmed the rather high concentrations TRR found in wheat commodities.

Field rotational crop studies

A series of field rotational crop studies was conducted in Northern Europe (NE), Southern Europe (SE) and the United States. Only the European studies analysed soil samples. In the four European trials, fluindapyr was incorporated into the soil at actual dose rates of 203–232 g ai/ha. This is lower than the anticipated seasonal rates of the currently registered uses of 300 g ai/ha for which crop rotation needs to be taken into account

Carrots/radish, wheat, lettuce, head cabbage, soya beans, and tomato plants were planted at intervals of 30 (±3), 120 (±10), and 270 (± 3) days after the application. In theUnited Statestrials conducted on 2 locations, fluindapyr was applied twice to soya beans as primary crop at 124–128 g ai/ha/application, RTI 12–15 days (21±2 days prior to typical harvest). At one site the seeds were harvested and the plant debris returned to the field and on the other site both seed and straw was removed. The plots were planted with the follow-on rotational crop of mustard, radish, or wheat at target plant back intervals of 30, 60, and 210 days following the last application (DALA).

Samples of mature commodities were analysed for fluindapyr and metabolites 3-OH-fluindapyr, DesMet-N1-fluindapyr-glucoside and free and conjugated 1-COOH-fluindapyr, pyrazole-carboxamide, pyrazole carboxylic acid and N-DesMet-pyrazole carboxylic acid.

In crops for human consumption, residues of fluindapyr and most of its metabolites were found incidentally, with fluindapyr only once at 0.022 mg/kg in radish roots at PBI of 30 days, pyrazole carboxylic acid in one trial at levels of 0.024–0.027 mg/kg on PBI 30, 120 and 300 days, and 1-COOH-fluindapyr once at 0.020 mg eq/kg in immature head cabbage at PHI 30 days and once at 0.018 mg eq/kg in mustard at PBI 30 days.

Quantified residues of fluindapyr were observed in samples of animal feed commodities at plant-back intervals up to 300 days, however, the findings were incidental and the identity of the metabolites varied between crop matrices. Fluindapyr was oberved in wheat straw (0.012–0.022 mg/kg, study 1) and radish tops (< 0.001–0.022 mg/kg, study 3) and metabolite 3-OH-fluindapyr in wheat straw (PBI 30–270 days, 0.012–0.034 mg eq/kg), soya bean hay (PBI 30–270 days, 0.010–0.024 mg eq/kg) and soya bean forage (PBI 120 days, 0.013 mg/kg). Free and conjugated 1-OH-Met-fluindapyr was found in wheat straw (PBI 30–270 days at < 0.01–0.066 mg/k eq), wheat hay (PBI 30 days, 0.010–0.011 mg eq/kg), and radish leaves (< 0.01–0.016 mg eq/kg). Metabolite 1-COOH-fluindapyr (free and conjugated) was a found in soya bean forage (0.014–0.017 mg eq/kg) and hay (< 0.01–0.028 mg eq/kg) at at PBI 30 and 120, as well as free and conjugated N-DesMet-pyrazole carboxylic acid.

The Meeting considered potential residues of 3-OH-fluindapyr, which is persistent in soil. Based on the assumption of a single treatment or subsequent annual applications at the maximum rate per year of 300 g ai/ha, the Meeting estimated soil concentrations of 0.012 and 0.036 mg/kg, respectively, taking into account information from the available European field dissipation studies. In two of the four European studies, the concentrations of 3-OH-fluindapyr in soil corresponded to concentrations expected after applying the single maximum rate per year (~0.012 mg/kg soil). In the two other studies, one soil contained approximately half of the expected soil concentration, whereas in the fourth study 3-OH-fluindapyr remained undetected. However, no clear relationship between soil concentrations for 3-OH-fluindapyr and its uptake into rotational crops was observed based on the plant samples analysed. Residues were found in feed commodities at up to 0.034 mg/kg, but were <LOQ of 0.01 mg/kg in edible commodities.

The Meeting concluded that no systematic occurence of 3-OH-fluindapyr in rotational crops is expected. Even at estimated plateau levels following long-year accumulation, residues in feed commodities are expected at maximum concentrations of 0.1 mg/kg or lower, while quantifiable concentrations are not expected in commodities for human consumption.

None of the other metabolites have a potential to cummulate in soil, . Considering the scattered and low levels found in both food and feed commodities, the Meeting concluded that potential residues found in rational crops will not contribute significantly to the total dietary intake nor to the total dietary burden and need not be further considered.

One exception is the common metabolite N-DesMet-pyrazole carboxylic acid, which was observed at relevant exposure levels in several food crops. This metabolite is also a metabolite formed after use of other active substances, such as bixafen, benzovindiflupyr, and inpyrfluxam. The Meeting considered the residues of N-DesMet-pyrazole carboxylic acid observed in field rotational crop data after use with fluindapyr, bixafen (Report 2021- extra Meeting) and inpyrfluxam or estimated concentrations following direct treatment with benzovindiflupyr. The highest STMRs from each of the compounds were used for the exposure estimation, assuming no combined field treatments since the compounds belong to the same chemical group of fungicidal agents (Table 2).

Table 136 Overview of anticipated N-DesMet-pyrazole carboxylic acid residues in rotational crops found after use of both fluindapyr (F), bixafen (B), and inpyrfluxam (I) in field rotational crop studies or estimated concentrations following direct treatment with benzovindiflupyr (Ben)

Notes:

[a] Single value found in confined rotational crop study

Summary of environmental fate

Fluindapyr is slowly photodegraded on the surface of soil, forming 3-OH-fluindapyr and pyrazole carboxamide. Laboratory soil degradation studies showed the formation of 3-OH-fluindapyr and *cis*- and *trans* 1-COOH-fluindapyr. Field studies showed DT_{50}s for total fluindapyr (1-COOH-fluindapyr, 3-OH-fluindapyr and pyrazole carboxylic acid) ranging from 55 to168 days (geometric mean of 91 days), with 3-OH-fluindapyr being the predominant metabolite.

Confined laboratory studies indicate that, 3-OH-fluindapyr may be persistent in soil and have a potential for residue carry over to the following cropping season if application is performed annually. However, there was sufficient information for the Meeting to conclude that 3-OH-fluindapyr levels in

edible commodities from rotational crops would remain below the LOQ of 0.01 mg/kg. Confined rotational crop studies indicated that in addition to parent and 3-OH-fluindapyr (free and conjugated), 1-COOH-fluindapyr, 1-OH-Met-fluindapyr, N-DesMet-fluindapyr, N-DesMet-pyrazole carboxylic acid, pyrazole carboxylic acid, and pyrazole carboxamide can be formed in both food and feed commodities. However, field rotational crop studies showed that none of the metabolites are expected in rotational crops at levels above 0.01 mg/kg, with exception of N-DesMet-pyrazole carboxylic acid, which is also formed after application of other fungicides within the same chemical class. The Meeting concluded that a TTC approach should be applied considering residues of this metabolite coming from the uses of the different fungicides.

Animal metabolism

The Meeting received animal metabolism studies on rats, lactating goats and laying hens, where animals were dosed with fluindapyr radiolabelled in the (phenyl ring) or the (e.g. pyrazole ring).

Rats

The metabolism of fluindapyr in rats was reviewed in the framework of the toxicological evaluation by the WHO Core Assessment Group of the 2022 JMPR.

Lactating goats

Two lactating goats were orally dosed by capsule once daily for 7–8 consecutive days with either pyrazole-labelled fluindapyr or phenyl-labelled fluindapyr at 7.3 or 7.5 ppm feed, corresponding to 0.35 or 0.23 mg/kg bw/day, respectively. The goats were sacrificed approximately 6 hours after the last dose. The majority of the total applied radioactivity (TAR) was recovered in the excreta (65-81 percent TAR), with lower levels in the GI tract (11–13 percent TAR). The radioactivity recovered in tissues (liver, kidney, muscle, and fat) accounted for 0.34 and 0.20 percent TAR, with the respective labels, with the highest amount in liver (0.27 percent and 0.16 percent TAR, respectively). A total of 0.017 and 0.034 percent TAR, respectively, was found in milk. Steady state conditions in milk were reached within 2–3 days of the first dose. TRR levels were higher in cream (0.030–0.088 mg eq/kg) compared to skimmed milk (0.004–0.015 mg eq/kg).

Radioactive residues extracted with either ethyl acetate (skimmed milk) or hexane followed by acetonitrile (fat samples and milk cream), acetonitrile and acetonitrile/water or acetone/water (liver, kidney, and muscle) accounted for at least 78 percent TRR, and liver samples from the acetone/water extractions were further treated with β-glucuronidase. The PES from all matrices was found to contain <10 percent TRR or a low residue level, therefore, no further characterization of unextracted residue was conducted.

Fluindapyr was the predominant compound in cream (75–93 percent TRR, 0.045–0.057 mg/kg), fat (74–75 percent TRR, 0.024–0.042 mg/kg), and muscle (32–39 percent TRR, 0.004–0.006 mg/kg), while it ranged from not detected (kidney) to 8.4 percent TRR in the other samples. Free and conjugated 1-OH-Met-fluindapyr was found in liver (up to 52 percent TRR and 0.13 mg eq/kg), kidney (up to 57 percent TRR and 0.059 mg eq/kg), and muscle (up to 41 percent TRR, 0.006 mg eq/kg). Free and conjugated 1-COOH-fluindapyr was found in liver (up to 27 percent TRR and 0.075 mg eq/kg) and kidney (up to 11 percent TRR and 0.011 mg eq/kg). Free and conjugated 1-OH-Met-N-DesMet-fluindapyr was identified in liver (up to 8.9 percent TRR and 0.025 mg eq/kg) and kidney (up to 24 percent TRR and 0.029 mg eq/kg). No individual metabolite in the remaining edible tissues (skimmed milk, cream, fat, or muscle) exceeded 0.01 mg eq/kg, although 1-OH-Met-fluindapyr and di-hydroxylated species accounted for 16 percent to 43 percent TRR in skimmed milk.

Chiral analysis of fluindapyr isolated from fat and cream, showed that the S/R enantiomeric ratio changed from about 50/50 to 35/65.

Laying hens

A group of laying hens was orally dosed by capsule with [phenyl-^{14}C]-fluindapyr or [^{14}C-pyrazole]-fluindapyr for 9 consecutive days at 10 ppm feed, corresponding with a mean daily dose level of 0.64–0.66 mg/kg bw/day. Hens were sacrificed approximately 6 hours after the last dose. The majority of radioactivity (TAR radioactivity was recovered in the excreta (93–96 percent TAR), and a minor part in tissues (0.15–0.16 percent TAR) and eggs (0.11–0.12 percent TAR). The highest TRR in edible tissues was measured in the liver (0.11–0.12 mg eq/kg), followed by fat (0.079–0.10 mg eq/kg), skin (0.044–0.057 mg eq/kg), and muscle (0.010–0.013 mg eq/kg). Residues in eggs ranged from 0.019 to 0.10 mg eq/kg and reached a steady state at day 6.

Radioactive residues extracted with hexane followed by acetonitrile (fat and skin), hexane, followed by acetone:water and ethyl acetate (eggs), acetone/water and ethyl acetate (liver), acetonitrile and acetonitrile/water (muscle) was at least 89 percent TRR. Liver aqueous extract samples were further treated with acid (HCl) or enzymatic hydrolysis (sulfatase) to release SO_4 conjugates. The PES from all matrices was <10 percent TRR and 0.05 mg eq/kg; therefore, no further characterization of unextracted residue was conducted.

Fluindapyr was the major component identified in skin (88-94 percent TRR, 0.041–0.050 mg/kg), fat (76–95 percent TRR, 0.073–0.090 mg/kg), egg (31–48 percent TRR, 0.018–0.028 mg/kg), and muscle (38 percent TRR, 0.004 mg/kg), but represented only about 5 percent TRR (0.005-0.006 mg/kg) in liver.

Metabolite N-DesMet-fluindapyr represented a large part of the radioactive residue in the liver (62 percent of the TRR, 0.067 mg eq/kg), of which a minor fraction was present as sulfate conjugate (< 2 percent of TRR). This metabolite was detected at even lower levels in the egg (up to 6.8 percent TRR, 0.004 mg eq/kg), fat (up to 2.0 percent TRR, 0.002 mg eq/kg), skin (up to 1.6 percent TRR, 0.001 mg eq/kg), and muscle (4.5 percent of TRR, < 0.001 mg eq/kg).

The 2 diastereomers of 1-OH-Met-fluindapyr and their sulfate conjugates represented 22 percent TRR in liver (0.026 mg eq/kg), 32 percent TRR in eggs (0.019 mg eq/kg), 11 percent TRR in fat (0.010 mg eq/kg), and 14 percent TRR in muscle (0.002 mg eq/kg), but less in skin (9.8 percent TRR, 0.004 mg eq/kg).

The 1-COOH-fluindapyr metabolite reached 12 percent TRR (0.001 mg eq/kg) in muscle and 7.2 percent TRR (0.008 mg eq/kg) in liver. The 2 diastereomers of 1-OH-Met-N-DesMet-fluindapyr and/or the corresponding sulfate conjugates reached 8.5 percent of TRR (0.010 mg eq/kg) in liver and 4 percent of TRR (< 0.001 mg eq/kg) in muscle.

Other metabolites generally represented less than 10 percent TRR and always at < 0.01 mg eq/kg, of which 2-OH-fluindapyr, 5'-OH-fluindapyr, 3-OH-fluindapyr, and 3-OH-Met-fluindapyr were identified in both phenyl and pyrazole extracts. A glycine conjugate of pyrazole carboxylic acid was detected at a trace level of 0.001 mg eq/kg (11.4 percent TRR) in muscle.

Chiral analysis of fluindapyr isolated from fat and skin, showed that the S/R enantiomeric ratio changed from about 50/50 to 18/82 in fat and to 23/77 in the skin.

Conclusions

The Meeting concluded that, in all species investigated (goats, hens and rats), TAR was predominantly eliminated in excreta. Though some qualitative and quantitative differences were observed between the metabolic profiles of rat, goat, and laying hen, in general, the metabolism was considered to be similar.

Metabolism involved mainly demethylation to N-DesMet-fluindapyr and hydroxylation to 1-OH-Met-fluindapyr, with further sulfation being (mainly in hen tissues) and glucuronidation (goat tissues). Hydroxylation leading to 3-OH and 5-OH species in hens and di-OH-fluindapyr species in goats was also observed.

Fluindapyr (parent) is the major component found in the majority of the goat and hen tissues and cream samples (31–95 percent TRR), but with rather low levels in kidney and liver tissues (0.7–8.4 percent TRR).

1-OH-Met-fluindapyr was quantified at major amounts (up to 57 percent TRR) in goat and up to 32 percent TRR in hen tissues. Other major metabolites were 1-COOH-fluindapyr accounting for up to 27 percent TRR, but only in goat liver and kidney and up to 12 percent TRR in hen liver and muscle, N-DesMet-fluindapyr accounting for 36–61 percent TRR, but in hen liver only, 1-OH-Met-N-DesMet-fluindapyr and its glucuronides (12–24 percent TRR) in goat kidney, and 1-SO_4-Met-fluidapyr (17–18 percent TRR) in hen liver.

Methods of analysis

The Meeting received description and validation data for analytical methods for determination of fluindapyr, 3-OH-fluindapyr, DesMet-fluindapyr-1N-glucoside, 1-OH-Met-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr, and 1-COOH-fluindapyr in plant matrices and for fluindapyr, N-DesMet-fluindapyr, 1-OH-Met-fluindapyr, 1-COOH-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr in animal commodities.

Plant commodities

Analytical methods are provided for the analysis of fluindapyr and/or metabolites in crops. The method selected for enforcement will depend on the compounds that are being analysed.

The QuEChERS (EN 15662:2009-2)-based method P3770G involves extraction with acetonitrile:water for direct analysis of fluindapyr, 3-OH-fluindapyr and DesMet-N- fluindapyr-glucoside by LC-MS/MS. For determination of 1-OH-Met-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr and 1-COOH-fluindapyr, the extract was hydrolysed (1 hour at 60 °C) with HCl, the pH adjusted to 4 to 6 with NaOH, and cleaned-up by dispersive SPE (solid phase extraction) for quantification by LC-MS/MS. The method was fully validated for the determination of fluindapyr, 3-OH-fluindapyr, fluindapyr-DesMet-N-glucoside in the range of 0.01 (LOQ) to0.1 mg/kg in crops with high water content (sugar beet leaves, wheat forage), high starch content (sugar beet root), high acid content (grapes), high oil content (almond, pecan), high protein content (soya bean (dry seeds) and dry beans), and high starch content (wheat grain), and wheat straw and (dry and difficult matrix). An independent laboratory validation (ILV) was conducted to qualify this procedure as an enforcement method.

Corresponding radio-validation experiments demonstrated that Method P3770G was not suitable for the analysis of incurred residues of the metabolites 1-OH-Met-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr, and 1-COOH-fluindapyr. Therefore, an alteration of the method was developed and validated (Method RA17.01), where the crop samples were extracted with water and acetonitrile, either by subsequent addition or combined addition (wheat straw) or acetontrile followed by water (high protein). The analytes in the extract were hydrolysed with 37 percent HCl (two hours at 80 °C), the pH adjusted (4–5), acetone and water added, followed by clean-up with SPE and quantification by LC-MS/MS. Method

RA.17.01 was fully validated for the determination of the (sum of) diastereomers 1-OH-Met-fluindapyr in crops with high oil content (almond and pecan nutmeat), high protein content (almond hulls, dry beans, soya bean seed), high acid content (grapes), high starch content (sugar beet roots, wheat grain and dry gluten) and high water content (sugar beet leaves and wheat forage), difficult matrices (wheat straw). A ILV was also performed

Both methods were subjected to radiovalidation, where incurred residues of fluindapyr were succesfully recovered from samples of wheat forage, grain and straw. Analytes involved were 3-OH-fluindapyr, 1-OH-Met-fluindapyr, 1-OH-Met-fluindapyr (both only in wheat forage and straw), 1-OH-Met-N-DesMet-fluindapyr, cis- and trans-1-COOH-fluindapyr, N-DesMet-pyr-acid, pyrazole carboxylic acid and pyrazole carboxamide. In addition DesMet-N-fluindapyr N1-Glu was succesfully recoverd from soya bean hay.

The Meeting concluded that the methods were sufficiently validated and are suitable to measure fluindapyr and its metabolites in plant commodities.

Animal commodities

In Method 133SRUS16R0208, samples of muscle, liver, kidney and eggs are blended with acetonitrile (2×) followed by extraction with acetone/water, and milk was extracted with acetonitrile. For analysis of fluindapyr and N-DesMet-fluindapyr, the extract was diluted and analysed by LC-MS/MS. For analysis of 1-COOH-fluindapyr-, 1-OH-Met-fluindapyr, and 1-OH-Met-N-DesMet-fluindapyr, the extract was hydrolysed with 4 mol/L HCl (80°C, 60 min), and cleaned-up by SPE before quantification by LC-MS/MS.

Fat was extracted with acetonitrile/hexane. For analysis of fluindapyr and N-DesMet-fluindapyr, the acetonitrile layer was diluted with water and cleaned-up by SPE before quantification. For analysis of 1-OH-Met-fluindapyr and 1-OH-Met-N-DesMet-fluindapyr, the acetonitrile layer was hydrolysed with 4 mol/L HCL (80 °C, 60 minutes) and cleaned-up before analysis by LC-MS/MS.

Method 133SRUS16R0208 was validated for the determination of fluindapyr, N-DesMet-fluindapyr, 1-OH-Met-fluindapyr (sum of both diastereomers), 1-OH-Met-N-DesMet-fluindapyr (sum of both diastereomers) in bovine muscle, fat, liver and kidney, and in poultry muscle, fat, liver and eggs in the range 0.01 (LOQ) to 0.1 mg/kg, and in the range of 0.005 (LOQ) to 0.05 mg/kg in milk. Validation was also conducted for 1-COOH-fluindapyr (sum of both diastereomers) in the range 0.01–0.1 mg/kg in bovine liver and kidney.

However, in a radiovalidation study, incurred residues of parent fluindapyr could not be succesfully (max 28 percent) recovered from goat (milk, muscle, liver) and hen (egg, fat) matrices. 1-OH-Met-fluindapyr was succesfully recovered from goat liver (110 percent) and egg (116 percent), 1-OH-Met-N-DesMet-fluindapyr from goat liver (90 percent), but the recovery of 1-COOH (both isomers) was questionable (280 percent).

The Meeting concluded that the analytical method for animal commodities is fit for measuring 1-OH-Met-fluindapy and 1-OH-Met-N-DesMet-fluindapyr, but is not fit for measuring residues of parent fluindapyr, 1-COOH-fluindapyr in animal matrices.

Stability of pesticide residues in stored analytical samples

The Meeting received information on storage stability of fluindapyr, 3-OH-fluindapyr, DesMet-fluindapyr-1N-glucoside, 1-OH-Met-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr, and 1-COOH-fluindapyr in wheat grain, wheat straw, grapes, oil seed rape seed, oil seed rape whole plant, and wheat dry gluten and of fluindapyr in wheat forage and hay (0.1 mg/kg fortification level). The data showed that residues of fluindapyr and metabolites (except for wheat forage; not tested for metabolites) are stable for at least 36

months under frozen conditions in crop commodities representative of the high water (oil seed rape whole plant), high acid (grapes), high starch (wheat grain), and high oil (oil seed raped seed) and high protein crops (wheat dry gluten).

The Meeting agreed that the demonstrated storage stability on various representative plant commodities covered the residue sample storage intervals used in the field trials considered by the current Meeting.

In addition, the Meeting received storage information of fluindapyr residues in animal matrices. Noting the uncertainties regarding the extraction efficiencies of the analytical method for fluindapyr and 1-COOH-fluindapyr, the Meeting cannot conclude on the storage stability of these analytes in animal commodities, except for 1-OH-Met-fluindapyr (both diastereomers) in liver and eggs and 1-OH-Met-N-Desmet-fluindapyr (both diastereomers) in liver,

Finally, the Meeting received storage stability information on spiked residue of fluindapyr in soil demonstrating that fluindapyr, 3-OH-fluindapyr, 1-COOH-fluindapyr, and pyrazole carboxylic acid are stable when stored frozen for period of 2 years.

Definition of the residue

Parent fluindapyr is a racemic mixture. In the absence of any indication that there is a difference in toxicology between the isomers of the parent or its metabolites, the Meeting concluded that they could be considered together and are therefore not reported individually.

Plant commodities

In the primary plant metabolism studies involving foliar applications, parent fluindapyr was the predominant residue, accounting for 63–65 percent TRR in grapes, 43–50 percent TRR in sugar beet roots, 46–56 percent TRR in wheat grains and 53–57 percent TRR in rice husked grain. Radioactive residues in soya bean seed were too low to detect any compound. Parent fluindapyr was also found in feed commodities, accounting for 15–18 percent TRR in sugar beet foliage to 31–37 percent TRR in wheat forage, with highest relative levels in rice straw (55–56 percent TRR).

Fluindapyr residues are not expected in rotational crops, and processing studies show that parent compound is also the main analyte in the processed commodities. Furthermore, suitable enforcement analytical methods exist to measure fluindapyr in plant commodities.

The Meeting concluded that fluindapyr is a suitable marker compound and decided to define the residue for compliance with the MRL for plants as fluindapyr.

In deciding which compounds should be included in the residue definition for dietary risk assessment of plant commodities, the Meeting considered the likely occurrence and the toxicological properties for the metabolites 1-OH-Met-fluindapyr (and its conjugates), 3-OH-fluindapyr, 1-COOH-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr (and its conjugate), N-DesMet-fluindapyr (and its conjugates), dehydro-fluindapyr, pyrazole carboxylic acid, pyrazole carboxamide, 3-OH-N-DesMet-fluindapyr, and the rotational crop metabolite N-DesMet-pyrazole carboxylic acid.

The Meeting concluded that metabolites 1-OH-Met-fluindapyr and its conjugate and 3-OH-fluindapyr are covered by the health based reference values for parent.

In metabolism studies, 1-OH-Met-fluindapyr and its conjugates accounted forup to 20 percent TRR (0.017/0.07 mg eq/kg) in grapes, 25 percent TRR (0.031 mg eq/kg) in sugar beet roots, and up to 17/22 percent TRR (0.17/0.11 mgkg eq) in rice grain. The compounds were not found in wheat grain, but contributed significantly to the total residue in wheat forage, hay and straw (35–60 percent TRR). In

contrast, in the wheat field trials, these metabolites were observed in grain, sometimes within the same range as parent fluindapyr. In sorghum grain, these metabolites were quantified in GAP-compliant field trials, but were <LOQ in maize grain, sweet corn, almond and pecan. The Meeting concluded that 1-OH-Met-fluindapyr and its conjugates should be included in the residue definition for dietary risk assessment for plant commodities.

3-OH-fluindapyr accounted for 6.1/1.7 percent TRR (0.002/0.005 mg eq/kg) in sugar beet root, up to 12–15 percent TRR (0.013/0.043 mg eq/kg) in grapes and 20/22 percent TRR (0.0042/0.0084 mg eq/kg) in wheat grain in primary crop metabolism studies. In the GAP-compliant field trials with wheat and sorghum, 3-OH-fluindapyr was found in grains. However, considering that the metabolite generally contributes less than 5 percent (with peaks up to 8.7 percent) to the residue of toxicological concern in GAP compliant field trials with cereals and also more than 80 percent of the residue of concern is covered in grapes without inclusion of 3-OH-fluindapyr, the Meeting decided not to include the metabolite in the residue definition for dietary risk assessment.

1-COOH-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr (and its N-conjugate), N-DesMet-fluindapyr and its conjugates, dehydro-fluindapyr, pyrazole carboxylic acid, pyrazole carboxamide, 3-OH-N-DesMet-fluindapyr were not consistently seen in all crops, contributed less than 6.1 percent TRR (0.005 mg eq/kg) individually, and the sum of them never exceed 10 percent TRR in any of the different primary crop metabolism studies. These metabolites were not further considered for the residue definition for dietary risk assessment for plant commodities.

The rotational crop metabolite N-DesMet-pyrazole carboxylic acid was found in several crops planted in rotation. Since the metabolite is a common metabolite, shared with fluxapyroxad, bixafen, benzovindiflupyr, and inpyrfluxam and is not covered by the health based reference values for fluindapyr, the Meeting concluded that the relevance of this metabolite should be evaluated against the TTC of a Cramer Class III compound (see Dietary Risk Assessment section)

The Meeting decided to define the residue for dietary risk assessment as the sum of fluindapyr and 1-OH-Met-fluindapyr and its conjugates, expressed as fluindapyr.

Animal commodities

Fluindapyr (parent) is a component found in the majority of the goat tissues and cream samples, but with rather low levels in kidney and liver. In poultry tissues the parent was observed in liver, muscle, skin and in eggs.

Noting that the analytical method used in the feeding studies is not fully suitable for quantification of the parent fluindapyr in animal commodities, the results of the dairy feeding studies were considered only qualitatively. In dairy cattle feeding studies, parent fluindapyr was observed in milk, liver and fat, but not muscle and kidney.

Parent fluindapyr is found in almost all goat and hen commodities in metabolism studies and is therefore a suitable marker compound.

The Meeting noted that no suitable analytical method exists to measure fluindapyr in animal commodities.

The Meeting decided to define the residue definition for compliance as fluindapyr.

The Log K_{ow} of fluindapyr is 4.1, indicating a potential to sequester into fatty matrices. In lactating goats, the ratio of fluindapyr in cream to skimmed milk was about 50 fold. It was 4 fold in fat to muscle in lactating goat, and approximately 15–18-fold in fat to muscle in laying hens. The Meeting considered the residue to be fat soluble.
