In deciding which additional compounds should be included in the residue definition for risk assessment for animal commodities, the Meeting considered the likely occurrence of the compound at 10 percent TRR and/or absolute concentrations at ≥0.01 mg eq/kg, and their toxicity. Metabolites 1-OH-Met-fluindapyr, 1-COOH-fluindapyr, N-DesMet-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr and its glucuronides, 1-SO_4-Met-fluidapyr, and 1-SO_4-Met-N-DesMet-fluidapyr were assessed. The Meeting concluded that all the metabolites, including their conjugates, are covered by the health based reference values for parent.

1-OH-Met-fluindapyr and it conjugates were found in all goat (up to 57 percent TRR) and hen tissues (up to 32 percent TRR) in the animal metabolism studies and were was also observed in the animal feeding studies. The Meeting concluded that 1-OH-Met-fluindapyr and its conjugates should also be included in the residue definition for dietary risk assessment for all animal tissues.

1-COOH-fluindapyr and its conjugates were found in the animal metabolism studies only in goat liver and kidney (up to 21–27 percent TRR; 0.005–0.075 mg eq/kg) and were also observed in the goat feeding study in these matrices. The compound was observed in hen liver and muscle (up to 12 percent TRR), but at levels < 0.01 mg eq/kg. The Meeting concluded that 1-COOH-fluindapyr and its conjugates should be included in the residue definition for dietary risk assessment in mammalian tissues.

N-DesMet-fluindapyr was observed at high relative and absolute levels in hen liver (36–61 percent TRR; 0.042–0.066 mg eq/kg) and at low levels in goat cream, fat and muscle and in hen skin, fat, eggs, and muscle, ranging from 1.3 to 6.8 percent TRR (< 0.001–0.004 mg eq/kg). This finding was confirmed in the laying hen feeding study. The Meeting concluded that N-DesMet-fluindapyr should be included in the residue definition for dietary risk assessment.

1-OH-Met-N-DesMet-fluindapyr accounted for 1.9–2.1 percent TRR (< 0.001 mg eq/kg) in skimmed milk and for 4.7–5.2 percent TRR, but < 0.001 mg eq/kg in goat muscle. The glucuronide conjugates were found in goat liver (4.3–8.9 percent TRR) and goat kidney (13–24 percent TRR), at levels ranging from 0.010 to 0.025 mg eq/kg. The metabolite was found in hen liver (8.5/4.0 percent TRR; 0.010/0.020 mg eq/kg) and muscle (1.9/4.0 percent TRR: < 0.001 mg eq/kg), but not distinguishable from its sulfate conjugate. The metabolites were also found in goat liver and kidney and in hen liver samples in the farm animal feeding studies. The Meeting concluded that 1-OH-Met-N-DesMet-fluindapyr and is conjugates should be included in the residue definition for dietary risk assessment.

1-SO_4-Met-fluidapyr and 1-SO_4-Met-N-DesMet-fluidapyr were observed at 17–18 percent TRR and 4.1–8.6 percent TRR in hen liver, with levels ranging from 0.008–0.022 mg eq/kg. The metabolites are expected to add insignificantly to the dietary intake at realistic dietary burden levels. Therefore, the Meeting concluded that these metabolites need not be included in the residue definition for dietary risk assessment.

The Meeting decided to define the residue for dietary risk assessment for animal commodities as the sum of fluindapyr, 1-OH-Met-fluindapyr, 1-COOH-fluindapyr, 1-OH-Met-N-DesMet-fluindapyr and their conjugates and N-DesMet-fluindapyr, expressed as fluindapyr.

Summary of residue definitions

The Meeting recommended the following residue definitions for fluindapyr:

Definition of the residue for compliance with the MRL assessment for plant commodities: *fluindapyr*

Definition of the residue for dietary risk assessment for plant commodities: *sum of fluindapyr and 3-(difluoromethyl)-N-[7-fluoro-1-(hydroxymethyl)-1,3-dimethyl-2,3-dihydro-1H-inden-4-yl]-1-methyl-1H-pyrazole-4-carboxamide (1-OH-Met-fluindapyr) and its conjugates, expressed as parent*

Definition of the residue for compliance with the MRL assessment for animal commodities: *fluindapyr*

Definition of the residue for dietary risk assessment for animal commodities: *sum of fluindapyr, 4-(3-(difluoromethyl)-1-methyl-1H-pyrazole-4-carboxamido)-7-fluoro-1,3-dimethyl-2,3-dihydro-1H-indene-1-carboxylic acid (1-COOH-fluindapyr), 3-(difluoromethyl)-N-[7-fluoro-1-(hydroxymethyl)-1,3-dimethyl- 2,3-dihydro-1H-inden-4-yl]-1-methyl-1H-pyrazole-4-carboxamide (1-OH-Met-fluindapyr), 3-(difluoromethyl)-N-[7-fluoro-1-(hydroxymethyl)-1,3-dimethyl-2,3-dihydro-1H-inden-4-yl]-1H-pyrazole-4-carboxamide (1-OH-Met-N-DesMet-fluindapyr) and their conjugates, and 3-(difluoromethyl)-N-(7-fluoro-1,1,3-trimethyl-2,3-dihydro-1H-inden-4-yl)-1H-pyrazole-4-carboxamide (N-DesMet-fluindapyr), , expressed as fluindapyr.*

The residue is fat soluble.

Results of supervised residue trials on crops

The Meeting received supervised residue trial data for fluindapyr on wheat, sorghum, maize, sweet corn, tree nuts and almonds. Product labels were available from the United States.

When calculating the sum of fluindapyr and 1-OH-Met-fluindapyr for STMR and HR estimations, values < LOQ were assumed to be at the LOQ. As the metabolite is expressed as parent equivalents, no molecular weight conversion factor was needed.

The highest individual total residue values from the trials was used to derive HRs and the highest residues.

Cereal grains - grasses

The Meeting received supervised residue trials on wheat, sorghum, maize and sweet corn.

Wheat, similar grains, and pseudocereals without husks

In the United States, the critical GAP for cereals grains, except rice, is 2 foliar applications of fluindapyr at 150 g ai/ha, with a retreatment interval (RTI) of 10 days and a pre-harvest interval (PHI) of 30 days for grain.

Seventeen field residue trials conducted in the United States in 2016 matched the GAP. The residue levels for MRL estimation in ranked order were (n=16): 0.010, 0.017, 0.018, 0.023, 0.025, 0.026, 0.029, 0.041, 0.053, 0.060, 0.087, 0.088, 0.10, 0.12, 0.19, and 0.26 mg/kg.

Total residue levels for dietary risk assessment in ranked order were (n=16): 0.020, 0.027, 0.040, 0.040, 0.044, 0.044, 0.059, 0.070, 0.078, 0.082, 0.097, 0.098, 0.13, 0.14, 0.20, and 0.27 mg/kg.

The Meeting estimated a maximum residue level of 0.4 mg/kg and an STMR of 0.074 mg/kg for fluindapyr in the Subgroup of Wheat, similar grains, and pseudocereals without husks.

Sorghum grain and millet

In the United States, the critical GAP for sorghum is for 2 foliar applications of fluindapyr at 150 g ai/ha, with an RTI of 10 days and a PHI of 30 days for grain.

Eight field residue trials conducted in the United States in 2015 and 2016 matched the GAP. The residue levels for MRL estimation in ranked order were (n=8): 0.10, 0.24, 0.29, 0.34, 0.37, 0.37, 0.43, and 0.43 mg/kg.

Total residue levels for dietary risk assessment in ranked order were (n=8): 0.14, 0.29, 0.35, 0.38, 0.41, 0.42, 0.48, and 0.56 mg/kg.

Noting that the GAP of United States label for cereal grains, except rice, is similar to the GAP for sorghum grain and includes millet, the Meeting estimated a maximum residue level of 1.0 mg/kg and an STMR of 0.395 mg/kg for fluindapyr in the Subgroup of Sorghum Grain and Millet.

Maize cereals

In the United States, the critical GAP for maize cereals is for 2 foliar applications of fluindapyr at 150 g ai/ha, with an RTI of 10 days and a PHI of 30 days for grain.

Twenty field residue trials conducted in the United States in 2015 and 2016 matched the United States GAP. The residue levels for MRL estimation in ranked order were (n=20): < 0.01 (20) mg/kg.

Total residue levels for dietary risk assessment in ranked order were (n=20): < 0.02 mg/kg.

Since no residues were observed in any of the residue field trials, the Meeting estimated a maximum residue level of 0.01(*) mg/kg and an STMR of 0.02 mg/kg for fluindapyr in the Subgroup of Maize cereals.

Sweet corns

In the United States, the critical GAP for sweet corn is for 2 foliar applications of fluindapyr at 150 g ai/ha, with an RTI of 10 days and a PHI of 14 days for kernel + cobs with husks removed.

Eight field residue trials conducted in the United States in 2016 matched the United States GAP. Residues were measured in kernels + cobs with husks removed. The residue levels for MRL estimation in ranked order were (n=8): < 0.01 (8) mg/kg.

Total residue levels for dietary risk assessment in ranked order were (n=8): < 0.02 mg/kg.

The Meeting estimated a maximum residue level of 0.01(*) mg/kg and an STMR and an HR of 0.02 mg/kg for fluindapyr in Sweet corn (corn-on-the cob) (kernels plus cob with husk removed).

Tree nuts

In the United States, the critical GAP for tree nuts is for 3 foliar applications of fluindapyr at 168 g ai/ha, with an RTI of 7 days and a PHI of 30 days. The Meeting received data on almonds and on pecan nuts.

Almonds

Five field residue trials conducted in the United States in 2016 matched the United States GAP for tree nuts. The residue levels in almond nutmeat for MRL estimation in ranked order were (n=5): < 0.01 (2), 0.011, 0.018, and 0.022 mg/kg.

Total residue levels for dietary risk assessment in ranked order were (n=5): < 0.020 (2), 0.021, 0.028, and 0.032 mg/kg (highest individual value 0.035 mg/kg).

Pecan

Five field residue trials conducted in the United States in 2016 matched the United States GAP for tree nuts. The residue levels in pecan nutmeat for MRL estimation in ranked order were (n=5): < 0.01 (3), 0.016, and 0.024 mg/kg.

Total residue levels for dietary risk assessment in ranked order were (n=5): < 0.020 (3), 0.025, and 0.034 mg/kg.

Statistical analysis showed that the residue data with almond and pecans were similar. The combined data for maximum residue estimation in ranked order were (n=10): < 0.01 (5), 0.011, 0.016, 0.018, 0.022, and 0.024 mg/kg.

The combined data for dietary risk assessment in ranked order were (n=10): < 0.020 (5), 0.021, 0.025, 0.028, 0.032, and 0.034 mg/kg.

Noting that both almond and pecan are representative commodities for tree nuts, the Meeting estimated a maximum residue level of 0.04 mg/kg and an STMR of 0.0205 mg/kg for fluindapyr for the Group of Tree nuts.

Residues in animal feeds

Forages and fodders

Wheat forage

The critical GAP in the United States for cereals grains, except rice, allows for 2 foliar applications of fluindapyr at 150 g ai/ha, with an RTI of 10 days and a PHI of 7 days for forage.

Field residue trials on wheat forage, conducted in the United States in 2016, matched this GAP. Residue levels (parent only) in ranked order were (n=17): 0.16, 0.41, 0.54, 0.86, 1.4, 1.5, 1.5, 1.9, 2.2, 2.3, 2.4, 2.4, 2.4, 3.5, 4.2, 6.7, and 8.8 mg/kg (highest individual value 11 mg/kg).

Total residue levels (parent + 1-OH-Met-fluindapyr and its conjugates) for dietary intake calculations in ranked order were (n=17): 0.44, 0.60, 0.64, 1.2, 1.6, 1.6, 1.8, 2.2, 2.5, 2.5, 2.5, 2.6, 2.8, 3.7, 4.5, 6.9, and 9.2 mg/kg (highest individual value 12 mg/kg).

The Meeting estimated a median residue of 2.6 mg/kg (as received) and a highest residue of 12 mg/kg (as received) for wheat forage.

Wheat hay and wheat straw (both 88 percent dry matter)

The critical GAP in the United States for cereals grains, except rice, allows for 2 foliar applications of fluindapyr at 150 g ai/ha, with an RTI of 10 days and a PHI of 14 days (hay) and 30 days (straw).

Field residue trials on wheat hay, conducted in the United States in 2016, matched this GAP. The residue levels for MRL estimation in ranked order were (n=17): 0.072, 0.60, 0.63, 0.67, 0.69, 0.80, 0.82, 0.98, 1.2, 1.3, 1.3, 1.8, 1.8, 2.4, 2.4, 4.8, and 6.4 mg/kg (highest individual value 6.6 mg/kg).

Total residue levels (parent + 1-OH-Met-fluindapyr and its conjugates) for dietary burden calculations in ranked order were (n=17): 0.98, 0.99, 1.1, 1.2, 1.2, 1.4, 1.6, 1.8, 1.9, 1.9, 2.1, 2.3, 2.5, 2.6, 3.0, 6.6 and 6.9 mg/kg (highest individual value 7.1 mg/kg)

Field residue trials conducted with wheat straw in the United States in 2016 were performed with two foliar applications of fluindapyr at rates of 146-157 g ai/ha with an RTI of 9-12 days and harvested 30 DALA. The residue levels for MRL estimation in ranked order were (n=16): 0.16, 0.32, 0.34, 0.41, 0.54, 0.54, 0.79, 1.2, 1.4, 1.4, 1.9, 2.0, 2.1, 2.8, 9.6, and 11 mg/kg (highest individual value 12 mg/kg).

Total residue levels (parent + 1-OH-Met-fluindapyr and its conjugates) for dietary burden calculations in ranked order were (n=16): 0.22, 0.59, 0.61, 0.65, 0.83, 1.1, 1.7, 1.8, 1.8, 1.9, 2.1, 2.1, 2.4, 3.1, 10, and 12 mg/kg (highest individual value 13 mg/kg).

Based on the data set for straw, the Meeting estimated a maximum residue level of 15 mg/kg (dw) based on a dry matter content of 88 percent for Wheat, hay and/or straw.

The Meeting estimated a median residue of 1.9 mg/kg (as received) and highest residue of 7.1 mg/kg (as received) for fluindapyr in wheat hay and a median residue of 1.8 mg/kg (as received) and a highest residue of 13 mg/kg (as received) for fluindapyr in wheat straw.

Sorghum forage (35 percent dry matter)

The critical GAP in the United States for sorghum allows for 2 foliar applications of fluindapyr at 150 g ai/ha, with a RTI of 10 days with no livestock feeding restrictions.

Field residue trials on sorghum forage, conducted in the United States in 2015 and 2016, matched this GAP. Residue levels (parent only) in ranked order were (n=9): 0.24, 0.38, 0.42, 0.55, 0.62, 1.3, 2.4, 4.5, and 5.0 mg/kg (highest individual value 5.1 mg/kg).

Total residue levels (parent + 1-OH-Met-fluindapyr and its conjugates) for dietary burden calculations in ranked order were (n=9): 0.43, 0.46, 0.51, 0.66, 0.71, 1.4, 2.8, 4.7, and 5.1 mg/kg (highest individual value of 5.2 mg/kg).

The Meeting estimated a highest residue of 5.2 mg/kg (as received) and a median residue of 0.71 mg/kg (as received) for sorghum forage.

Sorghum stover (88 percent dry matter)

The critical GAP in the United States for sorghum allows for 2 foliar applications of fluindapyr at 150 g ai/ha, with an RTI of 10 days with a PHI of 30 days.

Field residue trials on sorghum stover, conducted in the United States in 2015 and 2016, matched this GAP. The residue levels for MRL estimation in ranked order were (n=8): 0.14, 0.16, 0.18, 0.21, 0.23, 0.44, 0.83, and 1.1 mg/kg (highest individual value of 1.7 mg/kg).

Total residue levels (parent + 1-OH-Met-fluindapyr and its conjugates) for dietary burden calculations in ranked order were (n=8): 0.19, 0.28, 0.32, 0.34, 0.45, 0.62, 0.95, and 1.8 mg/kg (highest individual value 2.4 mg/kg).

The Meeting estimated a maximum residue level of 3 mg/kg (dw), based on a dry matter content of 88 percent) for sorghum stover. The Meeting estimated a median residue of 0.395 mg/kg (as received) and a highest residue of 2.4 mg/kg (as received) for sorghum stover

Maize forage (40 percent dry matter)

The critical GAP in the United States for maize allows for 2 foliar applications of fluindapyr at 150 g ai/ha, with a RTI of 10 days and a PHI of 7 days.

Field residue trials on maize forage, conducted in the United States in 2015 and 2016, matched this GAP. Residue levels (parent only) in ranked order were (n=21): 0.077, 0.18, 0.23, 0.25, 0.33, 0.36, 0.44, 0.45, 0.48, 0.57, 0.73, 0.77, 0.79, 0.90, 0.96, 1.3, 1.4, 1.5, 1.8, 2.1, and 7.6 mg/kg (highest individual value 9.2 mg/kg).

Total residue levels (parent + 1-OH-Met-fluindapyr and its conjugates) for dietary burden calculations in ranked order were (n=21): 0.087, 0.21, 0.27, 0.35, 0.39, 0.46, 0.51, 0.56, 0.59, 0.64, 0.83, 0.86, 0.94, 0.97, 1.1, 1.4, 1.5, 1.5, 1.9, 2.3, and 8.2 mg/kg (highest individual residue 9.8 mg/kg).

The Meeting estimated and a median residue of 0.83 mg/kg (as received) and a highest residue of 9.8 mg/kg (as received) for maize forage.

Maize stover (83 percent dry matter)

The critical GAP in the United States for maize allows for 2 foliar applications of fluindapyr at 150 g ai/ha, with an RTI of 10 days and a PHI of 10 days.

Field residue trials on maize forage, conducted in the United States in 2015 and 2016, matched this GAP. The residue levels for MRL estimation in ranked order were (n=20): < 0.01, 0.22, 0.34, 0.34, 0.36, 0.54, 0.55, 0.57, 0.60, 0.76, 0.84, 0.89, 0.89, 1.1, 1.4, 1.7, 1.7, 2.0, 2.4, and 2.6 mg/kg (highest residue 2.8 mg/kg).

Total residue levels (parent + 1-OH-Met-fluindapyr and its conjugates) for dietary burden calculations in ranked order were (n=20): < 0.02, 0.30, 0.44, 0.61, 0.64, 0.66, 0.76, 0.83, 0.82, 0.90, 1.0, 1.0, 1.2, 1.4, 1.8, 2.0, 2.2, 2.7, 2.6, and 2.8 mg/kg (highest individual value 3.0 mg/kg).

The Meeting estimated a maximum residue level of 5 mg/kg (dw) based on a dry matter content of 83 percent. The Meeting estimated a median residue of 0.95 mg/kg (as received) and a highest residue of 3.0 mg/kg (as received) for maize stover.

Sweet corn forage (48 percent dry matter)

The critical GAP in the United States for sweet corn allows for 2 foliar applications of fluindapyr at 150 g ai/ha, with an RTI of 10 days with no livestock feeding restrictions.

Eight field residue trials on sweet corn forage, conducted in the United States in 2016, matched this GAP. Residue levels (parent only) in ranked order were (n=8): 0.022, 0.14, 0.18, 0.25, 0.33, 0.77, 0.98, and 5.4 mg/kg. (highest individual value 6.8 mg/kg).

Total residue levels (parent + 1-OH-Met-fluindapyr and its conjugates) for dietary burden calculations in ranked order were (n=8): 0.069, 0.24, 0.27, 0.47, 0.89, 0.93, 1.1, and 5.5 mg/kg (highest individual residue 6.9 mg/kg).

The Meeting estimated a median residue of 0.68 mg/kg (as received) and a highest residue of 6.9 mg/kg (as received) for sweet corn forage.

Sweet corn stover (83 percent dry matter)

The critical GAP in the United States for sweet corn allows for 2 foliar applications of fluindapyr at 146 g ai/ha, with an RTI of 10 days and a PHI of 10 days.

Eight field residue trials on sweet corn forage, conducted in the United States in 2016, matched this GAP. The residue levels for MRL estimation in ranked order were (n=8): 0.17, 0.19, 0.26, 0.28, 0.63, 0.65, 1.3, and 13 mg/kg.

Total residue levels (parent + 1-OH-Met-fluindapyr and its conjugates) for dietary burden calculations in ranked order were (n=8): 0.46, 0.59, 0.65, 0.83, 0.88, 0.88, 1.7, and 13 mg/kg.

The Meeting estimated a maximum residue level of 30 mg/kg (dw), based on a dry matter content of 83 percent. The Meeting estimated a median residue of 0.855 mg/kg (as received) and a highest residue of 13 mg/kg (as received) for sweet corn stover.

Miscellaneous animal feed

Almond hulls (90 percent dry matter)

The same trials as for almond (nutmeat) were considered for almond hulls. Five trials on almonds matched the criticalUnited StatesGAP on tree nuts (3 foliar applications each at 168 g ai/ha, an RTI of 7 days and harvested 30 DALA).

Residue levels (parent only) in ranked order were (n=5): 1.7, 2.5, 3.4, 6.0, and 8.2 mg/kg. Total residue levels (parent + 1-OH-Met-fluindapyr and its conjugates) for dietary burden calculations in ranked order were (n=5): 2.1, 2.9, 3.4, 6.0, and 8.2 mg/kg.

The Meeting estimated a maximum residue level of 20 mg/kg (dw), based on a dry matter content of 90 percent and a median residue of 3.4 mg/kg (as received) for fluindapyr in almond hulls.

Fate of residues during processing

High temperature hydrolysis

The Meeting received information on the hydrolysis of fluindapyr simulating typical processing conditions (pH 4, 6 and 6 with 90, 100 and 10 °C for 20, 60 and 20 minutes). No significant hydrolysis of fluindapyr was observed at the conditions studied. The Meeting concluded that fluindapyr is stable under the conditions of pasteurization, boiling, baking and brewing, as well as sterilization.

Residues in processed commodities

The fate of fluindapyr residues during commercial processing has been examined in wheat, sorghum, and maize. Processing factors derived for MRL estimation are based parent only. Processing factors derived for STMR estimation for food and median residue level estimation in feed are based on the residue definition for dietary risk assessment including total residue (parent + 1-OH-Met-fluindapyr). The results are shown in Table 3.

Table 137 Estimation of processing factors for commodities based on parent (MRL estimation) or parent + 1-OH-Met-fluindapyr (STMR and median residue level estimation)

Crop	Residue (mg/kg) in RAC		Processed commodity	Individual processing factors	Mean or best estimate PF	Residue (mg/kg) in processed commodity	
	MRL [a]	STMR [b]				MRL-P [a]	STMR-P or median residue-P [b]
Wheat	0.4	0.074	Whole meal flour	0.71, 0.81, 0.86, 1.0	0.845	-	0.063
			Total bran	0.95, 1.1, 1.4, 1.5	1.24	0.5 [c]	0.92
			White flour	0.28, 0.29, 0.30, 0.55	0.355	-	0.026
			Whole meal bread	0.44, 0.46, 0.54, 0.54	0.495	-	0.037
			Gluten feed meal	0.35, 0.37, 0.40, 0.71	0.458	-	0.034 [d]
			Germ	0.15, 0.42, 0.53, 0.60	0.425	-	0.031
Sorghum	1.0	0.395	Flour	0.42	0.42	-	0.17
			Aspirated grain fraction	6.9	6.9	7 [e]	2.7 [f]

Crop	Residue (mg/kg) in RAC		Processed commodity	Individual processing factors	Mean or best estimate PF	Residue (mg/kg) in processed commodity	
	MRL [a]	STMR [b]				MRL-P [a]	STMR-P or median residue-P [b]
Maize	0.01*	0.02	Flour	< 0.74	< 0.74	-	0.02
			Grits	< 0.8	< 0.8	-	0.02
			Meal	< 0.8	< 0.8	-	0.02
			Starch	< 0.8	< 0.8	-	0.02
			Refined bleached deodorized oil (wet milled)	1.1	1.1	-	0.022
			Refined bleached deodorized oil (dry milled)	1.8	1.8	0.03 [g]	0.36
			Aspirated grain fraction	27	27	0.5 [h]	0.54 [i]

Notes:

[a] parent only

[b] parent + 1-OH-fluindapyr

[c] MRL-P was based on the mean PF of 1.26 (individual values of 1.38, 1.51, 1.0 and 1.14) for parent only.

[d] A median residue-P of 0.025 was also derived for dietary burden estimation for MRL estimation, based on the individual PFs of 0.33, 0.41, 0.42 and 0.92, with a mean PF of 0.52 and a median residue based on parent only of 0.047 mg/kg.

[e] MRL-P was based on the single PF of 6.5 for parent only.

[f] A median residue-P of 2.31 was also derived for dietary burden estimation for MRL estimation, based on the single PF of 6.5 and a median residue based on parent only of 0.355 mg/kg.

[g] MRL-P was based on the single PF of 2.3 for parent only.

[h] MRL-P was based on the single PF of 44 for parent only.

[i] A median residue-P of 0.44 was also derived for dietary burden estimation for MRL estimation, based on the single PF of 44 and a median residue STMR based on parent only of 0.01 mg/kg

Residues in animal commodities

Farm animal feeding studies

The Meeting received farm animal feeding studies in lactating cows and laying hens.

Noting the uncertainties regarding the analytical method used (limited extraction efficiency of parent fluindapyr in a radio validation study) in both the dairy cow and laying hen feeding studies, the Meeting concluded that the results cannot be used for quantitative estimation of maximum residue level, STMR and HR estimation. Therefore, no details of the study were summarized here.

Farm animal dietary burden

Dietary burdens were calculated for beef cattle, dairy cattle, broilers and laying poultry based on feed items evaluated by the current JMPR. Some processed and forage commodities do not appear in the Recommendations Table (because no maximum residue level is needed), but they are used in estimating livestock dietary burdens.

Table 138 Processed and forage commodities used in estimating livestock dietary burdens based on parent (P) or parent fluindapyr + 1-OH-Met-fluindapyr and its conjugates (T)

Codex classification	Commodity	Median residue (-P) (mg/kg) [a]	Highest residue (-P) (mg/kg) [a]

Notes:

[a] Levels for cereal straw, hay, and forage are presented on as received basis.

The dietary burdens, estimated using the OECD diets listed in Appendix IX of the 2016 edition of the FAO manual, are presented in Annex 6 of the 2020 JMPR Report and summarised below.

The Meeting performed two mean and maximum dietary burden calculations; one based on parent only for MRL estimation and one based on parent + 1-OH-Met-fluindapyr (and its conjugates) for STMR and HR estimations (Tables 5 and 6).

Table 139 Estimated maximum and mean dietary burdens of farm animals based on parent only for MRL estimation

	Animal dietary burden: fluindapyr, ppm of dry matter diet							
	US-Canada		EU		Australia		Japan	
	max	mean	max	mean	max	mean	max	mean
Beef cattle	3.772	3.965	25.66	4.202	44❶	12.84	0.176	0.176
Dairy cattle	15.11	10.369	18.17	3.809	35.6❷	12.84	11.64	7.117
Poultry – broiler	0.32	0.32	0.302	0.302	0.301	0.301	0.274	0.274
Poultry – layer	0.323	0.323	4.7❸	1.757	0.301	0.301	0.245	0.245

Notes:

❶ Highest maximum beef or dairy cattle dietary burden suitable for MRL estimates for mammalian tissues

❷ Highest maximum dairy cattle dietary burden suitable for MRL estimates for mammalian milk

❸ Highest maximum poultry dietary burden suitable for MRL estimates for poultry tissues and eggs.

Table140 Estimated maximum and mean dietary burdens of farm animals based on total intake

	Animal dietary burden: fluindapyr + 1-OH-Met-fluindapyr and its conjugates, ppm of dry matter diet							
	US-Canada		EU		Australia		Japan	
	max	mean	max	mean	max	mean	max	mean
Beef cattle	4. 051	4.090	27.36	4.445	48❶	13.4	0.212	0.212

Notes:

❶ Highest maximum beef or dairy cattle dietary burden suitable for HR estimates for mammalian tissues

❷ Highest mean beef or dairy cattle dietary burden suitable for STMR estimates for mammalian tissues and milk.

❸ Highest maximum poultry dietary burden suitable for HR estimates for poultry tissues and eggs.

❹ Highest mean poultry dietary burden suitable for STMR estimates for poultry tissues and eggs.

Animal commodity maximum residue levels

In the absence of a suitable analytical method for animal commodities no MRLs for animal commodities were recommended

RECOMMENDATIONS

On the basis of the data obtained from supervised trials, the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessments.

Definition of the residue for compliance with the MRL assessment for plant commodities: *fluindapyr*

Definition of the residue for compliance with the MRL assessment for animal commodities: *fluindapyr*

Definition of the residue for dietary risk assessment for plant commodities: *sum of fluindapyr and 3-(difluoromethyl)-N-[7-fluoro-1-(hydroxymethyl)-1,3-dimethyl-2,3-dihydro-1H-inden-4-yl]-1-methyl-1H-pyrazole-4-carboxamide (1-OH-Met-fluindapyr) and its conjugates, expressed as parent*

Definition of the residue for dietary risk assessment for animal commodities: sum of fluindapyr, 4-(3-(difluoromethyl)-1-methyl-1H-pyrazole-4-carboxamido)-7-fluoro-1,3-dimethyl-2,3-dihydro-1H-indene-1-carboxylic acid (1-COOH-fluindapyr), 3-(difluoromethyl)-N-[7-fluoro-1-(hydroxymethyl)-1,3-dimethyl-2,3-dihydro-1H-inden-4-yl]-1-methyl-1H-pyrazole-4-carboxamide (1-OH-Met-fluindapyr), 3-(difluoromethyl)-N-[7-fluoro-1-(hydroxymethyl)-1,3-dimethyl-2,3-dihydro-1H-inden-4-yl]-1H-pyrazole-4-carboxamide (1-OH-Met-N-DesMet-fluindapyr) and their conjugates, and 3-(difluoromethyl)-N-(7-fluoro-1,1,3-trimethyl-2,3-dihydro-1H-inden-4-yl)-1H-pyrazole-4-carboxamide (N-DesMet-fluindapyr), , expressed as fluindapyr.

The residue is fat-soluble.

FUTURE WORK

Information to demonstrate the extraction efficiency of fluindapyr and related metabolites in animal commodities.

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The ADI for fluindapyr is 0–0.04 mg/kg bw/day. The International Estimated Daily Intakes (IEDIs) for fluindapyr were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the JMPR. The results are shown in Annex 3 of the 2022 JMPR Report.

The IEDIs ranged from 1–5 percent of the maximum ADI. The Meeting concluded that long-term dietary exposure to residues of fluindapyr from uses considered by the JMPR is unlikely to present a public health concern.

Acute dietary exposure

The ARfD for fluindapyr is 0.6 mg/kg bw. The International Estimate of Short Term Intakes (IESTIs) for fluindapyr were calculated for the food commodities and their processed commodities for which HRs/HR-Ps or STMRs/STMR-Ps were estimated by the present Meeting and for which consumption data were available. The results are shown in Annex 4 of the 2022 JMPR Report.

The IESTIs varied from 0–1 percent of the ARfD for children and 0–1 percent of the ARfD for the general population. The Meeting concluded that acute dietary exposure to residues of fluindapyr from uses considered by the present Meeting is unlikely to present a public health concern.

Threshold of toxicological concern (TTC) consideration for metabolites

The Meeting concluded that metabolite N-DesMet-pyrazole carboxylic acid, found in rotational crop studies (root crop and oil seeds), could be assessed using the TTC approach (Cramer Class III threshold of 1.5 µg/kg bw per day). The Meeting estimated a dietary exposure for metabolite N-DesMet-pyrazole carboxylic acid 0.366 µg/kg bw per day.

The Meeting concluded that the estimated dietary exposure to residues of N-DesMet-pyrazole carboxylic acid from uses considered by the current JMPR is below the TTC for Cramer Class III compounds and is unlikely to present a public health concern. Should further uses be considered in the future, these conclusions may need to be re-evaluated.

FLUPYRADIFURONE (285)

First draft prepared by Mr D Lunn, Ministry for Primary Industries, Wellington, New Zealand

EXPLANATION

Flupyradifurone is an insecticide with the structure of butenolides, acting as an agonist of nicotinic acetylcholine receptor. It was first evaluated by the JMPR for toxicology in 2015 and for residues by the 2016, 2017 and 2019 JMPRs.

The 2015 Meeting established an ADI of 0–0.08 mg/kg bw and an ARfD of 0.2 mg/kg bw and the 2016 JMPR established the following residue definitions:-

For compliance with the MRL (plant commodities): *Flupyradifurone*

For estimation of dietary exposure (for plant commodities): *Sum of flupyradifurone, difluoroacetic acid (DFA) and 6-chloronicotinic acid (6-CNA), expressed as parent equivalents*

For compliance with the MRL and for estimation of dietary exposure (animal commodities): *Sum of flupyradifurone and difluoroacetic acid, expressed as parent equivalents*

The residue is not fat-soluble.

The Fifty-second Session of the CCPR (2021) listed flupyradifurone for further evaluation by the 2022 JMPR and the current Meeting received revised GAP information and new supporting residue information from the manufacturer for mango, papaya, pineapple, sesame seeds and sunflower seeds.

RESIDUE ANALYTICAL METHODS

Analytical methods

A number of analytical methods (for enforcement and data collection) for plant and animal matrices were evaluated by the 2016 and 2019 Meetings. Method RV-001-P10-02 was shown to be suitable for measuring residues of parent flupyradifurone, difluoroacetic acid (DFA), 6-chloronicotinic acid (6-CNA) and also difluoroethyl-amino-furanone (DFEAF) in a range of plant commodities with a high water content, high acid content, high oil content and high starch/protein content.

A slight modification of this method (RV-001-P10-03) was also evaluated by the 2019 JMPR for measuring residues of parent flupyradifurone, DFA, 6-CNA (and DFEAF) in blackberry, raspberry and avocado.

As summarised by the 2019 JMPR, in these methods, residues are extracted twice from plant material with acetonitrile/water (4/1, v/v) with 2.2 mL/L formic acid and extracts are purified by C-18 SPE (silica or trifunctional amide columns for DFA), with analysis by HPLC-MS/MS.

Validation data for Method RV-001-P10-02 used for determination of flupyradifurone-related residues in mango and papaya are summarized below.

Table 1 Summary of analytical method 01304 (RV-001-P10-02) validation results for plant commodities.

USE PATTERN

Flupyradifurone has been registered in a number of countries for use as a foliar spray to a range of fruit, vegetable and field crops. Information on new uses were provided to the Meeting and those relevant to the supervised trials submitted to the current Meeting are summarized below.

Table 4 Registered uses of flupyradifurone (200 SL formulation) for the crops for which supervised trials were submitted

Crop	Country	Application						Minimum PHI, days (notes)
		Method	max rate (kg ai/ha)	Interval days	Water L/ha (min-max)	max seasonal rate (kg ai/ha)	max seasonal number	
Assorted tropical and sub-tropical fruits – smooth inedible peel								
Mango	United States[1]	foliar	0.2	14	min 234 (ground) min 93 (air)	0.41		1
	Brazil	foliar	0.2	7	300-1000		2	3
	Australia	foliar	0.2 (0.02 kg ai/hL)	14			2	3
Papaya	United States[1]	foliar	0.2	14	min 234 (ground) min 93 (air)	0.41		1
	Brazil	foliar	0.2	7	300-1000		2	3
	Australia	foliar	0.2 (0.02 kg ai/hL)	14			2	3
Pineapple	United States	foliar	0.2	7	min 94 (ground) min 28 (air)	0.41		0
	Brazil	foliar	0.2	7	300-1000		2	3
Oilseeds								
Sesame	United States	foliar	0.2	10	min 94 (ground) min 28 (air)	0.41		14
Sunflower Subgroup 20B)	United States[2]	foliar	0.2	10	min 94 (ground) min 28 (air)	0.41		14

Notes:

[1] Included in the US Subgroup 24B: Abiu; Akee apple; Avocado; Avocado, Guatemalan; Avocado, Mexican; Avocado, West Indian; Bacury; Banana; Banana, dwarf; Binjai; Canistel; Cupuacú; Etambe; Jatobá; Kei apple; Langsat; Lanjut; Lucuma; Mabolo; **Mango**; Mango, horse; Mango, Saipan; Mangosteen; Paho; **Papaya**; Pawpaw, common; Pelipisan; Pequi; Pequia;

Persimmon, American; Plantain; Pomegranate; Poshte; Quandong; Sapote, black; Sapote, green; Sapote, white; Sataw; Screw-pine; Star apple; Tamarind-of-the-Indies; Wild loquat; cultivars, varieties, and hybrids of these commodities.

(2) Included in the US Subgroup 20B: Calendula; Castor oil plant; Chinese tallowtree; Euphorbia; Evening primrose; Jojoba; Niger seed; Rose hip; Safflower; Stokes aster; **Sunflower**; Tallowwood; Tee oil plant; Vernonia; cultivars, varieties, and/or hybrids of these

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received information on supervised field trials involving foliar applications of flupyradifurone on the following crops.

Group	Crop	Countries	Table
Assorted tropical and sub-tropical fruits-inedible peel (FI)			
Assorted tropical and sub-tropical fruits – smooth inedible peel – large	Mango	Brazil	5
	Papaya	Brazil	6
Assorted tropical and sub-tropical fruits – inedible rough or hairy peel - large	Pineapple	United States	7
Oilseeds and oilfruits (SO)			
Small seed oilseeds	Sesame seed	United States	8
Sunflower seeds	Sunflower seed	United States	9

The new supervised trials were well documented with laboratory and field reports. Laboratory reports included method validation and/or procedural recoveries with spiking at residue levels similar to those occurring in samples from the supervised trials. Dates of analyses or duration of residue sample storage were also provided. Although trials included control plots, no control data are recorded in the tables unless residues in control samples exceeded the LOQ.

Intervals of freezer storage between sampling and analysis were recorded for all trials and were covered by the conditions of the freezer storage stability studies reviewed by previous JMPR meetings.

Residues and application rates have generally been rounded to two significant digits and residue concentrations are presented without correction for concurrent method recoveries. Where duplicate samples were analysed, mean values have been calculated from unrounded individual values and reported in brackets.

The results from trials conducted according to the maximum GAP and used for the estimation of maximum residue levels have been (underlined).

When residues were not quantifiable, they are shown as below the LOQ of the relevant analytical method (e. g. < 0.01 mg/kg).

Residue results are all expressed as flupyradifurone equivalents, using molecular weight conversion factors of 3.01 (DFA), 1.83 (6-CNA) and 1.77 (DFEAF).

For the calculation of sum of flupyradifurone, DFA and 6-CNA, expressed as parent equivalents (total residues), the Meeting used the approach adopted by the 2016 JMPR:

"Where parent or DFA residues were not detected or were less than the LOQ (*i.e.* < 0.01 mg/kg for parent or 0.05 mg/kg for DFA) the LOQ value was utilized for maximum residue estimation and dietary intake assessment. For 6-CNA, values less than the LOQ were not added for calculation of total residues of flupyradifurone."

Parent	DFA	6-CNA	Total
<0.01	0.05	0.01	0.07
0.01	<0.05	0.01	0.07
<0.01	<0.05	<0.01	<0.06
0.01	0.05	<0.01	0.06
0.01	0.05	0.01	0.07

In some trials, residue concentrations of DFEAF were also reported. While DFEAF is neither included in the residue definition for compliance with MRL nor the one for estimation of dietary exposure for plant commodities, DFEAF concentrations are shown in the following tables for consistency with the previous JMPR Evaluations.

Assorted tropical and sub-tropical fruits – smooth inedible peel – large

Mango

In field trials on mango, conducted in Brazil (2019), two foliar sprays of flupyradifurone (200 SL formulation) were applied to maturing fruit 10 days before harvest (BBCH 76–78) and 7 days later (BBCH 79–80). All applications were made as simulated commercial applications using a knapsack mist-blower with spray volumes of 509–524 L/ha. No adjuvant was used in the applications. Treated plots ranged from 150–315 m^2 (six trees).

Duplicate samples of ripe fruit (12 units, minimum of 6 kg) were processed (weighed, separated into pulp and peel, with stones weighed and discarded) and placed in frozen storage (< -20 °C) within 5 hours. The frozen samples were shipped to the analytical laboratory where they were homogenized with dry ice and then stored frozen for up to 8 months before extraction and analysis.

Residues of flupyradifurone and its metabolites DFA, 6-CNA and DFEAF were determined according to method RV-001-P10-02 by HPLC-MS/MS, using external standards. Overall mean concurrent recovery rates ranged from 83-104 percent in samples spiked with 0.01–0.5 mg/kg (See Table 2 above). The LOQs were 0.01 mg/kg for all analytes and matrices except DFA (0.05 mg/kg in whole fruit, pulp, peel).

Table 5 Residues in mango from trials conducted in Brazil, involving two foliar applications of flupyradifurone (200 SL formulation), retreatment interval of 7 days. [Ref: RARV0287]

Notes:

[1] Calculated residues in whole fruit based on a flesh+peel content of 80-90 percent w/w (median 87 percent w/w).

Papaya

In field trials on papaya, conducted in Brazil (2019), two foliar sprays of flupyradifurone (200 SL formulation) were applied to maturing fruit 10 days before harvest (BBCH 75–81) and 7 days later (BBCH

79-81). All applications were made as simulated commercial applications using a motorised pump and single cone hand-gun to apply spray volumes of 660–1092 L/ha. No adjuvant was used in the applications. Treated plots ranged from 50–140 m^2 (minimum of four trees).

Samples of ripe fruit (12 units, min 5 kg) were placed in frozen storage (< -20 °C) within 24 hours. The frozen samples were shipped to the analytical laboratory where they were homogenized with dry ice and then stored frozen for up to 6 months before extraction and analysis.

Residues of flupyradifurone and its metabolites DFA and 6-CNA were determined according to method RV-001-P10-02 by HPLC-MS/MS, using internal standards. Overall mean concurrent recovery rates ranged from 88–95 percent in samples spiked with 0.01–10 mg/kg (See table 2 above). The LOQs were 0.01 mg/kg for flupyradifurone and 6-CAN and 0.05 mg/kg for DFA.

Table 6 Residues in papaya from trials conducted in Brazil, involving two foliar applications of flupyradifurone (200 SL formulation), with a retreatment interval of 7 days. [Ref: I17-009]

Assorted tropical and sub-tropical fruits – inedible rough or hairy peel - large

Pineapple

In field trials on pineapple, conducted in Hawaii and Puerto Rico, two foliar sprays of flupyradifurone (200 SL formulation) were applied 7–8 days apart using pressurised backpack sprayers (with 2 or 3 flat fan

nozzles) to apply spray volumes of 560–2440 L/ha. No adjuvant was used in the applications except in trials HI157 and HI160, where a non-ionic surfactant was added. Treated plots ranged from 37–74 m^2.

Samples of ripe fruit (12 units) were trimmed to remove the crowns, quartered longitudinally and single quarters were placed in frozen storage (< -18 °C) within 3 hours. The frozen samples were shipped to the analytical laboratory where they were homogenized with dry ice and then stored frozen for up to 17 months before extraction and analysis.

Residues of flupyradifurone and its metabolites DFA and 6-CNA were determined according to method RV-001-P10-03 by HPLC-MS/MS using internal standards. Overall mean concurrent recovery rates ranged from 93–101 percent in samples spiked with 0.01–0.5 mg/kg (See Table 3 above). The LOQs were 0.01 mg/kg for flupyradifurone, 6-CNA and 0.02 mg/kg for DFA.

Table 7 Residues in pineapple from trials in Hawaii and Puerto Rico, involving two foliar applications of flupyradifurone (200 SL formulation), with retreatment intervals of 7–8 days. [Ref: IR4-11711]

Notes:

Mean values calculated from unrounded individual values. For flupyradifurone and DFA, values below the respective LOQs were set at LOQ for calculation.

The three Hawaiian trials and the two Puerto Rican trials were conducted in the same locations (in Wahiawa and Manati, respectively) but since the application dates differed by more than 30 days in all cases, they are all considered independent.

Small seed oilseeds

Sesame seed

In field trials on sesame, conducted in United States, two foliar sprays of flupyradifurone (200 SL formulation) were applied 9–11 days apart using a tractor-mounted boom sprayer (8 nozzles) or pressurised backpack mini-boom sprayers (2–6 nozzles) to apply spray volumes of 234–280 L/ha. A non-ionic adjuvant was added to the spray mixtures. Treated plots ranged from 140–548 m^2.

Duplicate composite samples (two separate runs through the plot) of sesame stalks or pods were harvested and allowed to dry in the field (if necessary) before threshing and cleaning. Seed samples (minimum of 0.9 kg) were frozen within 1 hour and shipped to the analytical laboratory where they were homogenized with dry ice and stored frozen for up to 13 months before extraction and analysis.

Residues of flupyradifurone and its metabolites DFA and 6-CNA were determined according to method RV-001-P10-03 by HPLC-MS/MS, using external standards. Overall mean concurrent recovery rates ranged from 75–92 percent in samples spiked with 0.01–2.5 mg/kg (See Table 3 above). The LOQs were 0.01 mg/kg for flupyradifurone, 6-CNA and 0.05 mg/kg for DFA.

Table 8 Residues in sesame seed from trials conducted in United States, involving two foliar applications of flupyradifurone (200 SL formulation), with retreatment intervals of 9–11 days. [Ref: IR4-11725]

Notes:

(1) Pods harvested and forced-air dried (24 hours at 32 °C) before threshing and seed sampling.

(2) Stalks air-dried in the field and/or greenhouse for 4-5 days before threshing and seed sampling.

(3) Plots harvested using a small-plot harvester.

(4) Stalks harvested and dried in the field for 25 days before threshing and seed sampling.

Sunflower seeds

In field trials on sunflower, conducted in United States, two foliar sprays of flupyradifurone (200 SL formulation) were applied during the seed ripening stage using vehicle-mounted, wheeled or backpack pressurised boom sprayers (3–9 nozzles) to apply spray volumes of 47–430 L/ha. A non-ionic adjuvant was added to the spray mixtures except in trials ND 238 and SD 358. Treated plots ranged from 21-186 m^2.

Duplicate samples of 12–24 flowerheads were clipped, manually or mechanically threshed and the seeds were screened to remove the debris, frozen within 1.5 hours and shipped to the analytical laboratory where they were homogenized with dry ice and stored frozen for up to 21 months before extraction and analysis.

Residues of flupyradifurone and its metabolites DFA and 6-CNA were determined according to method RV-001-P10-03 by HPLC-MS/MS, using external standards. Overall mean concurrent recovery rates ranged from 92–98 percent in samples spiked with 0.01–0.5 mg/kg (See Table 3 above). The LOQs were 0.01 mg/kg for flupyradifurone, 6-CNA and 0.05 mg/kg for DFA.

Notes:

Trials ND240 and ND 241 not considered independent (differing only in the variety used).

FATE OF RESIDUES IN STORAGE AND IN PROCESSING

Information and Data from Residues in Processed Commodities

A study on the effects of heating at different pH and temperature on the flupyradifurone residues was evaluated by the 2016 JMPR which concluded that flupyradifurone was not degraded during the simulation of pasteurization (pH 4, 90 °C, 20 minutes), baking, boiling or brewing (pH 5, 100 °C, 60 minutes) or during sterilization (pH 6, 120 °C, 20 minutes).

The 2016 JMPR also evaluated the effects of processing on the concentrations of flupyradifurone residues in orange, apples, grapes, tomato, soybean, potato, barley, maize, wheat, cotton and peanut.

Subsequently, processing studies on peaches, plums and cherries were evaluated by the 2017 JMPR and cocoa, coffee and hop processing studies were evaluated by the 2019 JMPR.

The current Meeting received information on the processing of pineapple, sesame seed and sunflower seed.

Pineapple

In one field trial on pineapple, conducted in Hawaii, two foliar sprays of flupyradifurone (200 SL formulation) with added non-ionic surfactant were applied at an exaggerated (5×) rate of 1.05 kg ai/ha, 8 days apart using a pressurised backpack sprayer (with 2 flat fan nozzles) to apply spray volumes of 1490 L/ha. The treated plot size was 45 m^2.

Samples (24 units) of treated and untreated ripe fruit were trimmed to remove the crowns, transported fresh to the processing facility and processed into juice and wet bran the same day.

Juice was prepared by trimming both ends of each fruit, hand peeling and scraping the remaining flesh from the peel. The peeled fruit, scraped flesh and end cuts were processed in a commercial juicer and the pulp and the juice were collected in separate containers. The juice, after the addition of an antifoam agent, was heated in a water bath to 88 °C for 30 seconds, then cooled to 8 °C in ice water bath and subsamples were taken, frozen and shipped to the analytical laboratory where they were stored frozen for up to 14 months before extraction and analysis.

Wet bran (process residue) was obtained by chopping the retained peel to a coarse consistency and combining it with the pulp left over from juicing. After thorough mixing, subsamples were taken, frozen and shipped to the analytical laboratory where they homogenized with dry ice and stored frozen for up to 14 months before extraction and analysis.

Residues of flupyradifurone and its metabolites DFA and 6-CNA were determined according to method RV-001-P10-03 by HPLC-MS/MS using internal standards. Overall mean concurrent recovery rates ranged from 92–103 percent in samples spiked with 0.01–0.5 mg/kg (See table 3 above). The LOQs were 0.01 mg/kg for flupyradifurone, 6-CNA and 0.02 mg/kg for DFA.

Sesame seed

In one field trial on sesame, conducted in United States, two foliar sprays of flupyradifurone (200 SL formulation) were applied at an exaggerated (5×) rate of about 1.0 kg ai/ha with added non-ionic surfactant, 9 days apart using a pressurised backpack mini-boom sprayer (4 nozzles) to apply spray

volumes of 280 L/ha. A non-ionic adjuvant was added to the spray mixtures. The treated plot size was 223 m^2.

Plots were harvested with a small plot harvester, the seed was sifted to remove debris and frozen within 1 hour and shipped and stored frozen at the processing facility for 3.6 months before being processed into oil.

Three subsamples (minimum of 11 kg) were screened to remove field debris, straw, etc and expelled for crude oil and presscake recovery using an electric screw press expeller with an attached heating element. The recovered oil was centrifuged and decanted to separate the crude oil from emulsion and particulate and the crude oil was subsampled, frozen and stored for shipment to the analytical laboratory where they were stored frozen for up to 8 months before extraction and analysis.

Residues of flupyradifurone and its metabolites DFA and 6-CNA were determined according to method RV-001-P10-03 by HPLC-MS/MS, using internal standards. Overall mean concurrent recovery rates ranged from 96–99 percent in samples spiked with 0.01–0.5 mg/kg (See Table 3 above). The LOQs were 0.01 mg/kg for flupyradifurone, 6-CNA and 0.05 mg/kg for DFA.

Table 11 Residues in sesame seed and crude oil from a trial involving two foliar applications of flupyradifurone (200 SL formulation), retreatment interval of 9 days. [Ref: IR4-11725]

Sunflower seed

In one field trial on sunflower, conducted in United States, two foliar sprays of flupyradifurone (200 SL formulation) were applied, 11 days apart, at an exaggerated (5×) rate of 1.03 kg ai/ha with added non-ionic surfactant during the seed ripening stage using a pressurised boom sprayer (5 nozzles) to apply spray volumes of 103 L/ha. The treated plot size was 535 m^2.

Triplicate samples of 120 flowerheads were clipped, mechanically threshed and the seeds frozen within 1 hour and shipped to the processing facility where they were stored frozen for 4 months before processing into meal and refined oil.

Seed samples were tempered (~60 °C for 90 minutes) before screening to remove field debris and partially dehulled using a seed scarifier. After further screening and aspiration, the partially dehulled seeds were heated on a bin air tray dryer (70–83 °C for 20 minutes) and flaked on a rotary drum dryer (2.5 mm drum spacing). The flaked seed was processed through an oil expeller to obtain crude oil and presscake.

The crude oil was centrifuged, heated to ~60 °C, mixed with phosphoric acid (0.2 percent v/v) then distilled water (5.0 percent *v/v)* and centrifuged to separate the oil and gum. The degummed oil was heated to about 40 °C before the addition of sodium hydroxide (0.3 percent v/v) and then heated to about 75 °C to separate the soapstock from the neutralized oil. The oil was separated from the soapstock via centrifugation and decanted.

The neutralized oil was washed with soft water (15 percent v/v) at 90 °C to remove traces of non-precipitated soap in the oil. The oil was separated from the water/soapstock via centrifugation, decanted and heated to ~ 105 °C to remove traces of moisture. The refined oil was subsampled, frozen and stored for shipment to the analytical laboratory where they were stored frozen for up to 8 months before extraction and analysis.

The presscake was mixed with hexane and the miscella (oil/hexane) was separated from the meal by vacuum filter. The meal was dried in a fluid bed dryer (70–83 °C) and then heated with a steam attachment to about 90 °C to remove any remaining solvent. The final moisture content of the toasted meal was 2.24 percent (UTC) and 3.36 percent (TRT). The toasted meal was milled and subsamples were frozen and stored for shipment to the analytical laboratory where they were stored frozen for up to 7 months before extraction and analysis.

Residues of flupyradifurone and its metabolites DFA and 6-CNA were determined according to method RV-001-P10-03 by HPLC-MS/MS, using external standards. Overall mean concurrent recovery rates ranged from 73–98 percent in samples spiked with 0.01–0.5 mg/kg (See table 3 above). The LOQs were 0.01 mg/kg for flupyradifurone, 6-CNA and 0.05 mg/kg for DFA.

Table 12 Residues in sunflower seed, refined oil and meal from a trial involving two foliar applications of flupyradifurone (200 SL formulation), retreatment interval of 11 days. [Ref: IR4-11674]

Trial No., Location, Country, Year (Variety)	Application		Matrix	DALA	Residues as parent (mg/kg)			
	Rate (kg ai/ha)	Water (L/ha)			Parent	DFA	6-CNA[1]	Parent + DFA + 6-CNA

Notes:

(1) Residues of 6-CNA were measured in all control samples of seeds and oil, ranging from 0.022 mg/kg to 0.024 mg/kg (mean values were 0.023 mg/kg in both matrices)

Processing factors

In processing studies conducted on pineapples, sesame seed and sunflower seed, flupyradifurone residues decreased in pineapple juice and sesame seed oil but concentrated in sunflower seed oil. In non-food commodities, residues decreased in sunflower meal but not in pineapple meal.

Table 13 Summary of calculated processing factors for flupyradifurone

RAC Commodity	Flupyradifurone		Total residue[1]	
	Residues (mean)	Processing Factor[2]	Residues (mean)	Processing Factor[2]
Pineapple without crown (RAC)	0.54	-	0.56 (0.56)[3]	-
Juice	0.17	0.32	0.19	0.34
Wet bran	0.55	1.0	0.57 (0.57[3]	1.0[3]
Sesame seed (RAC)	2.2	-	2.6	-
Oil (crude)	0.29	0.13	0.34	0.13

RAC Commodity	Flupyradifurone		Total residue[1]	
	Residues (mean)	Processing Factor[2]	Residues (mean)	Processing Factor[2]
Sunflower seed (RAC)	0.3	-	0.37 (0.35)[3]	-
Oil (refined)	0.36	1.2	-[4]	nc[4]
Meal	0.012	0.04	0.062 (0.062)[3]	0.17 (0.18)[3]

Notes:

[1] Total residue = flupyradifurone + DFA + 6-CNA, all expressed as flupyradifurone equivalents

[2] Each value represents a separate study where residues were above the LOQ in the RAC. The processing factors (PFs) are the ratios of the residue in the processed item divided by the residue in the Raw Agricultural Commodity.

[3] Residue values in brackets are for the sum of flupyradifurone and DFA (as parent equivalents), relevant for calculating processing factors for animal feed commodities.

[4] Total residue value compromised because 6-CNA residues measured in control samples. Processing factor not calculated

APPRAISAL

Flupyradifurone, is a butenolide insecticide acting as an agonist of nicotinic acetylcholine receptor. It was first evaluated by the JMPR for toxicology in 2015 and for residues by the 2016, 2017 and 2019 JMPRs.

The 2015 Meeting established an ADI of 0–0.08 mg/kg bw and an ARfD of 0.2 mg/kg bw and the 2016 JMPR established the following residue definitions:-

- For compliance with the MRL (plant commodities): *Flupyradifurone*
- For estimation of dietary exposure (for plant commodities): Sum of flupyradifurone, difluoroacetic acid (DFA) and 6-chloronicotinic acid (6-CNA), expressed as parent equivalents
- For compliance with the MRL and for estimation of dietary exposure (animal commodities): *Sum of flupyradifurone and difluoroacetic acid, expressed as parent equivalents*

The residue is not fat-soluble.

The Fifty-second Session of the CCPR (2021) listed flupyradifurone for further evaluation by the 2022 JMPR and the current Meeting received revised GAP information and new supporting residue information from the manufacturer for mango, papaya, pineapple, sesame seeds and sunflower seeds.

METHODS OF ANALYSIS

A number of analytical methods (for enforcement and data collection) for plant and animal matrices were evaluated by the 2016 and 2019 Meeting, including the HPLC-MS/MS Method RV-001-P10-02 and RV-001-P10-03 and shown to be suitable for measuring residues of parent flupyradifurone, difluoroacetic acid (DFA), 6-chloronicotinic acid (6-CNA) and also difluoroethyl-amino-furanone (DFEAF) in a range of plant commodities with a high water content, high acid content, high oil content and high starch/protein content.

The current Meeting received validation and concurrent recovery data supporting the use of Method RV-001-P10-02 for mango and Method RV-001-P10-03 for pineapple fruit, juice and wet bran, sesame seed and oil and for sunflower seed, oil and meal.

Conclusions

The Meeting concluded that the analytical methods used in the supervised trials and processing studies provided to this Meeting were suitable for measuring residues of flupyradifurone and its DFA and 6-CNA metabolites, with LOQs of 0.01 mg/kg for all analytes and matrices except DFA (0.02–0.05 mg/kg). The Meeting also noted that the frozen sample storage periods in the trials were all within the acceptable (52 month) storage stability interval for high water, high acid, high oil, high protein, and high starch content matrices.

RESULTS OF SUPERVISED RESIDUE TRIALS ON CROPS

Supervised trials were available for the use of flupyradifurone on mango, papaya, pineapple, sesame seed and sunflower seed. Product labels were available from Australia, Brazil and the United States of America (United States).

Residue results are all expressed as flupyradifurone equivalents, using molecular weight conversion factors of 3.01 (DFA) and 1.83 (6-CNA). For dietary exposure estimation, total residues (the

sum of flupyradifurone, DFA and 6-CNA, expressed as parent equivalents) were calculated using the approach adopted by the 2016 JMPR:

"Where parent or DFA residues were not detected or were less than the LOQ (i.e. < 0.01 mg/kg for parent or 0.05 mg/kg for DFA) the LOQ value was utilized for maximum residue estimation and dietary intake assessment. For 6-CNA, values less than the LOQ were not added for calculation of total residues of flupyradifurone."

Table 14 Approach followed for the summing of residues

Parent	DFA	6-CNA	Total
< 0.01	0.05	0.01	0.07
0.01	< 0.05	0.01	0.07
< 0.01	< 0.05	< 0.01	< 0.06
0.01	0.05	< 0.01	0.06
0.01	0.05	0.01	0.07

Mango

The critical GAP for flupyradifurone on mango in the United States is for foliar applications of 0.2 kg ai/ha, with a minimum retreatment interval of 14 days, a PHI of 1 day and a maximum seasonal application rate of 0.41 kg ai/ha. No trials matched this GAP.

The GAP for flupyradifurone on mango in Brazil is for up to 2 foliar applications of 0.2 kg ai/ha, with a minimum retreatment interval of 7 days and a PHI of 3 days.

In five independent trials on mangos, conducted in Brazil and matching the Brazilian GAP, flupyradifurone residues (for maximum residue level estimation) in whole fruit were: 0.14, 0.2, 0.22, 0.23 and 0.3 mg/kg.

For dietary exposure estimation, since the total residues (sum of flupyradifurone, DFA and 6-CNA, expressed as parent equivalents) did not appear reach a plateau in three of the five decline trials, the Meeting agreed it was not possible to estimate an STMR and HR for mango.

The Meeting estimated a maximum residue level of 0.7 mg/kg for flupyradifurone in Mango.

Papaya

The critical GAP for flupyradifurone on papaya in the United States is for foliar applications of 0.2 kg ai/ha, with a minimum retreatment interval of 14 days, a PHI of 1 day and a maximum seasonal application rate of 0.41 kg ai/ha. No trials matched this GAP.

The GAP for flupyradifurone on papaya in Brazil is for up to 2 foliar applications of 0.2 kg ai/ha, with a minimum retreatment interval of 7 days and a PHI of 3 days.

In five independent trials on papaya, conducted in Brazil and matching the Brazilian GAP, flupyradifurone residues in whole fruit (for maximum residue level estimation) were: 0.02, 0.068, 0.1, 0.11 and 0.2 mg/kg.

For dietary exposure estimation, since the total residue concentrations (sum of flupyradifurone, DFA and 6-CNA, expressed as parent equivalents) did not appear to reach a plateau in three of the five decline trials, the Meeting agreed it was not possible to estimate an STMR and HR for mango.

The Meeting estimated a maximum residue level of 0.4 mg/kg for flupyradifurone in Papaya.

Pineapple

The critical GAP for flupyradifurone on pineapple in the United States is for foliar applications of 0.2 kg ai/ha, with a minimum retreatment interval of 7 days, a PHI of 0 days and a maximum seasonal application rate of 0.41 kg ai/ha.

In five independent trials on pineapple, conducted in the United States and matching theUnited StatesGAP, flupyradifurone residues in trimmed whole fruit (for maximum residue level estimation) were: 0.046, 0.062, 0.11, 0.12 and 0.155 mg/kg.

For dietary exposure estimation, total residues (sum of flupyradifurone, DFA and 6-CNA, expressed as parent equivalents) in trimmed whole fruit were (n = 5): 0.066, 0.082, 0.13, 0.14 and 0.175 mg/kg and the highest individual value was 0.19 mg/kg.

The Meeting estimated a maximum residue level of 0.3 mg/kg for flupyradifurone, an STMR of 0.13 mg/kg and an HR of 0.19 mg/kg for total residues in Pineapple.

Sesame seed

The GAP for flupyradifurone on sesame in the United States is for foliar applications of 0.2 kg ai/ha with a minimum retreatment interval of 10 days, a PHI of 14 days and a maximum seasonal application rate of 0.41 kg ai/ha.

In four independent trials on sesame (including one decline trial), conducted in the United States and matching theUnited StatesGAP application rate and timing, flupyradifurone residues in sesame seed samples taken 14–19 DALA were: 0.1, 0.12, 0.38 and 1.1 mg/kg.

Based on the residue decline rate shown in the decline trial, the Meeting considered that residues in samples taken 19 DALA would be within 25 percent of the expected residues in samples taken 14 DALA (GAP), and agreed that the data set was sufficient to estimate a maximum residue level.

For dietary exposure estimation, total residues (sum of flupyradifurone, DFA and 6-CNA, expressed as parent equivalents) in sesame seed were (n=4): 0.38, 0.52, 1.2 and 2.0 mg/kg and the highest individual value was 2.0 mg/kg. The medan residue was 0.86 mg/kg.

In field studies on succeeding crops evaluated by the 2016 JMPR, the overall mean and highest total residues in rape seed as a rotational crop were 0.16 mg/kg. The Meeting decided to add the mean residue found in rape seed as a rotational crop (0.16 mg/kg) to the median residue obtained from the sesame seed residue trials (0.86 mg/kg) to estimate an overall STMR of 1 mg/kg for total flupyradifurone residues in the sesame seed.

The Meeting estimated a maximum residue level of 3 mg/kg for flupyradifurone and an STMR of 1 mg/kg for total residues in Sesame seed.

Sunflower seed

The GAP for flupyradifurone in the United States on sunflowers (US sub-group 20B) is for foliar applications of 0.2 kg ai/ha with a minimum retreatment interval of 10 days, a PHI of 14 days and a maximum seasonal application rate of 0.41 kg ai/ha.

In eight independent trials on sunflower, conducted in the United States and matching theUnited StatesGAP, flupyradifurone residues in sunflower seed (for maximum residue level estimation) were: 0.0135, 0.028, 0.028, 0.04, 0.16, 0.17, 0.25 and 0.44 mg/kg.

For dietary exposure estimation, total residues (sum of flupyradifurone, DFA and 6-CNA, expressed as parent equivalents) in sunflower seed were (n=8): 0.075, 0.078, 0.09, 0.096, 0.21, 0.22, 0.3 and 0.49 mg/kg. The median residue was 0.15 mg/kg.

The Meeting decided to add the mean residue found in rape seed as a rotational crop (0.16 mg/kg) to the median residue obtained from the sunflower seed residue trials (0.15 mg/kg) to estimate an overall STMR of 0.31 mg/kg for total flupyradifurone residues in the sunflower seeds subgroup.

The Meeting estimated a maximum residue level of 0.8 mg/kg for flupyradifurone and an overall STMR of 0.31 mg/kg for total residues in the subgroup of Sunflower seeds.

Fate of residues during processing

Residues in processed commodities

The current Meeting received information on the processing of pineapple, sesame seeds and sunflower seeds. Residues decreased in pineapple juice and and sesame oil, but increased in sunflower oil.

Processing factors were calculated for total residues (dietary risk assessment) and for flupyradifurone+DFA (livestock dietary burden estimation).

For processed food commodities, STMR-Ps were calculated using the STMRs for the raw commodities and applying the calculated mean processing factors for total residues.

For sunflower oil, no processing factor for total residues could be estimated because significant residues of 6-CNA were found in the control samples.

Table 15 Calculated STMR-Ps and median-Ps for processed food and feed commodities

RAC	Processing factors		Flupyradifurone+DFA+6-CNA	Flupyradifurone + DFA
	Calculated Processing factors [a]	Best Estimate	STMR-P [b] (mg/kg)	median-P [c] (mg/kg)
Pineapple			STMR=0.13	median=0.13
Juice	0.34	0.34 [b]	0.044	
Wet bran	1.0	1.0 [c]		0.13
Sunflower seed			STMR=0.31	median=0.31
Meal	0.18	0.18 [c)]		0.056
Sesame seed			STMR=1.0	
Oil (crude)	0.13	0.13 [b]	0.13	

Notes:

[a] The ratios of the residue in the processed item divided by the residue in the Raw Agricultural Commodity

[b] Flupyradifurone + DFA + 6-CNA, expressed as parent equivalents

[c] Flupyradifurone + DFA, expressed as parent equivalents

Residues in animal commodities

Farm animal dietary burden

The maximum dietary burdens estimated by the 2016 JMPR were 72 ppm for beef, dairy cattle and 15 ppm for poultry.

Dietary burdens were calculated for beef cattle, dairy cattle, broilers and laying poultry based on feed items evaluated by the current and previous JMPRs and using the most recent version of the OECD livestock dietary burden calculator. The results are presented in Annex 6 and summarised below.

Table 16 Estimated maximum and mean dietary burdens of farm animals

Animal dietary burden: Sum of flupyradifurone+DFA residues (as parent), ppm dry matter diet								
	US-Canada		EU		Australia		Japan	
	max	mean	max	mean	max	mean	max	mean
Beef cattle	23	7.7	77❶	17	77	23❸	8.2	5.4
Dairy cattle	47	11	67	13	77❷	21❹	50	8.8
Poultry – broiler	2.9	2.9	4.8	3.5	4.0	4.0	2.7	2.7
Poultry – layer	2.9	2.9	17❺	6.2❻	4.0	4.0	2.4	2.4

Notes:

❶ Highest maximum cattle dietary burden suitable for HR and MRL estimates for mammalian tissues.

❷ Highest maximum dairy cattle dietary burden suitable for MRL estimates for mammalian milk.

❸Highest mean cattle dietary burden suitable for STMR estimates for mammalian tissues.

❹ Highest mean dairy cattle dietary burden suitable for STMR estimates for milk.

❺ Highest maximum poultry dietary burden suitable for HR and MRL estimates for poultry tissues and eggs.

❻ Highest mean poultry dietary burden suitable for STMR estimates for poultry tissues and eggs.

Animal commodity maximum residue levels

Noting that the additional feed commodities considered by the Meeting increased the maximum dietary burdens estimated by the 2016 JMPR by less than 7 percent (cattle) and less than 10 percent (poultry), the Meeting agreed that the maximum residue levels, HRs and STMRs for cattle and poultry commodities need not be re-estimated.

RECOMMENDATIONS

On the basis of the data obtained from supervised trials, the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessments.

Definition of the residue for compliance with the MRL for plant commodities: *Flupyradifurone*

Definition of the residue for dietary risk assessment for plant commodities: *Sum of flupyradifurone, difluoroacetic acid (DFA) and 6-chloronicotinic acid (6-CNA), expressed as parent equivalents*.

Definition of the residue for compliance with the MRL for animal commodities: *Sum of flupyradifurone and difluoroacetic acid, expressed as parent equivalents*.

Definition of the residue for dietary risk assessment for animal commodities: *Sum of flupyradifurone and difluoroacetic acid, expressed as parent equivalents.*

The residue is not fat-soluble.

Table 4 Recommendations for residues of flupyradifurone from the 2022 JMPR

CCN	Commodity	Recommended Maximum residue level (mg/kg)		STMR or STMR-P mg/kg	HR or HR-P mg/kg
		New	Previous		
FI 0353	Pineapple	0.3		0.13	0.19
SO 2091	Sunflower seeds (subgroup)	0.8		0.31	
SO 0700	Sesame seed	3		1.0	
OC 7000	Sesame seed oil (crude)			0.13	
JF 0341	Pineapple juice			0.044	
AM 3591	Pineapple process residue (wet bran)			0.13	
AM 0702	Sunflower seed meal			0.056	

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The ADI for flupyradifurone is 0–0.08 mg/kg bw. The International Estimated Daily Intakes (IEDIs) for flupyradifurone were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the JMPR. The results are shown in Annex 3 of the 2022 JMPR Report.

The IEDIs ranged from 6–20 percent of the maximum ADI. The Meeting concluded that long-term dietary exposure to residues of flupyradifurone from uses considered by the JMPR is unlikely to present a public health concern.

Acute dietary exposure

The ARfD for flupyradifurone is 0.2 mg/kg bw. The International Estimate of Short Term Intakes (IESTIs) for flupyradifurone were calculated for the food commodities and their processed commodities for which HRs/HR-Ps or STMRs/STMR-Ps were estimated by the present Meeting and for which consumption data were available. The results are shown in Annex 4 of the 2022 JMPR Report.

The IESTIs varied from 0–8 percent of the ARfD for children and 0–5 percent of the ARfD for the general population. The Meeting concluded that acute dietary exposure to residues of flupyradifurone from uses considered by the present Meeting is unlikely to present a public health concern.

FLUTRIAFOL (248)

First draft prepared by Hidetaka Kobayashi, Agricultural Chemicals Office, Ministry of Agriculture, Forestry and Fisheries, Japan; and Makoto Irie, Food and Agricultural Materials Inspection Center, Japan

EXPLANATION

Flutriafol, a triazole fungicide, was first evaluated for toxicology and residues by the 2011 JMPR, which established the ADI of 0–0.01 mg/kg bw and the ARfD of 0.05 mg/kg bw. The compound was evaluated by the 2015 JMPR for additional MRLs.

The following residue definitions for flutriafol were recommended by the 2011 JMPR and confirmed by the 2015 JMPR.

Definition of the residue for both compliance with MRL and estimation of dietary intake (for plant and animal commodities): flutriafol

The residue is fat soluble.

At the Fifty-First Session of CCPR (2019), flutriafol was scheduled for evaluation of additional use on hops by the 2020 JMPR. At the Forty-third Session of the Codex Alimentarius Commission (2020), flutriafol was scheduled for evaluation of additional use on barley, rice, tree nuts and sweet corn by the 2021 JMPR. The current Meeting received new information on methods of analysis, use patterns, supervised field trials and storage and processing studies on hops, barley, rice, sweet corn, almond and pecan.

RESIDUE ANALYSIS

Analytical methods

The current JMPR received three methods of analysis for flutriafol and its metabolites. The IUPAC name and structure of flutriafol and its metabolites are shown in Table 1.

Table 1 Name and structure of flutriafol and its metabolites

Common name IUPAC name	Structure
Flutriafol (*RS*)-2,4′-difluoro-alfa-(1*H*-1,2,4-triazol-1-ylmethyl)benzhydryl alcohol	1,2,4-triazole (T) 1*H*-1,2,4-triazole	
Triazole alanine (TA) 2-amino-3-(1,2,4-triazol-1-yl)propanoic acid	
Common name IUPAC name	Structure
Triazole acetic acid (TAA) 2-(1,2,4-triazol-1-yl)acetic acid	Triazole lactic acid (TLA) 2-hydroxy-3-(1,2,4-triazol-1-yl)propanoic acid	
Method #1 (Carringer (2015), TCI-14-393; Carringer (2015), TCI-14-392; Chadwick (2019), S17-02483; and Rice (2011), 65573)

The method of analysis is for flutriafol in barley (hay, grain and flour), sweet corn (forage, corn-on-the-cob and stover), rice (whole plant, straw, grain with husk, husked rice, husks, polished rice and bran) and almond (nutmeat and hulls). Samples were extracted with acetonitrile-water (7:3, v/v) and centrifuged. The supernatant was made up to 150 mL with acetonitrile-water (7:3, v/v) and 1 mL of the solution was added to 9 mL of acetonitrile-water (5:5, v/v). The solution was introduced to LC-MS/MS (turbo ion spray in positive mode) with a C_{18} column. The gradient solvent system was the mixture of solution A and solution B of 6:4→1:9 (v/v) (solution A: water containing 0.1 percent (v/v) of formic acid, solution B: methanol containing 0.1 percent (v/v) of formic acid). The monitored transitions were 302→70 (quantitation) and 302→123 (confirmation). Determination was using by external matrix-matched standard. The calibration curves for flutriafol were linear (Table 2).

The LOQs for all matrices were 0.01 mg/kg. Mean recoveries of flutriafol were 80-82 percent (barley, hay), 82-87 percent (barley, grain), 93 percent (barley, flour), 101–109 percent (rice, whole plant), 93–106 percent (rice, straw), 101–105 percent (rice grain with husk), 102–110 percent (risk, husked), 106–107 percent (rice husks), 101–109 percent (rice, polished), 109–110 percent (rice bran), 84–105 percent (sweet corn, forage), 83–89 percent (sweet corn, corn-on-the-cob), 80–81 percent (sweet corn, stover), 101–109 percent (almond nutmeat), and 104–108 percent (almond hulls)(Table 3).

Table 2 Linearity of calibration curve for Method #1

Analyte	Matrix	Linear range (mg/kg)	R
Flutriafol	Barley (all matrices)	0.012–0.099	>0.998
	Rice (all matrices)	0.0030–0.75	>0.980
	Tree nuts (all matrices)	0.0050–0.10	>0.998
	Sweet corn (all matrices)	0.012–0.10	>0.998

Table 3 Method validation data for Method #1

Analyte	Matrix	Fortification mg/kg	n	Recovery range percent (mean)	RSD percent
flutriafol	Barley, hay	0.01	5	75-94 (82)	9.6
		1.0	5	72-84 (80)	5.8
	Barley, grain	0.01	5	81-91 (87)	4.6

Analyte	Matrix	Fortification mg/kg	n	Recovery range percent (mean)	RSD percent
		1.0	5	72-80 (82)	9.4
	Barley, flour	0.01	5	89-97 (93)	3.4
		1.0	5	87-105 (93)	7.6

Method #2 (Carringer (2015), TCI-14-393; Carringer (2015), TCI-14-392; and Rice (2011), 65573)

The method was for 1,2,4-triazole (T), triazole alanine (TA) and triazole acetic acid (TAA) in barley (hay, grain and flour), sweet corn (forage, corn-on-the-cob and stover) and almond (nutmeat and hulls). Samples were extracted with methanol-water (8:2, v/v). The extract, to which celite was added, was filtered and methanol-water (8:2, v/v) was added to the filtrate. It was processed through solid phase extraction (SPE). Then, aliquots were taken for different derivation processes for T, TA and TAA.

For T, the aliquot was derivatized with dansyl chloride and partitioned into ethyl acetate. For TA, the aliquot was derivatized by reaction with HCl (3 mol/L) in n-butanol followed by heptafluorobutyric anhydride. For TAA, the aliquot was derivatized by reaction with HCl (3 mol/L) in n-butanol. Each of derivative mixtures was evaporated to dryness and then dissolved in 2.5 mL of acetonitrile-water (3:7, v/v). They were individually introduced to LC/MS/MS (turbo ion spray in positive mode) with C18 column. The solvent system was 0.1 percent (v/v) formic acid (aq) – acetonitrile (8:2→1:9, v/v). Mass transitions monitored were shown in Table 4. Determination was using by derivatized stable isotope internal standards.

The LOQs were 0.01–0.16 mg/kg (Table 5). For barley (hay, grain and flour), sweet corn (forage, corn-on-the-cob and stover) and almond (nutmeat and hulls), the mean recovery ranges for T, TA and TAA were 78–100 percent, 87–109 percent and 93–111 percent, respectively (Table 6).

The method for T, TA and TAA in hops was Method Meth-160 with a LOQ of 0.01 mg/kg.

Table 4 Mass transition monitored in Method #2

Analyte	Mass transition	
	Quantitation	Confirmation
1,2,4-triazole (T)	303 →181	303→195
Triazole alanine (TA)	409→70	409→284 409→210
Triazole acetic acid (TAA)	184→70	184→128

Method #3 (Chadwick (2019), S17-02483)

The method is for T, TA, TAA and triazole lactic acid (TLA) in rice (whole plant, straw, grain with husk, husked rice, husks, polished rice and bran). Samples were extracted with methanol-water (8:2, v/v), centrifuged and filtered through glass wool. The supernatant was dried under N_2 gas and the volume adjusted to 5 mL with water, and then introduced to LC-MS/MS (turbo ion spray in positive mode), using a polar end capped C_{18} column. Gradient solvent system was 0.5 percent (v/v) acetic acid in methanol - 0.5 percent (v/v) acetic acid (aq) (2:8->7:3). Mass transitions monitored and HPLC column used are shown in Table 7. Determination was using by derivatized stable isotope internal standards. The calibration curves were linear (R>0.980) between 0.0020–2.0 mg/kg for all analytes/matrices.

The LOQs were 0.010 mg/kg for T, TA, TAA and TLA. Mean recoveries of T, TA, TAA and TLA were 90–110 percent, 72–116 percent, 81–112 percent and 74–110 percent, respectively (Table 8).

STABILITY OF PESTICIDE RESIDUES IN STORED ANALYTICAL SAMPLES

The 2011 JMPR concluded that flutriafol residues were stable for at least 4 months in animal commodities, for at least 5 months in soya bean seed[4a], for at least 12 months in apple[1], barley grains[5] and coffee beans[6], for at least 23 months in grapes[2], for at least 24 months in cabbage[1] and oilseed rape[4a], and for at least 25 months in wheat[5] (grains and straw), pea seed[5] and sugar beet root[1]. The 2011 JMPR also concluded that triazole metabolite residues were stable for at least 4 months in apple fruits and juice[1] and for at least 5 months in animal commodities (1/high water content, 2/high acid content and high water content, 4a/high oil content and very low water content, 5/high starch and/or protein content and low water and fat content, 6/difficult or unique commodities).

For hops, the Meeting received data on the storage stability of triazole metabolites stored frozen (Rodgers (2016), 82662).

The stability study of triazole metabolites was conducted on hops (dried cones) stored frozen at approximately -20 °C. Samples of untreated homogenized hops were fortified at 0.1 mg/kg for T and TAA, and at 1.2 mg/kg for TA then placed in storage at approximately -20 °C, except for the 0 day analysis set. These samples were analysed after 0, 3, 6 and 9 months frozen storage. All samples were analysed in duplicate using Method Meth-160. The residues of triazole metabolites were determined using LC-MS/MS. The LOQ was 0.01 mg/kg (Table 9).

Table 9 Recovery from stored fortified samples of hops (separately fortified with T, TA and TAA)

Time stored (days/months)		Fortification level (mg/kg)	percent Recovery

USE PATTERN

The Meeting received the GAP for barley; rice; sweet corn; almond and walnut; pecan and other tree nuts; and hops as shown in Table 10. While the labels provided cover a broader spectrum of uses, only those relevant to the current evaluation are reported.

Table 10 Use pattern of flutriafol

Notes:

[1] Other tree nuts include African tree nut, brazil nut, burr oak, butternut, cajou, cashew, castanha-do-maranhao, coconut, coquito nut, dika nut, Guiana chestnut, hazelnut, heartnut, hickory nut, Japanese horse-chestnut, macadamia nut, monogongo nut, monkey-pot, pachira nut, pecan and sapucaia nut.

[2] Corn includes field corn, field corn grown for seed, sweet corn, and popcorn

[3] Maximum two foliar applications, or one at planting and one foliar application.

[4] When conditions are favourable for disease

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

Residue levels are reported as measured, without correction for recovery. When residue concentrations were less than LOQ, they are shown as below the LOQ, e.g., < 0.01 mg/kg. Residues for metabolites were expressed as the compounds. Residue values from the trials conducted according to the maximum GAP were used for the estimation of maximum residue levels, STMR and HR. These results are underlined.

Laboratory reports included method validation including batch recoveries with spiking at residue levels similar to those occurring in samples from the supervised trials. Dates of analysis or duration of residue sample storage were also provided. Field reports provided data on the sprayers used and their calibration, plot size, residue sample size and sampling date. The results of field trials are shown in tables indicated in Table 11.

Cereal grains

Barley (Carringer (2015), TCI-14-393)

The Meeting received 12 supervised trials conducted in 2014 on barley in United States. In these trials, barley received two foliar applications of flutriafol (125 g/L SC) at 0.127–0.130 kg ai/ha with intervals of 6–8 days. In 11 trials, plants were harvested at 28–37 days after the last application (DALA). One trial was a decline study (harvested at 17–45 DALA).

The residues of flutriafol and its metabolites in barley (grain) were analysed by Method #1 and Method #2, respectively. The LOQs were 0.01 mg/kg for flutriafol and T, 0.06 mg/kg for TA, and 0.05 mg/kg for TAA. Samples were stored at ≤-20 °C for ≤ 329 days before analysis. Procedural recoveries in barley (hay, grain and straw) of flutriafol, T, TA and TAA were 69–102 percent, 79–107 percent, 87–113 percent and 98–119 percent, respectively.

In some trials, TA and/or TAA were detected in the control sample. Since TA and TAA in control samples were considered to be derived from previous treatment with other pesticides, they should not be attributed to flutriafol treatment. In the table, analytical values for control sample were shown if they were higher than LOQ. The results are shown in Table 12.

Notes:

[a] Residues in untreated samples are denoted by (c XXX). For trials in which no value is listed, residues were not observed >LOQ (0.01 mg/kg for all matrices except TA (0.06 mg/kg) and TAA (0.05 mg/kg)). Residues in treated samples were not corrected for background levels observed in corresponding untreated samples

Sweet corn (Carringer (2015), TCI-14-392)

The Meeting received 16 supervised trials conducted in 2014 on sweet corn in United States. In 12 trials, sweet corn received an in-furrow application of flutriafol (125 g/L SC) at 0.289–0.305 kg ai/ha when planting and two foliar applications of flutriafol (125 g/L SC) at 0.126–0.131 kg ai/ha with an interval of 6–8 days. In four trials, sweet corn received two foliar applications of flutriafol (125 g/L SC) at 0.128–0.136 kg ai/ha with an interval of 7–8 days. Corn-on-the-cob was harvested 0 DALA (on the day of the last application). Two trials were decline study (0–14 DALA for corn-on-the-cob and forage, and 0–21 DALA for stover).

The residues of flutriafol and its metabolites (T, TA and TAA) in sweet corn (corn-on-the-cob) were analysed by Method #1 and Method #2, respectively. The LOQs were 0.01 mg/kg for flutriafol, T and TAA and 0.16 mg/kg for TA. Samples were stored at ≤-20°C for ≤287 days before analysis. Procedural recoveries for sweet corn (corn-on-the-cob, forage and stover) of flutriafol, T, TA and TAA ranged 71–102 percent, 84–107 percent, 71–114 percent, and 91–120 percent, respectively.

The results are shown in Table 13.

[b] In-furrow application at planting.

[c] DBH – Days before harvest of sweet corn forage/corn-on-the-cob.

[d] RTI between 2 foliar applications.

[e] Residues in untreated samples are denoted by (c XXX). For trials in which no value is listed, residues were not observed >LOQ (0.01 mg/kg for all matrices except for TA in K+CWHR for which the LOQ is 0.16 mg/kg). Residues in treated samples were not corrected for background levels observed in corresponding untreated samples.

Rice (Chadwick (2018), S17-02483 and Chadwick (2019), S18-04372)

The Meeting received 12 supervised trials conducted in 2017–2018 on rice in Bulgaria, France, Italy, Portugal and Spain. In these trials, rice received one foliar application of flutriafol (250 g/L SC) at 0.119–0.134 kg ai/ha. Straw (12 trials) and grains with husk (8 trials) were harvested at 27–28 days after treatment (DAT). In addition, for decline study, whole plants were collected and analysed at 0–21 DAT in six trials.

The residues of flutriafol and its metabolites (T, TA, TAA and TLA) in rice (whole plant, straw and grains with husk) were analysed by Method #1 and Method #3, respectively. LOQs were 0.01 mg/kg. Samples were stored at ≤-20 °C for ≤ 88 days before analysis. Procedural recoveries for rice (whole plant,

straw and grains with husk) of flutriafol, T, TA, TAA and TLA ranged 82–112 percent, 81–120 percent, 72–120 percent, 70–119 percent, and 70–120 percent, respectively.

The results are shown in Table 14.

Tree nuts

Almond (Rice (2011), 65573)

The Meeting received five supervised trials conducted in 2010 on almond in United States. In these trials, almond received six foliar applications of flutriafol (125 g/L SC) at 0.127–0.134 kg ai/ha with intervals of 6–8 days. Almonds were harvested at 14 DALA. One trial was a decline study in which samples were harvested at 1–28 DALA.

The residues of flutriafol and its metabolites (T, TA and TAA) in nutmeat and hulls of almonds were analysed by Method #1 and Method #2, respectively. The LOQs were 0.01 mg/kg for flutriafol, T and TAA; 0.2 mg/kg for TA in nutmeat; and 0.15 mg/kg for TA in hulls. Samples were stored at ≤-20 °C for ≤ 230 days (almond nutmeat) or ≤92 days (almond hulls) before analysis. Procedural recoveries for almond (nutmeat and hulls) of flutriafol, T, TA and TAA ranged 77–112 percent, 73–111 percent, 73–113 percent and 96–119 percent, respectively.

The results are shown in Table 15.

Notes:

[a] Days before the earliest harvest.

[b] Residues in untreated samples are denoted by (c XXX). For trials in which no value is listed, residues were not observed >LOQ (0.01 mg/kg for all analytes except TA for which the LOQ is 0.2 mg/kg). Residues in treated samples were not corrected for background levels observed in corresponding untreated samples.

Pecan (Rice (2011), 65573)

The Meeting received five supervised trials conducted in 2010 on pecan in United States. In these trials, pecan received six foliar applications of flutriafol (125 g/L SC) at 0.126–0.132 kg ai/ha with intervals of 6–8 days. Pecans were harvested at 11–14 DALA.

The residues of flutriafol and its metabolites (T, TA and TAA) in pecan nutmeat were analysed by Method #1 and Method #2, respectively. The LOQs were 0.01 mg/kg for flutriafol, T and TAA and 0.2 mg/kg for TA. Samples were stored at ≤-20 °C for ≤ 162 days before analysis. Procedural recoveries for pecan nutmeat of flutriafol, T, TA and TAA ranged 80–112 percent, 88–109 percent, 73–104 percent, and 98–114 percent, respectively.

The results are shown in Table 16.

Notes:

[a] Days before harvest.

[b] Residues in untreated samples are denoted by (c XXX). For trials in which no value is listed, residues were not observed >LOQ (0.01 mg/kg). Residues in treated samples were not corrected for background levels observed in corresponding untreated samples.

Hops (Carringer (2014), TCI-13-365)

Four field trials on hops were conducted in the United States during the 2013 growing season. The treated plots received four foliar airblast applications of the SC formulation (125 g ai/L), normally at 0.128 kg ai/ha with intervals of 9–11 days. At all test sites, one untreated control and duplicate treated green hops cone samples were harvested at maturity 7 DALA. The green hops cones were collected and dried at 32–53 ºC for ~3–8.5 hours to a moisture content of ~8–10 percent prior to the collection of the dried cone samples. The samples were placed in frozen storage within 0.5 hours after collection.

The analytical method RAM 219/04 was used for analysis of flutriafol residues on hops, dried cone samples with HPLC-MS/MS. The LOQ was 0.01 mg/kg for flutriafol.

Triazole metabolite residues in/on hops, dried cones, were also determined using HPLC-MS/MS. The analytical method was Method Meth-160. The LOQs were 0.01 mg/kg for T and TAA triazole metabolites and 0.05 mg/kg for TA.

Both analytical methods were validated on hops dried cones prior to sample analysis. Additionally, concurrent procedural recovery samples were analysed in conjunction with each analytical set for quality control purposes. These samples were extracted and analysed according to the same procedure as the study samples. Procedural recoveries for flutriafol, T, TA and TAA in hops ranged from 89–132 percent, 77–101 percent, 69–91 percent and 107–121 percent, respectively.

The results were shown in Table 17. No residues of T were found above the LOQ in any of the samples analysed.

Animal feed commodities

Barley, straw and hay (Carringer (2015), TCI-14-393)

The Meeting received 12 supervised trials conducted in 2014 on barley in United States. In these trials, barley received two foliar applications of flutriafol (125 g/L SC) at 0.127–0.130 kg ai/ha with intervals of 6–8 days. In 11 trials, plants were harvested at 28–37 days after the last application (DALA) for straw and 14–16 DALA for hay. One trial was a decline study (harvested at 17–45 DALA for straw and 1–28 DALA for hay). Samples as received were analysed.

The residues of flutriafol and its metabolites in barley (straw and hay) were analysed by Method #1 and Method #2, respectively. The LOQs were 0.01 mg/kg for flutriafol and T, 0.03 mg/kg for TA, and 0.04 mg/kg for TAA. Samples were stored at ≤-20°C for ≤329 days before analysis. Procedural recoveries in barley (hay, grain and straw) of flutriafol, T, TA and TAA were 69–102 percent, 79–107 percent, 87–113 percent and 98–119 percent, respectively.

In some trials, TA and/or TAA were detected in the control sample. As TA and TAA were considered natural origin, the increase of TA and TAA from the control should be attributed to flutriafol treatment. In the table, analytical values for control sample were shown if they were higher than LOQ. The results (as received) are shown in Table 18 (straw) and Table 19 (hay).

Sweet corn, forage and stover (Carringer (2015), TCI-14-392)

The Meeting received 16 supervised trials conducted in 2014 on sweet corn in United States. In 12 trials, sweet corn received an in-furrow application of flutriafol (125 g/L SC) at 0.289–0.305 kg ai/ha when planting and two foliar applications of flutriafol (125 g/L SC) at 0.126–0.131 kg ai/ha with an interval of 6-8 days. In four trials, sweet corn received two foliar applications of flutriafol (125 g/L SC) at 0.128–0.136 kg ai/ha with an interval of 7–8 days. Corn-on-the-cob and forage were harvested 0 DALA (on the day of the last application) and stover was harvested 6–7 DALA. Two trials were decline studies (0–14 DALA for corn-on-the-cob and forage, and 0–21 DALA for stover). Samples as received were analysed.

The residues of flutriafol and its metabolites (T, TA and TAA) in sweet corn (forage and stover) were analysed by Method #1 and Method #2, respectively. The LOQs were 0.01 mg/kg for flutriafol, T, TA and TAA. Samples were stored at ≤-20 °C for ≤ 287 days before analysis. Procedural recoveries for sweet corn (corn-on-the-cob, forage and stover) of flutriafol, T, TA and TAA ranged 71–102 percent, 84–107 percent, 71–114 percent, and 91–120 percent, respectively.

The results (as received) are shown in Table 20 (forage) and Table 21 (stover).

<u>Rice, straw and whole plant</u> (Chadwick (2018), S17-02483 and Chadwick (2019), S18-04372)

The Meeting received 12 supervised trials conducted in 2017–2018 on rice in Bulgaria, France, Italy, Portugal and Spain. In these trials, rice received one foliar application of flutriafol (250 g/L SC) at 0.119–0.134 kg ai/ha. Straw (12 trials) was harvested at 27–28 days after treatment (DAT). In addition, for

decline study, whole plants were collected and analysed at 0–21 DAT in six trials. Samples as received were analysed.

The residues of flutriafol and its metabolites (T, TA, TAA and TLA) in rice (whole plant, straw and grains with husk) were analysed by Method #1 and Method #3, respectively. LOQs were 0.01 mg/kg. Samples were stored at ≤-20 °C for ≤ 88 days before analysis. Procedural recoveries for rice (whole plant, straw and grains with husk) of flutriafol, T, TA, TAA and TLA ranged 82–112 percent, 81–120 percent, 72–120 percent, 70–119 percent, and 70–120 percent, respectively.

The results (as received) are shown in Table 22 (straw) and Table 23 (whole plant).

Almond hulls (Rice (2011), 65573)

The Meeting received five supervised trials conducted in 2010 on almond in United States. In these trials, almond received six foliar applications of flutriafol (125 g/L SC) at 0.127–0.134 kg ai/ha with intervals of 6–8 days. Almonds were harvested at 14 DALA. One trial was a decline study in which samples were harvested at 1–28 DALA. Samples as received were analysed.

The residues of flutriafol and its metabolites (T, TA and TAA) were analysed by Method #1 and Method #2, respectively. The LOQs were 0.01 mg/kg for flutriafol, T and TAA and 0.15 mg/kg for TA. Samples were stored at ≤-20°C for ≤230 days (almond nutmeat) or ≤92 days (almond hulls) before analysis. Procedural recoveries for almond (nutmeat and hulls) of flutriafol, T, TA and TAA ranged 77–112 percent, 73–111 percent, 73–113 percent and 96–119 percent, respectively.

The results (as received) are shown in Table 24.

Table 24 Residues of flutriafol and its metabolites in almond hulls after foliar application of flutriafol 125 g/L SC (as received)

FATE OF RESIDUES IN STORAGE AND PROCESSING

Barley (Carringer (2015), TCI-14-393)

One field trial applied flutriafol as a foliar spray at an exaggerated (5 × GAP) rate of 2 × 0.640 kg ai/ha with an application interval of 7 days. Barley grain was harvested at 30 DALA.

The barley grain was processed as follows (Figure 1). Cleaned barley was hulled and resulted in blocked barley and husks. For production of pearled barley, blocked barley was processed in an abrasive testing mill. After milling, the material was separated with a 24-mesh sieve. Material on top of the sieve was pearled barley.

Conditioned blocked barley was fed through the break side of a Chopin mill. Breaking of the barley was accomplished by three break rolls. After passing through the break rolls, the material was fed onto the break sifter screens (140 and 800 micron). Material exiting the break rolls passed over the number 120 screen first. Material passing through the 120-screen was break flour. Material not passing through was conveyed over the number 25 screen. Material passing through the 25-screen was middlings. Material not passing through was conveyed to the end of the sifter. Material exiting the end was coarse bran.

Middlings were then fed into the reduction side of the Chopin mill. Reduction was achieved through two reduction rolls. After passing through the reduction rolls, the material was passed over a 160-micron screen. Material passing through the screen was reduction flour. Material remaining on top of the screen was shorts. Shorts were passed through the reduction roll two additional times. Break and reduction flours were combined and mixed for 13-17 minutes, resulting barley flour.

The coarse bran was conveyed by beater bars over a number-140 (128 micron) screen. Material passing through the screen was shorts and was added to shorts from the reduction mill. Material passing over the screen and exiting the end was bran.

Pearled barley, barley flour and bran were placed into frozen storage (≤-12 °C) for ≤ 64 days before analysis.

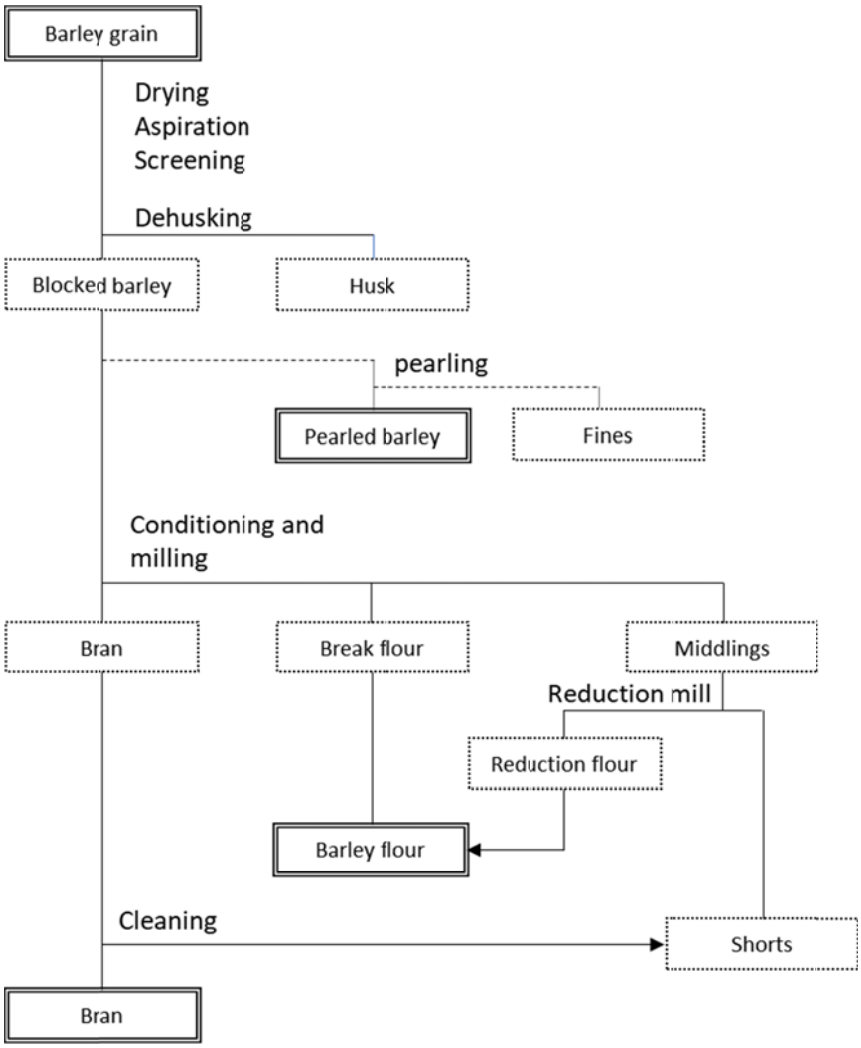

Figure 1 Barley processing to pearled barley, barley flour and barley bran

Residues of flutriafol and metabolites (T, TA and TAA) in barley and its processed commodities were analysed with Method #1 and Method #2, respectively. LOQs were 0.01 mg/kg for flutriafol and T; 0.06 mg/kg and 0.07 mg/kg for TA in barley grain and barley flour, respectively; and 0.05 mg/kg and 0.02 mg/kg for TAA in barley grain and barley flour, respectively. Concurrent recoveries of flutriafol at fortification levels of 0.01–4.0 mg/kg in barley grain, pearled barley, bran and flour were 79–120 percent with RSD≤16 percent. Concurrent recoveries of T (fortification levels of 0.01–0.8 mg/kg), TA (fortification levels of 0.06 and 0.8 mg/kg in grain and pearled barley; 0.09 and 0.8 mg/kg for bran; and 0.07 and 0.8 mg/kg for flour), and TAA (fortification levels of 0.05 and 0.8 mg/kg for grain and pearled barley; 0.03 and 0.8 mg/kg for bran; and 0.02 and 0.8 mg/kg for flour) were 88–107 percent, 87–110 percent and 92–115 percent, respectively.

Residue levels of T and TAA in all matrices were <LOQ. The processing factors for flutriafol were 0.48–0.92 (Table 25).

Table 25 Residues of flutriafol in barley (RAC and processed commodities) after foliar application at exaggerated rate

Location, year (variety)	Application No	RTI (days)	kg ai/ha	DALA	Products	Residue (mg/kg)[a]			
						Flutriafol (processing factor)	T	TA	TAA
Ephrata, WA, United States 2014 (Champion)	2	7	0.639 0.640	30	Barley grain (RAC)	2.1	<0.01	0.55 c 0.20	<0.05
					Pearled barley	1.1 (PF 0.52)	<0.01	0.22	<0.02
					Bran	1.9 (PF 0.92)	<0.01	0.39	0.035
					Flour	1.0 (PF 0.48)	<0.01	0.29	<0.02

Notes:

[a] Residues in untreated samples are denoted by (c XXX). For trials in which no value is listed, residues were not observed >LOQ (0.01 mg/kg for all analytes except TA in bran (0.09 mg/kg) and flour (0.07 mg/kg) and TAA in flour (0.02 mg/kg)). Residues in treated samples were not corrected for background levels observed in corresponding untreated samples. Processing factors are denoted as (PF XXX).

Rice (Chadwick (2018), S17-02483 and Chadwick (2019), S18-04372)

Twelve field trials applied as a foliar spray of flutriafol (125 g/L SC) at a rate of 0.119-0.134 kg ai/ha were conducted in Bulgaria, France, Italy, Spain and Portugal in 2017 and 2018. Rice was harvested at 27-28 DAT.

Processing procedure is shown in Figure 2. Rice grain (with husk) harvested were stored for 0–4 days at 7 °C, and dried if the moisture content was >15 percent. Using a rice mill, rice husks were removed from the cleaned rice grain by rubber rolls rotating in opposite directions at different speeds. Husks were then separated from the remaining husked rice by aspiration. Husked rice was processed through a decorticator to obtain an abrasion of between 25.0–29.0 percent and the specimens polished rice and bran were sampled. Husked rice, husks, polished rice and bran were placed into frozen storage (≤-18 °C) for ≤ 30 days before analysis.

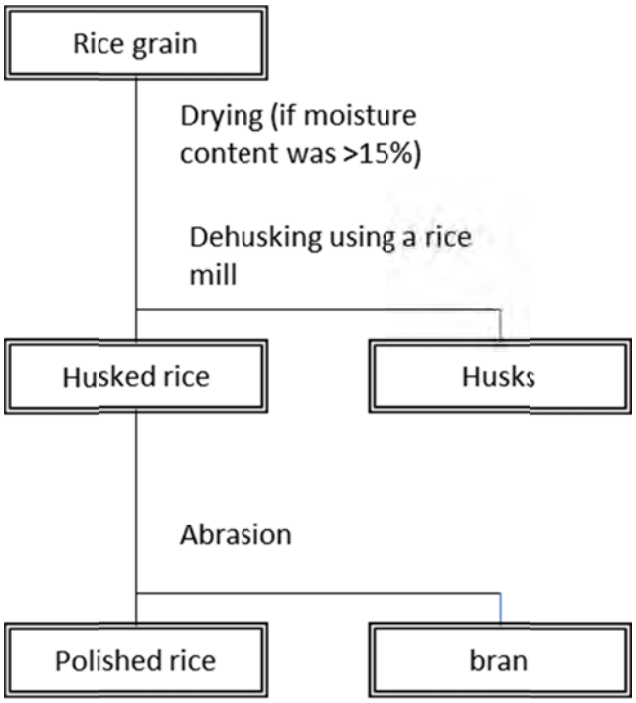

Figure 2 Rice grain (with husk) processing to husked rice and polished rice

Residues of flutriafol and its metabolites (T, TA, TAA and TLA) in rice and its processed commodities were analysed with Method #1 and Method #3, respectively. LOQs were 0.01 mg/kg for all analytes and all matrices. Procedural recoveries for rice (husked rice, polished rice, husks and bran) of flutriafol, T, TA, TAA and TLA ranged 99–119 percent, 71–118 percent, 72–139 percent, 71–116 percent and 71–113 percent, respectively.

The processing factors of flutriafol and its metabolites in rice grain processing were shown in Table 27.

Table 27 Processing factors for flutriafol in rice (summary)

Portion	Flutriafol
	Calculated processing factors[a] (Mean or best estimate)
Husked rice	0.35, 0.40, 0.53, 0.61 (0.46)
Husk	5.4, 5.9, 6.5, 7.9 (6.2)
Polished rice	0.16, 0.34, 0.38, 0.44 (0.36)
Bran	0.44, 0.57, 0.67, 3.7 (0.62)

Notes:

[a/] Each value represents a separate trial. The factor is the ratio of the residue in inedible portion divided by the residue in the edible portion.

Hops (Block (2016), S14-00843)

The Meeting received a processing study for hops which were conducted in Germany. The trials received 4 applications of flutriafol 125g/L SC at the application rate of 0.125 kg ai/ha at 45–48 days before harvest (DBH), 36–37 DBH and 21–22 DBH and at 0.625 kg ai/ha (5 × GAP) at 7 DBH. Samples of hops from the untreated and treated plots of all trials were taken at 7 days after last application and kiln-dried afterwards.

The processing was done according to brewery standards and the standard operating procedures. The processing phase simulated the processing of hops to malt, wort, young beer, brewer´s yeast and beer. Process products samples from hop were analysed for residues of flutriafol and its triazole metabolites (T, TA, TAA and TLA).

Brewing procedure was shown in Figure 3.

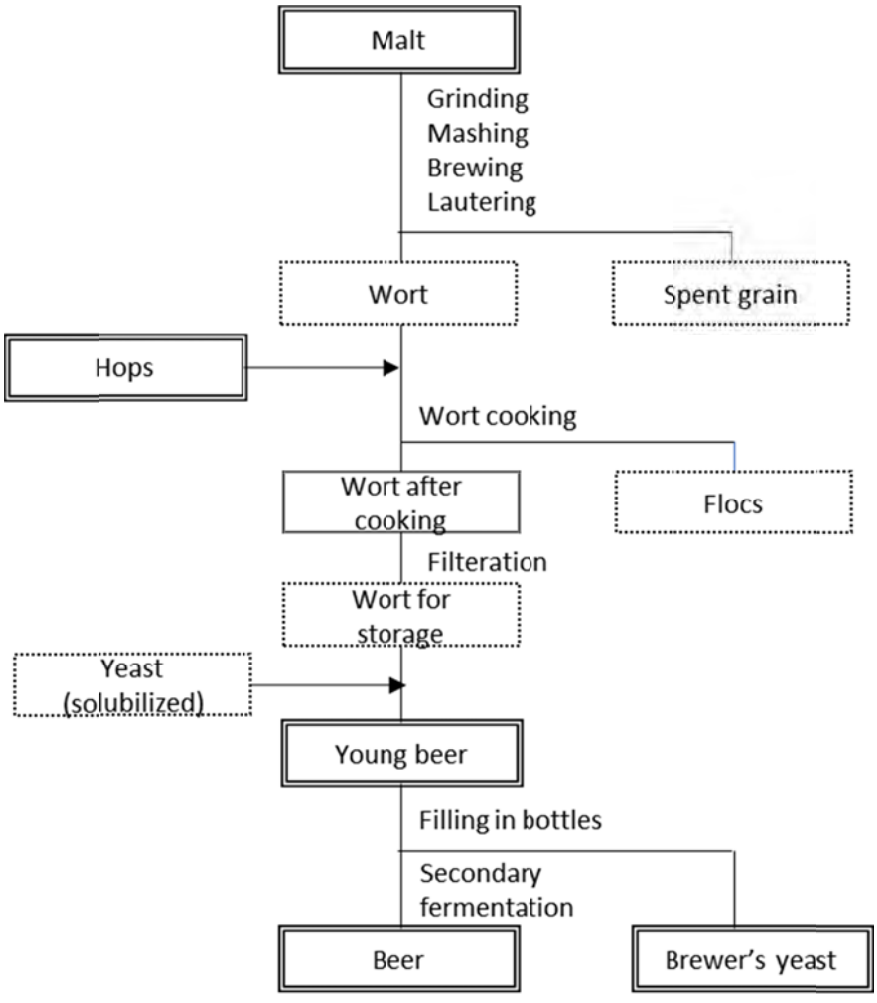

Figure 3 Hops processing to beer

The analytical method referenced AGR/MOA/FLUTRI-1 was validated for determination of flutriafol in hop processed products (hops and beer). This method was already validated for flutriafol in wheat. A confirmation for the validation was performed in brewer's yeast.

The analytical method referenced AGR/MOA/TRZ-1 was validated for determination of T, TA, TAA and TLA in hop processed products (hops and beer). This method was already validated for T, TA and TAA in wheat and for TLA in wheat and barley. The method was also confirmed for the analysis of triazole metabolites in brewer's yeast.

For the validation in hops and beers, for each compound, the analysis of two control sample, one reagent blank, five samples fortified at 0.01 mg/kg and five samples fortified at 0.1 mg/kg were performed. For the confirmation of validation on brewer's yeast and for each compound, the analysis of one control sample, three samples fortified at 0.01 mg/kg and three samples fortified at 0.1 mg/kg were performed.

The recoveries of analytes from hops were 75–87 percentfor flutriafol, 78–101 percent for T, 65–100 percentfor TA, 78–108 percent for TAA, and 77–102 percent for TLA respectively. The recoveries from beer were 88–109 percent for flutriafol, 74–114 percent for T, 81–103 percent for TA, 94–110 percent for TAA, and 76–89 percent for TLA. The LOQ was 0.01 mg/kg for all analytes.

The recoveries of analytes from brewer's yeast were 90–95 percent for flutriafol, 79–116 percent for T, 62–94 percent for TA, 73–107 percent for TAA, and 92–104 percent for TLA respectively.

The samples were stored at a target temperature of -20°C in the freezers. Samples were stored frozen for less than 245 days from frozen storage to analyses, and 109 days from ambient storage to analyses.

The results were shown in Table 28 and Table 29.

APPRAISAL

Flutriafol, whose IUPAC name is (*RS*)-2,4'-difluoro-alfa-(1*H*-1,2,4-triazol-1-ylmethyl)benzhydryl alcohol, is a triazole fungicide. It was first evaluated for toxicology and residues by the 2011 JMPR. The ADI of flutriafol is 0–0.01 mg/kg bw and the ARfD is 0.05 mg/kg bw. The compound was evaluated by the 2015 JMPR for additional MRLs.

The following residue definitions for flutriafol were recommended by the 2011 JMPR and confirmed by the 2015 JMPR :

Definition of the residue for compliance with the MRL and dietary risk assessment for plant and animal commodities: *flutriafol*

The residue is fat soluble.

At the Fifty-first Session of the CCPR (2019), flutriafol was scheduled for evaluation of the additional uses for hops by the 2020 JMPR and postponed to the current JMPR. At the Forty-third Session of CAC (2020), flutriafol was scheduled for evaluation of additional use on almond, pecan, barley, sweet corn and rice by the 2021 JMPR. The current Meeting received new information on methods of analysis, storage studies, use patterns, supervised field trials and processing studies on hops, barley, rice, sweet corn, almond and pecan.

Methods of analysis

The Meeting received information on a method of analysis for supervised field trials.

Method #1 was for analysis of flutriafol in barley, sweet corn, rice and almond. Flutriafol was extracted with acetonitrile/water (7:3, v/v) and quantified by LC-MS/MS. The method was validated for flutriafol in barley (hay, grain and flour), sweet corn (forage, corn-on-the-cob and stover), rice (whole plant, straw, grain with husk, husked rice, husks, polished rice and bran) and almond (nutmeat and hulls) with an LOQ of 0.01 mg/kg.

Stability of pesticide residues in stored analytical samples

The 2011 JMPR concluded that when stored frozen flutriafol residues were stable for at least 5 months in soya bean seed; at least 12 months in apple, barley grains and coffee beans; for at least 23 months in grapes; for at least 24 months in cabbage and oilseed rape; and for at least 25 months in wheat (grains and straw), pea seed, and sugar beet root. The periods of demonstrated storage stability for flutriafol residues cover the frozen storage intervals used in the field trials.

Results of supervised residue trials on crops

Cereal grains

Barley

The critical GAP for flutriafol on barley in the United States is two foliar applications each at 0.128 kg ai/ha with a minimum interval between sprays of 7 days and a PHI of 30 days. In trials conducted in the United States matching theUnited StatesGAP, residues of flutriafol in barley were (n=11): 0.11, 0.12, 0.15, 0.17, 0.18, 0.20, 0.23, 0.29, 0.34, 0.77 and 0.84 mg/kg.

The Meeting estimated a maximum residue level and STMR of 1.5 and 0.20 mg/kg, respectively.

Rice

The critical GAP for flutriafol on rice in Italy is one foliar application at 0.125 kg ai/ha and a PHI of 28 days. In trials conducted in Bulgaria, France, Italy, Portugal and Spain matching the Italian GAP, residues of flutriafol in rice grain(with husk; n=8) were: 0.57, 0.82, 0.87, 1.1 (3), 1.4 and 1.6 mg/kg.

The Meeting estimated a maximum residue level and STMR for rice grain of 4 and 1.1 mg/kg, respectively.

Residues of flutriafol in husked rice were (n=8): 0.13, 0.14, 0.29, 0.34, 0.39, 0.44, 0.49 and 0.54 mg/kg.

The Meeting estimated a maximum residue level and STMR for husked rice of 1 and 0.365 mg/kg, respectively.

In trials matching the Italian GAP, residues of flutriafol in polished rice were (n=4): 0.26, 0.38, 0.42 and 0.47 mg/kg. Corresponding processing factors for rice with rice grain to polished rice were 0.16-0.44 (median 0.36, See Processing section). The Meeting agreed to utilise the residue data on rice grain together with the median processing factor from rice grain to polished rice to estimate a maximum residue level and an STMR for polished rice of 1.5 [4×0.36] and 0.40 mg/kg [1.1×0.36], respectively.

Sweet corn (Corn-on-the-cob)

The critical GAP for flutriafol on sweet corn in the United States is for two foliar applications each at 0.128 kg ai/ha with a minimum interval between sprays of 7 days with a PHI of 7 days. The Meeting received 16 trials conducted in the United States. Of these trials only four matched the United States cGAP, i.e., the majority consisted of an in-furrow application followed by foliar applications.

The Meeting noted that a rotational crop study provided to the 2011 JMPR indicated that uptake from soil may be significant, and could not use 12 of the provided trials to estimate the potential contribution from the in-furrow application to the final residue.

The Meeting could therefore not estimate a maximum residue level, STMR and HR of corn-on-the-cob due to an insuffient number of trials.

Tree nuts

Almonds

The critical GAP for flutriafol on almond in the United States is six foliar applications each at 0.128 kg ai/ha with a minimum interval between sprays of 7 days and a PHI of 14 days. In trials conducted in the

United States matching the GAP, residues in flutriafol in almonds were (n=5): < 0.01, 0.012, 0.064, 0.066 and 0.41 mg/kg (highest individual value: 0.42 mg/kg).

The Meeting estimated a maximum residue level, STMR and HR for almonds of 0.8, 0.064 and 0.42 mg/kg, respectively.

Pecan

The critical GAP for flutriafol on tree nuts in the United States is four foliar applications each at 0.128 kg ai/ha with a minimum interval between sprays of 14 days and a PHI of 14 days.

Since no trials matched the GAP, the Meeting could not estimate a maximum residue level and STMR of pecans.

Dried herbs

Hops, dry

The critical GAP for hops in the United States allows four applications each at 0.128 kg ai/ha with a maximum seasonal rate of 0.51 kg ai/ha at a minimum interval of 14 days and a PHI of 7 day.

Data were available from supervised trials on hops (dried cones) in United States.

Residues in hops from independent trials in the United States with four applications of 0.13 kg ai/ha at intervals of 9–11 days at a total application rate of 0.51 kg ai/ha with a PHI of 7 days were (n=3): 4.6, 7.3 and 8.0 mg/kg.

The Meeting could not estimate maximum residue level and STMR for hops due to insufficient trial numbers.

Animal feed commodities

Barley, hay and/or straw

The critical GAP for flutriafol on barley in the United States is two foliar applications each at 0.128 kg ai/ha with a minimum interval between sprays of 7 days and a PHI of 30 days (for straw) or 14 days (for hay).

In trials conducted in the United States matching the United States GAP, residues of flutriafol in barley, straw (as received) were (n=11): 0.28, 0.49, 0.57, 0.64, 0.98, 1.0, 1.2 (2), 1.8, 3.4 and 5.9 mg/kg (highest individual value: 6.4 mg/kg).

In trials conducted in the United States matching the United States GAP, residues of flutriafol in barley, hay (as received) were (n=12): 0.25, 0.32, 0.39, 0.54, 0.92, 0.93, 1.1, 1.7 (2), 1.9, 3.2 and 4.9 mg/kg (highest individual value: 5.0 mg/kg).

Based on data for straw which lead to a higher maximum residue level than data for hay, the Meeting estimated the maximum residue level of flutriafol in barley hay and/or straw of 10 mg/kg (dw, based on 89 percent DM content).

The Meeting estimated median and highest residue of flutriafol in barley, straw of 1.0 and 6.4 mg/kg, respectively (as received), and median and highest residue in barley, hay of 1.0, 5.0 mg/kg, respectively (as received).

Rice straw

The critical GAP for flutriafol on rice in Italy is one foliar application at 0.125 kg ai/ha and a PHI of 28 days.

In trials conducted in Bulgaria, France, Italy, Portugal and Spain matching the Italian GAP, residues of flutriafol in rice straw (as received) were (n=12): 0.45, 0.76, 0.92, 1.1 (2), 1.3, 1.4, 1.9 (2), 2.1, 2.4 and 4.0 mg/kg. The Meeting estimated the maximum residue level for flutriafol in rice straw of 6 mg/kg (dw, based on 90 percent DM content) and median and highest residue of 1.4 and 4.0 mg/kg, respectively (as received).

Sweet corn, stover

The critical GAP for flutriafol on sweet corn in the United States is two foliar applications each at 0.128 kg ai/ha with a minimum interval between sprays of 7 days and a PHI of 7 days.

In trials matching critical GAP, residues of flutriafol in sweet corn stover were (n=4): 0.50, 0.83, 2.1 and 4.1 mg/kg.

The Meeting noted that rotational crop study provided to 2011 JMPR indicated that uptake from soil may be significant and could not assume the impact from in-furrow application.

The Meeting considered four trials insufficient to estimate a maximum residue level for corn stover.

Almond hulls

The critical GAP for flutriafol on almond in the United States is six foliar applications each at 0.128 kg ai/ha with a minimum interval between sprays of 7 days and a PHI of 14 days.

In trials conducted in the United States matching theUnited StatesGAP, residues of flutriafol in almond hulls (as received) were (n=5): 1.3, 1.8, 2.0, 4.0 and 6.7 mg/kg. The Meeting estimated the maximum residue level for flutriafol in almond hulls of 15 mg/kg (dw, based on 90 percent DM content) and median of 2.0 mg/kg, respectively (as received).

Fates of residues during processing

Processing

The Meeting estimated processing factors for flutriafol as follows. STMR-P and maximum residue levels for polished rice were derived from processing factors.

Table 30 Calculated STMR-Ps for processed food and feed commodities

RAC	Processed commodity	Processing factor	RAC STMR (mg/kg)	STMR-P or median (mg/kg)	Maximum residue level for RAC (mg/kg)	Maximum residue level for processed commodity (mg/kg)
Barley	Pealed barley	0.52	0.20	0.099	1.5	-
	Barley bran	0.92	0.20	0.17		-
	Barley flour	0.48	0.20	0.091		-
Rice grain with husk	Polished rice	0.36	1.1	0.40	4	1.5
	Husks	6.2	1.1	6.8 (as received)	4 (dw)	20 (dw)
	Rice bran	0.62	1.1	0.68		

				(as received)		

Residues in animal commodities

Farm animal dietary burden

The OECD diets include barley (straw and hay) and rice (straw, grain, husks and bran). Dietary burdens were calculated for beef cattle, dairy cattle, broilers and laying poultry based on feed items evaluated by the Meeting. The dietary burdens, estimated using the OECD diets listed in Appendix IX of the 2016 edition of the FAO manual, are presented in Annex 6 and summarised below.

Table 31 Estimated maximum and mean dietary burdens of farm animals

	Animal dietary burden of flutriafol, ppm of dry matter diet							
	US-Canada		EU		Australia		Japan	
	Max	Mean	max	mean	max	mean	Max	mean
Beef cattle	2.3	1.4	4.8	2.1	11❶	4.6❷	2.6	0.97
Dairy cattle	4.2	2.0	5.2	2.0	11❸	4.6❹	1.2	0.52
Poultry – broiler	0.44	0.44	0.24	0.24	0.78	0.78	0.23	0.23
Poultry – layer	0.44	0.44	1.2❺	0.49	0.78	0.78 ❻	0.21	0.21

Notes:

❶ Highest maximum beef cattle dietary burden suitable for MRL estimates for mammalian tissues.

❷ Highest mean beef cattle dietary burden suitable for STMR estimates for mammalian tissues.

❸ Highest maximum dairy cattle dietary burden suitable for MRL estimates for mammalian milk.

❹ Highest mean dairy cattle dietary burden suitable for STMR estimates for milk.

❺ Highest maximum poultry dietary burden suitable for MRL estimates for poultry tissues and eggs.

❻ Highest mean poultry dietary burden suitable for STMR estimates for poultry tissues and eggs.

Animal commodity maximum residue levels

The calculations used to estimate highest total residues for use in estimating maximum residue levels, STMR and HR values are shown below.

Table 32 Residues in milk and tissues from cattle dosed with flutriafol in the diet

Cattle	Feed Level (ppm) for milk residues	Residues (mg /kg) in milk	Feed Level (ppm) for tissue residues	Residues (mg /kg)			
				Muscle	Liver	Kidney	Fat
HR Determination (beef or dairy cattle)							
Feeding Study [a]	16	< 0.01	16	< 0.01	0.77	0.02	0.02
Dietary burden and estimate of highest residue	11	< 0.0069	11	< 0.0069	0.53	0.014	0.014
STMR determination (beef or dairy cattle)							
Feeding Study [b]	5	< 0.01	5	< 0.01	0.33	< 0.01	< 0.01
Dietary burden and estimate of highest residue	4.6	< 0.0029 [c]	4.6	< 0.0029 [c]	0.30	< 0.0092	< 0.0092

Notes:

[a] Highest residues for tissues and mean residues for milk

[b] Mean residues for tissues and mean residues for milk

[c] Calculated based on the feeding study of feed level at 16 ppm

Table 33 Residues in eggs and tissues from poultry dosed with flutriafol in the diet

Poultry	Feed Level (ppm) for egg residues	Residues (mg /kg) in egg	Feed Level (ppm) for tissue residues	Residues (mg /kg)		
				Muscle	Liver	Fat
HR Determination (poultry – broiler or layer)						
Feeding Study [a]	5	0.03	5	< 0.01	0.10	0.07
Dietary burden and estimate of highest residue	1.2	0.0072	1.2	< 0.0024	0.024	0.017
STMR determination (poultry – broiler or layer)						
Feeding Study [b]	5	0.03	5	< 0.01	0.07	0.06
Dietary burden and estimate of highest residue	0.78	0.0047	0.78	< 0.0016	0.011	0.0094

Notes:

[a] Highest residues for tissues and mean residues for egg.

[b] Mean residues for tissues and mean residues for egg.

The Meeting confirmed its decision in 2015 of maximum residue levels of 0.02 (fat) mg/kg for meat (from mammals other than marine mammals), 0.01 (*) mg/kg for milks, 0.02 mg/kg for mammalian fats (except milk fats) and 1 mg/kg for edible offal (mammalian).

The Meeting estimated maximum residue levels of 0.03 (fat) mg/kg for poultry meat and 0.03 mg/kg for poultry fats to replace previous recommendations, and confirmed its decision in 2015 of maximum residue levels of 0.03 mg/kg for poultry, edible offal of, and 0.01(*) mg/kg for eggs.

RECOMMENDATIONS

On the basis of the data from supervised trials the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessment.

Definition of the residue for compliance with MRL and dietary intake for plant and animal commodities: *flutriafol*

The residue is fat soluble.

Table 34 Residue levels suitable for establishing maximum residue limits and for IEDI and IESTI assessments

CCN	Commodity	Recommended Maximum residue level (mg/kg)		STMR or STMR-P mg/kg	HR or HR-P mg/kg
		New	Previous

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The International Estimated Daily Intakes for the 17 GEMS/Food cluster diets, based on the recommendations of the current JMPR, were in the range 9–30 percent of the maximum ADI of 0.01 mg/kg bw for flutriafol. The results are shown in Annex 3 to the report.

The Meeting concluded that the long-term dietary exposure from residues of flutriafol, from uses that have been considered by the JMPR, is unlikely to present a public health concern.

Acute dietary exposure

The International Estimated Short Term Intake (IESTI) for flutriafol was calculated. The results are shown in Annex 4 to the Report.

The IESTIs for flutriafol from the intake of the residue evaluated by the Meeting were 0–30 percent for general population and 0–70 percent for children of the ARfD (0.05 mg/kg bw). The Meeting concluded that acute dietary exposure from the residues of flutriafol, from uses that have been considered by the JMPR, is unlikely to present a public health concern.

INDOXACARB (216)

First draft prepared by Dr Julian Cudmore, Chemicals Regulation Division of the Health and Safety Executive, United Kingdom

EXPLANATION

Indoxacarb is an indeno-oxadiazine insecticide that is used for the control of lepidopteran and other insect pests. It was first evaluated by the 2005 JMPR when an ADI of 0–0.01 mg/kg bw and an ARfD of 0.1 mg/kg bw were established. The residue definition for compliance with the MRL for plant and animal commodities and dietary risk assessment for plant commodities is the sum of indoxacarb and its R enantiomer. The residue definition for dietary risk assessment for animal commodities is sum of indoxacarb, its R enantiomer and methyl 7-chloro-2,5-dihydro-2-[[[4-(trifluoromethoxy)phenyl]amino]carbonyl]indeno[1,2-e][1,3,4]oxadiazine-4a(3H)- carboxylate (IN-JT333), expressed as indoxacarb. The residue is fat soluble.

Indoxacarb has been evaluated for additional uses in 2007, 2009 and 2013. At the Fifty-first Session of the CCPR, indoxacarb was scheduled for the evaluation by the current Meeting for additional uses on bush berries, okra, beans with pods, pulses, beetroot, maize and tree nuts. The current Meeting received information on residue analysis, storage stability, use pattern, supervised field trials and processing.

RESIDUE ANALYSIS

Analytical Methods

One new analytical method (DuPont 36189) was received by the current Meeting. All other analytical methods outlined below have been considered previously by the JMPR. However, additional validation data were received by the current Meeting.

In all the analytical methods, indoxacarb and its R enantiomer are determined and reported together; the methods are not enantioselective and the LOQ refers to the sum of indoxacarb (S isomer) and its R enantiomer.

Method AMR 4271-96

The method was considered by the 2005 JMPR. The method is based on multi-residue method DFG S19 with a modified extraction solvent. Samples are extracted with water/acetone/ethyl acetate/cyclohexane. Extracts are cleaned up by gel permeation chromatography (GPC) and by adsorption chromatography on silica gel. Analytes are determined by capillary GC-ECD on a non-polar stationary phase. The method was validated with an LOQ of 0.01 mg/kg for apple, cabbage, grape and tomato and an LOQ of 0.02 mg/kg for cotton seed.

The Meeting received additional validation data for blueberries which is summarized in Table 1.

AMR 3493-95

The method was considered by the 2005 JMPR. Analytes are extracted from crop samples into ethyl acetate after the addition of water. An aliquot from the extraction solution is concentrated by evaporation under nitrogen and cleaned up by solid phase extraction with silica and carbon. The cleaned-up extract is then analysed by GC-MSD. The method was validated with an LOQ of 0.02 mg/kg for apple.

The Meeting received additional validation data for maize grain which is summarized in Table 1.

AMR 2712 93

The method was considered by the 2005 JMPR with additional recovery data considered by the 2009 JMPR for a range of commodities. Residues are extracted from crop matrices with hexane-acetonitrile and the acetonitrile extract is concentrated and cleaned up by solid-phase extraction with a combination of silica and strong anion exchanger. The analytes are measured by reversed-phase HPLC (2-column system with switching) with UV detection at 310 nm. The method was validated with an LOQ of 0.01 mg/kg for high water crops.

The Meeting received additional validation data for snap beans, dry beans and beetroot which is summarised in Table 1.

DuPont 36189

This method was used in the residue trials for maize and tree nuts. Residues are extracted twice with hexane-acetonitrile. The acetonitrile layer is collected and a portion is evaporated to dryness under nitrogen. The residue is reconstituted in acetonitrile and 0.01 M formic acid. Final analysis is by LC-MS/MS using gradient elution on a C18 column. The ion mass transition m/z 528 → 249 was used for quantification. Validation data are summarized in Table 1.

STABILITY OF PESTICIDE RESIDUES IN STORED ANALYTICAL SAMPLES

New storage stability data for indoxacarb and its R enantiomer on blueberries, peppers, snap beans, beetroots and maize were submitted to the Meeting. Samples were ground, homogenized with dry ice and fortified with indoxacarb at 1 mg/kg for blueberries, 0.1 mg/kg for peppers, 0.03 mg/kg for snap beans, 0.3 mg/kg for dry beans, 0.1 mg/kg for beetroots and 0.1 mg/kg for maize grain. Samples were stored at ≤ -18 ° C for the duration of the storage stability studies. The sample preparation and storage conditions reflect those employed in the residue trials.

For maize and pepper only, the initial fortified samples were analysed prior to storage and served as the time zero samples. At subsequent time periods, one - three stored samples were taken and analysed along with at least one stored control sample and one stored control sample freshly fortified with indoxacarb to serve as a procedural recovery sample.

Residues were determined in the stored samples using analytical method AMR 4271-96 for blueberries, analytical method AMR 3493-95 for peppers, analytical method AMR 2712-93 for snap beans, dry beans and beetroots, and analytical method AMR 3493-95 for maize grain.

Results from the storage stability samples are summarized in Table 2.

Table 2 Stability of indoxacarb residues in various commodities when stored at ≤ -18 ºC

USE PATTERN

Information on the registered uses of indoxacarb was provided to the Meeting and is summarised in Table 3.

In some trials the formulation was based on racemic indoxacarb and in others indoxacarb 3S+1R was used. In all situations, the application rate and spray concentration are expressed in terms of the active ingredient, indoxacarb.

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received data from supervised residue trials conducted on blueberries, pepper, snap beans, dry beans, beetroot, maize and tree nuts. In all cases residues were measured and expressed as indoxacarb and its R enantiomer.

Bush berries

Blueberries

Thirteen residue trials were on blueberries from Canada and the United States in 2003 were provided to the Meeting. The trials were conducted with a WG formulation. A total of 4 applications with an individual application of approximately 123 g ai/ha were made. The re-treatment interval was 6–9 days.

Samples were collected 6–8 days after the last application and immediately frozen and stored at ≤ -18 ºC for up to 476 days prior to analysis.

Residues of indoxacarb and its R enantiomer in blueberries were determined using analytical method AMR 4271-96. Procedural recoveries were conducted at fortification levels of 0.02 and 1 mg/kg with recoveries in the range of 92–113 percent.

The three trials conducted in Fennville, MI, were conducted at the same trial site with similar dates of application and harvest. Therefore, these three trials are regarded as replicate trials.

A summary of the trials is outlined in Table 4.

Notes:

Values in parentheses = mean of two independent representative treated samples taken at the trial site.

Fruiting vegetables, other than cucurbits

Peppers

Nine residue trials were conducted on bell (six trials) and non-bell peppers (three trials) in the United States in 1996–1997.

The trials were conducted with a WG formulation. A total of 4 applications with an individual application of 75 g ai/ha were made. The re-treatment interval was 4–5 days.

Samples were collected 0–21 days after the last application and immediately frozen and stored at ≤ -18 ºC for up to 7 months prior to analysis.

Residues of indoxacarb and its R enantiomer in peppers were determined using analytical method AMR 3493-95. Procedural recoveries were conducted at fortification levels of 0.02, 0.1 and 0.2 mg/kg with recoveries in the range of 80–114 percent.

The two trials conducted in 1996 in Bradenton, FL were conducted at the same trial site. However, the dates of application and harvest were > 30 days apart and hence the trials can be regarded as independent trials. The two trials conducted in 1997 in Bradenton, FL were also conducted at the same trial site. As the varieties of pepper tested are significantly different Bell pepper vs non-bell pepper), these trials are regarded as independent trials.

A summary of the trials is outlined in Tables 5 and 6 for bell and non-bell peppers respectively.

Legume vegetables: Beans with pods

Snap beans/ common beans with pods

Nine residue trials were conducted on snap beans in the United States in 2005.

The trials were conducted with a WG formulation. A total of 4 applications in eight trials and 5 applications in one trial were made. The individual application rate was approximately 123 g ai/ha. The re-treatment interval was 5–8 days.

Samples were collected 0–13 days after the last application and immediately frozen and stored at ≤ -18 ºC for up to 203 days.

Residues of indoxacarb and its R enantiomer in snap beans were determined using analytical method AMR 271293. Procedural recoveries snap beans were conducted at fortification levels of 0.03 and 0.1 mg/kg with recoveries in the range of 91–109 percent.

The two trials conducted in Citra, FL were conducted at the same trial site. However, the application timings and harvest were > 30 days apart and hence the trials can be regarded as independent trials.

A summary of the trials is outlined in Table 7.

Pulses

Dry beans

Sixteen residue trials were conducted on dry beans in the United States in 2006.

The trials were conducted with an EG formulation. A total of 4 applications in fifteen trials and 5 applications in one trial were made. The individual application rate was approximately 123 g ai/ha. The re-treatment interval was 6–8 days.

Samples were collected 0–22 days after the last application and immediately frozen and stored at ≤ -18 ºC for up to 225 days prior to analysis.

Residues of indoxacarb and its R enantiomer in dry beans were determined using analytical method AMR 2712 93. Procedural recoveries for dry beans were conducted at fortification levels of 0.01, 0.3 and 1 mg/kg with recoveries in the range of 69–120 percent.

For the trials conducted in Velva, ND, Moxee, WA and Arlington, WI, replicate trials were conducted at the same time but with a different formulation type (WG formulation).

A summary of the trials is outlined in Table 8.

Root and tuber vegetables

Beetroot

Five residue trials were conducted on beetroot in the United States in 2004.

The trials were conducted with a WG formulation. A total of 4 applications were made. The individual application rate was approximately 123 g ai/ha. The re-treatment interval was 3–4 days.

Samples were collected 3–14 days after the last application and immediately frozen and stored at ≤ -18 ºC for up to 515 days, for root samples, and up to 519 days, for beetroot tops, prior to analysis.

Residues of indoxacarb and its R enantiomer in beetroot were determined using analytical method AMR 271293. Procedural recoveries were conducted at fortification levels of 0.01, 0.1 and 1 mg/kg with recoveries in the range of 83–104 percent.

Information was also provided on the residue levels in the beetroot tops/ leaves, but as this is not consumed by humans or livestock, the information has not been presented.

A summary of the trials is outlined in Table 9.

Cereal grains

Maize

Twenty one residue trials were conducted on maize in the United States in 2015.

The trials were conducted with an EC formulation. A total of 2 applications were made. The individual application rate was approximately 123 g ai/ha. The re-treatment interval was 4–6 days.

An adjuvant was used in the trials.

Grain samples were collected 12–14 days after the last application. samples were immediately frozen and stored at ≤ -18 ºC for up to 161 days prior to analysis.

Residues of indoxacarb and its R enantiomer were determined using analytical method DuPont 36189. Procedural recoveries were conducted at fortification levels of 0.01 and 0.1 mg/kg with recoveries in the range of 88–117 percent.

A summary of the trials is outlined in Table 10.

Tree nuts

Seventeen residue trials were conducted on almonds (six trials), pecan (six trials) and pistachios (five trials) in the United States in 2017.

The trials were conducted with three soil directed applications, at an individual rate of 0.757 g ai/ha, and with three foliar sprays, at an individual application rate of 124 g ai/ha. The soil directed applications were conducted with a RB formulation and the foliar applications were conducted with a WG formulation.

An adjuvant was used in the trials for the foliar applications. The label states that for best results an adjuvant should be used.

Samples of nutmeats were collected 0–15 days after the last application. Samples were immediately frozen and stored at ≤ -18 ºC for up to 319 days prior to analysis.

Residues of indoxacarb and its R enantiomer were determined using analytical method DuPont 36189. Procedural recoveries were conducted at fortification levels of 0.01 and 0.1 mg/kg with recoveries in the range of 93–108 percent.

The trials conducted in Fresno, CA, were conducted at different trial sites and are therefore regarded as independent trials.

A summary of the trials is outlined in tables 11, 12 and 13 for almonds, pecan and pistachios respectively.

PRIMARY FEED COMMODITIES OF PLANT ORIGIN

Legume animal feeds

Bean forage

Nine residue trials were conducted on bean (snap beans) forage in the United States in 2005.

The trials were conducted with a total of 4 applications in eight trials and 5 applications in one trial. The individual application rate was approximately 123 g ai/ha. The re-treatment interval was 5– days.

Samples were collected 0–13 days after the last application, at the same time as the fresh seed with pods were harvested. The samples were immediately frozen and stored at ≤ -18 ºC for up 205 days, prior to analysis.

Residues of indoxacarb and its R enantiomer in snap bean forage was determined using analytical method AMR 271293. Procedural recoveries for the whole plant were conducted at fortification levels of 0.5 and 10 mg/kg with recoveries in the range of 82–95 percent.

The two trials conducted in Citra, FL were conducted at the same trial site. However, the application timings and harvest were > 30 days apart and hence the trials can be regarded as independent trials.

A summary of the trials is outlined in Table 14.

Notes:

Values in parentheses = mean of two independent representative treated samples taken at the trial site.

† Trials regarded as independent as treatments > 30 days apart.

Maize forage and fodder (stover)

Twenty one residue trials were conducted on maize in the United States in 2015.

The trials were conducted with a total of 2 applications. The individual application rate was approximately 123 g ai/ha. The re-treatment interval was 4–7 days. At each trial site two replicate trials were conducted; one replicate to collect forage samples and one replicate to collect stover samples.

An adjuvant was used in the trials.

Forage samples were collected -0–29 days after the last application and stover samples were collected 12–14 days after the last application. Samples were immediately frozen and stored at ≤ -18 º for up to 161 days prior to analysis.

Residues of indoxacarb and its R enantiomer were determined using analytical method DuPont 36189. Procedural recoveries were conducted at fortification levels of 0.01, 0.1 and 5 mg/kg for forage

with recoveries in the range of 99–124 percent. For stover procedural recoveries were conducted at fortification levels of 0.01. 0.1 and 15 mg/kg with recoveries in the range of 67–108 percent.

A summary of the trials is outlined in Tables 15 and 16 for forage and stover respectively.

Almond hulls

Six residue trials were conducted on almonds the United States in 2017.

The trials were conducted with three soil directed applications, at an individual rate of 0.757 g ai/ha, and with three foliar sprays, at an individual application rate of 124 g ai/ha.

An adjuvant was used in the trials. The label states that for best results, use an adjuvant helps increase coverage, penetration and thus performance.

Samples of almond hulls were collected -0–15 days after the last application. Samples were immediately frozen and stored at ≤ -18 ºC for up to 319 days prior to analysis.

Residues of indoxacarb and its R enantiomer were determined using analytical method DuPont 36189. Procedural recoveries were conducted at fortification levels of 0.01, 0.1, 1 and 5 mg/kg with recoveries in the range of 86–104 percent.

The trials conducted in Fresno, CA were conducted at different trial sites and are therefore regarded as independent trials.

A summary of the trials is outlined in Table 17.

FATE OF RESIDUES DURING PROCESSING

The nature of the residue on processing was considered by the JMPR in 2005. It was concluded that indoxacarb was generally stable on hydrolysis. Approximately 7–30 percent was lost during baking and boiling conditions with the products of hydrolysis being minor and polar in nature.

The current Meeting received information on procedures simulating commercial processing practices for maize. Samples of grain were taken from trials conducted at a high and low application rate.

High application rate

Samples were taken from three trials. The trials were conducted in the United States in 2015 at an application rate of 2 × 616 g ai/ha with a RTI of 5 days. Grain was collected 14 days after the final application and processed into flour, starch, grits, dry milling meal, dry milling oil, wet milling meal and wet milling oil.

Production of processed fractions

After the removal from the freezer, representative whole grain samples were collected from the bulk samples before processing and placed into frozen storage. The moisture content was determined, and if this was > 15 percent the samples were dried at 54–71 °C until the moisture content was < 15 percent. Samples were then cleaned by aspiration and screening, with light impurities removed. After aspiration,

samples were screened in a Enhance 2 screen cleaner to separate large and small foreign particles (screenings) from the cleaned grain.

Dry milling

Samples of whole grain were moisture conditioned to 20–22 percent and tempered for approximately 2 hours. After tempering, the samples were fed into a disc mill to crack the kernels. The corn stock from the mill was dried for around 30 minutes at 54–71 °C. The dried corn stock was screened/sieved to separate bran, germ, grits, meal and flour. Where necessary, germ was milled, screened and/or aspirated to remove endosperm and hull material.

Germ fractions were dried at 54–71 °C. Samples of grits, meal and flour were collected and stored frozen prior to analysis.

To produce crude oil, germ material was heated to 71–79 °C and then flaked using a flaking roll. The flaked material was placed in a stainless-steel extractor and submerged in hexane at 48–60 °C. After 30 minutes, hexane was drained from the crude oil and the extraction process repeated two more times with fresh hexane. Following the third extraction and draining, hexane was removed from the spent flakes using ambient air. The hexane was removed from the crude oil by vacuum evaporation followed by heating to 91–96 °C. The crude oil was collected for refining.

The crude oil was subject to alkali refining. Based on the free fatty acid content of the crude oil, a specified amount of sodium hydroxide was added. The mixture was then heated in a water bath for 15 minutes at 20–24 °C and then for 12 minutes at 63–67 °C. Neutralized oil and soapstock were separated by centrifugation.

The alkali refined oil was then subjected to bleaching. The refined oil was heated to 40–50 °C and an activated bleaching earth added. The solution was then placed under a vacuum and stirred. The temperature was increased to 85–100 °C and held for 10–15 minutes after which the solution was allowed to cool. The bleaching oil was filtered and then placed in a steam bath at 220–230 °C for approximately 30 minutes under vacuum. The oil was allowed to cool and 0.5 percent citric acid solution was added. The resulting fraction (bleached-deodorized oil–refined oil) was collected and stored frozen prior to analysis.

Wet milling

A representative sample of grain was steeped in 48–54 °C water containing 0.1–0.2 percent sulfur dioxide for 22- 48 hours. At the end of this process, the water was drained, and a representative fraction collected and stored frozen prior to analysis. The steeped grain was passed through a disc mill and a majority of the germ and hull was then removed by a hydroclone filter. Germ and hulls were dried at 74–91 °C to achieve a final moisture content of between 5–10 percent. After drying, the germ and hulls were separated using aspiration and screening.

Corn stock, collected from the disc mill, was screened, with the bran (hull material) collected and discarded. The process water (starch and gluten combined) passing through the screen was separated into starch and gluten by centrifugation. The starch was dried in an oven at 54–71 °C until the moisture content was less than 15 percent. The starch was then stored frozen until analysis.

Germ samples were moisture conditioned to 12 percent, heated to 88–104 °C, flaked using a flaking roll and then pressed to liberate crude oil along with press-cake (with residual crude oil).

The press-cake was placed in a stainless-steel extractor and submerged in hexane at 49–60 °C. After 30 minutes hexane was drained from the crude oil and the extraction process repeated two more

times with fresh hexane. Following the third extraction and draining, residual hexane was removed with ambient air. The resulting solvent extracted press-cake was collected and stored frozen prior to analysis.

Hexane was removed from the crude oil by vacuum evaporation and heating the samples to 91–96 °C. The crude oil was then subjected to alkali refining, bleaching and deodorizing using the same process as outlined for dry milling. The resulting refined oil was collected and stored frozen prior to analysis.

Low application rate

Samples were taken from three trial sites where the application rate was 2 × 123 g ai/ha (trials 7, 12 and 21 summarized in Table 10). Samples of grain were collected from the bulk samples and stored and then analysed separately, from the field trial samples, prior to processing. The grain samples were processed into aspirated grain fractions.

Generation of Aspirated Grain Fraction (AGF)

To generate aspirated grain fractions, the moisture content of the samples was determined and if it was > 13 percent, the samples were dried at 43–57 °C until the moisture content was < 13 percent. Each sample was placed in a dust generation room containing a holding bin, two bucket conveyors, and a screw conveyor. As the samples moved in the system (120 minutes), aspiration was used to remove light impurities (grain dust). Light impurities were categorized using sieves of 2360 microns, 200 microns, 1180 microns, 850 microns and 425 microns. The samples passing through the 2360 micron sieve were combined to produce the AGF sample.

Storage stability and analysis

Processed fractions were stored for up to 28 days prior to analysis. Samples were analysed using analytical method DuPont 36189. Procedural recoveries were conducted at fortification levels of 0.01 and 0.1 for all processed fractions. For aspirated grain, procedural recoveries were also conducted at 0.3 mg/kg. The procedural recoveries obtained were: aspirated grain (67–108 percent), flour (89–104 percent), starch (92–111 percent), grits (84–93 percent), dry milling meal (85–103 percent), dry milling oil (88–109 percent), wet milling meal (94–108 percent) and wet milling oil (98–112 percent).

The residues in the treated maize grain and processed fractions are outlined in tables 18 and 19.

Table 18 Residues of indoxacarb in maize grain and processed fractions

APPRAISAL

Indoxacarb is an indeno-oxadiazine insecticide that is used for the control of lepidopteran and other insect pests. Indoxacarb was first evaluated by the 2005 JMPR when an ADI of 0–0.01 mg/kg bw and an ARfD of 0.1 mg/kg bw were established. The residue definition for compliance with the MRL for plant and animal commodities and dietary risk assessment for plant commodities is the sum of indoxacarb and its R enantiomer.

The residue definition for dietary risk assessment for animal commodities is: *sum of indoxacarb, its R enantiomer and methyl 7-chloro-2,5-dihydro-2-[[[4-(trifluoromethoxy)phenyl]amino] carbonyl]indeno[1,2-e][1,3,4]oxadiazine-4a(3H)- carboxylate, expressed as indoxacarb (IN-JT333*).

The residue is fat soluble.

Indoxacarb has been evaluated for additional uses in 2007, 2009 and 2013. At the Fifty-first Session of the CCPR, indoxacarb was scheduled for the evaluation by the current Meeting for additional uses on bush berries, okra, beans with pods, pulses, beetroot, maize and tree nuts. The present Meeting

received information on residue analysis, storage stability, use pattern, supervised field trials and processing.

Methods of analysis

The Meeting received information on analytical method DuPont 36189, used in the supervised residue trials for maize and tree nuts. The method was also used to determine residues in the processed fractions of maize. The method involved extraction with hexane-acetonitrile with final determination achieved using LC-MS/MS. The Meeting concluded that the method was validated for dry commodities and crops of a high oil content with an LOQ of 0.01 mg/kg for the sum of indoxacarb and its R enantiomer.

The meeting also received additional validation data to support methods, previously considered by the JMPR, used in the residue trials and new storage stability studies. The Meeting concluded that the methods were validated and are suitable to measures indoxacarb and its R enantiomer in blueberries, snap beans (beans with pods), dry beans, beetroots and maize.

For peppers, no additional validation data were provided for analytical method AMR 3493-95. The Meeting noted that the JMPR previously concluded that this method was validated at an LOQ of 0.02 mg/kg for apple and that procedural recovery data generated in the trials for peppers (bell and non-bell) was acceptable. The Meeting concluded that the method was sufficiently validated for peppers with an LOQ of 0.02 mg/kg.

Stability of pesticide residues in stored analytical samples

The Meeting noted that the 2005 and 2009 JMPR considered storage stability data for a range of crops. Based on the overall data available, the Meeting concluded that indoxacarb (and its R enantiomer) are stable for at least 24 months (high water crops), 11 months (high protein), 18 (high starch) and 11 months (high oil crops).

This Meeting received additional information on storage stability of indoxacarb (and its R enantiomer) in blueberries, peppers, snap beans, dry beans, beetroots and maize. The Meeting agreed that the data were sufficient to support the storage stability of indoxacarb (and its R isomer) for at least 17 months (blueberries), 11 months (peppers), 7 months (fresh beans), 7 months (dry beans), 18 months (beetroots) and 13 months (maize grain).

Results of supervised residue trials on crops

Supervised trials were available for the use of indoxacarb on blueberries, peppers, snap beans, dry beans, beetroots, maize grain and tree nuts. The residue levels reported are the sum of indoxacarb and its R enantiomer.

Bushberries

Blueberries

The critical GAP for bushberries is from the United States and consists of 4 foliar applications each at 123 g ai/ha with a re-treatment interval (RTI) of 7 days and a PHI of 7 days.

Residues of indoxacarb in independent trials, conducted in the United States, approximating the critical GAP were (n= 11): 0.25, 0.28, 0.35, 0.37, 0.47, 0.58, 0.58, 0.77, 0.81, 0.84 and 1.04 mg/kg.

Noting that the registered use is on bushberries and blueberry is a representative of this subgroup the Meeting decided to make a recommendation for the Subgroup of bushberries. The Meeting

estimated a maximum residue level of 2 mg/kg, a STMR of 0.58 mg/kg and a HR of 1.04 mg/kg for indoxacarb in the Bushberries subgroup.

Legume vegetables: Beans with pods

Snap beans/ common beans with pods

The critical GAP for beans with pods, except soya beans is from the United States and consists of 4 foliar applications each at 123 g ai/ha with a RTI of 7 days and a PHI of 3 days.

Residues of indoxacarb in independent trials approximating the critical GAP were (n= 8): 0.11, 0.12, 0.13, 0.15, 0.17, 0.17, 0.20 and 0.59 mg/kg.

The Meeting noted that the registered use is on beans with pods, except soya beans. Therefore, the Meeting estimated a maximum residue level of 0.9 mg/kg, a STMR of 0.16 mg/kg and a HR of 0.59 mg/kg for indoxacarb in the subgroup of Beans with pods, except soya beans.

Pulses

Dry beans

The critical GAP for dry beans, except soya beans is from the United States and consists of 4 foliar applications each at 123 g ai/ha with a RTI of 7 days and a PHI of 7 days.

Residues of indoxacarb in independent trials, conducted in the United States, approximating the critical GAP were (n= 12): < 0.01 (7), 0.01, 0.011, 0.022, 0.03 and 0.07 mg/kg.

The Meeting estimated a maximum residue level of 0.09 mg/kg, a STMR of 0.01 mg/kg for indoxacarb in dry bean.

The Meeting noted that the 2005 JMPR estimated maximum residue levels of 0.5 mg/kg for soya bean (dry) and 0.2 mg/kg for mung bean (dry). The 2009 JMPR estimated a maximum residue level of 0.1 mg/kg for cowpea (dry). On the basis of the previous recommendations and the GAP considered by the current Meeting for dry beans being different to the GAPs previously considered for cowpea, mung beans and soya bean, the current Meeting estimated a maximum residue level of 0.09 mg/kg and a STMR of 0.01 mg/kg for indoxacarb in the subgroup of dry beans, except cowpea, mung bean and soya bean.

Root and tuber vegetables

Beetroot

The critical GAP for beetroot is from the United States and consists of 4 foliar applications each at 123 g ai/ha with a RTI of 3 days and a PHI of 7 days.

Residues of indoxacarb, in independent trials, conducted in the United States, approximating the critical GAP were (n= 5): 0.12, 0.13, 0.18, 0.19 and 0.22 mg/kg.

The Meeting estimated a maximum residue level of 0.5 mg/kg, a STMR of 0.18 mg/kg and a HR of 0.22 mg/kg for indoxacarb in beetroots.

Cereal grains

Maize

The critical GAP for maize (field and popcorn) is from the United States and consists of 2 applications each at 123 g ai/ha with a RTI of 5 days and a PHI of 14 days.

Residues of indoxacarb in independent trials, conducted in the United States, approximating the critical GAP on field corn were (n= 21): < 0.01 (19), 0.011 and 0.012 mg/kg.

Noting that the registered use is on maize (field) and maize (popcorn) the Meeting decided to make a recommendation for the Subgroup of maize cereals. The Meeting estimated a maximum residue level of 0.015 mg/kg and a STMR of 0.01 mg/kg for indoxacarb in the subgroup of maize cereals.

Tree nuts

The critical GAP for tree nuts is from the United States and consists of 3 foliar applications each at 123 g ai/ha with a RTI of 7 days and a PHI of 5 days. The residue trials were conducted with 3 × 0.757 kg ai/ha, applied as a soil treatment, followed by 3 foliar applications at 124 g ai/ha with the RTI and PHI reflecting the GAP. The Meeting considered that the soil applications would not contribute significantly to residue levels at harvest and the trials could be used to support the GAP.

Almond

Six trials were conducted in the United States at a rate of 3 × 0.757 g ai/ha (applied as a soil treatment) along with 3 ×124 g ai/ha applied as a foliar treatment.

Residues of indoxacarb in independent trials approximating the critical GAP were (n=6): < 0.01, 0.011, 0.013, 0.016, 0.022 and 0.023 mg/kg

Pecan

Six trials were conducted in the United States at a rate of 3 × 0.757 g ai/ha (applied as a soil treatment) along with 3 × 124 g ai/ha applied as a foliar treatment

Residues of indoxacarb in independent trials approximating the critical GAP were (n=6): < 0.01, 0.01, 0.019, 0.028, 0.033 and 0.034 mg/kg

Pistachios

Residues of indoxacarb in independent trials approximating the critical GAP were (n=5): < 0.01 (2), 0.011, 0.018 and 0.045 mg/kg (highest individual value 0.046 mg/kg).

Summary–Tree nuts

Nothing that the median residues of indoxacarb for each tree nut type are within a 5- fold range and that there is no evidence of a difference in the residue populations for the different tree nuts by the Kruskal-Wallis test, the Meeting decided to make a recommendation for the Group of tree nuts based on the combined data.

Residues of indoxacarb in independent trials approximating the critical GAP were (n= 17): < 0.01 (5), 0.011 (3), 0.013, 0.016, 0.019, 0.022, 0.023, 0.028, 0.033, 0.034 and 0.045 mg/kg (highest individual value 0.046 mg/kg).

The Meeting estimated a maximum residue level of 0.07 mg/kg, a STMR of 0.013 mg/kg and a HR of 0.046 mg/kg for indoxacarb in tree nuts.

Residues in animal feed items

Bean forage

The critical GAP for bean forage is from the United States and consists of 4 applications each at 123 g ai/ha with a RTI of 7 days and a PHI of 3 days.

Residues of indoxacarb in independent trials, conducted in the United States, approximating the critical GAP were (n= 8): 6.8, 9, 10 (2), 12, 16.5, 17.4 and 32 mg/kg.

The Meeting estimated a median residue of 11 mg/kg and a highest residue of 32 mg/kg for indoxacarb in bean forage.

Maize forage

The critical GAP for maize forage is from the United States and consists of 2 applications each at 123 g ai/ha with a RTI of 5 days and a PHI of 1 day.

Residues of indoxacarb in independent trials, conducted in the United States, approximating the critical GAP were (n= 21): 0.78, 1.1, 1.2, 1.3 (3), 1.5 (4), 1.6, 1.7, 1.8, 2.0, 2.3 (2), 2.6, 2.7 (2), 2.8 and 3.4 mg/kg.

The Meeting estimated a median residue of 1.6 mg/kg (as received) and a highest residue of 3.4 mg/kg (as received) for indoxacarb in maize forage.

Maize stover

The critical GAP for maize fodder is from the United States and consists of 2 applications each at 123 g ai/ha with a RTI of 5 days and a PHI of 14 day.

Residues of indoxacarb in independent trials, conducted in the United States, approximating the critical GAP were (n= 21): 0.96, 1.1 (2), 1.3 (2), 1.6, 1.7 (2), 1.9, 2.4, 2.8, 3.0, 3.5, 3.7 (2), 3.8, 3.9, 4.2, 5.1, 5.9 and 9.1 mg/kg.

The Meeting noted that the residue levels in maize stover were covered by the GAP considered by the 2005 JMPR for sweet corn stover with a median residue of 3.7 mg/kg and a highest residue of 9.8 mg/kg. The Meeting noted that the previous recommendation was for maize fodder (dry). Therefore, the Meeting estimated a Maximum residue level of 25 mg/kg for maize stover based on the GAP for sweet corn stover and withdrew the previous recommendation of 25 mg/kg (dry) for maize fodder (dry).

Almond hulls

The critical GAP for tree nuts is from the United States and consists of 3 applications each at 123 g ai/ha with a RTI of 7 days and a PHI of 5 days.

Six trials were conducted in the United States at a rate of 3 × 0.757 g ai/ha (applied as a soil treatment) along with 3 × 124 g ai/ha applied as a foliar treatment. The residue trials were conducted with 3 × 0.757 kg ai/ha , applied as a soil treatment, followed by 3 foliar applications at 124 g ai/ha with the RTI and PHI reflecting the GAP. The Meeting considered that the soil applications would not contribute significantly to residue levels at harvest and the trials could be used to support the GAP.

Residues of indoxacarb in independent trials, conducted in the United States, approximating the critical GAP were (n= 6): 1.8, 2, 2.5, 2.8, 3.0 and 3.8 mg/kg.

The Meeting estimated a median residue of 2.65 mg/kg, a highest residue of 3.8 mg/kg and a maximum residue level of 9 mg/kg (dry weight) in almond hulls.

Fate of residues during processing

The Meeting received new information on the fate of indoxacarb (and its R enantiomer) residues during processing in maize. The Meeting noted that the individual processing factors for each processed fraction were significantly different and therefore decided not to estimate processing factors, MRLs, STMR-P and HR-P for processed commodities.

Residues in animal commodities

Farm animal feeding studies

The 2005 JMPR considered a lactating dairy cow feeding study and the 2009 JMPR considered a laying hen feeding study.

Farm animal dietary burden

Dietary burdens were calculated for beef cattle, dairy cattle, broilers and laying poultry based on the sum residue of indoxacarb and its R enantiomer and the feed items considered by the current Meeting and evaluated by the JMPR in 2005, 2007 and 2009. Some processed and forage commodities do not appear in the Recommendations Table (because no maximum residue level is needed), but they are used in estimating livestock dietary burdens.

The dietary burdens, estimated using the OECD diets listed in Appendix IX of the 2016 edition of the FAO manual, are presented in Annex 6 of the 2021 JMPR Report and summarised below.

Table 19 Estimated maximum and mean dietary burdens of farm animals

	Animal dietary burden: indoxacarb (and its R enantiomer) ppm of dry matter diet							
	United States-Canada		European Union		Australia		Japan	
	max	mean	max	mean	max	mean	max	mean
Beef cattle	8.769	3.503	23.36	12.4	72.06❶	25.26❸	4.329	1.629
Dairy cattle	21.78	8.273	33.45	11.89	71.06❷	24.60❹	15.01	6.007
Poultry – broiler	0.094	0.094	0.04	0.037	0.06	0.06	0.009	0.099
Poultry – layer	0.094	0.094	0.705❺	0.182❻	0.06	0.06	0.022	0.012

Notes:

❶ Highest maximum beef cattle dietary burden suitable for MRL estimates for mammalian tissues

❷ Highest maximum dairy cattle dietary burden suitable for MRL estimates for mammalian milk

❸Highest mean beef or dairy cattle dietary burden suitable for STMR estimates for mammalian tissues.

❹ Highest mean dairy cattle dietary burden suitable for STMR estimates for milk.

❺Highest maximum poultry dietary burden suitable for MRL estimates for poultry tissues and eggs.

❻Highest mean poultry dietary burden suitable for STMR estimates for poultry tissues and eggs.

Dietary burden and estimate of median residue	24.6	0.068	0.68	25.3	0.026	< 0.01	0.03	0.66

Notes:

† Total residue determined as indoxacarb, its R enantiomer and IN-JT333, expressed as indoxacarb in accordance with the residue definition for risk assessment.

** Residues < 0.01 mg/kg except for one sample.

Based on indoxacarb and its R enantiomer in milk, the Meeting estimated a maximum residue of 0.2 mg/kg for indoxacarb for milk, replacing the previous recommendation of 0.1 mg/kg. For cream, the Meeting estimated a HR of 2.2 mg/kg based on the sum of indoxacarb and its R enantomer. On the assumption of 40 percent milk fat in cream, the Meeting estimated a maximum residue level of 6 mg/kg for milk fats, replacing the previous recommendation of 2 mg/kg.

Based on indoxacarb and its R enantiomer in tissues, the Meeting estimated maximum residue levels of 2 mg/kg for mammalian meat (fat) and of 0.05 mg/kg for edible offal (mammalian), which

confirms the previous recommendations made by the 2009 JMPR. For fat the Meeting estimated a maximum residue level of 2 mg/kg.

Based on the mean estimated residues of indoxacarb, its R isomer and the metabolite IN-JT333 in milk and tissues, the Meeting estimated STMRs of 0.07 for milk, of 0.15 mg/kg for mammalian meat, of 0.03 mg/kg for edible offal (mammalian) and of 0.66 mg/kg for mammalian fat. The Meeting estimated an STMR of 0.68 mg/kg for cream and on the assumption of a fat content of 40 percent estimated an STMR of 1.7 mg/kg for milk fats.

Based on the highest estimated residues of indoxacarb, its R isomer and the metabolite IN-JT333 in tissues, the Meeting estimated HR of 0.46 mg/kg for mammalian meat, of 0.06 mg/kg for edible offal (mammalian) and of 1.90 mg/kg for mammalian fat.

Poultry

The new feed items considered by the current Meeting did not contribute significantly to the dietary burden of poultry and the Meeting confirmed its previous recommendations.

RECOMMENDATIONS

On the basis of the data obtained from supervised trials, the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessments.

Definition of the residue for compliance with the MRL and dietary risk assessment for plant commodities: *the sum of indoxacarb and its R enantiomer*

Definition of the residue for compliance with the MRL for animal commodities: *the sum of indoxacarb and its R enantiomer*

Definition of the residue for dietary risk assessment for animal commodities: *sum of indoxacarb, its R enantiomer and methyl 7-chloro-2,5-dihydro-2-[[[4- (trifluoromethoxy)phenyl]amino]carbonyl]indeno[1,2-e][1,3,4]oxadiazine-4a(3H)- carboxylate (IN-JT333), expressed as indoxacarb*.

The residue is fat-soluble.

Table 22 Residue levels suitable for establishing maximum residue limits and for IEDI and IESTI assessments

CCN	Commodity	Recommended maximum residue level (mg/kg)		STMR or STMR-P mg/kg	HR or HR-P mg/kg
		New	Previous		
AM 0660	Almond hulls	9 (dw)	-	2.65	3.8

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The ADI for indoxacarb is 0–0.01 mg/kg bw. The International Estimated Daily Intakes (IEDIs) for indoxacarb were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the JMPR. The results are shown in Annex 3 of the 2021 JMPR Report.

The IEDIs ranged from 2–20 percent of the maximum ADI. The Meeting concluded that long-term dietary exposure to residues of indoxacarb from uses considered by the JMPR is unlikely to present a public health concern.

Acute dietary exposure

The ARfD for indoxacarb is 0.1 mg/kg bw. The International Estimate of Short Term Intakes (IESTIs) for indoxacarb were calculated for the food commodities and their processed commodities for which HRs/HR-Ps or STMRs/STMR-Ps were estimated by the current Meeting and for which consumption data were available. The results are shown in Annex 4 of the 2022 JMPR Report.

The IESTIs varied from 0–20 percent of the ARfD for children and 0–10 percent of the ARfD for the general population. The Meeting concluded that acute dietary exposure to residues of indoxacarb from uses considered by the current Meeting is unlikely to present a public health concern.

INPYRFLUXAM (329)

The first draft was prepared by Dr Chris Anagnostopoulos, Benaki Phytopathological Institute, Greece

EXPLANATION

Inpyrfluxam (S-2399) is a broad spectrum fungicide belonging to the succinate dehydrogenase inhibitor (SDHI) group of fungicides which have a mode of action that inhibits energy production processes in pathogenic fungi.

Inpyrfluxam was scheduled at the Fifty-second Session of the CCPR (2022), for toxicology and residue evaluation as a new compound by the 2020 JMPR. The Meeting received information on identity, physical-chemical properties, fate of residues in the environment, plant and animal metabolism, rotational crops, analytical methods, storage stability, use patterns, residues resulting from supervised trials, fate of residues during processing and livestock feeding studies.

IDENTITY

ISO common name:	Inpyrfluxam
IUPAC name:	3-(Difluoromethyl)-1-methyl-*N*-[(3*R*)-1,1,3-trimethyl-2,3-dihydro-1*H*-inden-4-yl]-1*H*-pyrazole-4-carboxamide
Chemical Abstract name:	3-(Difluoromethyl)-*N*-[(3*R*)-2,3-dihydro-1,1,3-trimethyl-1*H*-inden-4-yl]-1-methyl-1*H*-pyrazole-4-carboxamide
Other names and codes	S-2399
CAS No.:	1352994-67-2
CIPAC No.	1005
Synonyms:	No synonyms
Structural Formula:	Molecular Formula:	$C_{18}H_{21}F_2N_3O$
Molecular Weight:	333.38 g/mol

Formulations

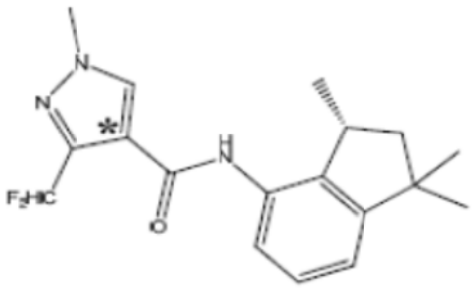
Inpyrfluxam (S-2399) is registered as a flowable concentrate (FC) formulation containing 34.05 percent w/v and as a suspension concentrate (SC) formulation containing 31.25 percent w/v or 37 percent w/v.

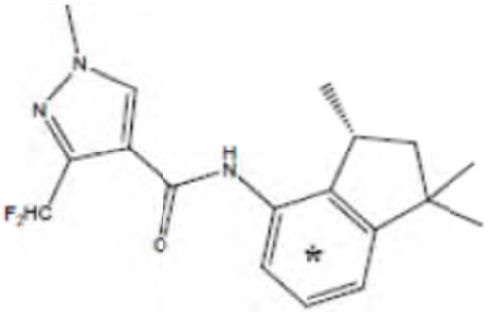
METABOLISM AND ENVIRONMENTAL FATE

The metabolism and environmental fate of inpyrfluxam was investigated in target crops (apples, soya bean, canola, corn, sorghum, rice and potatoes), rotational crops and livestock (laying hens and lactating

goats), soil, water and sediment systems (rice paddies). Chemical names, structures, and code names of metabolites and degradation products of inpyrfluxam are shown in Table 3. All the compounds were identified in at least one matrix in studies with radiolabelled inpyrfluxam.

The test substance chemical structures with the position of [^{14}C] radiolabel are shown below.

[Pyrazolyl-4-^{14}C] inpyrfluxam	[Phenyl-U-^{14}C] inpyrfluxam
	




Note:

Plant metabolism

The Meeting received studies depicting the metabolism of inpyrfluxam in apple (fruit crop), soya bean and canola (pulse and oilseed crops), maize, sorghum and rice (cereal crops) and potato (root crop).

Apple

The metabolism of inpyrfluxam in apples was investigated by Fleischmann (2018, Report TPM-0013). Inpyrfluxam was labelled at two positions; [pyrazolyl-4-^{14}C] inpyrfluxam (2.22 GBq/mmol, ≥ 96.7 percent purity) and [phenyl-U-^{14}C]inpyrfluxam (4.48 GBq/mmol, ≥ 98.3 percent purity) and applied in apple trees (Fuji variety) grown outdoors, at a test site in Madera, California, following foliar applications. A 40

percent SC formulation was isotopically diluted with distilled water to 21.4–22.1 mg ai/m^2 and applied three times (with a manually-operated, trigger-pulled, pump sprayer), with approximate 10-day intervals 35, 24 and 14 days before harvest (BBCH stage not specified in the report), at a nominal rate equivalent to 214–221 g ai/ha.

Samples of apple fruit and leaves were collected 14 days after the final application. Fruits were rinsed with acetonitrile and separated into peel and flesh before homogenisation. Processed samples were extracted twice with acetonitrile:water (1:1) and once with acetonitrile. Leaf samples although collected were not analysed.

All plant samples (extracts, rinses and post-extraction solids) were analysed by combustion/LSC to determine the total radioactive residues (TRR). The TRR of processed matrices were determined from combustion data and in the apple fruit is equal to the sum of fractions from the rinse, peel and pulp. The TRR in peel and flesh were determined from the summation of the residues in the extracts and the unextracted solids. Metabolites were identified by radio-HPLC, radio-TLC and LC-MS.

Apple peel extracts were initially stored in a freezer at approximately -17 °C until subjected to repeat analysis 665 days after the initial chromatography was performed. The profiles from the repeat analysis showed the overall ratio of inpyrfluxam, 3'-OH-S-2840 and 1'-CH_2OH-S-2840 to be similar indicating that resides were stable during the duration of the study.

The total radioactive residues (TRR) and extraction efficiency of the different solvent systems used in the study, as determined by LSC are presented in Table 4.

Table 4 Identification of residues in apple matrices treated with [pyrazolyl-4-^{14}C] inpyrfluxam and [phenyl-U-^{14}C] inpyrfluxam.

Fraction	[Pyrazolyl-^{14}C] radioactivity, %TRR (mg/kg)		[Phenyl-^{14}C] radioactivity, %TRR (mg/kg)	
	Apple rinse		Apple rinse	
Rinse with acetonitrile	64.0 (0.192)		58.2 (0.145)	
	Peel	Pulp	Peel	Pulp
Acetonitrile:water (Extract 1)	17.3 (0.052)	2.7 (0.008)	22.1 (0.055)	2.0 (0.005)
Acetonitrile:water (Extract 2)	8.0 (0.024)	1.3 (0.004)	9.6 (0.024)	1.6 (0.004)
Acetonitrile (Extract 3)	2.7 (0.008)	0.3 (0.001)	2.0 (0.005)	0.4 (0.001)
Total extractable, %TRR	*28.0 (0.084)*	*4.3 (0.013)*	*33.7 (0.084)*	*4.0*

	Total fruit		Total fruit	
Total TRR[1], (mg/kg) in whole fruit including rinse	96.3 (0.3)		95.9 (0.25)	

Notes:
PES: Post-extraction solids
1 TRR based on sum of extracts 1-3 + PES

The total TRR of the fruit rinse, peel and flesh was 0.30 mg/kg eq for the [pyrazolyl-^{14}C] label and 0.25 mg/kg eq for the [phenyl-^{14}C] label. The majority of radioactivity was recovered in the fruit rinse (58–64 percent TRR, 0.14–0.19 mg/kg eq) and first extracts (17–22 percent TRR, 0.052–0.055 mg/kg eq) for both radiolabels. Radioactivity in the flesh was markedly lower than in the peel for both treatment groups. unextracted solids contained ≤0.014 mg/kg eq (4.7 percent TRR).

The chromatographic profiles for both labels were similar. Parent inpyrfluxam was the only major component found in all samples, ranging from 1.0 percent TRR (0.002 mg/kg) in flesh to 57 percent TRR

(0.13 mg/kg eq) in the fruit rinse. Minor metabolites identified were 3'-OH-S-2840, which was detected in all matrices at levels not exceeding 0.021 mg/kg eq (6.8 percent TRR) and 1-CH_2OH-S-2840, detected in the flesh and peel at levels ≤0.011 mg/kg eq (4.3 percent TRR). In pulp, several unidentified metabolites were observed for both radiolabels. However, no unidentified metabolites exceeded 1 percent TRR and 0.01 mg/kg eq. TLC and HPLC confirmed the presence of the identified metabolites (reference compounds used are presented in Table 3). The distribution of metabolites in each sample matrix is displayed in Table 5.

Chiral-HPLC analysis of inpyrfluxam from the test substance formulation and apple fruit extracts showed that no isomerisation of the chiral centre was observed during the course of the study.

The metabolism of inpyrfluxam in/on apples proceeds by oxidation to form the hydroxylated metabolites, 3'-OH-S-2840 and 1'-CH_2OH-S-2840 (Figure 1).

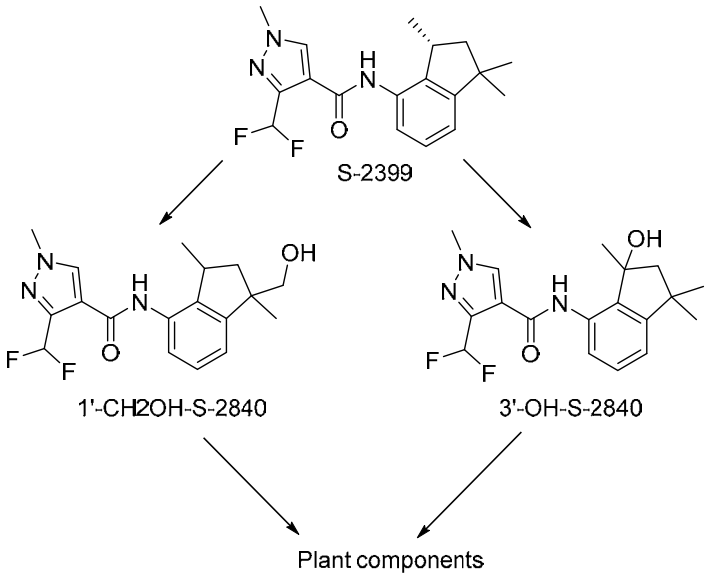

Figure 1 Proposed metabolic pathway of inpyrfluxam in apple after foliar application

Soya bean–foliar application (pulse and oilseed crops)

The metabolism of inpyrfluxam in soya beans was investigated by Fleischmann (2017, Report TPM-0015). The test system was soybean plants grown in a sandy loam soil in plots located outdoors at a test site in Madera, California.

Inpyrfluxam was labelled at two positions; [pyrazolyl-4-^{14}C] inpyrfluxam (2.22 GBq/mmol, ≥95.4 percent purity) and [phenyl-U-^{14}C] inpyrfluxam (4.48 GBq/mmol, ≥95.1 percent purity) in soya beans (var. Glycine max) following two foliar applications. A 40 percent SC formulation was isotopically diluted with distilled water to 10.7–11.3 mg ai/m^2 and applied twice with a 36-day interval (at BBCH 60 and 75) at a rate equivalent 107–113 g ai/ha.

Samples of soya bean forage and soya bean hay were collected 20 and 33 days after the final application (forage harvested at BBCH 75 and dried plants picked up as hay 3 days later), samples of immature pods were taken 11 days after the last application (BBCH 77) and mature pods were taken 53 days after the final application (BBCH 89). Samples were separated into pods and seeds and a portion of mature bean pods were rinsed before homogenisation.

In all samples, with the exception of soya bean hay samples from the [pyrazolyl-^{14}C] inpyrfluxam treatment group, residues were extracted twice with acetonitrile:water (1:1) and once with acetonitrile. Further extraction of the post-extraction solids (PES) was performed when >10 percent total radioactive residues (TRR) and >0.05 mg/kg was detected. Sequential extraction procedures solubilised plant natural components into a mixture of pectin (acetonitrile:0.1 M HCl (1:1)) followed by EGTA (Egtazic acid) in sodium acetate buffer, lignin (DMSO), hemicellulose (24 percent KOH) and cellulose (72 percent H_2SO_4) fractions. The hemicellulose extracts containing >10 percent TRR were partitioned with ethyl acetate. In soya bean hay samples from the [pyrazolyl-^{14}C] inpyrfluxam treatment group, initial extracts were purified by solid phase extraction (C_{18} cartridge), concentrated to dryness and reconstituted in 0.1 percent formic acid in water:acetonitrile for LC-MS/MS.

All plant samples (extracts, rinsates and post-extraction solids) were analysed by combustion/LSC to determine the total radioactive residues (TRR). Metabolites were identified by HPLC, TLC, LC-MS and LC-MS/MS (reference compounds used are presented in Table 3).

The total radioactive residues (TRR) and extraction efficiency of the different solvent systems used in the study, as determined by LSC are presented in Tables 6 and 7.

Note:
[a] TRR based on sum of rinse + extracts + PES (initial).

The sample extracts and rinsates were subjected to HPLC, TLC and LC-MS characterisation. Samples were stored in a freezer at approximately -17 °C until subjected to repeat extraction and analysis 364 days after the initial chromatographic analyses. The TRR values from the storage stability extractions were similar (within 5 percent) of the initial TRR of the immature rice plants. The chromatographic profiles from repeat analyses of the immature rice extracts showed a slight decrease in the level of 3'-OH-S-2840 in the [phenyl-^{14}C]inpyrfluxam labelled sample after freezer storage. Additional stability analyses performed on rice straw, rice hulls and rice grain extracts demonstrated similarity to the original results for both radiolabels.

Parent inpyrfluxam was extensively metabolised in soya beans. Characterisation of the residues showed the parent compound, inpyrfluxam accounted for the major part of the residue in forage samples (40.3–50.5 percent TRR, 0.561–0.786 mg/kg eq) but declined as the plant matured. Residues of inpyrfluxam in hay were between 0.424–0.495 mg/kg (17.8–22.1 percent TRR). In edamame (immature) pods, parent levels ranged from 0.241–0.414 mg/kg (34.0–65.2 percent TRR) and in mature pods ranged from 0.130–0.216 mg/kg (10.9–29.2 percent TRR), including the surface rinse fraction. Only trace levels of inpyrfluxam residues were detected in the soya bean seeds.

In forage, 3'-OH-S-2840 was present at the highest levels (15.3–22.1 percent TRR, 0.238–0.308 mg/kg). *N*-des-Me-S-2840 whilst 1'-CH_2OH-S-2840B was identified but in low levels below 3.7 percent TRR (0.058 mg/kg). As the plants matured, the residue levels of the metabolites decreased.

In hay, 3'-OH-S-2840 was present at the highest levels (14.3–14.7 percent TRR, 0.321–0.349 mg/kg), whilst *N*-des-Me-S-2840 was detected at low levels (≤2.4 percent TRR, 0.05 mg/kg). Also, the minor metabolites 1'-CH_2OH-S-2840B, which was exclusive to the [pyrazolyl-^{14}C]inpyrfluxam-treated hay and the sugar conjugate isomers, Glc-NDM-inpyrfluxam, exclusive to the [phenyl-^{14}C]inpyrfluxam labelled samples, were detected.

In immature pods metabolites, 3'-OH-S-2840 and *N*-des-Me-S-2840 were identified in both labels and 1'-CH_2OH-S-2840B was detected only in the [phenyl-^{14}C] label at levels below 10 percent TRR. Unretained polar components amounted to 26.8 percent TRR (0.191 mg/kg) for the [pyrazolyl-^{14}C] label.

In immature seeds, *N*-des-Me-DFPA and *N*-des-Me-S-2840 were detected but in all cases at levels were below 10 percent TRR. The majority of the residue (61.6 percent TRR, 0.067 mg eq/kg) was characterised as multiple polar components with a single component representing 4.6 percent TRR (0.005 mg eq/kg) and not further characterized.

In mature pods, for the [phenyl-^{14}C] label, 3'-OH-S-2840 was identified as the most dominant metabolite at 11.6 percent TRR (0.086 mg/kg), whilst *N*-des-Me-S-2840 and 1'-CH_2OH-S-2840B were also characterized at low levels <3.9 percent TRR. For the [pyrazolyl-^{14}C] label, polar components were present at high levels (48.9 percent TRR, 0.588 mg/kg), with 3'-OH-S-2840, *N*-des-Me-S-2840 and a *N*-des-Me-DFPA conjugates all detected at levels no greater than 2.1 percent TRR.

In seed, the major fraction contained unretained polar components (11.7-63.8 percent TRR, 0.004-0.140 mg/kg). In [pyrazolyl-^{14}C]inpyrfluxam treated seeds, the *N*-des-Me-DFPA conjugate (17.5 percent TRR, 0.038 mg/kg) was also detected, which was characterized as *N*-glycoside by acid hydrolysis. Following [phenyl-^{14}C]inpyrfluxam treatment, 3'-OH-S-2840, Glc-NDM-inpyrfluxam and 1'-CH_2OH-S-2840B were characterized at low levels <10 percent TRR.

The distribution of metabolites in each sample matrix is displayed in Table 8 and the proposed metabolic pathway of inpyrfluxam in soya bean after foliar application is shown in Figure 2.

Table 8 Nature of residue in soya beans treated with [Pyrazolyl-4-^{14}C] inpyrfluxam and [Phenyl-U-^{14}C] inpyrfluxam analysed by HPLC analysis

Notes:
ND: Not detected.
[a] Sum of isomers.
[b] Unretained by HPLC, TLC revealed multiple components present.

Chiral-HPLC analysis of inpyrfluxam from the test substance formulation and in the extracts was not performed in the current study.

Samples were stored frozen (-17 °C) between harvest and analysis. All samples were extracted and metabolite characterisation performed within 90 days of sampling, therefore storage stability data are not required. However, the chromatographic system for characterisation of the soluble residues was modified to provide better resolution of the component peaks. Therefore, selected sample extracts and matrices were reanalysed, providing storage stability data. Harvest 4 [pyrazolyl-^{14}C]inpyrfluxam mature seed extract was analysed for storage stability 624 days after the initial analysis and no substantial changes were observed, indicating that resides were stable during the duration of the study.

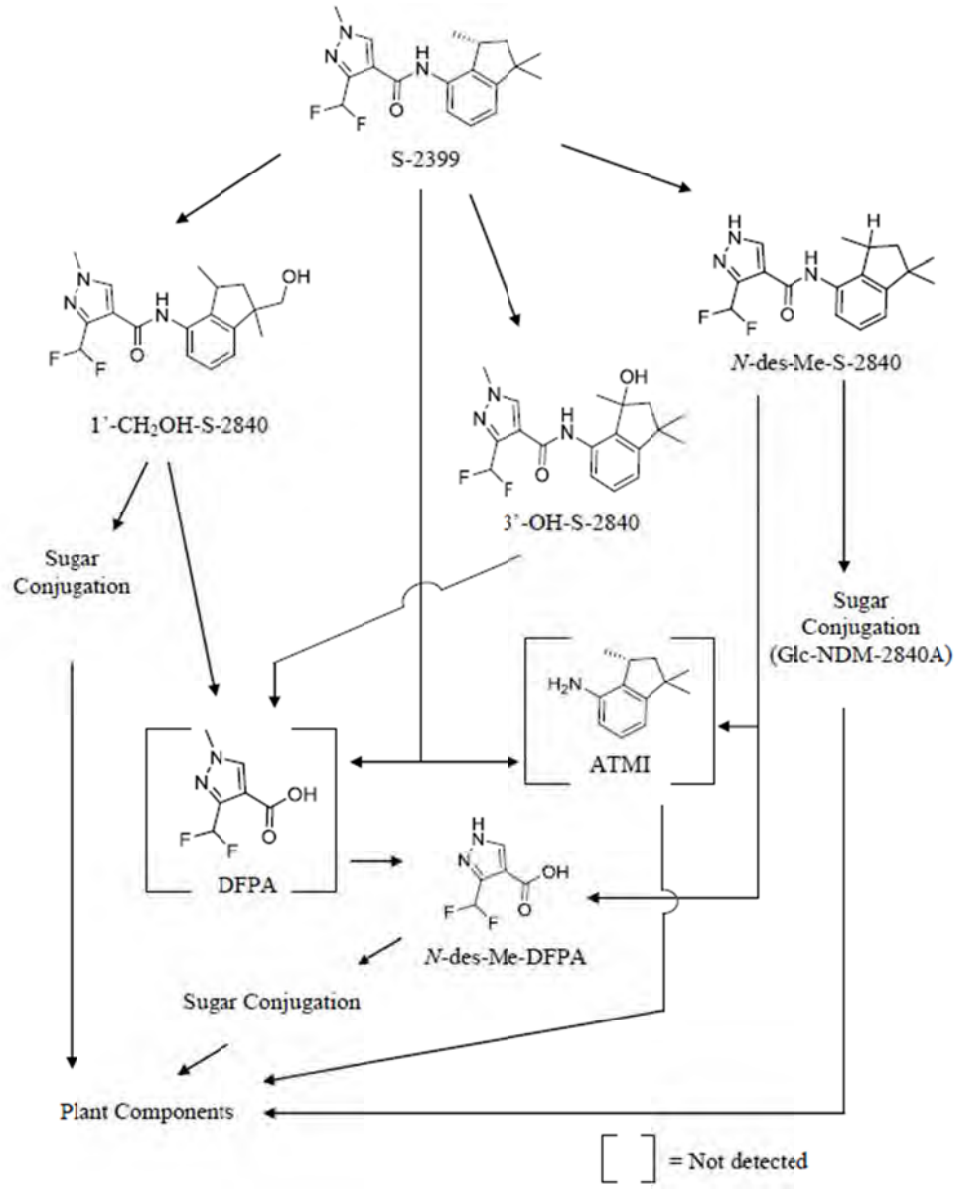

Figure 2 Proposed metabolic pathway for inpyrfluxam in soya bean after foliar application

Maize-seed application (cereal crops)

The metabolism of inpyrfluxam in corn (seed treatment) was investigated by Hguyen *et al*. (2016, Report TPM-0017). The test system was corn seeds grown in a sandy loam soil in plots located outdoors at a test site in Tulare County, California in the year 2014.

Inpyrfluxam was labelled at two positions; [pyrazolyl-4-^{14}C]inpyrfluxam (2.11 GBq/mmol, 97.8 percent purity) and [phenyl-U-^{14}C]inpyrfluxam (4.51 GBq/mmol, 99 percent purity) and applied in corn (var. TA 304-02) following seed application. Corn seeds were first coated uniformly with blank formulation before being individually spiked with the test substance and planted after 3–4 days. Treatments of either [pyrazolyl-^{14}C]inpyrfluxam or [phenyl-^{14}C]inpyrfluxam were made at a target rate of 0.014 mg ai/seed (49.6 g ai/tonne seeds).

Samples of forage, stover, grain, sweet corn were harvested from individual plots. Corn forage was sampled at late dough/early dent stage, sweet corn (kernels plus cob with husks removed at the

milk/succulent stage, approximately 95 days after planting) and stover and grains were harvested at maturity, when grain was separated from the cob (approximately 126 days after planting). Grain-free mature cobs and stalks were processed as corn stover.

Samples were homogenised and analysed to determine the total radioactive residue (TRR) by LSC however ^{14}C-residues were not found above the LOQ (0.005 mg/kg) in the sweetcorn, forage, stover and grain in both labels, thus no metabolite identification was required.

Sorghum-seed application (cereal crops)

The metabolism of inpyrfluxam in sorghum (seed treatment) was investigated by Hguyen *et al.* (2016, Report TPM-0017). The test system was sorghum seeds grown in a sandy loam soil in plots located outdoors at a test site in Tulare County, California in the year 2014.

Inpyrfluxam was labelled at two positions; [pyrazolyl-4-^{14}C]inpyrfluxam (2.11 GBq/mmol, 97.8 percent purity) and [phenyl-U-^{14}C]inpyrfluxam (4.51 GBq/mmol, 99 percent purity) and applied in sorghum (var. GA 3543) following seed application. Sorghum seeds were treated with a slurry prepared by mixing the test substance with the blank formulation and an appropriate volume of water. Treatments of either [pyrazolyl-^{14}C]inpyrfluxam or [phenyl-^{14}C]inpyrfluxam were made at a target rate of 50 g ai/tonne seeds.

Samples of sorghum were harvested from individual plots. Sorghum forage samples were collected at the soft dough to hard dough stage. The remaining plants were harvested at maturity and separated into grain and stover. Samples were homogenised and analysed to determine the total radioactive residue (TRR) by LSC. ^{14}C-residues were not found above the LOQ (0.005 mg/kg) in the sorghum forage, grain and stover samples in both labels, thus no metabolite identification was required.

Rice (cereal crops)–foliar treatment

The metabolism of inpyrfluxam in rice (foliar treatment) was investigated by Fleischmann *et al.* (2017b, Report TPM-0014). The test system was rice seeds (CM205 variety) grown in trays and transplanted (at the 4 leaf stage of growth) in plots (clay soil, pH 7.8) located outdoors at a test site in Madera, California.

Inpyrfluxam was labelled at two positions; [pyrazolyl-4-^{14}C]inpyrfluxam (2.22 GBq/mmol, ≥ 96.4 percent purity) and [phenyl-U-^{14}C]inpyrfluxam (4.48 GBq/mmol, ≥98.8 percent purity) in rice (var. *Oryza sativa L.*) following foliar application. A 40 percent SC formulation was isotopically diluted with distilled water to 95–108.1 mg ai/ha and applied once 28 days (at BBCH 77) before normal commercial harvest

Samples of the immature whole plant (BBCH not specified) were taken for analysis 14 days after application. Samples of rice heads and straw were collected at normal commercial harvest, 28 days after application and rice heads were separated into brown rice and hulls. Homogenised samples were extracted twice with acetonitrile:water (1:1) and once with acetonitrile. Further sequential extraction procedures solubilised plant natural components into a mixture of pectin (acetonitrile:0.1 M HCl (1:1) followed by EGTA (egtazic acid) in sodium acetate buffer, lignin (DMSO), hemicellulose (24 percent KOH) and cellulose (72 percent H_2SO_4) fractions. Sample extracts containing parent compound were partitioned with hexane:water to isolate the parent in the hexane fraction. The hexane extracts were combined, concentrated and subject to further analysis using chiral chromatography. The hemicellulose extracts containing >10 percent TRR were partitioned three times with ethyl acetate before analysis of the organic fractions by HPLC. All plant samples (extracts and post-extraction solids) were analysed by LSC to determine the total radioactive residues (TRR). Metabolites were identified by radio-HPLC and TLC-radioluminography.

The total radioactive residues (TRR) and extraction efficiency of the different solvent systems used in the study, as determined by LSC are presented in Table 9 and Table 10.

Notes:

[a] TRR based on sum of extracts + PES (initial).

[b] Individual extracts were combined prior to radioanalysis.

All plant samples (extracts and post-extraction solids) were analysed by LSC to determine the total radioactive residues (TRR). Metabolites were identified by HPLC and TLC characterisation.

In immature rice, the only major component for both radiolabels detected in the neutral extract was parent inpyrfluxam, present at 81.2–86.7 percent TRR (0.247–0.308 mg/kg). The metabolite, 3′–OH-S2480 was detected at the next highest level, between 5.6–7.1 percent TRR (0.016–0.027 mg/kg), with trace levels of *N*-des-Me-S-2840 and 1'-CH_2OH-S-2840 (two isomers) also detected in both labelled extracts. The acidic acetonitrile extracts for both labels contained predominantly parent at 2.5 percent TRR (0.007 mg/kg) and 3.4 percent TRR (0.013 mg/kg) for the [pyrazolyl-^{14}C] and [phenyl-^{14}C] labels, respectively.

In rice grain and rice straw, chromatographic profiles were similar. In grain, inpyrfluxam accounted for 60.6 percent TRR (0.039 mg/kg) and 78.6 percent TRR (0.038 mg/kg) for the [pyrazolyl-^{14}C] and [phenyl-^{14}C] labels, respectively. 3'-OH-S-2840 was present at low levels between 5.9 percent TRR (0.004 mg/kg) and 7.0 percent TRR (0.003 mg/kg). The sugar conjugate, Gly-1'-CH_2OH-S-2840 was present at higher levels in the [pyrazolyl-^{14}C] treated samples at 16 percent TRR (0.010 mg/kg) than the [phenyl-^{14}C] treated samples (3.1 percent, 0.002 mg/kg).

Similarly, in the straw samples, inpyrfluxam was present as the major residue (67.7-77.8 percent TRR, 0.576-0.721 mg/kg) and 3'-OH-S-2840 was detected at the next highest level of 12 percent TRR (0.102 mg/kg) and 6 percent TRR (0.055 mg/kg) for the [pyrazolyl-^{14}C] and [phenyl-^{14}C] labels, respectively. In the [pyrazolyl-^{14}C] label, the conjugate, Gly-1'-CH_2OH-S-2840 and DFPA-$CONH_2$ were detected at 5.2 percent TRR (0.040 mg/kg) and 4.6 percent TRR (0.039 mg/kg), respectively. In both labels, trace levels of *N*-des-Me-S-2840 and 1'-CH_2OH-S-2840 were also found. Characterisation of the acidic acetonitrile extracts from both radiolabels showed that the majority of residues were from the parent, inpyrfluxam. Partitioning of the base soluble extracts with ethyl acetate resulted in 1.1 percent TRR (0.009 mg/kg) and 1.2 percent TRR (0.011 mg/kg) in the organic fractions from the [pyrazolyl-^{14}C]inpyrfluxam and [phenyl-^{14}C]inpyrfluxam treated samples, respectively.

In rice hulls, residues from both the [pyrazolyl-^{14}C]inpyrfluxam and [phenyl-^{14}C]inpyrfluxam treatments were characterised as a mixture of inpyrfluxam, at levels of 41.8 percent TRR (0.639 mg/kg) and 52.5 percent TRR (0.881 mg/kg), 1'-CH_2OH-S-2840, detected at 33.9 percent TRR (sum of isomers; 0.517 mg/kg) and 18 percent TRR (0.277 mg/kg) and 3'-OH-S-2840at 12 percent TRR (0.102 mg/kg) and 6 percent TRR (0.055 mg/kg), respectively. The major component in the acidified acetonitrile extracts for each label was inpyrfluxam, at 1.9-3.3 percent TRR (0.029-0.055 mg/kg).1'-CH_2OH-S-2840 (1.6 percent TRR, 0.024 mg/kg) was also detected in the extract from the [pyrazolyl-^{14}C] label. Partitioning of the base soluble fractions with ethyl acetate released 1.6 percent TRR (0.025 mg/kg) and 2.4 percent TRR (0.041 mg/kg) in the organic fractions from the [pyrazolyl-^{14}C]inpyrfluxam and [phenyl-^{14}C]inpyrfluxam treated samples, respectively. The main component in the organic fraction was inpyrfluxam. For both labels, there were also small amounts of undifferentiated peaks that were consistent with sugar conjugates of 1'-CH_2OH-S-2840.

The distribution of metabolites in each sample matrix is displayed in Table 11 and the proposed metabolic pathway of inpyrfluxam in rice after foliar application is shown in Figure 3.

Note:
[a] Sum of isomers.

Chiral separation of the hexane soluble fractions showed only the R-enantiomer of inpyrfluxam was present in rice sample extracts. No isomerisation of the chiral carbon in inpyrfluxam occurred between the time of application and sample harvest in this study.

Samples were stored in a freezer at approximately -17 °C until subjected to repeat extraction and analysis 364 days after the initial chromatographic analyses. The TRR values from the storage stability extractions were similar (within 5 percent) of the initial TRR of the immature rice plants. The chromatographic profiles from repeat analyses of the immature rice extracts showed a slight decrease (5.2 percent) in the level of 3'-OH-S-2840 in the [phenyl-^{14}C]inpyrfluxam labelled sample after freezer storage. Additional stability analyses performed on rice straw, rice hulls and rice grain extracts demonstrated similarity to the original results for both radiolabels, indicating that resides were stable during the duration of the study.

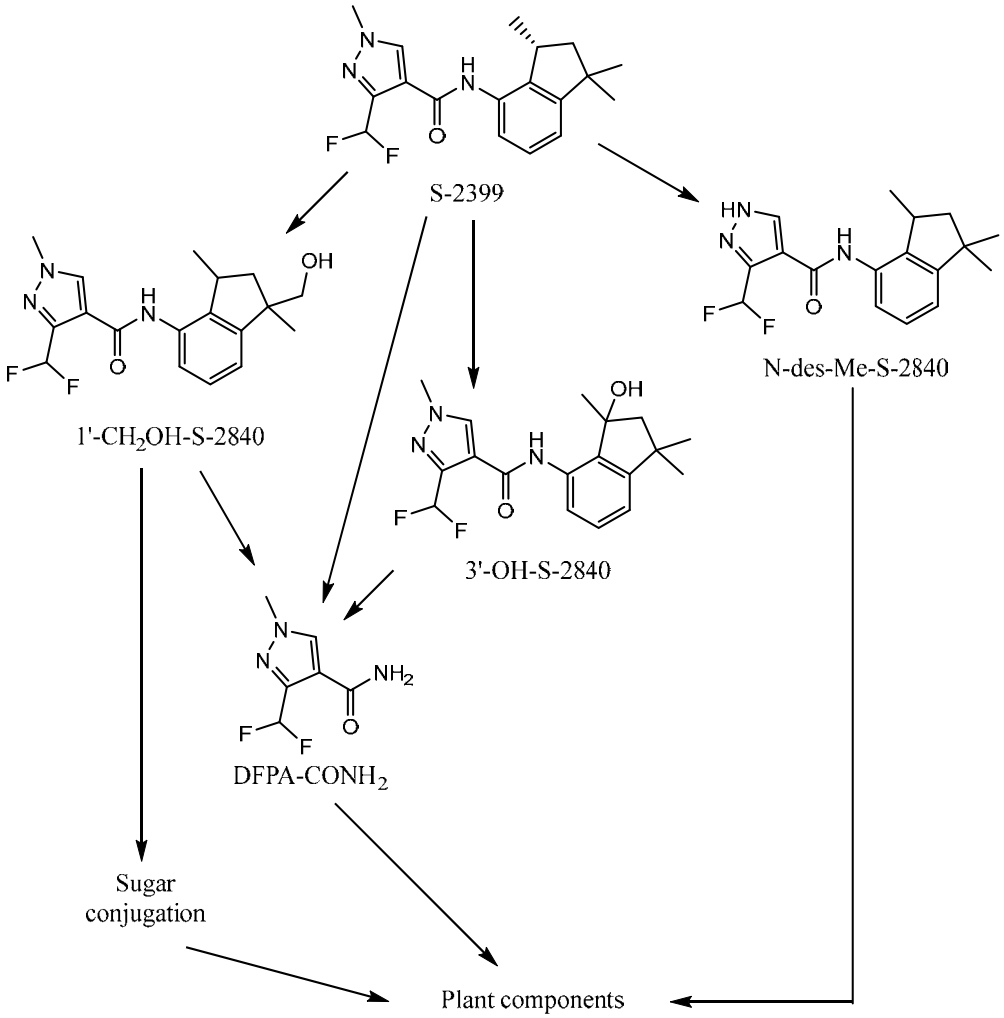

Figure 3 Proposed metabolic pathway of inpyrfluxam in rice after foliar application

Rice (cereal crops)–granular treatment

The metabolism of inpyrfluxam in rice (granular treatment) was investigated by Fleischmann (2017, Report TPM-0016). The test system was rice seeds (CM205 variety) grown in trays (above ground wooden boxes) and transplanted (at the 4 leaf stage of growth) in plots (clay soil, pH 7.8 and 1.1 percent organic matter) located outdoors without protection except a wind break at a test site in Madera, California. The crops were irrigated with 19–38mm water per irrigation event.

Inpyrfluxam was labelled at two positions; [pyrazolyl-4-^{14}C]inpyrfluxam (2.22 GBq/mmol, ≥ 97.1 percent purity) and [phenyl-U-^{14}C]inpyrfluxam (4.48 GBq/mmol, ≥ 95.9 percent purity) in rice (*Oryza sativa L.*) following granular application. A 4 percent granular formulation was applied in a single application (at BBCH 13–14) at a nominal rate equivalent to 400 g ai/ha (equivalent to 2 g ai/nursery box).

Immature rice plants were harvested 30 days after application (BBCH 30) and mature rice plants were harvested 132 days after treatment (BBCH 89) and were separated into straw, hulls and rice grain.

Homogenised samples were extracted twice with acetonitrile:water (1:1) and once with acetonitrile. Further sequential extractions solubilised plant natural components into a mixture of pectin (acetonitrile:0.1 M HCl (1:1)) followed by EGTA (egtazic acid) in sodium acetate buffer, lignin (DMSO), hemicellulose (24 percent KOH) and cellulose (72 percent H_2SO_4) fractions. Sample extracts containing

parent compound were partitioned with hexane:water to isolate the parent in the organic fraction. The hexane extracts were combined, concentrated and subjected to further analysis using a chiral chromatography. The hemicellulose extracts containing >10 percent TRR were partitioned three times with ethyl acetate before analysis of the organic fractions by HPLC.

The total radioactive residues (TRR) and extraction efficiency of the different solvent systems used in the study, as determined by LSC are presented in Table 12 and Table 13.

Note:
† TRR based on sum of extracts + PES (initial).

All plant samples (extracts and post-extraction solids) were analysed by LSC to determine the total radioactive residues (TRR). Metabolites were identified by radio-HPLC and TLC-radioluminography. Which reference compounds were used.

In immature rice plants, parent inpyrfluxam accounted for a large proportion of the residues at 20 percent and 38.2 percent TRR (0.779 mg/kg and 0.721 mg/kg) for the [pyrazolyl-^{14}C] and [phenyl-^{14}C] labelled samples, respectively. In addition, 1'-CH_2OH-S-2480 (sum of isomers, 5.8–6.2 percent TRR, 0.109–0.241 mg/kg), 3'-OH-S-2840 (1.2-3.6 percent TRR, 0.023–0.142 mg/kg) and DFPA-$CONH_2$ (pyrazolyl label only, 2.2 percent TRR, 0.086 mg/kg) were also identified. Another dominant residue existed as the glycosidic derivative of 1'-CH_2OH-S-2840, which was present at 16.8–26.0 percent TRR (0.315–1.010 mg/kg).

In mature straw, 1'-CH_2OH-S-2840 and its glycosidic derivatives existed as the major components at 23.6–25.7 percent TRR (0.273–0.342 mg/kg) and 31.7–38 percent TRR (0.407–0.498 mg/kg), respectively. inpyrfluxam accounted for 0.030 mg/kg (1.9–2.8 percent TRR) for both radiolabels, whilst *N*-des-Me-DFPA, 3'-OH-S-2840 and DFPA-$CONH_2$ were identified in the [pyrazolyl-^{14}C] labelled sample extracts at levels ≤2.1 percent TRR (0.034 mg/kg).

In mature rice hulls residues from the [pyrazolyl-^{14}C]inpyrfluxam consisted of 1'-CH_2OH-S-2840 as the most dominant residue (40.1 percent TRR, 0.070 mg/kg), followed by DFPA-$CONH_2$ (17.5 percent TRR, 0.031 mg/kg) and *N*-des-Me-DFPA (5.3 percent TRR, 0.009 mg/kg). Parent was not detectable, indicating extensive metabolism in hulls. In the [phenyl-^{14}C] labelled hull samples, 1'-CH_2OH-S-2840 was detected at 50.8 percent TRR (0.080 mg/kg) and its glycosidic conjugates were present at 9.4 percent TRR (0.015 mg/kg).

In rice grain residues from the [pyrazolyl-^{14}C]inpyrfluxam label, were very low, with DFPA and/or *N*-des-Me-DFPA constituting the major residues (23.1 percent TRR, 0.002 mg/kg), whilst DFPA-$CONH_2$ (1.5 percent TRR, ≤ 0.001 mg/kg) and 1'-CH_2OH-S-2840 (4.7 percent TRR, ≤ 0.001 mg/kg) were also identified. Grain from the [phenyl-^{14}C]inpyrfluxam treated rice contained residues of 1'-CH_2OH-S-2840 (6.8 percent TRR, ≤ 0.001 mg/kg). No parent was detectable for either radiolabel.

The distribution of metabolites in each sample matrix is displayed in Table 14 and the proposed metabolic pathway of inpyrfluxam in rice after granule application is shown in Figure 4.

Chiral separation of the hexane soluble fractions showed only the R-enantiomer of inpyrfluxam was present in rice sample extracts. No isomerisation of the chiral carbon in inpyrfluxam occurred between the time of application and sample harvests in this study.

Samples were stored in a freezer at approximately -27 °C after harvest. Immature rice plants were extracted 48 days after harvest. Initial chromatographic profiling of the [pyrazolyl-4-^{14}C] residues from rice forage was performed 61 days after harvest. Enzyme hydrolysis of this extract, performed 307 days after the initial analysis showed a similar magnitude of inpyrfluxam to the 61 day extract, demonstrating stability of inpyrfluxam when stored frozen for up to 307 days. Comparison of residue components following re-extraction after 429 days of frozen storage showed that the magnitude of the major components inpyrfluxam, 3'-OH-S-2840 and 1'-CH_2OH-S-2840 were similar for the [pyrazolyl-^{14}C] label. Similarly, the [phenyl-^{14}C] label extracts showed the magnitude of the major components inpyrfluxam, 3-OH-S-2840, 1'-CH_2OH-S-2840 and the peak characterised as glycosides of 1'-CH_2OH-S-2840 were similar in rice forage stored frozen for up to 196 days. Additional stability analysis was performed on straw, hulls and grain extracts for both labels, demonstrating agreement between the initial and repeat analyses for the sugar conjugates of 1'-CH_2OH-S-2840, 1'-CH_2OH-S-2840 and inpyrfluxam. Analyses indicated stability of these compounds after 555 days of storage. Chromatographic profile comparison of the extracts indicated the stability of 1'-CH_2OH-S-2840 in rice hulls for 517 days and *N*-des-Me-DFPA, DFPA and 1'-CH_2OH-S-2840 in rice grain after 428 days of frozen storage. Based on the above it can be concluded that residues were stable in the whole duration of the study.

Oilseed - seed treatment (pulse and oilseed crops)

The metabolism of inpyrfluxam in canola (seed treatment) was investigated by Nguyen (2017, Report TPM-0031).

Inpyrfluxam was labelled at two positions; [pyrazolyl-4-^{14}C]inpyrfluxam (2.11 GBq/mmol, ≥95.4 percent purity) and [phenyl-U-^{14}C]inpyrfluxam (4.51 GBq/mmol, ≥97.7 percent purity) in canola (var. *Star*) following seed treatment. The test substance was mixed with an appropriate amount of inpyrfluxam FS formulation blank, isotopically diluted and applied at a target rate of 5 g ai/tonne of seed (4.68 or 5.13 mg ai/seed). Seeding was performed in containers with sandy loam soil in California, United States. The

period between treatment and seeding is 7 days and between seeding and harvesting is approximately 4 months.

Samples of mature seeds of canola, were harvested from individual plots at BBCH 97-99 (approximately 161 days after planting) and the total radioactive residues (TRR) analysed by LSC. ^{14}C-residues were not found above the LOQ (0.005 mg/kg) in canola seed samples in both labels, thus no metabolite identification was required.

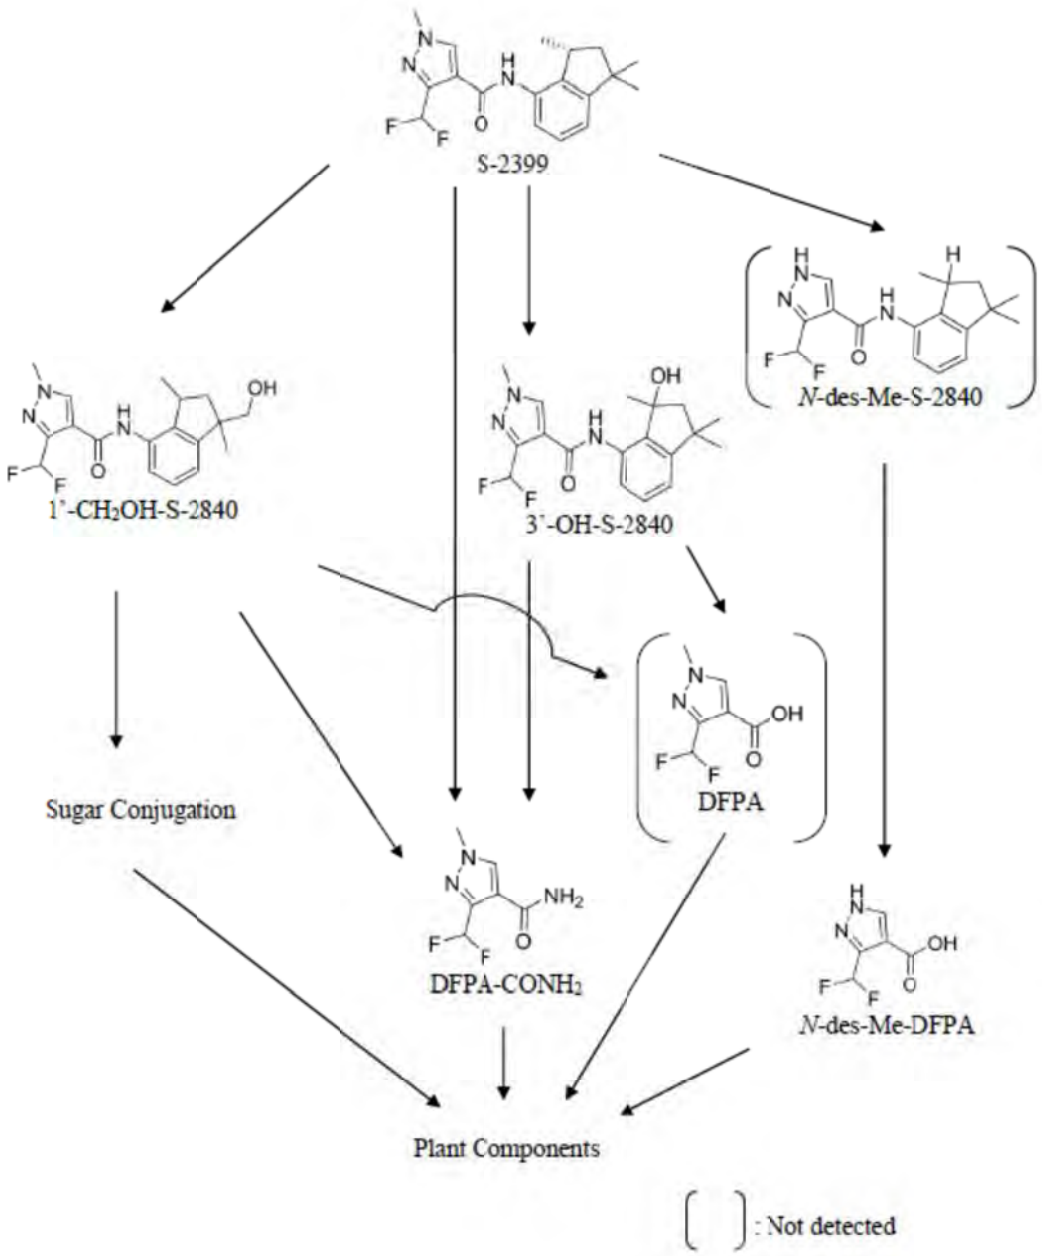

Figure 4 Proposed metabolic pathway of inpyrfluxam in rice after granular application.

Potatoes - seed treatment (root crops)

The metabolism of inpyrfluxam in potato (seed treatment) was investigated by Jalal (2017, Report TPM-0042). The test system was potatoes seeds (Red La Soda variety) planted in plots (loamy sand) located outdoors at a test site in Tulare, California.

Inpyrfluxam was labelled at two positions; [pyrazolyl-4-^{14}C]inpyrfluxam (2.11 GBq/mmol, ≥ 97.9 percent purity) and [phenyl-U-^{14}C]inpyrfluxam (4.51 GBq/mmol, ≥98.7 percent purity) in in potato (var. *Red La Soda*) following seed application. The test substance was mixed with an appropriate amount of inpyrfluxam 3.2 FS VTC-1412-39 formulation blank and isotopically diluted and applied at a target rate of 50 g ai/tonne of seed. Potato seeds were planted the same day after application.

Samples of the mature tubers were harvested at the appropriate growth stage (BBCH 49; 84–85 days from treatment and planting) and samples of foliage (collected at BBCH 48; 71–72 days from treatment and planting) were also taken from the plots. Surface radioactivity was extracted into acetone and homogenised tuber samples were extracted twice with acetone and twice with acetone:water (60:40). All plant samples (extracts and post-extraction solids) were analysed by LSC to determine the total radioactive residues (TRR). The TRR in treated foliage samples from the two radiolabels varied in the range of 0.151 mg/kg for the phenyl label and 0.385 mg/kg for the pyrazolyl label. No further analysis was made of the foliage samples.

To identify conjugates in tuber samples, the acetone extract was evaporated to dryness and dissolved in acetonitrile:water (1:1, v:v) before being subjected to acid hydrolysis with 2 M HCl (at 100 ºC for 2 hours). The hydrolysates were partitioned with ethyl acetate and the metabolites in the aqueous extract fractions were separated by fraction collection.

The total radioactive residues (TRR) and extraction efficiency of the different solvent systems used in the study, as determined by LSC are presented in Table 15 and Table 16.

The sample extracts were subjected to radio-HPLC and 2D-TLC characterisation. Characterisation of the acetonitrile fraction showed the presence of the parent and metabolites in free form, while the aqueous fraction contained polar conjugated metabolites that did not correspond to any of the available reference compounds. The acetonitrile fraction contained the parent, inpyrfluxam at a concentration of 0.002 mg/kg. This fraction also contained 3'-OH-S-2840, 1'-CH_2OH-S-2840 (isomers) and 1'-COOH-S-2840 (isomers) in free form, all in trace quantities (≤0.002 mg/kg). The acetonitrile fraction also contained some polar conjugated material (0.002 mg/kg) at or near the origin of the TLC plate. The entire radioactivity in the aqueous fraction (*ca.* 0.004 mg/kg) was polar residues that stayed immobile at the TLC origin.

For the [pyrazolyl-^{14}C] label, the acetonitrile fraction contained inpyrfluxam at a concentration of 0.002 mg/kg. This fraction also contained 3'-OH-S-2840, 1'-CH_2OH-S-2840, 1'-COOH-S-2840, DFPA and *N*-des-Me-DFPA in free form, all in trace quantities (≤0.002 mg/kg). The highest residue present was the metabolite 1'-COOH-S-2840, accounting for 22.3 percent TRR (0.009 mg/kg), of which 18.5 percent TRR was in conjugated form. The aqueous fraction contained a few polar conjugated components in addition to DFPA (0.001 mg/kg) and *N*-des-Me-DFPA (0.004 mg/kg). Unidentified components totalled 40.8 percent TRR (0.017 mg/kg).

In tubers from the [phenyl-^{14}C] label, parent accounted for 15 percent TRR (0.002 mg/kg) of residues. The metabolite, 1'-COOH-S-2840 (isomers) also accounted for a similar proportion, of which 9.2 percent TRR (0.001 mg/kg) was present in conjugated form. The other metabolites present included 3'-OH-S-2840 and 1'-CH_2OH-S-2840, each of which individually accounted for ≤0.001 mg/kg (≤6 percent TRR) and unknowns totalled 49.7 percent TRR (0.006 mg/kg).

By TLC, the ethyl acetate fractions showed the bulk of the polar conjugated residue at the TLC origin disappeared after acid hydrolysis, indicating that the metabolites were released from the conjugates during hydrolysis. Ethyl acetate fractions of the hydrolysates from the [phenyl-^{14}C] label samples could not be analysed further due to matrix interferences, low concentrations of residues (0.003 mg/kg) and large quantities of UV-active nonradioactive species. Similar problems occurred with the [pyrazolyl-^{14}C] labelled extracts, however the higher concentration of residues (0.020 mg/kg) meant that analysis could be performed by preparative HPLC.

Low TRR values in tubers indicated that the uptake of inpyrfluxam from the treated seeds was low. The absorbed test substance metabolised into a number of metabolites, none of which were present in any significant quantity (≥0.01 mg/kg) in the tuber tissue. inpyrfluxam was shown to metabolise via the routes of oxidation, amide bond cleavage and conjugation in potato tubers. The distribution of metabolites in tubers is displayed in Table 17 and the proposed metabolic pathway of inpyrfluxam in potatoes after seed treatment is shown in Figure 5.

Notes:

[a] 'Free' represents the levels present before acid hydrolysis and 'conjugated' represents levels after hydrolysis. The 'total' is the sum of the free and conjugated residue levels.

[b] Sum of isomers.

[c] Sum of >8 unidentified components.

Chiral-HPLC analysis of inpyrfluxam from the test substance formulation and in the extracts was not performed in the current study.

At 198 days after the initial extraction, representative freezer-stored potato tuber samples from both radiolabels were re-extracted and reanalysed to determine the storage stability of the samples. The results showed that the distribution of radioactive residues and the overall recoveries in the respective

extracts and in the Remaining unextracted solids were similar. The metabolite compositions were approximately similar in both extractions, indicating that the major inpyrfluxam metabolites in the potato tuber samples were stable during freezer storage for the duration of the study.

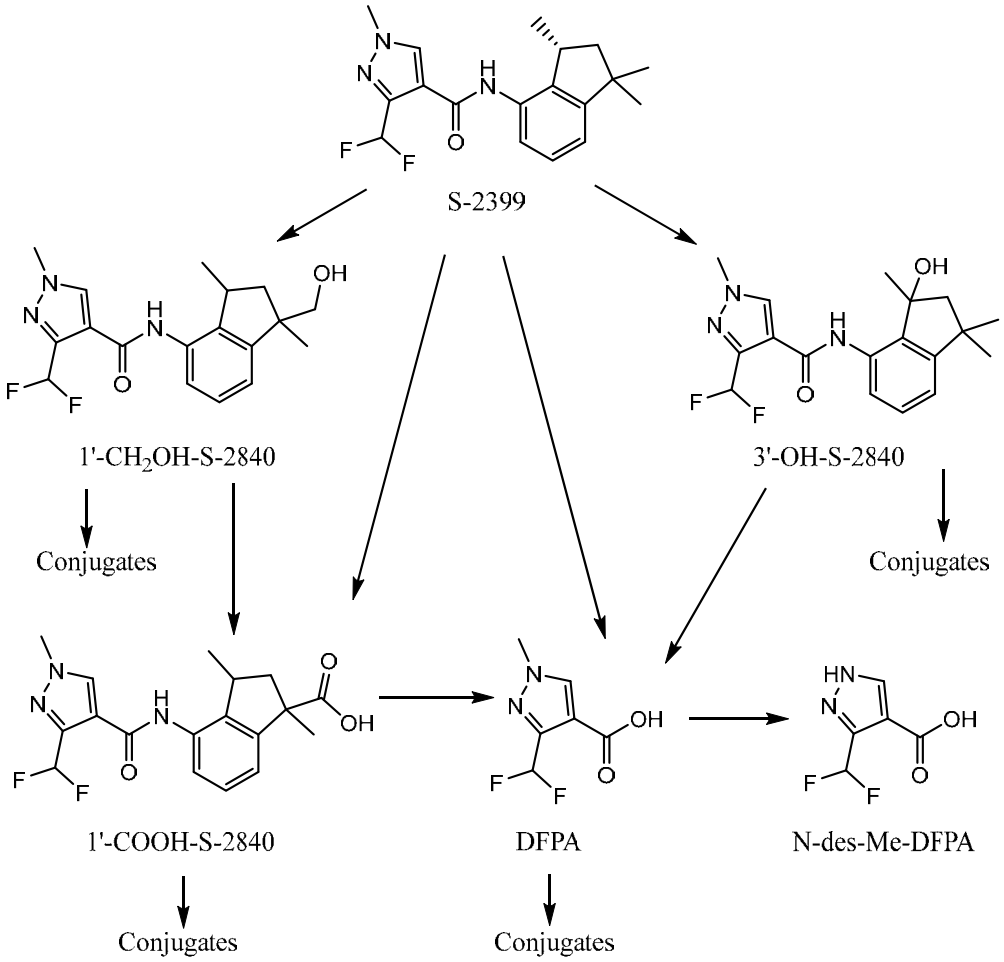

Figure 5 Proposed metabolic pathway of inpyrfluxam in potato tubers

Conclusions–Primary crops

Plant metabolism studies have been conducted with [pyrazolyl-4-^{14}C]inpyrfluxam and [phenyl-U-^{14}C]inpyrfluxam and applied to apple (fruit crop), soya bean and canola (pulse and oilseed crops), corn, sorghum and rice (cereal crops) and potato (root crop) at rates that accommodate the anticipated maximum total seasonal application rates. Uptake and transport of inpyrfluxam in the maize, sorghum, oilseed and potato studies were the seed was treated is low. In the rest of the studies in soya bean, rice and apple in which inpyrfluxam was applied via foliar application and residues were taken up by the plant, metabolism of the parent proceeds via oxidation to form the hydroxylated components, 3'-OH-S-2840 and 1'-CH_2OH-S-2840; the latter forming multiple glycoside conjugates. The glycoside conjugates are further transformed into plant constituents associated with pectin, lignin, hemicellulose and cellulose. DFPA-$CONH_2$ can be also formed from the degradation of 3'-OH-S-2840 and 1'-CH_2OH-S-2840, which is further metabolised into plant components. Additional minor pathways include the demethylation of inpyrfluxam or cleavage of the amide bond to DFPA and ATMI. DFPA is rapidly demethylated to *N*-des-Me-DFPA followed by sugar conjugation and metabolism into multiple high polarity components, whilst ATMI is

rapidly decomposed. Demethylation of inpyrfluxam generates *N*-des-Me-S-2840, which can be metabolised to *N*-des-Me-DFPA or conjugated to sugar to form Glc-NDM-2480, both of which are further metabolised into plant constituents. The proposed metabolic pathway for inpyrfluxam in plants is shown in Figure 6.

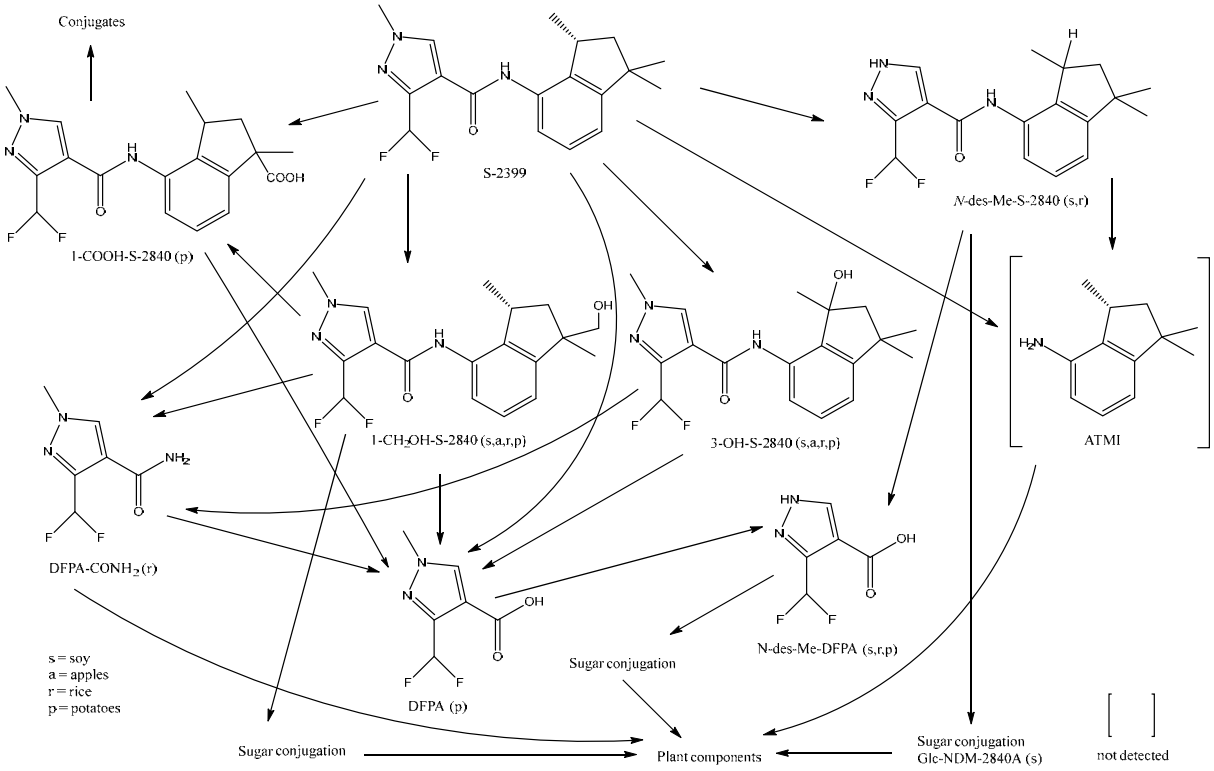

Figure 6 Proposed metabolic pathway of inpyrfluxam in primary crops

Animal metabolism

The Meeting received metabolisms studies in lactating goats (ruminants) and laying hens (poultry). Both the studies were conducted with [pyrazolyl-4-^{14}C]inpyrfluxam and [phenyl-U-^{14}C]inpyrfluxam.

Laboratory animals

Metabolism in laboratory animals was evaluated by the WHO Panel of the current Meeting.

Lactating goats

The metabolism of inpyrfluxam in lactating goats (Alpine breed) was investigated by Fleischmann *et. al* (2016, TPM-0024). In this study a target dose of 0.51 mg/kg body weight/day (13.74 ppm feed per day) for [pyrazolyl-^{14}C]inpyrfluxam and 0.64 mg/kg body weight/day (15.74 ppm feed per day) for the [phenyl-^{14}C] inpyrfluxam was given to a two goats (51.7 and 42.1 kg) on five consecutive days via gelatine capsules. Milk was collected twice daily during the dosing period, and the goat was sacrificed ca. 6–7 hours after the final dose on the 5th day. Tissue samples were analysed within 60 days of sacrifice and urine/faeces samples within 30 days of sacrifice.

Radioactivity in liquid samples (skimmed milk, urine and cage washes) was measured by LSC. Skimmed milk and fat were separated by centrifugation of the whole milk samples. TRR in milk fat, muscle, fat, liver and kidney samples were determined by solubilisation/LSC and in faeces by

combustion/LSC. Radiolabelled residues were characterised by HPLC using co-chromatography with reference standards. The identity of the radioactivity was assigned based on HPLC retention times with reference standards. Identities of components were confirmed by TLC using a comparison of the R_f values to standards which were analysed with the sample, or by LC-MS.

Total radioactive residues in milk, tissues and excreta are summarized in Table 18 and extraction efficacy of the solvent systems used are summarized in Table 19. The majority of the dosed radioactivity (≥ 76.5 percent) was recovered in excreta whilst the highest tissue radioactivity was in liver and kidney at 0.24–0.26 percent of the dose (0.33–0.35 mg/kg) and 0.02 percent of the dose (0.17 mg/kg), respectively. Radioactivity in the muscle and fat tissues were qualitatively similar for both radiolabels and residues in milk reached a plateau at day 1 and very low levels (0.09–0.12 percent of the dose) were excreted in whole milk. In all days the TRR in milk fat was <0.01 percent (0.011–0.042 mg/kg) and in skimmed milk 0.01–0.02 percent of the dose (0.013–0.041 mg/kg).

Different extraction procedures were employed depending on the sample. Muscle, liver and kidney samples were extracted twice with acetonitrile:water (1:1) and once with acetonitrile. To further investigate metabolites in the liver and kidney extracts, hydrolysis experiments were performed with the addition of β-glucuronidase and 0.5 M, 1 M and 2 M HCl to concentrated samples. Milk fat was extracted twice with hexane:acetone (4:1) and once with acetone, while skimmed milk was extracted once with acetone. Extracts were centrifuged, concentrated and analysed with HPLC. Fat samples were extracted once with hexane:acetone (4:1) and twice with acetone, combined, concentrated and partitioned between hexane and acetonitrile. The acetonitrile fraction was concentrated and analysed with HPLC.

The profile of the radioactive residues in tissues and milk are summarized in Table 20 and Table 21. In liver, the major residues characterised were 1'-COOH-S-2840 (35.3–42.1 percent TRR, 0.122–0.132 mg/kg) and the glucuronide conjugate of 1'-CH_2OH-S-2840 (15.9–19.2 percent TRR, 0.050–0.066 mg/kg). At lower levels, parent inpyrfluxam (4.9–5.9 percent TRR, 0.017–0.019 mg/kg) and metabolite 1'-CH_2OH-S-2840 (4.9–6.3 percent TRR, 0.015–0.022 mg/kg) were also found. Similar in kidney, the major residues characterized were 1'-COOH-S-2840 (45.4–49.7 percent TRR, 0.078–0.080 mg/kg) and Glu-1'-CH_2OH-S-2840 (24.5–33.5 percent TRR, 0.040–0.057 mg/kg). In muscle (flank and loin), the major residues characterized were 1'-COOH-S-2840 (27.1–46.4 percent TRR, 0.004–0.010 mg/kg) and Glu-1'-CH_2OH-S-2840 (16.0–28.6 percent TRR, 0.002–0.005 mg/kg). Metabolites DFPA-$CONH_2$ and 1'-CH_2OH-S-2840 were also found but at lower levels. Parent was not detected.

In fat, the major component of the residues was 1'-COOH-S-2840 28.8–39.7 percent TRR (0.003–0.018 mg/kg). inpyrfluxam was present at levels between 8.2–15.8 percent TRR (0.002–0.004 mg/kg).

Laying hens

The metabolisms of inpyrfluxam in laying hens (Hyline Brown breed; mean body weights 1716-1777g on day 1) was investigated by Fleischmann (2016, TPM-0025). In the study a target dose of 12.44 ppm feed per day for the [pyrazolyl-^{14}C] label and 13.13 ppm feed per day for the [phenyl-^{14}C]inpyrfluxam label was given in 2 groups (10 hens each) on 7 consecutive days via gelatine capsules. Eggs and excreta were collected twice daily. The hens were sacrificed approximately 6 hours after the last dose administration and samples of liver, muscle (breast and thigh), fat (abdominal and subcutaneous) and gastrointestinal tracts with contents were taken. All samples were stored frozen (-20 °C) and analysed 40 days after sacrifice, In liver the identification of the metabolites took more than 6 months, thus extracted were stored and analysed after 286 days. The distribution of components in the chromatographic were similar with the postulated sulfate conjugates of 1'-CH_2OH-S-2840 unchanged (Percent ROI changed ≤ 6 percent).

Radioactivity in excreta and gastrointestinal tract was measured by combustion/LSC. TRR in liver, muscle and fat samples were determined by solubilisation/LSC. Radiolabelled residues were characterised by HPLC using co-chromatography based retention times of reference standards. Identities of components were confirmed by TLC using a comparison of the R_f values to standards which were analysed with the sample, or by LC-MS.

The total recovery of radioactivity was 82.7 percent in the [pyrazolyl-^{14}C] group and 84.6 percent in the [phenyl-^{14}C] group. The majority of the dosed radioactivity was eliminated in the excreta, accounting for 80.3 percent and 81.7 percent of the total dose for the [pyrazolyl-^{14}C] and [phenyl-^{14}C] groups, respectively.

Different extraction procedures were employed depending on the sample. Fat samples were extracted once with hexane/acetone (4:1) and then twice with acetone. The organic extracts were separated from solids by centrifugation. Extracts were combined, concentrated and partitioned three times with acetonitrile. The acetonitrile layers were concentrated prior to HPLC analysis. Excreta, egg, liver, thigh and breast muscle samples were extracted twice with acetonitrile:water (1:1) and then once with acetonitrile. Egg extracts were separated from solids by centrifugation, combined, concentrated and partitioned three times with hexane. The aqueous and hexane layers were radioassayed by LSC and the water extracts were concentrated for HPLC analysis. Excreta, liver, thigh and breast muscle organic extracts were separated from solids by centrifugation, concentrated and analysed by HPLC. Residues in liver extracts were subjected to enzyme or chemical hydrolysis. Neutral solvent extracts were treated with

β-glucuronidase and sulfatase to assess the hydrolysis of sulfate and hydrolysis of glucuronic acid ester. A portion of the unknowns, Rt37 and Rt39 was also treated with 1 M HCl.

The unknowns, Rt37 and Rt39 (both [pyrazolyl-^{14}C] and [phenyl-^{14}C] labelled metabolites) were isolated and purified using solid phase extraction (SPE) and analysed by high resolution LC-MS. A chemically hydrolysed product of one of the isolated metabolites was also analysed using LC-MS/MS.

The post-extraction solids (PES) for all matrices were combusted and radiocarbon quantified by LSC.

The profile of the radioactive residues in tissues and eggs are summarized in Table 22 and Table 23. The TRR were high in gastrointestinal tract at 0.8–1.1 percent of the dose (2.124–2.478 mg/kg) and liver at 0.11–0.22 percent of the dose (0.268–0.526 mg/kg). Combined subcutaneous and abdominal fat had lower radioactivity at 0.01–0.03 percent of the dose (0.069–0.109 mg/kg) whilst combined thigh and breast muscle had the lowest radioactivity concentrations of 0.012–0.022 mg/kg (representing 0.01–0.02 percent of the dose).

The profile of the radioactive residues in tissues and eggs are summarized in Table 24 and Table 25.

In eggs, the major residue components were parent inpyrfluxam at 11.5–11.9 percent TRR (0.002 mg/kg) and 1'–CH_2OH-S-2840 (sum of isomers, 29.8–31.6 percent TRR, 0.006–0.008 mg/kg). Sulfate conjugates of 1'-CH_2OH-S-2840, 1'-COOH-S-2840, 3'-OH-S-2840 (sum of isomers) and *N*-des-Me-S-2840 were present at ≤9.2 percent TRR (≤0.002 mg/kg).

In liver the major residues characterized were the sulfate conjugates of 1'-CH_2OH-S-2840 (44.0–51.7 percent TRR, 0.112–0.164 mg/kg) and metabolites *N*-des-Me-S-2840 (4.6–9.5 percent TRR, 0.015–0.024 mg/kg) and 1'-COOH-S-2840 (6.5–11.0 percent TRR, 0.020–0.028 mg/kg) were identified at lower levels. Inpyrfluxam was not detected.

In muscle (thigh and breast), the major residues characterized were sulfate conjugates of of 1'-CH_2OH-S-2840 (10.2–47.7 percent TRR, 0.002–0.011 mg/kg), 1'-COOH-S-2840 (9.8–16.4 percent TRR, 0.002–0.003 mg/kg), 1'-CH_2OH-S-2840 (3.4–11.1 percent TRR, 0.001–0.002 mg/kg) and DFPA-$CONH_2$ (11.8–14.5 percent TRR, 0.001–0.002 mg/kg). inpyrfluxam (≤4.9 percent TRR, ≤0.001 mg/kg) was also identified as minor component.

In the abdominal and subcutaneous fat, parent inpyrfluxam (55.0–80.7 percent TRR, 0.045–0.075 mg/kg) was the major part of the residue in contrast with other tissues. Other components identified at low levels were 1'-CH_2OH-S-2840 (2.3–2.7 percent TRR, 0.002–0.003 mg/kg), *N*-des-Me-S-2840 (2.5–3.3 percent TRR, 0.002–0.003 mg/kg), 3'-OH-S-2840 (1.5–2.7 percent TRR, 0.001–0.002 mg/kg) and 1'-COOH-S-2840 (1.2–3.2 percent TRR, 0.001–0.003 mg/kg).

Conclusions–Animals

Animal metabolism have been conducted with [pyrazolyl-4-^{14}C] inpyrfluxam and [phenyl-U-^{14}C] inpyrfluxam in laying hens (poultry) and lactating goats (ruminants). The majority of the administered dose was rapidly excreted and parent inpyrfluxam was extensively metabolised in several poultry and ruminant matrices, proceeding via several pathways:

- Oxidation to form 1'-CH$_2$OH-S-2840 isomers, which is further transformed by conjugation to sulfate or glucuronic acid, or by oxidation to form 1'-COOH-S-2840 isomers and to 1',1'-bis-(CH$_2$OH)-S-2840;

- *N*-demethylation to form *N*-des-Me-S-2840, amide cleavage to form DFPA-$CONH_2$ or oxidation to 3'-OH-S-2840.

The proposed metabolic pathway for inpyrfluxam in livestock is shown in Figure 7.

Rotational crop studies

The Meeting received data from a radiolabelled, confined study in rotational crops (sorghum, lettuce and radish) as well as field rotational crop studies for lettuce (leafy crop), carrot (root crop) and wheat or barley (grain crops).

Confined rotational crop studies

A confined rotational crop study was conducted in California (United States) during the years 2015–2017 (Jalal, 2017; Report: TPM-0047). inpyrfluxam as [phenyl-^{14}C] inpyrfluxam and -[pyrazolyl-^{14}C]inpyrfluxam was applied outdoor to bare, soil (sandy loam) as a spray application formulated in 40 SC formulation at a rate of nominally 235 g ai/ha. Rotational crops were planted into the treated soil 30, 120 and 365 days after application. Samples of immature and mature lettuce leaves, radish roots and tops and sorghum forage, stover and grain were harvested. In addition, surface soil samples were collected immediately after application and at the time of sowing for each crop.

Total radioactivity in the sample matrices was measured by combustion/LSC. For samples with radioactivity levels greater than 0.01 mg/kg eq, samples were extracted twice with acetonitrile, twice with

water and a final rinse was performed with acetonitrile (using a solvent extractor). Post-extraction solids (PES) were measured by combustion/LSC. Representative PES samples containing significant radioactivity were characterised by sequential acidic hydrolytic treatments (2M HCl in 100 °C for 2–4 hours). In samples containing significant TRR (≥ 0.01 mg/kg), further analysis was conducted to identify the components of the radioactivity using HPLC and 2D-TLC by co-injection of reference standards.

Residues in all crops declined over time (Table 26). In lettuce, TRRs ranged from 0.012 mg/kg (mature, 365 DAT) to 0.103 mg/kg (immature, 120 DAT). For radish, the TRRs ranged between 0.022 mg/kg (mature roots, 365 DAT) to 0.367 mg/kg (mature tops, 120 DAT). In sorghum, total residues ranged from 0.012 mg/kg (sorghum grain, 30 and 120 DAT) to 1.074 mg/kg (sorghum stover, 120 DAT).

As to ensure that residues are stable during the study period, freezer-stored crop samples (30 DAT mature lettuce, mature radish tops and roots, sorghum stover and grain) from both radiolabels were re-extracted and analysed 17–21 months after the initial extraction. The distribution of residues in the extracts and PES was similar for the initial and final extractions.

Total radioactive residues in soil of the treated plots were 0.8–2.3 mg/kg. In the aerobic soil degradation study by Jalal (2017, Report: TPM-0023) an average half-life (DT_{50}) of inpyrfluxam in aerobic soil was over 365 days, thus varying portions of the applied inpyrfluxam or its soil metabolites are available to the crops planted 30, 120 and 365 DAT. As soil metabolites 3'-OH-S-2840 and 1'-COOH-S-2840 were the major degradates of inpyrfluxam in soil under aerobic conditions, thus uptake of these metabolites cannot be excluded.

Table 26 Summary of total radioactive residues in rotational crop matrices following soil application of [^{14}C]inpyrfluxam at a rate of 235 g ai/ha

Notes:
DAP: Time between planting and harvest.
DAT: Time between treatment and harvest.

In lettuce (Table 27), inpyrfluxam was present in the sample extracts from both radiolabels at each sampling interval at levels between 5.5 percent and 28.9 percent TRR (0.001–0.029 mg/kg) and 17.4 percent and 46.2 percent TRR (0.011–0.019 mg/kg) for the [pyrazolyl-^{14}C] and [phenyl-^{14}C] labels, respectively. Major metabolites present at 30 and 120 DAT for both labels were the conjugated isomers of 1'-CH_2OH-S-2840 (7.6–21.2 percent TRR, 0.008–0.021 mg/kg). For the [pyrazolyl-^{14}C] label, free DFPA was present in all samples at levels between 9.9 percent and 22.4 percent TRR (0.004–0.022 mg/kg) and conjugated DFPA was detected at >10 percent TRR in mature lettuce at 30 and 120 DAT (12.5–16.6 percent TRR, 0.009–0.014 mg/kg). At 365 DAT, *N*-des-Me-DFPA was present in its free form at 28 percent TRR (0.006 mg/kg). In the [phenyl-^{14}C] label, metabolite 3'-OH-S-2840 was identified at 120 and 365 DAT (7.7–11.7 percent TRR; 0.001–0.008 mg/kg) and conjugated 1'-CH_2OH-S-2840 (13.3–21.2 percent TRR;

0.007–0.021 mg/kg) a 30 and 120 DAT. Free 1'-CH_2OH-S-2840 was also detected but at DFPA derivatives were detected.

Table 27 Nature of residue in lettuce as a rotational crop treated with [Pyrazolyl-4-^{14}C] inpyrfluxam and [Phenyl-U-^{14}C]inpyrfluxam by HPLC analysis

Notes:
[a] Sum of isomers.
[b] Contains no more than 12 components, of which the largest was 25.7% TRR, 0.005 mg/kg.

In radish tops (Table 28), inpyrfluxam represents the major component of the residue at 30 DAT (6.1–15 percent TRR, 0.014–0.017 mg/kg) and one sample of mature radish at 365 DAT (10.5 percent TRR, 0.009 mg/kg). In the [pyrazolyl-^{14}C] label, metabolites *N*-des-Me-S-2840, DFPA-$CONH_2$ and conjugates of DFPA, *N*-des-Me-1'-CH_2OH-S-2840 and 1'-COOH-S-2840 were detected at significant levels (up to 17.1 percent TRR, up to 0.038 mg/kg). In the [phenyl-$^{1,\ 4}$C] label *N*-des-Me-S-2840 (free) and

conjugates of *N*-des-Me-1'-CH_2OH-S-2840, 3'-OH-S-2840 and 1'-COOH-S-2840 were detected up to levels of 22.1 percent TRR (0.019 mg/kg).

In radish roots (Table 28), inpyrfluxam represents the major component of the residue at 30, 120 and 365 DAT of both immature (28.2–58.9 percent TRR, 0.006–0.019 mg/kg) and mature samples (33.0–54.8 percent TRR, 0.007–0.045 mg/kg). Other major components (>10 percent TRR) were identified as non-conjugated DFPA, 3'-OH-S-2840, 1'-COOH-S-2840 at 23.6 (0.005 mg/kg), 11.9 (0.003 mg/kg) and 25.7 (0.006 mg/kg) percent TRR, respectively in immature roots. The PES fractions from the [pyrazolyl-^{14}C] and [phenyl-^{14}C] labelled immature and mature radish roots from all planting periods contained low levels of residues (≤0.004 mg/kg) and were therefore not analysed further.

Table 28 Nature of residue in radish as a rotational crop treated with [pyrazolyl-4-^{14}C] inpyrfluxam and [phenyl-U-^{14}C]inpyrfluxam by HPLC analysis

Notes:
DAT: Days after treatment.
Conj: Conjugate.
† Sum of isomers.
‡ Contains no more than 11 components, of which the largest was 15.8% TRR, 0.005 mg/kg.

In sorghum forage (Table 29), the parent compound inpyrfluxam accounted for only 4.1 percent TRR and 0.007 mg/kg, with only trace amounts observed at 365 DAT in the [pyrazolyl-^{14}C] label. At 30 DAT, the only major component (>10 percent TRR) was free 1'-CH_2OH-S-2840 which was present in the [phenyl-^{14}C] label only (13.8 percent TRR, 0.013 mg/kg).

At 120 DAT, conjugated 1'-CH_2OH-S-2840 (13 percent TRR, 0.015 mg/kg) and *N*-des-Me-1'-CH_2OH-S-2840 conjugate (12.3 percent TRR, 0.015 mg/kg) were identified. Last at 365 DAT, *N*-des-Me-1'-CH_2OH-S-2840 conjugate was the only major component detectable (10.1 percent TRR, 0.004 mg/kg) in the phenyl-^{14}C label). In the [pyrazolyl-^{14}C] labelled samples, the only major metabolite detected was the conjugated DFPA (11.1 percent TRR, 0.021 mg/kg) at 120 DAT.

In sorghum stover, inpyrfluxam was present at minor levels and accounted for no more than 1.8 percent TRR (0.020 mg/kg) in both radiolabels. At 30 DAT, the conjugated 1'-CH_2OH-S-2840 was identified in both the [phenyl-^{14}C] label (13.5 percent TRR, 0.092 mg/kg) and the [pyrazolyl-^{14}C] label (10.3 percent TRR, 0.078 mg/kg). Also present in the [pyrazolyl-^{14}C] labelled extracts at major levels was the conjugated DFPA conjugate at 11 percent TRR (0.083 mg/kg). At 120 DAT, the conjugated 1'-CH_2OH-S-2840 was detected (13.3 percent TRR, 0.167 mg/kg) in the [phenyl-^{14}C] label and the conjugated DFPA (11.6 percent TRR, 0.129 mg/kg) in the [pyrazolyl-^{14}C] label. At 365 DAT, no metabolites were detected at levels exceeding 10 percent TRR.

In sorghum grain, the total residue in the acetonitrile extracts from both radiolabels of all planting intervals was below 0.001 mg/kg. In the 30 DAT aqueous extract of the [phenyl-^{14}C] label, residue levels were low (0.006 mg/kg) and not analysed further, whilst for the [pyrazolyl-^{14}C] label, 59.9 percent TRR (0.029 mg/kg) was extracted. Chromatographic identification and acid hydrolysis showed that the extracted residue contained the conjugated forms of DFPA (22.6 percent TRR, 0.011 mg/kg) and *N*-des-Me-DFPA (8.6 percent TRR, 0.004 mg/kg). For the 120 DAT samples labelled with [pyrazolyl-^{14}C]inpyrfluxam, the aqueous extract contained 49 percent TRR (0.031 mg/kg) and contained conjugated material which was postulated to contain the same metabolites as were present in the 30 DAT extracts. Residues from the [phenyl-^{14}C] label were not analysed further due to low levels present (0.005 mg/kg). For the 365 DAT samples, residue levels in the aqueous extracts were below 0.01 mg/kg and were therefore not analysed further. The 365 DAT [phenyl-^{14}C] and 120 DAT [pyrazolyl-^{14}C] labelled sorghum grain contained 0.006 mg/kg and 0.031 mg/kg (48 percent and 50 percent TRR), respectively as bound residues in PES. Acid hydrolysis and solvent partitioning of the [phenyl-^{14}C] labelled grain PES with ethyl acetate released 0.002 mg/kg of the bound residues. The extract was not further analysed due to low radioactivity levels. Metabolite identification of the acid hydrolysed PES from the [pyrazolyl-^{14}C] label showed DFPA as the major component (14 percent TRR, 0.008 mg/kg) with other minor metabolites below 4 percent TRR. The base hydrolysed protein and lignin fractions from the [phenyl-^{14}C] labelled samples accounted for <0.002 mg/kg and the fractions from the [pyrazolyl-^{14}C] labelled samples accounted for 0.007 mg/kg and 0.001 mg/kg, respectively. The unhydrolysed cellulose-containing fractions remaining after acid and base hydrolysis of each PES retained approximately 0.001–0.002 mg/kg of residue.

The results in sorgun commodities are shown in Table 29.

Conj: Conjugate.
† Sum of isomers.
‡ Contains no more than 11 components, of which the largest was 15.8% TRR, 0.005 mg/kg.

The proposed metabolic pathway is shown in Figure 6. Inpyrfluxam was extensively metabolised into a large number of metabolites, many of which formed complex conjugates with naturally occurring compounds and became incorporated as unextractable residues in various plant constituents. Parent inpyrfluxam underwent a number of transformation processes including oxidation, demethylation, amide bond cleavage, as well as combinations of these processes. The primary oxidation products of inpyrfluxam were 3'-OH-S-2840, 1'-CH_2OH-S-2840and 1'-COOH-S-2840 and were present in both free and conjugated forms. The amide bond cleavage of the parent inpyrfluxam and its metabolites produced DFPA and DFPA-$CONH_2$. The metabolites, *N*-des-Me-S-2840, *N*-des-Me-1'-CH_2OH-S-2840 and *N*-des-Me-DFPA were produced as a result of the loss of the *N*-methyl group in the pyrazolyl ring of the parent inpyrfluxam, its oxidation products and the cleavage product, respectively. The radioactivity from both radiolabels were distributed extensively in various fractions of the PES including starch, proteins, lignin and cellulose.

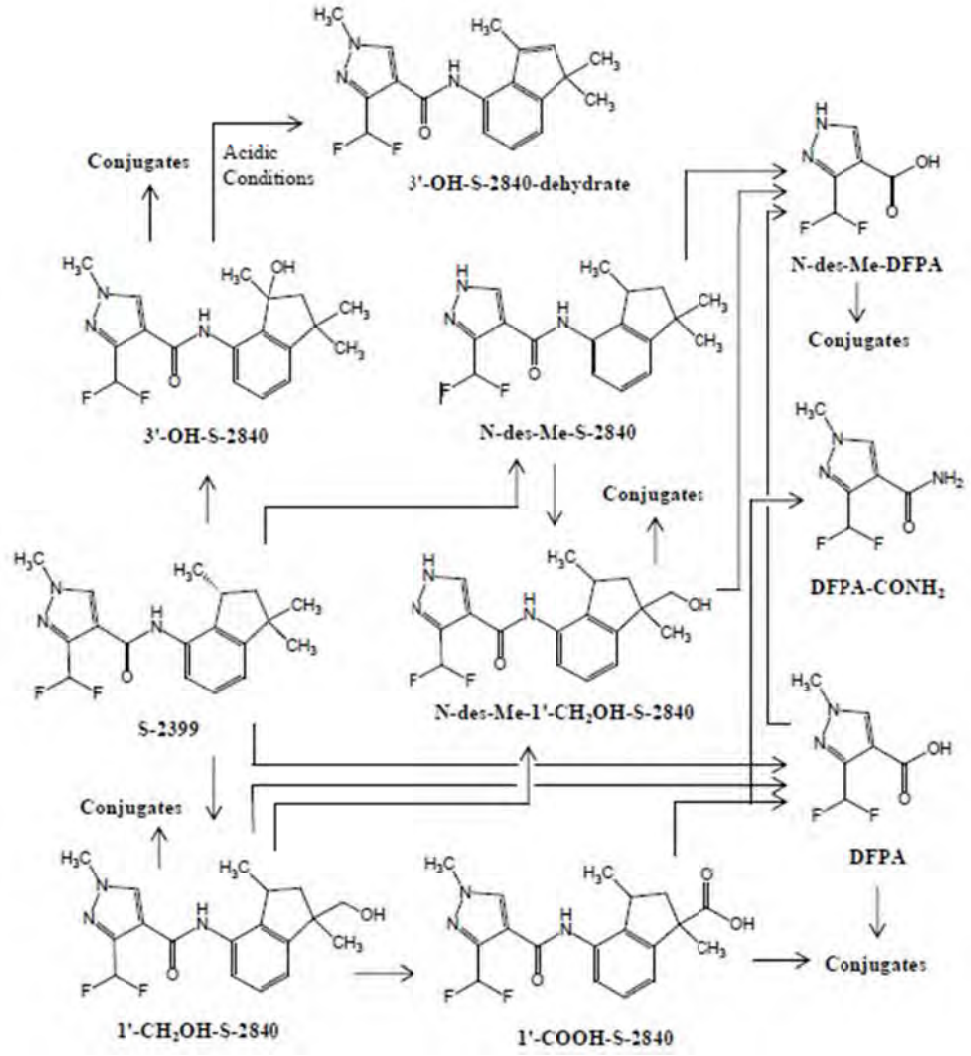

Figure 8 Proposed metabolic pathway for inpyrfluxam in rotational crops

Field rotational crop studies

Six field rotational trials conducted to investigate the magnitude of residues in rotational crops in Europe, Canada and the United States of American were submitted to the Meeting.

In the study conducted in Europe during 2016-2017 (Bousquet, 2018; TPR-0080), one foliar application of inpyrfluxam as a 40 SC was made at a rate of 240 g ai/ha and at BBCH 30 to 65, to winter barley (260-2016 GE01; treated GS 30 or 51-55) and spring wheat (260-2016 IT02; treated GS 31 or 65). In 260-2016 GE01, soil texture was loam with a pH of 6.9 and organic matter content of 2.25 percent. In 260-2016 IT02, soil texture was sandy loam with a pH of 6.8 and organic matter content of 4.98 percent. The primary crop was destroyed to simulate crop failure and incorporated in the soil whilst preparing the soil for rotational crops within 13–14 days of application.

Rotational crops of lettuce (leafy crop), carrot (root crop) and wheat or barley (grain crops) were sown or planted at three plant-back intervals (PBIs) of 28 ± 2, 120 ± 5 and 350 ± 15 days after application and sampled at normal commercial harvest.

Inpyrfluxam and its metabolites were analysed using the previously validated analytical methods, SUM-1601V and SUM-1701V (validation was performed within the reported study). The LOQ was 0.01 mg/kg (0.005 mg/kg for metabolite isomers) for inpyrfluxam, 3'-OH-S-2840, DFPA-$CONH_2$, *N*-des-Me-S-2840 and DFPA. Procedural recoveries for parent and metabolites in lettuce and carrot matrices fortified at the LOQ and 10× LOQ were in the acceptable range of 70–120 percent. Samples were stored frozen for a maximum of 371 days before analysis, which is covered by the storage stability (cucumber/apple, wheat/maize grain and potato tuber).

Residues of inpyrfluxam and its metabolites were < 0.01 mg/kg in all rotated crop matrices at PBIs of 120 ± 5 days and 350 ± 15 days. At the shortest PBI of 28 ± 2 days, all residues in lettuce, carrot roots and tops and cereal grain were <0.01 mg/kg. In cereal straw, residues at the LOQ (0.01 mg/kg) were detected for 3'-OH-S-2840, at 0.017 and 0.019 mg/kg for 1'-COOH-S-2840, at 0.023 mg/kg for 1'-CH_2OH-S-2840 and at 0.09 and 0.1 mg/kg for DFPA (Table 30).

Table 30 Residues of inpyrfluxam and its metabolites in rotational crops (lettuce, carrot, cereals) planted after foliar application with inpyrfluxam (40 SC) at 240 g ai/ha on cereals (crop failure after 13-14 days) in Europe.

Notes:
[a] Days between sowing and sampling the succeeding crop.
[b] Plant-back interval = days between the last application to the treated plot and sowing of succeeding crop.
[c] Analytically determined as two separate groups of isomers but presented summed; 1'-COOH-S-2840A + 1'-COOH-S-2840B; 1'-CH2OH-S-2840A + 1'-CH2OH-S-2840B; N-des-Me-1'-CH2OH-S-2840A + N-des-Me-1'-CH2OH-S-2840B.

In the study conducted in Manitoba (CAN) during 2015 and 2016 (Bitter, 2017, 201700151), one foliar outdoor application of inpyrfluxam as a 2.84 SC was made on wheat (*var.* WFT 603) at BBCH 39-45 at a rate of 100 g ai/ha. Soil texture was sandy clay loam with a pH (water) of 7.7 and organic matter content of 3.1 percent. Sampling of the primary crop was performed after growth to maturity and the crop was collected and destroyed–the protocol states that minimum soil tillage should take place before planting the following crop. Wheat and field peas were planted into the plot 328 days after the last application of test substance formulation and canola was planted 339 days after the last application.

Wheat forage, wheat hay, wheat grain, wheat straw, field pea vines, field pea hay, field pea seed and canola seed were analysed for inpyrfluxam and conjugates using a modification of the Valent analytical method RM-50C. The limit of quantification (LOQ) for each analyte was 0.01 mg/kg in food commodities and 0.02 mg/kg in feed items. The limit of detection (LOD) was 0.005 mg/kg in food commodities and 0.01 mg/kg in feed items. Samples were stored for a maximum period of 157 days prior to analysis, which is supported by the available storage stability studies.

Residues were not detected in any of the matrices from the 11 month PBI. Procedural recoveries for parent and aglycones of DFPA and 1'-CH_2OH-S-2840 (fortified at levels between 0.01 and 0.2 mg/kg) were in the acceptable range of 70-120 percent (Table 31).

Table 31 Residues of inpyrfluxam and its metabolites in rotational crops (wheat, pea, canola) planted after foliar application with inpyrfluxam (2.84 SC) on wheat (crop failure) in Canada.

Notes:
[a] Days between sowing and sampling the succeeding crop.
[b] Plant-back interval = days between the last application to the treated plot and sowing of succeeding crop.
[c] Analysed as aglycones.

In the study conducted in North Dakota (the United States) during 2015 and 2016 (Bitter, 2017, 201700152), one foliar outdoor application of inpyrfluxam as a 2.84 SC was made on wheat (*var.* WFT 603) at a rate of 120 g ai/ha and BBCH 61. Sampling of the primary crop was performed after growth to maturity and the crop was harvested and tilled into the ground near the treated plot . Wheat and canola were planted into the plot 328 days and 312 days after the last application of test substance formulation, respectively.

Canola seed and wheat forage, hay, grain and straw were analysed for inpyrfluxam and conjugates using a modification of the Valent analytical method RM-50C. The limit of quantification for each analyte was 0.01 mg/kg in food commodities and 0.02 mg/kg in feed items. Samples were stored for a maximum period of 143 days prior to analysis, which is supported by the available storage stability studies.

Residues were not detected in any of the matrices from the 10 month PBI (Table 32). Procedural recoveries for parent and aglycones of DFPA and 1'-CH_2OH-S-2840 (fortified at levels between 0.01 and 0.2 mg/kg) were in the acceptable range of 70–120 percent.

Notes:
[a] Days between sowing and sampling the succeeding crop.
[b] Plant-back interval = days between the last application to the treated plot and sowing of succeeding crop.
[c] Analysed as aglycones.

In the study conducted in Oklahoma (United States) during 2015 and 2016 (Bitter, 2017, 01700154), two foliar outdoor application (14 day interval) of inpyrfluxam as a 2.84 SC was made on soya bean (*var.* P39T67R) at a total rate of 210 g ai/ha at BBCH 63–65 and 71. Sampling of the primary crop was performed after growth to maturity and the crop was destroyed; protocol states that after harvest the soil should be lightly tilled following usual agricultural practices. Sorghum and cotton were planted into the plot 273 days after the last application of test substance formulation.

Sorghum forage, grain and stover were analysed for inpyrfluxam and conjugates (using a modification of the Valent analytical method RM-50C. Unginned cotton was collected, processed into cottonseed and cotton gin trash and the seed was analysed for the same metabolites. The limit of quantification for each analyte was 0.005 mg/kg in food commodities and 0.01 mg/kg in feed items. Samples were stored for a maximum period of 110 days prior to analysis, which is supported by the available storage stability studies.

Residues were not detected in any of the matrices from the 9 month PBI (Table 33). Procedural recoveries for parent and aglycones of DFPA and 1'-CH_2OH-S-2840 (fortified at levels between 0.01 and 0.2 mg/kg) were in the acceptable range of 70-120 percent.

Environmental fate in soil

The Meeting received studies depicting the environmental fate of inpyrfluxam in soils. Soil studies included laboratory under aerobic and anaerobic conditions, photodegradation studies, and field dissipation studies were submitted.

Aerobic degradation in soil

The route of degradation of inpyrfluxam in soil under aerobic condition was investigated by Jalal (2017, TPM-0023) in Penn series soil and by Gohre (2017, TPM-0044) in Atwater, Newhaven and Woodside farm soils. In addition, the route of degradation of metabolites 3'-OH-S-2840 and 1'-COOH-S-2840 were investigated by Cooper (2017, TPM-0033 and TPM-0049).

Inpyrfluxam was labelled at two positions; [pyrazolyl-4-^{14}C]inpyrfluxam and [phenyl-U-^{14}C]inpyrfluxam. The study parameters are summarized in Table 35.

Table 35 Summary of soil metabolism and dissipation studies conducted with inpyrfluxam under aerobic conditions

Study ID	Radiolabel position	Application, g ai/ha	Application, mg ai/kg soil dry weight basis, DM	Soil types	Incubation	Sampling (days)
TPM-0023	[pyrazolyl-4-^{14}C]inpyrfluxam	234	0.650	Penn Series	20 ± 2°C	0, 7, 14, 30, 63, 93, 120, 150 and 182
	[phenyl-U-^{14}C]inpyrfluxam	228	0.634		50 ± 10%	
TPM-0044	[pyrazolyl-4-^{14}C]inpyrfluxam	215	0.603	Atwater, Newhaven, Woodside farm	20 ± 2°C	0, 14, 30, 61, 90, 120

The soil extracts were analysed by LSC and 2D TLC and occasionally by HPLC to quantify and identify major radioactive components. In addition, 1 M NaOH traps were included to collect $^{14}CO_2$ and tetraethylene glycol dimethyl ether traps were included to trap radioactive organic volatiles.

In study TPM-0023, the rate and route of inpyrfluxam metabolism was investigated in Penn Series soil. The principal degradation routes were oxidation of the 3'-position in the indenyl ring to

produce 3'-OH-S-2840 (14.4 percent AR phenyl, 15.5 percent AR pyrazolyl) and the oxidation of one of the 1'-CH_3 groups of the indenyl ring to form 1'-COOH-S-2840 (6.6 percent AR phenyl, 5.9 percent AR pyrazolyl). Minor amount of *N*-des-Me-DFPA was observed (<5 percent AR). No isomerization from inpyrfluxam *R*-isomer to its *S*-isomer occurred during the study period. The distribution of the applied radioactivity in inpyrfluxam and its metabolites is presented in Table 36.

Table 36 Distribution (percent of Applied Radioactivity) in inpyrfluxam, in its metabolites, in volatiles and in bound residue fractions of soil at various sampling intervals

Notes:
Ph: [phenyl-U-^{14}C]inpyrfluxam; Py: [pyrazolyl-4-^{14}C]inpyrfluxam.
[a] Individual peaks did not exceed 2% of applied radioactivity at any sampling interval.

The DT_{50} of inpyrfluxam was 213 days, 240 days, and 242 days, using the SFO, DFOP and IORE kinetic models, respectively. The corresponding DT_{90} were 707, 1149 and 3102 days, respectively. The PestDF results showed that the representative half-life (Slow $t_{1/2}$) DT_{50} was 398 days. The degradation of inpyrfluxam in soil under aerobic conditions was a gradual process, resulting in the formation of one major and many minor metabolites, which were mineralized slowly into the soil lattice of fulvic acid, humic acid and humin.

In the study TPM-0044, the rate and route of inpyrfluxam metabolism was investigated in three soils (Atwater, Newhaven and Woodside farm) under aerobic condition using [pyrazolyl-4-^{14}C]inpyrfluxam (PYR-label) at a rate of 0.603 mg/kg (DM). Treated soil samples were incubated at 20 ± 2 °C and approximately 50 percent of the maximum water holding capacity (MWHC) in the dark for a maximum of 120 days and were periodically collected and extracted. Duplicate soil samples were taken at 0, 14, 30, 61, 90 and 120 days after treatment. The test systems were equipped with NaOH traps for the collection of evolved $^{14}CO_2$ and tetraethylene glycol dimethyl ether traps to trap organic volatiles. The soil extracts were analysed by LSC and by HPLC and 2D TLC to quantify and identify major radioactive components. In addition, radioactive volatiles from the soil were quantified by LSC. The post-extraction soil (PES) was analysed by combustion analysis. The PES sample containing significant radioactivity was fractionated into fulvic acid, humic acid and humin and the residue in each fraction was analysed by LSC and/or combustion analysis and when appropriate, by HPLC.

The average material balance for the study was 98.7 ± 2.2, 98.1 ± 3.5 and 99.3 ± 1.5 percent AR, for Atwater, Newhaven and Woodside farm soils, respectively. The majority of the applied radioactivity was extracted at 120 DAT and only a small portion was bound (9.1 percent AR for the Atwater soil, 12.2 percent AR for the Newhaven soil and 9.3 percent for the Woodside farm soil). The $^{14}CO_2$ produced was insignificant (0.3, 0.8 and 0.3 percent AR for the Atwater, Newhaven and Woodside farm soil respectively).

The principal degradation routes were oxidation of the 1′ methyl group and at the 3-carbon on the indene ring to form 1'-COOH-S-2840 and 3'-OH-S-2840. The degradation products with the largest proportion observed in the study were 3'-OH-S-2840 (maximum 20.7 percent AR) and 1'-COOH-S-2840 (maximum 9.6 percent AR) for the Atwater soil; 1'-COOH-S-2840 (22.8 percent AR), 3'-OH-S-2840(10.5 percent AR) for the Newhaven soil; and 1'-COOH-S-2840 (30.1 percent AR) and 3'-OH-S-2840(8.4 percent AR) for the Woodside farm soil.

Hydrolysis of the central amide linkage or dealkylation of the N-methyl group on the pyrazolyl ring to yield DFPA, DFPA-$CONH_2$ and *N*-des-Me-DFPA or *N*-des-Me-S-2840 was observed in minor yields. No isomerization from inpyrfluxam *R*-isomer to its *S*-isomer occurred during the study period.

The distribution of the applied radioactivity in inpyrfluxam, its metabolites is presented in Table 37.

Table 37 Radioactivity distribution in total soil extracts for the Atwater, Newhaven and Woodside soil trials as percent of applied radioactivity.

Notes:
[1]: Duplicate samples were analysed at each timepoint.
[2] Chromatographically, 1'-CH2OH-S-2840A, 1'-COOH-S-2840A, 1'-CH2OH-S-2840B and 1'-COOH-S-2840B elute close together between 32-34 minutes by HPLC and tentative assignments have been made. A definitive assignment was made by 2D-TLC analysis.

DT_{50}s were estimated at 121, 101 or 331 days (SFO, Single First Order) for the Atwater, Newhaven or Woodside Farm sites, respectively. A DT_{50} of 1,720 days (DFOP, Double First-Order in Parallel, slow $t_{1/2}$) was also calculated for the Newhaven site. PestDF chose the DFOP value as its best fit, which is not realistic. A visual inspection of the data reveals that around 50 percent loss of inpyrfluxam was observed by 60 days. It is well understood, that one of the deficiencies of closed laboratory studies is that there is no carbon renewal, hence the rate of degradation at later intervals can be lower due to decreased microbial activity. The biomass values for the Newhaven soil suggest that the soil was less microbially active at 120 days. In this case, the DFOP model overemphasizes the slow degradation rate (k1). Therefore, the appropriate value for modelling would be the SFO value of 101 days.

The proposed metabolic pathway for inpyrfluxam in soil under aerobic conditions is shown in Figure 8.

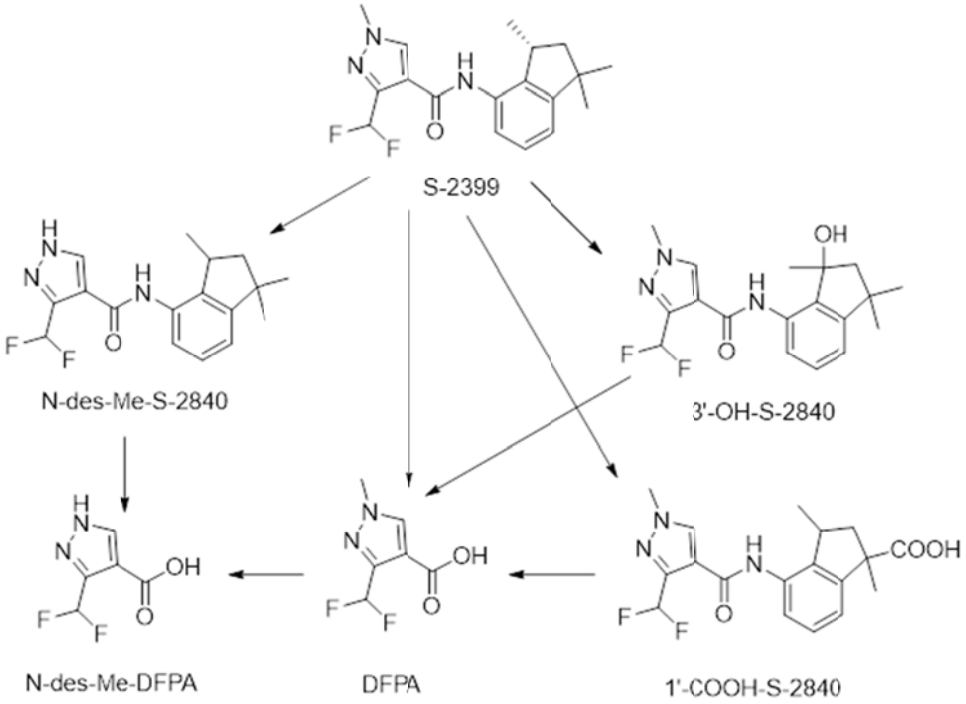

Figure 8 Proposed aerobic soil degradation pathway of inpyrfluxam.

In the study TPM-0057, the data of the rate of degradation of inpyrfluxam in aerobic soil from the studies TPM-0023 and TPM-0044 were normalised and the CAKE 3.2 software was used to determine the normalised degradation rate of inpyrfluxam following the FOCUS Kinetics Guidance (2014). The data were fitted to SFO and DFOP kinetics for inpyrfluxam only and the data normalised to 20 °C and pF are given in the Table 38 below.

Table 38 Normalization of laboratory DT_{50} values for inpyrfluxam

Soil name	Classification	pH	Study temp (°C)	Study matrix potential (% MWHC)	Actual study moisture content (% w/w)	Moisture content at pF2 (w/w)	Moisture correction factor	Experimental SFO DT_{50} (d)	DT_{50} (d) at 20 °C and pF 2
Penn	Loam	6.8	20	50	24.1	23.8	1	213	213
Atwater	Sandy loam	7.5	20	50	16.1	14.3	1	121	121
Newhaven	Silt loam	5.7	20	50	38.4	33.0	1	1720	1720
Woodside	Loam	7.5	20	50	29.0	28.6	1	331	331
Geomean DT_{50} value									348

In the same study, attempts were then made to additionally fit the metabolite (1'-COOH-S-2840 and 3'-OH-S-2840) data, using the best fit kinetics for the parent molecule. Given that the metabolites did not show significant decline during the incubation there is clearly significant uncertainty in the calculated DT_{50} values. This is particularly the case for 3'-OH-S-2840 at Atwater and 1'-COOH-S-2840 at Penn where the fitted DT_{50} values of >10,000 days are clearly nonsensical. The fitted formation fractions are subject to lesser uncertainty since the decline of the parent can be linked to the formation of the metabolite. The absence of robust DT_{50} values for the metabolite results in some uncertainties in the formation fractions but since degradation is generally expected to be slow, then these uncertainties are less than would otherwise occur. In Table 41 the results of the kinetic determinations for metabolites 1'-COOH-S-2840 and 3'-OH-S-2840 in four laboratory soils are summarized.

Table 39 Kinetic determinations for metabolites 1'-COOH-S-2840 and 3'-OH-S-2840

Soil	Penn	Atwater	Newhaven	Woodside
Parent kinetic	SFO	SFO	DFOP	DFOP
Overall Chi^2 error%	4.75	2.55	3.13	2.21

Soil photolysis

Photodegradation of inpyrfluxam was investigated by Schick (2014, TPM-0005). Inpyrfluxam was labelled at two positions; [pyrazolyl-4-^{14}C]inpyrfluxam and [phenyl-U-^{14}C]inpyrfluxam and applied to thin layers of not sterilized soil (2.15 mg/kg) in individual photolysis vessels. The physicochemical characteristics of the soil are presented in Table 43. Light-exposed samples were irradiated with a Xenon lamp (wavelengths <290 nm filtered out, similar spectrum to natural sunlight) continuously for up to 13 days. All samples were maintained at 20 ± 3.3 °C and continuously aerated throughout the incubation period. Dark control samples were also analysed. Traps to collect organic volatiles and CO_2 were included.

Table 40 Soil physicochemical properties used in the study TPM-0005

Soil name	Classification	CEC (meq/100 g soil)	pH (1:1 soil:water ratio)	Organic matter (%)
Penn Soil	Loam	7.6	6.8	1.9

The DT_{50} and DT_{90} results for the pyrazolyl and phenyl labeled inpyrfluxam set are shown in the Table 44 below. The degradation rate constant (k) and estimated half-life (DT_{50}) of [^{14}C] inpyrfluxam were calculated assuming first-order kinetics using Microsoft Excel® version 2000. The degradation constants were calculated using the percent inpyrfluxam in each sample from the following equation:

$\ln C = -kt + \ln C0$ ($y = mx + b$) (m = slope)

where:

k = degradation rate constant

C = chemical concentration (inpyrfluxam expressed as percent of applied radiocarbon)

t = time

C_0 = initial concentration

The DT_{50} of [^{14}C] inpyrfluxam was calculated using the following equations:

$$DT_{50} = \frac{\ln 2}{-m} = \frac{0.693}{k}$$

Since the degradation in dark control samples was similar to that in the light exposed samples, the degradation in the light-exposed samples was corrected to account only for the effect of photolysis on degradation. The adjusted degradation rate constant was calculated as follows, and DT_{50} and DT_{90} shown in Table 41

$$k_{photolysis} = k_{light} - k_{dark}$$

Table 41 DT_{50} and DT_{90} results for the pyrazolyl and phenyl labelled inpyrfluxam

Sample set	DT_{50} hours (days)	DT_{90} hours (days)	R2
[phenyl-U-^{14}C]inpyrfluxam			
Light	2057 (86)	6833 (285)	0.2866
Dark	11951 (498)	39700 (1654)	0.0294
Photolysis	2484 (104)	8253 (344)	N/A
[pyrazolyl-4-^{14}C]inpyrfluxam)			
Light	2773 (116)	9210 (384)	0.8226
Dark	2795 (116)	9285 (387)	0.5191
Photolysis	346574 (14441)	1151293 (47971)	N/A

Using the light intensity of the Xenon lamp from 290-800 nm and 290-400 nm, the DT_{50} and DT_{90} for irradiated samples can be converted to equivalent solar days (30-50°N global summer day as per OECD, and summer days at 30, 40, and 50 °N). A summary of the results is presented in Table 42.

Table 42 DT_{50} and DT_{90} results for the pyrazolyl and phenyl labelled inpyrfluxam expressed as days in artificial light, summer days and global solar days.

	Days under Continuous Artificial Light	Summer days at 30°N (290-800 nm)	Summer days at 40°N (290-800 nm)	Summer days at 50°N (290-800 nm)	Global solar days (290-400 nm)
[phenyl-U-^{14}C]inpyrfluxam					
DT_{50}	104	279	252	235	235
DT_{90}	344	928	837	780	780
[pyrazolyl-4-^{14}C]inpyrfluxam)					
DT_{50}	14441	38956	35149	32762	32761
DT_{90}	47971	129409	116762	108833	108829

[^{14}C]inpyrfluxam was observed to photodegrade very slowly on a loam soil, with a nominal photolytic half-life (determined as the half-life in light-exposed samples corrected for the degradation in dark controls) of between 104 and 14441 days, indicating that photolysis is not a significant loss mechanism. The main degradation product was 3-'OH-S-2840 (mean maximum of 8.3 percent AR at day 13). Soil bound residues represented less than 3 percent AR. No isomerization from inpyrfluxam *R*-isomer to its *S*-isomer occurred throughout the study.

Field dissipation

The Meeting received nine field dissipation studies from which, five were conducted in North America (Foster, 2017; TPR-0031, TPR-0032, TPR-0053 Bitter, 2017; TPR-0034, TPR-0033) and four in Europe (LeBrun, 2018; TPR-0085). In these studies, the dissipation and mobility of inpyrfluxam and its

metabolites 3'-OH-S-2840, 1'-COOH-S-2840A and 1'-COOH-S-2840B were assessed following two applications of inpyrfluxam at rate of 115 g ai/ha and 100 g ai/ha or one application at a rate of 200 g ai/ha in bare uncropped soil. In all cases inpyrfluxam was applied as a SC formulation.

Soil samples (cores) from each plot and the control were taken on at several time period depending on the study. At each sampling event, five soil cores per subplot were taken. For each core, the 0–15 cm segment was collected and only in study TPR–0031, samples were also collected followed for the 15–90 cm core. Samples were frozen at the site and stored at the laboratory (maximum storage length 705 days) and covered by storage stability studies in soil (727 days). Samples were then cut into 15 cm segments (0–15 cm, 15–30 cm, 30–45 cm, 45–60 cm, 60–75 cm and 75–90 cm) and corresponding depth segments from each plot hand mixed and were analysed using the validated Method RM-50S (TPA-0070). The LOQ was 0.01 mg/kg for each analyte. Overall, concurrent recovery samples for inpyrfluxam and its metabolites gave results ranging from 90.2 to 96.6 percent recovery, with relative standard deviations up to 10.7 percent.

In the trials conducted in North America, inpyrfluxam residues in the 15–cm (6-inch) surface soil layer were 55–87.4 percent of the amount applied. The highest detected individual plot residue was 0.190 mg/kg (study TPR-0031) which was detected immediately after the second application. Average residues declined to < LOD (0.005 mg/kg) by 210–730 days after the second application. Residues of 3'-OH-S-2840 were above the LOQ at several DALA depending on the study (Table 43). Residues of 1'-COOH-S-2840A and 1'-COOH-S-2840B were not detected (Table 44). Similar in the trials conducted in Europe, movement of inpyrfluxam was not observed from the 0-30 cm soil segment to lower layers.

In study TPR-0031, residues of inpyrfluxam in the 15–30 cm soil segment was detected above the LOQ (0.01 mg/kg) in one sample (0.0137 mg/kg) at 29 days after the second application; all other samples were less than the LOQ for depths of 15–90 cm. In this trial flooding of the treated plot was observed that might lead to leaching of residues. However, the leaching potential is expected to be low in loam soil and under the environmental conditions of the region (Mississippi) since minimal residues were found in the lower levels even after the trial plot had received excessive rainfall.

Notes:
[a] Days after last application.
[b] For sampling intervals containing residues and non-detects, "N.D." was replaced with 1/2LOD (0.0025 mg/kg) to calculate the mean.
[c] One day prior to the next application.
[d] Not detected, below LOD (0.005 mg/kg).
[e] Cores sampled after the application when the spray had dried—typically collection started between 1 and 3 hours after application.
[f] Values in parentheses are <LOQ (0.01 mg/kg).
[g] Samples collected at 89 days after the last application for Plots A and B and at 96 days after the last application for Plot C.

Environmental fate in water/sediment systems

The Meeting received studies investigating the rate and route of hydrolysis and photodegradation in water.

Hydrolysis in water

In study by Freedlander (TPM-0030) the rate and route of hydrolysis of inpyrfluxam was studied in three aqueous sterile buffer solutions (at pH 4, 7and 9) using [pyrazolyl-4-^{14}C]inpyrfluxam applied at 1.00 µg/mL. Solutions were incubated in the dark at 50 ± 0.5 °C and samples were analysed at 0 and 5 days of incubation by LSC and HPLC/RAM. In all three buffers inpyrfluxam was hydrolysed less than 10 percent (after 5 days), thus additional investigation was not performed. Isomerization in the chiral carbon was not observed. In conclusion, [^{14}C]inpyrfluxam is considered to be hydrolytically stable.

Aqueous photolysis

In study by Ponte (TPM-0008) the photodegradation of inpyrfluxam was studied in sterilized aqueous phosphate buffer (pH 7, 0.01 M sodium phosphate monobasic monohydrate) irradiated at 25 ± 1 °C with a xenon lamp (wavelengths <290 nm filtered out, similar spectrum to natural sunlight) for up to 15 days). Samples were analysed by LSC, HPLC and TLC in duplicate immediately after treatment (time 0) and 1, 3, 6, 9, 13 and 15 days after treatment.

Minimal degradation of inpyrfluxam was observed in light-exposed and dark control samples throughout the study period. inpyrfluxam ranged from 95.7 to 102.1 percent AR in light exposed samples and from 97.9 to 104.5 percent AR in dark controls. Although 3'-OH-S-2840 slightly increased up to 5.8 and 4.1 percent AR in light exposed and dark controls throughout the 15-day irradiation/incubation period, the degradate was detected in the purity check and T0 samples as an impurity. The half-lives of inpyrfluxam could not be correctly calculated since inpyrfluxam was stable to degradation in pH 7 buffer in the presence and in the absence of light irradiation but they were estimated to be over one year. In

conclusion, the results of the study indicate that photolysis is not a significant mode of dissipation of inpyrfluxam in aqueous solutions.

In another study by Ponte (TPM-0010) the photodegradation of inpyrfluxam was studied in sterilized natural water at 0.98 mg/L [pyrazolyl-4-^{14}C]inpyrfluxam and 1.00 mg/L [phenyl-^{14}C]inpyrfluxam. Solutions were subjected to continuous irradiation at 25 ± 1 °C with a xenon lamp (wavelengths <290 nm filtered out, similar spectrum to natural sunlight) for up to 16 days. Samples were analysed by LSC, HPLC and TLC in duplicate immediately after treatment (time 0) and 1, 3–4, 7, 10, 14 and 16 days after treatment.

Total recoveries for pyrazolyl labelled samples averaged 102.6 ± 2.3 and 104.3 ± 2.1 percent AR for light exposed and dark control sets, respectively.

In phenyl labelled samples, total recoveries averaged 98.7 ± 2.5 and 98.6 ± 1.3 percent AR for light exposed and dark control sets, respectively. inpyrfluxam degraded slowly in light-exposed samples and represented an average of 86.0 and 70.7 percent AR in PYR and PH labelled samples, respectively, following 16 days of continuous irradiation.

In PYR labelled samples, 3'-OH-S-2840, which was an impurity at time 0 (3.7 percent AR), reached an average of 6.8 percent AR by Day 14. DFPA-$CONH_2$ was present as a maximum average of 3.4 percent AR by Day 16 and DFPA represented a maximum average of 4.7 percent AR on Day 14. Radiocarbon recovered in the traps for volatiles represented <0.3 percent AR throughout the study.

In the PH labelled light exposed samples, the degradate 3'-OH-S-2840 was also observed at a maximum average of 8.6 percent AR by the end of the study. An area of radioactivity eluting in the polar region by HPLC represented up to 6.2 percent AR at Day 16 which was comprised of at least two polar degradates. The organic volatiles represented <0.3 percent AR, while $^{14}CO_2$ represented an average of 3.7 percent AR at the end of the study.

The half-life of inpyrfluxam in natural water are summarized in Table 48 and the proposed degradation pathway of inpyrfluxam in natural water when exposed to artificial sunlight in Figure 9.

Table 48 DT_{50} values for inpyrfluxam in natural water when exposed to artificial sunlight

Sample Set	DT_{50} (hours/days)[1]	DT_{50} in sunlight days		
		United States (40 °N summer)[2]	OECD (30-50 °N, summer)[3]	JMAFF (35 °N spring)[4]
[pyrazolyl-4-^{14}C]inpyrfluxam	2105/88	188	171	549
[phenyl-U-^{14}C]inpyrfluxam	857/36	77	69	223

Notes:
[1] Continuous Suntest irradiation.
[2] Average summer irradiation in the 300-800 nm range at 40 °N latitude.
[3] Average summer irradiation in the 300-400 nm range at 30-50 °N latitude.
[4] Average spring irradiation in the 300-400 nm range at 35 °N latitude in Tokyo.

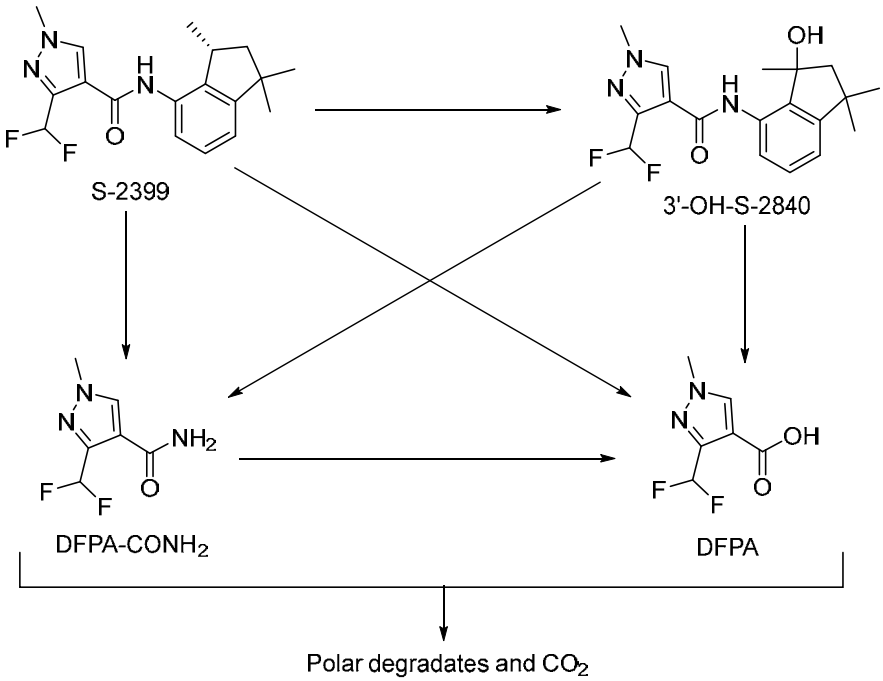

Figure 9 Proposed degradation pathway of inpyrfluxam in sterilized natural water exposed to artificial sunlight

Rice paddies

Since rice is included in the intended uses of inpyrfluxam, the Meeting received five studies investigating the degradation of inpyrfluxam in water/sediment systems (TPM-0041, TPM-0048, TPM-0050, TPM-0036, TPM-0038, TPM-0039).

In study by Gohre (TPM-0041) the biotransformation of inpyrfluxam in two water/sediment system (Golden Lake and Taunton River) was investigated under aerobic aquatic conditions using [phenyl-^{14}C] inpyrfluxam and [pyrazolyl-4-^{14}C] inpyrfluxam.

Two test systems (sediment and water) were collected from the top 0–5 cm layer (Golden Lake) and 0–2.5 cm layer (Taunton River). The sediment was thoroughly mixed and passed through a 2-mm mesh sieve with a minimum of air-drying. The sediment and water was stored in the dark before being used. The sediments characteristics are summarised in Table 49.

Table 49 Chemical and Physical characteristics of test sediments (TPM-0041)

Sediment characteristic	Golden Lake	Taunton River
USDA Particle size distribution		
% sand (50 µm - 2 mm)	80	58
% silt (2 µm - 50 µm)	15	36
% clay <2 µm	5	6
pH (H_2O)	7.8	5.9
% Moisture 1/3 bar	20.4	39.4
Cation exchange capacity (meq/100g)	13.0	6.5
% Organic carbon (Walkley Black)	1.6	3.7
% Organic Matter	2.8	6.3
USDA Textural class	Loamy sand	Sandy loam
Microbial Biomass Carbon (µg/g dry weight)	389 (0 DAT) 444 (112 DAT; untreated control)	401 (0 DAT) 503 (112 DAT; untreated control)

Sediment characteristic	Golden Lake	Taunton River
	460 (112 DAT; solvent control) 456 (112 DAT; inpyrfluxam control)	478 (112 DAT; solvent control) 480 (112 DAT; inpyrfluxam control)

A beaker (cylinder internal diameter of 5.2 cm) charged with 50 g (dry weight) of sediment and 165 mL of water has a water surface area of about 21.6 cm^2 (water column depth of about 6.3 cm (Golden Lake) and 5.1 cm (Taunton River). The aerobic aquatic test systems were dosed with a final water concentration of 0.018 µg/mL for both radiolabels in the Golden Lake systems, and a final water concentration of 0.015 µg/mL and 0.014 µg/mL for the PH-label and PY-label in the Taunton River systems, respectively. The test systems were incubated at 20 ± 2 °C in the dark with a constant humidified air flow for a maximum of 112 days and were periodically collected and extracted. The test systems were equipped with 1 M NaOH traps for the collection of evolved and tetraglyme/ethylene glycol traps for ^{14}C volatile capture. A pre-incubation period of 26–27 days was performed for the Golden Lake system and 14-15 days for the Taunton River system before dosing. Untreated control soils, organic solvent controls and non-radiolabelled inpyrfluxam samples were used to measure the effect on the microbial biomass at the end of sampling. Duplicate soil samples were taken at 0, 3, 7, 14, 30, 63 and 112 days after treatment (DAT). The trap solutions were analysed at the same points immediately after removal.

The physical parameters of the aerobic systems (oxygen concentration, redox and pH) were measured and the water separated from the sediment. The water phase and all extracts were analysed by LSC. The water phase was subjected to Solid Phase Extraction (SPE) and the organosoluble fraction was analysed by HPLC after concentration. Confirmation was performed by 2D-TLC.

The sediment samples were extracted with acetone, twice with acetone:water (3:2) and with acetone:water:HCl (c) (60:40:1). Activity in the neutral extracts were analysed by HPLC and confirmed by 2D-TLC after concentration. The acidic extracts contained < 4 percentAR and therefore no further analysis was performed. Representative Post-extracted sediments (PES) at 112 DAT were subjected to further additional sequential solvent extractions with ethyl acetate, dioxane and hexane. Total radioactivity in PES was determined by combustion. The $^{14}CO_2$ collected in the NaOH trapping solution and organic volatiles collected in tetraglyme/ethylene glycol traps were quantified by LSC. The potential isomerisation from [^{14}C] inpyrfluxam was evaluated using chiral HPLC analysis on the extracts obtained from the 112 DAT samples.

No significant change in the microbial biomass carbon was recognized between the initiation and termination of the incubation (Table 49). Thus, microbial viability was proved to be satisfactorily maintained during the incubation period.

It was confirmed that no isomerisation of [^{14}C] inpyrfluxam occurred during incubation period based on chiral HPLC analysis. The distribution and mass balance of applied radioactivity of [^{14}C] inpyrfluxam in water phase, extractable, sediment-bound and volatile fractions are summarised in Table 50 to Table 53. The quantification of inpyrfluxam and the degradates in the whole system is summarised in Table 54 to Table 57.

The average mass balance for the study was 98.6 ± 1.4 percent AR (PH-label) and 99.2 ± 1.0 percent AR (PY-label) for the Golden Lake system, and 98.8 ± 1.2 percent AR (PH-label) and 99.4 ± 1.9 percent AR (PY-label) for the Taunton River system. The radioactivity remaining in sediment following the neutral and acidic extractions, post extraction sediment (PES) or sediment-bound radioactivity, was insignificant, reaching 6 percent of the AR (Golden Lake) and 3 percent of the AR (Taunton River) by the end of the study (112 DAT). Additional extractions of the Golden Lake PES extracted low amounts of

activity from the sediment (~2 percent AR). No further analysis was performed on the PES. The cumulative production of $^{14}CO_2$ was insignificant reaching a maximum of 0.4 percent AR at 112 DAT in the Golden Lake system.

Two degradates were observed above 5 percent AR: 3´-OH-S-2840 (max. 6.8 percent AR), and 1'-COOH-S-2840, (max. 13.1 percent AR). N-demethylation of the pyrazolyl ring to produce N-des-Me-S-2840 was minor as well as hydrolysis of the amide bond to produce the pyrazolyl derivatives DFPA and DFPA-$CONH_2$.

Generally, all degradates were observed to be declining in both sediments by the end of the study (112 DAT) except 1'-COOH-S-2840 in the Golden Lake sediment. The aerobic aquatic metabolism degradation pathway of inpyrfluxam is summarized in Figure 9. The PestDF kinetics (consistent with the FOCUS approach) for Golden Lake and Taunton River were evaluated from 0–63 days (112 day data points were considered to have unacceptable data scatter). The total ^{14}C from the acidic extract was added to the identified inpyrfluxam from other extracts as a conservative approach. The calculated Single First Order DT_{50} values were 154 (χ^2 = 1.1) and 368 days (χ^2 = 1.5) for Golden Lake and Taunton River, respectively.

Inpyrfluxam degraded slowly in two sediment/water systems (Golden Lake and Taunton River) under aerobic aquatic conditions. The majority of the dose remained unchanged after 112 days of aerobic aquatic exposure and ultimate mineralization to bound residues and CO_2 was minor. Whole system aerobic aquatic half-lives were estimated at 154 and 368 days (SFO) for Golden Lake and Taunton River, respectively. Chi2 error values were 1.1 and 1.5, respectively. Degradate formation was primarily to 1'-COOH-S-2840 and 3'-OH-S-2840, formed at average maximums of 13.1 and 6.8 percent AR, respectively.

In study TPM-0048 the mineralisation and degradation rate of inpyrfluxam in a natural surface water was performed using two radiolabels, [phenyl-^{14}C] inpyrfluxam and [pyrazolyl-4-^{14}C] inpyrfluxam, at 20 ± 2˚C and in the dark for a maximum of 61 days. Natural water was collected from The Lake at Studley Royal, Ripon UK and the test system was named 'Fountains Abbey'. Prior to use the water was stored in the dark in an environmental chamber routinely maintained at 4 ± 2°C, with free access to air. Water was 100 µm sieved prior to use and subsequent characterisation. The water characteristics are summarised in Table 58.

Table 58 Characteristics of the tested natural water

Water characteristic	Fountains Abbey water
Sampling water temperature	19.1°C
Sampling water oxygen content	10.14 mg/L
Sampling water pH	8.6
Water depth sampled	0-10 cm
Water depth above sediment	30 cm
Total Organic Carbon (TOC) 9mg/L)	0.13
Dissolved Organic Carbon (DOC) (mg/L)	0.00
pH	8.0
Suspended Solids (mg/L)	3
Electrical Conductivity (µS/cm)	285

The mineralisation and degradation rate of inpyrfluxam in a natural surface water was performed using two radiolabels, [phenyl-^{14}C] inpyrfluxam and [pyrazolyl-4-^{14}C] inpyrfluxam, at 20 ± 2 ˚C and in the dark for a maximum of 61 days. The test vessels were attached to a flow-through system for continuous aeration. Two concentrations were used for each label. The concentrations of the PY-label were 0.103 mg/L and 0.0102 mg/L, and the concentrations for the PH-label were 0.103 mg/L and 0.0101 mg/L. The test systems were equipped with 2 M NaOH traps for the collection of evolved $^{14}CO_2$ and ethanediol traps for ^{14}C volatile capture. Sterile samples were tested at the higher concentration (0.103 mg/L.) Untreated blank controls were used to measure oxygen content and pH. Solvent controls and reference controls using sodium [^{14}C] benzoate were used to demonstrate that the microbial population was viable in the test system.

Duplicate samples were taken at 0, 3, 7, 14, 21, 30 and 61 days after treatment (DAT). Duplicate of sterilised water samples were taken at 0, 14, 30 and 61 days after treatment (DAT). The trap solutions were analysed at the same points. Dissolved oxygen and pH were measured in the blank controls at each sampling point. The water from each vessel and the water used for rinsing the vessel (extract 1) were analysed for radioactive content by LSC and were analysed for test substance and metabolites by HPLC. Then, the vessel was rinsed with acetonitrile (extract 2), sonicated and the solution analysed by LSC. The $^{14}CO_2$ collected in the NaOH trapping solution and organic volatiles collected in ethanediol traps were counted by LSC. The potential isomerisation from [^{14}C] inpyrfluxam was evaluated using chiral HPLC.

During incubation, oxygen levels were > 8 mg/L at all sampling times, showing that the water samples were maintained under aerobic conditions. Recorded pH values were in the range 8.1 to 8.5 (no change with respect to original value). The profiles of mineralisation rates of sodium [^{14}C]benzoate in the reference and solvent controls were similar showing that the acetonitrile did not inhibit the microbial degradation of sodium [^{14}C]benzoate in the natural water. Mineralisation exceeded 50 percent AR within 7 days and therefore the natural water used was microbially active and the study was valid. It was confirmed that no isomerisation of [^{14}C] inpyrfluxam occurred during incubation period based on chiral HPLC analysis.

The distribution and mass balance of applied radioactivity of both radiolabelled [^{14}C] inpyrfluxam and at both concentrations in surface water, vessel wash and volatile fractions were very similar and are summarised in Table 59. Inpyrfluxam and metabolites were separately determined in all natural water samples collected. The quantification of inpyrfluxam and the degradates is summarised in Table 60.

Table 59 Ranged of average percent recovery of applied radioactivity recovered from natural water treated with [^{14}C] inpyrfluxam (low and high concentration)

Incubation group	% AR present in			
	Surface water	Vessel wash	Volatiles	Total
PH-label, low rate	90.0-95.9	0.4-2.0	≤ 0.2	92.1-96.2
PH-label, high rate	91.2-95.0	0.4-2.0	≤ 0.4	93.2-96.6
PY-label, low rate	*93.2-99.6	ND-1.7	ND	*94.3-100.4
PY-label, high rate	88.6-93.4	0.4-1.5	ND	90.1-94.0
Sterile (PH-label, high rate)	91.9-96.5	0.3-0.5	ND	92.8-97.0

Notes:
Values are the mean of two replicates and are ranges over the period 0 to 61 DAT
ND = Not detected, * One replicate from 61 DAT has been excluded due to low mass balance

Table 60 Average percent recovery of [^{14}C] inpyrfluxam and metabolites expressed as applied radioactivity from natural water samples

Incubation group	% AR present as		
	inpyrfluxam at 0 DAT	inpyrfluxam at 61 DAT	Unknowns (max)
PH-label, low rate	91.2	92.1	1.3
PH-label, high rate	92.4	90.6	3.3
PY-label, low rate	94.1	96.5*	3.9
PY-label, high rate	89.7	90.4	3.9
Sterile (PH-label, high rate)	91.3	94.2	0.6

Notes:
Values are the mean of two replicates, *One replicate excluded due to low mass balance

Ethanediol traps did not contain any detectable radioactivity. $^{14}CO_2$ was insignificant reaching a maximum of 0.4 percent AR for the phenyl-label at high concentration (30 DAT). The largest metabolite was present at ≤ 4 percent AR (maximum 3.9 percent AR, 14 DAT pyrazolyl-label at high and low concentration) and it was not identified. Degradation rates of [^{14}C] inpyrfluxam were obtained by CAKE software (Version 2.0) in line with FOCUS guidelines). The calculated Single First Order DT_{50} values are summarsied in Table 61, showing that no degradation of inpyrfluxam could be demonstrated under sterile and non-sterile conditions.

Table 61 Degradation rate of [^{14}C] inpyrfluxam

Group	DT_{50} (days)	DT_{90} (days)	X^2
PH-label, low rate	3190	10600	1.41
PH-label, high rate	1540	5120	1.10
PY-label, low rate*	5850	19400	2.10
PY-label, high rate	23600	78500	1.42
Sterile (PH-label, high rate)	3.45×10^{12}	1.15×10^{13}	1.6

Note:
* One replicate excluded due to low mass balance

No individual metabolites were detected at > 5 percent AR at any sampling interval (maximum 3.9 percent AR, 14 DAT pyrazolil-label at high and low concentration). Degradation rate DT_{50} values calculated as ≥ 1540 days under non-sterile and sterile conditions confirm that no significant degradation occurred during the study.

In study TPM-0036 the biotransformation of inpyrfluxam in two water/sediment system (Sharkey and Golden Lake) was investigated under anaerobic aquatic conditions using [phenyl-^{14}C] inpyrfluxam and [pyrazolyl-4-^{14}C] inpyrfluxam.

Two test systems (sediment and water) were collected from the top 5–10 cm layer (Sharkey) and 0–5 cm layer (Golden Lake). The sediment was thoroughly mixed and passed through a 2-mm mesh sieve with a minimum of air-drying. The sediment and water was stored in the dark before being used. The sediment characteristics are summarised in Table 62.

Table 62 Chemical and Physical characteristics of test sediments (TPM-0036)

Sediment characteristic	Sharkey	Golden Lake
USDA Particle size distribution		
% sand (50 µm - 2 mm)	18	89
% silt (2 µm - 50 µm)	19	6
% clay <2 µm	63	5
pH (H_2O)	6.4	8.0
% Moisture 1/3 bar	45.8	11.8
Cation exchange capacity (meq/100g)	32.6	10.1
% Organic carbon (Walkley Black)	1.45	0.93
% Organic Matter	2.5	1.6
USDA Textural class	Clay	Sand
Microbial Biomass Carbon as percent organic carbon	2.2 (1 DAT) 1.2 (103 DAT*; untreated control) 0.64 (103 DAT; solvent control) 0.61 (103 DAT; inpyrfluxam control)	0.35 (1 DAT) 0.17 (114 DAT; untreated control) 1.63 (114 DAT; solvent control) 2.13 (114 DAT; inpyrfluxam control)

Notes:
*The intended endpoint of the study was 102 DAT, but the study was extended to 180 days. Treatment inpyrfluxam controls were sampled at 209 DAT instead. The microbial biomass as percent organic carbon for this sample was 1.47%.

The anaerobic aquatic test systems (50 g of dry weight sediment with 181 mL water for Sharkey and 175 mL water for Golden Lake) were dosed after the anaerobic conditions were established (28–30 days for the Sharkey system and 41–43 days for the Golden Lake system). The concentrations applied to the Sharkey phenyl and pyrazolyl systems were 0.019 and 0.020 µg/mL, respectively, and 0.014 µg/mL for both radiolabels in the Golden Lake systems. The test systems were incubated at 20 ± 2 °C in the dark for a maximum of 180 days in the Sharkey system and 112 days in the Golden Lake system and were periodically collected and extracted. The physical parameters of the anaerobic system (oxygen concentration, redox and pH) were measured at each sampling date. The test systems were equipped with NaOH traps for the collection of evolved $^{14}CO_2$ and evolved $^{14}CH_4$ was analysed by oxidation of a sample of the biometer flask headspace gas. Untreated control soils, organic solvent controls and non-radiolabelled inpyrfluxam samples were used to measure the effect on the microbial biomass at the end of sampling.

Duplicate soil samples were taken at 0, 7, 14, 32, 67, 102 and 180 days after treatment (DAT) for the Sharkey system and at 0, 14, 30, 63 and 112 for the Golden lake system. All samples were measured for $^{14}CH_4$ and $^{14}CO_2$ production, dissolved oxygen concentration, redox potential, and pH at the time of analysis. The sediment and the water phases were separated by decantation and analysed separately. For the Sharkey samples, the water phase was centrifuged, decanted and aliquots analysed by LSC and HPLC, and representative samples by TLC. For the Golden Lake system, the water phase was centrifuged, decanted and aliquots analysed by LSC. After pH adjustment (pH 5), the water was passed through a reverse phase cartridge, washed with water and eluted with acetonitrile. The aliquots were analysed by LSC and HPLC. Representative samples were analysed by TLC. The sediment samples were extracted with acetone, twice with acetone:water (3:2) and with acetone:water:HCl (c) (60:40:1). Activity in the neutral

extracts were analysed by LSC and HPLC after concentration and representative samples were analysed by TLC. The acidic extracts were partitioned with ethyl acetate, concentrated and aliquots of both phases were counted by LSC. Final extracts were analysed by HPLC and representative samples by TLC. The post-extracted sediments (PES) at 180 DAT (Sharkey system) was subjected to additional sequential solvent extractions with ethyl acetate, dioxane and hexane, and a sonic dismembrator. Finally, it was fractionated into humin, humic acid and fulvic acid. Total radioactivity in PES was determined by combustion. The activity in the water phase and all extracts was counted by LSC. Water and sediment extracts were analysed by HPLC and 2D-TLC to identify and quantify [^{14}C] inpyrfluxam and its [^{14}C]labelled metabolites. The $^{14}CO_2$ collected in the NaOH trapping solution and headspace samples were counted by LSC. The potential isomerisation from [^{14}C] inpyrfluxam was evaluated using chiral HPLC analysis on the extracts obtained from the end of the study samples and on the test substances prior to application.

The microbial biomass and organic carbon values were viable and typical for sediment/water systems under anaerobic conditions. It was confirmed that no isomerisation of [^{14}C] inpyrfluxam occurred during incubation period based on chiral HPLC analysis. The distribution and mass balance of applied radioactivity of [^{14}C] inpyrfluxam in water phase, extractable, sediment-bound and volatile fractions are summarised in Table 63 to Table 66.

Table 71 Summary of the mass balance data for exhaustive extraction and fractionation of sediment-bound activity in Sharkey sediment as percent of applied radioactivity

Sample description	Average of the two replicates (%AR)	
	180 DAT PH-label	180 DAT PY-label
Starting sediment bound (PES)	9.65	9.04
Exhaustive extraction		
Ethyl Acetate	3.32	2.88
Dioxane	1.53	1.27
Hexane	0.37	0.34
Dismembrator	2.21	2.12
Fractionation		
Humin	1.34	0.93
Humic acid	0.22	0.11
Fulvic acid	0.56	0.18
Total	9.55	7.82
% Recovery	99.11	86.27

The average material balance for the Sharkey studies was 98.9 ± 1.5 percent (phenyl) and 96.8 ± 3.4 percent (pyrazolyl) of the applied radioactivity (AR); and the average material balance for the Golden Lake studies was 98.9 ± 1.3 percent (phenyl) and 101.1 ± 2.3 percent (pyrazolyl) of the applied radioactivity (AR). Non-extractable radioactive residues (PES, post extraction sediment) increased to 10 percent of the AR (phenyl) and 9 percent of the AR (pyrazolyl) by the end of the study for the Sharkey system and to 4 percent of the AR (phenyl) and 3 percent of the AR (pyrazolyl) by the end of the study for the Golden Lake system. The production of ^{14}C-volatile activity ($^{14}CO_2$ and $^{14}CH_4$) was insignificant, ranging from 0.0 to 0.1 percent of the AR throughout the study.

In the Sharkey system, 3′-OH-S-2840 was the largest degradate found in both labels with a maximum average of 1.7 percent AR and 4.1 percent AR for the phenyl and pyrazolyl labels, respectively. Minor amounts (<1 percent AR) of ATMI, 1′-COOH-S-2840 and N-des-Me-S-2840 were observed in the phenyl label samples. DFPA-$CONH_2$, DFPA, 1′-COOH-S-2840 and N-des-Me-S-2840 were observed in minor amounts (≤2 percent AR) in the pyrazolyl samples. In the Golden Lake system 3′-OH-S-2840 was the largest degradate found in both labels with a maximum average of 3.2 percent AR and 5.3 percent AR for the phenyl and pyrazolyl labels, respectively. Only one other degradate, 1′-COOH-S-2840 (3 percent AR) was observed in one phenyl label sample. Minor amounts of DFPA (<1 percent AR) were observed in the pyrazolyl samples. These degradates were considered transitory because they were not seen in duplicate samples and disappeared rapidly once they were formed. No significant unknown degradates (>2 percent AR) were observed.

The DT_{50} and DT_{90} of inpyrfluxam in each soil was calculated using the USEPA PestDF kinetic software (this is consistent with the FOCUS approach). The whole system anaerobic aquatic half-life based on the SFO model was estimated at 3537 days (χ^2 = 1.5) for the phenyl and pyrazolyl labels combined for the Sharkey system and 3498 days (χ^2 = 1.8) for the Golden Lake system.

Inpyrfluxam degraded slowly in both sediment/water systems (Sharkey and Golden Lake) under anaerobic aquatic conditions. The majority of the dose remained unchanged after 180 days (Sharkey) or 112 days (Golden Lake) of anaerobic aquatic exposure (87–91 percent of the dose for both labels). No significant degradates (>5 percent of the dose) were formed and ultimate mineralization to bound residues and CO_2 was minor. Whole system anaerobic aquatic half-lives were estimated at 3537 and 3498 days (SFO) for Sharkey and Golden Lake, respectively. 3′-OH-S-2840 was the only degradate found consistently in both sediments and both labels. A variety of other transitory degradates were seen (ATMI, DFPA-$CONH_2$, DFPA, N-des-Me-S-2840 and 1′-COOH-S-2840) in very low amounts.

In study TPM-0038 and TPM-0039 the dissipation, mobility and degradation of inpyrfluxam and its transformation products was determined in an aquatic field dissipation study following planting of rice seed.

In study TPM-0038, treated and control paddies were sown with rice seeds at a drill rate of 83 kg/ha. The treated paddy was sown with inpyrfluxam 3.2 FS (flowable concentrate for seed treatment) treated seed (10 g ai/100 kg seed) which introduced 0.187 gram of inpyrfluxam to the paddy. The control plot was sown with untreated seed. The sediment and soil characteristics of the test site are summarised in Table 72. The irrigation water-source had a pH of 7.4, a conductivity of 0.66 mmhos/cm and a total suspended solids of 4 mg/L. No known compounds that would analytically interfere with inpyrfluxam were used over the three-year period before the study

Table 72 Chemical and Physical characteristics of test sediments and soil (TPM-0038 and TPM-0039)

Characteristic	Untreated Control		Treated

USDA Textural class	Clay	Clay	Silty clay	Clay loam

After sowing, both paddies were flooded (5 cm of water) in accordance with local agricultural practices. A permanent flood condition (12.7 cm of water) was established in the treated and untreated control paddies 32 days after sowing. At the late boot stage of rice crop development, a broadcast foliar application of inpyrfluxam 2.84 SC (suspension concentrate) was made to the rice canopy in the treated paddy at a nominal rate of 99.8 g as/ha (71 days after sowing). Paddy water, sediment (0–5 cm) and soil (5–15 cm) samples were collected for residue analysis at pre-determined intervals and analysed for inpyrfluxam and its major transformation products (3′-OH-S-2840, 1′-COOH-S-2840-A, and 1′-COOH-S-2840-B). The pre-determined intervals began on the day of broadcast foliar application (0 days after application [DAA]) and continued through 88 DAA. The permanent flood was maintained at a relatively constant depth until it was released 27 days after broadcast foliar application (DAA) (98 days after planting). Sediment and soil sampling continued after the flood release at pre-determined intervals through 88 DAA (159 days after sowing). Application verification pads (from treated and control paddies) were analysed at 0 DAA to confirm that the target application rate for inpyrfluxam was achieved.

Samples were taken (duplicates) at the day of broadcast application. Triplicate soil and sediment samples from the control and treated paddy were taken -78, 0, 1, 5, 14, 26, 42, 61 and 88 DAA (days after broadcast application). Paddy water samples were collected at -39, 0, 1, 3 (sample taken before adding water to reset the water depth), 3(sample taken after addition of water to reset the water depth), 5, 7, 14 and 26 DAA from the control paddy (2 replicates) first, followed by collection from the treated paddy (3 replicates). If an irrigation event was to take place the same day as a scheduled sampling event, water samples were collected prior to the addition of irrigation water. Samples were analysed according to the analytical method RM-50V.

Results from the analysis of saturation pad samples after the test substance application confirmed that the target application rate for inpyrfluxam was achieved. The transit stability test demonstrated the stability of inpyrfluxam during shipment, handling, and storage. In the paddy water, fortified samples showed average recoveries for inpyrfluxam, 3′-OH-S-2840, 1′-COOH-S-2840-A, and 1′-COOH-S-2840-B of between 81.3 percent and 120 percent. In the sediment and soil, fortified samples showed average recoveries for inpyrfluxam, 3′-OH-S-2840, 1′-COOH-S-2840-A, and 1′-COOH-S-2840-B of between 70.1 percent and 116 percent. Hence the methods were considered to be performing appropriately.

Results from the analysis of paddy water samples for inpyrfluxam, 3′-OH-S-2840 and 1′-COOH-S-2840 collected from the treated plot are summarized in Table 73. Treated paddy water was sampled 32 days after sowing to determine whether inpyrfluxam residues were present in the paddy water from the

seed treatment. Results from the analysis of sediment (0-5 cm) samples for inpyrfluxam, 3′-OH-S-2840 and 1′-COOH-S-2840 collected from the treated plot are summarized in Table 74. Results from the analysis of soil (5-15 cm) samples for inpyrfluxam, 3′-OH-S-2840 and 1′-COOH-S-2840 collected from the treated plot are summarized in Table 75.

DAA = days after application.

The only 1'-COOH-S-2840 observed was and only in the water phase at low-level concentrations (maximum 5.1 µg/L). S-2399 dissipated quickly from the paddy water with a calculated half-life (DT_{50}) of 0.485 days by the best fit model (IORE, χ^2 = 6.8). The dissipation of INPYRFLUXAM from the paddy sediment was considerably slower than from the paddy water with an estimated half-life (DT_{50}) of 105 days by the best fit model (SFO, χ^2 = 53).

The average mass of inpyrfluxam from duplicate paddy water samples and the mass of inpyrfluxam in the sediment were summed to obtain the mass of inpyrfluxam in the total system. inpyrfluxam dissipated rapidly from the total system with an estimated half-life (DT_{50}) of 0.86 days by the best fit model (DFOP, χ^2 = 5.7). Table 7.8.1/03-9 summarises the results from the total system.

The dissipation half-life of inpyrfluxam following foliar application to a flooded rice field was determined using the PestDF tool. inpyrfluxam dissipated quickly from the paddy water with a calculated half-life (DT_{50}) of 0.485 days by the best fit model (IORE, χ^2 = 6.8). The dissipation of S-2399 from the paddy sediment was considerably slower than from the paddy water with an estimated half-life (DT_{50}) of 105 days by the best fit model (SFO, χ^2 = 53). The average mass of S-2399 from duplicate paddy water samples and the mass of S-2399 in the sediment were summed to obtain the mass of S-2399 in the total system. S-2399 dissipated rapidly from the total system with an estimated half-life (DT_{50}) of 0.86 days by the best fit model (DFOP, χ^2 = 5.7). The results from paddy water, paddy sediment and from the total system are sumamrised in Table 76

Notes:
SFO = Single First Order; DFOP = Double First Order in Parallel; IORE = Intermediate Order Rate Equation.

Inpyrfluxam declines rapidly in the water phase. Formation of the 1'-COOH-S-2840 transformation product in the water phase was observed at low-level concentrations, and its decline was evident within the study period. Inpyrfluxam was observed in the sediment and soil phases at very low concentrations,

with no transformation product residues observed in sediment and soil samples collected at any sampling event. The dissipation half-life of inpyrfluxam following foliar application to a flooded rice field was calculated using the PestDF tool. Inpyrfluxam dissipated quickly from the paddy water with a calculated half-life of 0.485 days by the best fit model (IORE). Dissipation of S-2399 from the paddy sediment was significantly slower with a calculated half-life of 105 days (SFO). S-2399 dissipated rapidly from the system as a whole (paddy water + paddy sediment) with a calculated half-life of 0.86 days by the best fit model (DFOP).

In study TPM-0039, treated and control paddies were sown with rice seeds by hand-broadcast (method equivalent to drilling) at a rate of 185 kg seed/ha. The treated paddy was sown with inpyrfluxam 3.2 FS (flowable concentrate for seed treatment) treated seed (10 grams of active ingredient per 100 kg of seed) which introduced 0.756 gram of S-2399 to the paddy. The control plot was sown with untreated seed. Two days after sowing, both paddies were flooded (average 11 cm of water). At the late boot stage of rice crop development (77 days after sowing), a broadcast foliar application of S-2399 2.84 SC (suspension concentrate) was made to the rice canopy in the treated paddy at a nominal rate of 100 g as/ha.

Paddy water, sediment (0-5 cm) and soil (5-15 cm) samples were collected for residue analysis at pre-determined intervals and analysed for inpyrfluxam and its major transformation products (3'-OH-S-2840 and 1'-COOH-S-2840). The pre-determined intervals began on the day of broadcast foliar application (0 days after application [DAA]) and continued through 90 DAA. The permanent flood was maintained at a relatively constant depth until it was released 28 days after broadcast foliar application (DAA). Sediment and soil sampling continued after the flood release at pre-determined intervals through 90 DAA. Application verification pads (from treated and control paddies) were analysed at 0 DAA to confirm that the target application rate for S-2399 was achieved.

Application verification pads were taken at the day of broadcast application of S-239 2.84SC. Triplicate soil and sediment samples from the control and treated paddy were taken -84, 0, 1, 5, 14, 28, 42, 60 and 90 DAA (days after broadcast application). Paddy water samples were collected at -32, 0, 1, 3 (sample taken before adding water to reset the water depth), 3 (sample taken after addition of water to reset the water depth), 5, 7, 14 and 28 DAA from the control paddy (2 replicates) first, followed by collection from the treated paddy (3 replicates). If an irrigation event was to take place the same day as a scheduled sampling event, water samples were collected prior to the addition of irrigation water. Samples were analysed according to the analytical method RM-50W.

For the application verification (saturation pad) samples, two fortified recovery samples were analysed with the entire batch of application verification samples. Recovery from fortified samples was 106 percent and 107 percent. For the paddy water matrix the overall average recoveries for S-2399, 3'-OH-S-2840 and 1'-COOH-S-2840 were between 78.6 and 120 percent for the fortified samples. For the sediment and soil matrices, the overall average recoveries for S-2399, 3'-OH-S- 2840 and 1'-COOH-S-2840 ranged from 82.1 to 101 percent, 79.9 to 95.4 percent, and 66.8 to 94.9 percent respectively for fortified samples. Hence the methods were considered to be performing appropriately Results from the analysis of paddy water samples for S-2399, 3'-OH-S-2840 and 1'-COOH-S-2840 collected from the treated plot are summarized in Table 77.

Table 77 Mean S-2399 and transformation product paddy water results

Mass balance calculations were not possible as the test substance was not radiolabelled. No degradates were observed in the water phase, soil or sediment above the LOQ. The dissipation half-life of S-2399 following foliar application to a flooded rice field was determined using the PestDF tool. S-2399 dissipated quickly from the paddy water with a calculated half-life (DT_{50}) of 0.0312 days by the best fit model (DFOP, χ^2 = 7.4). There was no dissipation from the paddy sediment over the course of the study.

The average mass of Inpyrfluxam from duplicate paddy water samples and the mass of S-2399 in the sediment, were summed to obtain the mass of S-2399 in the total system. S-2399 dissipated rapidly from the total system with an estimated half-life (DT_{50}) of 0.0641 days by the best fit model (DFOP, χ^2 = 13). Table 80 summarises the results from the paddy water and total system.

Table 80 Dissipation of S-2399 in paddy water, paddy sediment and total system

IORE	0.0844	13.4	16	N = 4.07, k = 0.0000429

Notes:
SFO = Single First Order; DFOP = Double First Order in Parallel; IORE = Intermediate Order Rate Equation.

Inpyrfluxam declines rapidly in the water phase. Inpyrfluxam was observed in the sediment and soil phases at very low concentrations. No transformation product residues were observed in the water phase, sediment and soil samples collected at any sampling event. Inpyrfluxam dissipated quickly from the paddy water with a calculated half-life of 0.0312 days by the best fit model (DFOP). There was no dissipation from the paddy sediment over the course of the study. S-2399 dissipated rapidly from the system as a whole (paddy water + paddy sediment) with a calculated half-life of 0.0641 days by the best fit model (DFOP).

In study TPM-0050 the biotransformation of inpyrfluxam in three water/sediment system (Goose River, Sharkey and Weweantic River) was investigated under aerobic aquatic conditions using [pyrazolyl-4-^{14}C]S-2399.

Three test systems (sediment and water) were collected from the top 0–5 cm layer (Goose River), 0–7.6 cm layer (Sharkey) and 0–7.6 cm layer (Weweantic River). The sediment was thoroughly mixed and passed through a 2-mm mesh sieve with a minimum of air-drying. The sediment and water were stored in the dark before being used. The sediments characteristics are summarised in Table 81.

Table 81 Chemical and physical characteristics of test sediments

% Organic carbon			
% Organic Matter	3.5	2.4	0.9
	6.0	4.2	1.6
USDA Textural class	Clay loam	Clay	Sand
Microbial Biomass Carbon (µg/g dry weight)	72.9 (0 DAT) 73.6 (111 DAT; untreated control) 31.4 (111 DAT; solvent control) 45.3 (111 DAT; S-2399 control)	67.9 (0 DAT) 60.1 (111 DAT; untreated control) 48.9 (111 DAT; solvent control) 69.8 (111 DAT; S-2399 control)	10.4 (0 DAT) <0.1 (111 DAT; untreated control) < 0.1 (111 DAT; solvent control) 3.5 (111 DAT; S-2399 control)

The aerobic aquatic test systems consisted in an incubation apparatus containing 50 g of dry weight sediment and water collected from the same location in a sediment:water ratio of 0.30 (Goose River), 0.29 Sharkey and 0.33 (Weweantic River). The systems were dosed at dry sediment concentrations at *ca*. 0.05 mg/kg (Goose River), 0.06 mg/kg (Sharkey) and 0.06 mg/kg (Weweantic River). The test systems were incubated at 20 ± 2 °C in the dark for a maximum of 111 days and were periodically collected and extracted. The test systems were equipped with 1 M NaOH traps for the collection of evolved $^{14}CO_2$ and tetraglyme/ethylene glycol traps for ^{14}C volatile capture. A pre-incubation period of 8-12 days was performed for the Goose River system, 14 days for the Sharkey sediment system and 4 days for the Weweantic River system before dosing.

Duplicate samples were removed at 0, 1, 3, 7, 15, 30, 45, 62, 76, 91 and 111 DAT and analysed immediately. The physical parameters of the aerobic systems (oxygen concentration, redox and pH) were measured and the water separated from the sediment. The water phase and all eluents were analysed by LSC. The water phase was adjusted to pH 5 and subjected to Solid Phase Extraction (SPE) with water and acetonitrile. Representative samples were analysed by TLC. The sediment samples were extracted with acetone, twice with acetone:water (3:2) and with acetone:water:HCl (c) (60:40:1). The acidic extract rotary-evaporated to remove the acetone was adjusted to pH 5 and subjected to SPE with water and acetonitrile. The activity of the extracts was determined by LSC. The extracts were analysed by HPLC and representative samples by TLC. Selected 62 and 111 DAT samples from the acidic extraction were analysed by HPLC. Representative PES at 111 DAT were subjected to further additional sequential solvent extractions with ethyl acetate, dioxane and hexane, and with a dismembrator (5:1 acetone:0.5 M HCl) for comparison. The radioactivity was determined by LSC and the extract was analysed by HPLC. Total radioactivity in PES was determined by combustion. The Goose River PES was finally subjected to a Humin, Humic Acid and Fulvic Acid Fractionation. The $^{14}CO_2$ collected in the NaOH trapping solution and organic volatiles collected in tetraglyme/ethylene glycol traps were quantified by LSC. The potential isomerisation from [^{14}C]S-2399 was evaluated using chiral HPLC analysis on the extracts obtained from the 111 DAT samples.

No significant change in the microbial biomass carbon was recognized between the initiation and termination of the incubation (Table 81). Thus, microbial viability was proved to be satisfactorily

maintained during the incubation period. It must be noted that values for the Weweantic River are considered not atypical for the type of sediment.

It was confirmed that no isomerisation of [^{14}C]S-2399 occurred during incubation period based on chiral HPLC analysis.

The distribution and mass balance of applied radioactivity of [^{14}C]S-2399 in water phase, extractable, sediment-bound and volatile fractions are summarised in Table 82 to Table 84. The quantification of S-2399 and the degradates in the neutral extracts and water phase is summarised in Table 85 to Table 87. The acidic sediment extracts at 62 and 111 DAT showed only the presence of S-2399, and 3'-OH-S-2840 and other unknowns in only very low percentage of applied radioactivity (Table 82).

The average mass balance was 99.5 ± 1.9 percent AR for the Goose River system, 99.6 ± 3.1 percent for the Sharkey system and 99.2 ± 1.1 percent for the Weweantic River system. The radioactivity remaining in sediment following the neutral and acidic extractions was 13 percent of the AR (Goose River), 5 percent of the AR (Sharkey) and 3 percent of the AR (Weweantic River) by the end of the study (111 DAT). Additional extractions (ethyl acetate extract, 4.5 percent of the AR; dioxane and hexane extract, <1 percent of the AR; dismembrator extract, 6.4 percent of the AR) of the Goose River and fractioning into humin (5.5 percent of AR), humic acid (0.8 percent of AR) and fulvic acid (1.0 percent of AR) fractions was performed. The total amount of carbon dioxide generated during the study phase was negligible, reaching 0.5 percent of the AR in the Goose River system, 0.1 percent in the Sharkey system and 0.0 percent in the Weweantic River system.

Two degradates were observed above 2.5 percent AR: 3´-OH-S-2840, and 1'COOH-S-2840. The maximum observed 3´-OH-S-2840 and 1'-COOH-S-2840 (as 1'-COOH-S-2840 A + 1'-COOH-S-2840 B) were 2.9 and 8.1 percent AR respectively at 111 DAT in the Goose River system and 2.8 percent AR at 91 DAT and 7.3 percent AR at 111 DAT respectively in the Sharkey system. In the Weweantic River system, the maximum observed 3´-OH-S-2840 and 1'-COOH-S-2840 were 2.2 and 5.2 percent AR at 62 DAT. The aerobic aquatic metabolism degradation pathway of S-2399 is summarized in Figure 10. Proposed aerobic aquatic degradation pathways of S-2399.

A whole system aerobic aquatic half-life was estimated using the PestDF kinetics (this is consistent with the FOCUS approach) for the three systems. As a conservative approach the radioactivity in the acidic extract was added to the identified S-2399 in the water and neutral sediment extract, for the DT_{50} calculation. The estimated aerobic aquatic half-lives for the Goose River, Sharkey and Weweantic River sediment systems were 319, 563 and 704 days (SFO) respectively. Chi^2 error values were 1.6, 1.3 and 1.1 percent, respectively.

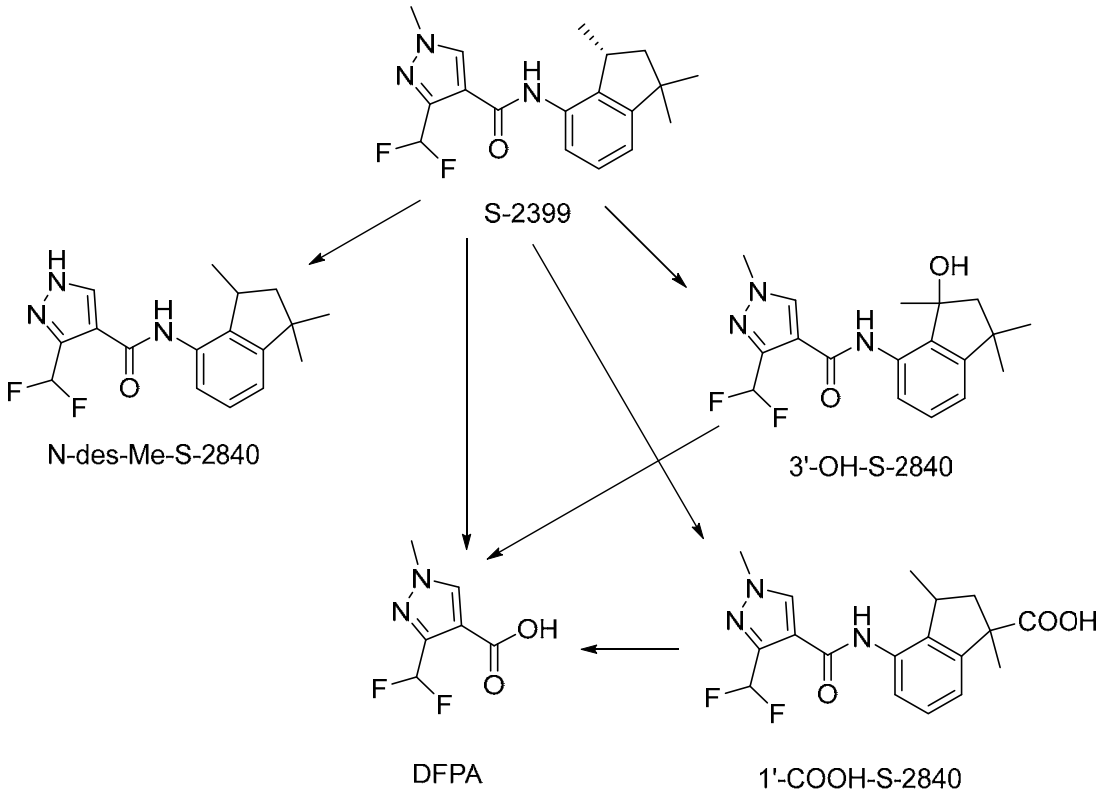

Figure 11 Proposed aerobic aquatic degradation pathways of Inpyrfluxam

The degradation pattern of Inpyrfluxam was similar in all three sediment systems. Inpyrfluxam declined to 75, 84 and 88 percent of the AR (total S-2399 in neutral and acidic extract and water) by the end of the 111 DAT study in the Goose River, Sharkey and Weweantic River sediment systems, respectively with aerobic aquatic half-lives estimated at 319, 563 and 704 days (SFO, PestDF). Degradate formation was primarily to 1'-COOH-S-2840 and 3'-OH-S-2840, formed at maximum levels of 8.1 and 2.9 percent AR respectively for the Goose River system, 7.3 and 2.8 percent AR respectively for the Sharkey system and 5.3 and 2.2 percent AR respectively for the Weweantic River system during the study.

RESIDUE ANALYSIS

Analytical methods

The meeting received analytical methods for the determination of inpyrfluxam and its metabolites in plant and livestock matrices. An overview of the analytical method is presented in Table 89.

Notes:
[a] Conjugated forms of the metabolites were hydrolysed and detected as inpyrfluxam, 1'-CH_2OH-S-2840-A, 1'- CH_2OH-S-2840-B, 1'-COOH-S-2840-A, or 1'-COOH-S-2840-B.

Plant materials

In apple, corn grain, corn stover, corn forage and soya bean the method RM-50C-1 was used for data generation. The analytical method RM-50C-1 determines residues of inpyrfluxam and its metabolites 3'-OH-S-2840, 1'-CH_2OH-S-2840-A, 1'-CH_2OH-S-2840-B, DFPA-$CONH_2$, 1'-COOH-S-2840-A and 1'-COOH-S-2840-B.

Residues are extracted from crops using three extractions with acetonitrile/water (1:1). The residues of inpyrfluxam, 3'-OH-S-2840 and 1'-CH_2OH-S-2840-A/-B are partitioned into hexane/ethyl acetate (4:1). The water fraction undergoes purification on a Strata-X column. The sample is split with one portion analysed for DFPA-$CONH_2$ and the other portion for the analysis of conjugates of 1'-COOH-S-2840-A, 1'-COOH-S-2840-B, 1'-CH_2OH-S-2840-A and 1'-CH_2OH-S-2840-B. The DFPA-$CONH_2$ portion is added to half of the hexane/ethyl acetate portion containing the other free compounds, evaporated to dryness, dissolved in methanol/water (1:1) and the residues are quantitated by HPLC-MS/MS. The remaining second fraction from the Strata-X column is hydrolysed with HCl (2 M) to free analytes from the

conjugates, purified on a Strata-X column, evaporated to dryness and dissolved in methanol/water (1:1) before being analysed by HPLC-MS/MS. The method also includes conditions for the optional use of internal standards.

Method RM-50C-1 was validated by fortification with inpyrfluxam, 3'-OH-S-2840, 1'-CH_2OH-S-2840-A, 1'-CH_2OH-S-2840-B, DFPA-$CONH_2$, 1'-COOHS-2840-A and 1'-COOH-S-2840-B at nominal concentrations of 0.01 mg/kg (LOQ) and 0.10 mg/kg to apples, corn grain and soya beans and 0.05 mg/kg for apple aglycone metabolites at nominal concentrations of 0.02 mg/kg (LOQ for livestock feed matrices) and 0.20 mg/kg to corn stover and forage.

For the analysis of metabolite *N*-des-Me-DFPA Method RM-50C-2 was used for data generation. Conjugated forms of the metabolite are cleaved by acid hydrolysis to form the free acid prior to analysis. This method is a supplemental procedure for extracts obtained utilising method RM-50C-1.

In method RM-50C-1, residues are removed from crops using three extractions of acetonitrile/water (1:1). In method RM-50C-2, the organic solvent is removed from the 10 mL extract aliquot and the total volume is returned to 10 mL using HPLC-grade water. The solution is partitioned with hexane/ethyl acetate (8:2). An aliquot of the aqueous layer is pH adjusted with concentrated HCl to create a 4 N acidic solution. The solution undergoes acid hydrolysis for 4 hours at 95 °C. The pH of the cooled solution is adjusted to pH 3 ± 1 using concentrated ammonium hydroxide and loaded onto an unbuffered, Agilent Chem Elut solid phase extraction (1 g, 20 cc) cartridge. *N*-des-Me-DFPA is eluted with ethyl acetate, rotary evaporated to dryness and reconstituted in methanol/water (1:1). An internal standard, *N*-des-Me-DFPA-13C3 was also used. Samples were analysed using HPLC/MS-MS.

Method RM-50C-2 was validated by fortification with *N*-des-Me-DFPA at nominal concentrations of 0.01 mg/kg (LOQ) and 0.10 mg/kg (10x LOQ) to apple, soya bean seed, corn grain and corn stover. The mass transitions employed in this method RM-50C-1 are summarised in Table 90.

Table 90 Mass transitions for analytes determined with the method RM-50C-1

Due to problems identified with the consistency of the Chem Elut SPF cartridges using in method RM-50C-2 the method RM-50C-2a was created in which a Waters Oasis HLB is used instead.

In method RM-50-2a, the organic solvent is removed from a 10 mL (or 20 mL for feed items such as corn stover) extract aliquot and the total volume is adjusted to 10 mL using HPLC-grade water.

Residues are partitioned against hexane/ethyl acetate (8:2) and residues in the aqueous layer are hydrolysed using a 4 N HCl solution for 4 hours at 95 °C. The solution is then cooled, the pH adjusted to 3 ± 1 using concentrated ammonium hydroxide and residues are purified using a solid phase extraction (SPE, Waters Oasis HLB) cartridge conditioned with methanol and water (1:1) and eluted with acetone. Residues are concentrated, reconstituted in methanol/water (1:1) and quantified by HPLC-MS/MS using an internal standard. The method was validated by fortification with inpyrfluxam and *N*-des-Me-DFPA at nominal concentrations of 0.02 mg/kg (LOQ) and 0.10 mg/kg. The mass transitions employed in methods RM-50C-2 and RM-50C-2a are summarised in Table 91.

Table 91 Mass transitions for analytes determined with the method RM-50C-2 and RM-50C-2a

Analyte	Ion Mode	Mass transition (m/z)
N-des-Me-DFPA	ESI^+	161.0 → 141.0
N-des-Me-DFPA-13C3	ESI^+	164.0 → 144.0

Note:
ESI+: Electron spray ionization mode in positive mode

An additional method SUM-1601V (TPA-0057 and TPR-0080) was used for data generation that determines residues of inpyrfluxam and its metabolites 3'-OH-S-2840, 1'-CH_2OH-S-2840-A, 1'-CH_2OH-S-2840-B, DFPA-$CONH_2$, 1'-COOH-S-2840-A and 1'-COOH-S-2840-B in wheat (whole plant), wheat (grain), potato (tubers), grapes, soya bean (seeds), lettuces (w/o roots), carrot (roots) and carrots (leaves + top).

Samples were homogenised with acetonitrile/water (1:1) and mechanically shaken for 30 minutes. The extracts are filtered through filter paper and Celite (40 g suspended is methanol (80 mL) in a Buchner funnel. The extraction/filtration process is repeated twice more, with the extracts combined and made up with acetonitrile/water (1:1).

For inpyrfluxam, 3'-OH-S-2840 and DFPA-$CONH_2$, an aliquot is transferred to a test tube, evaporated to dryness with nitrogen at 40 °C then reconstituted in water/methanol (3:1 v/v) prior to analysis.

For DFPA, 1'-COOH-S-2840-A and B and 1'-CH_2OH-S-2840-A and B, an aliquot of the combined extract is hydrolysed with 4 M hydrochloric acid for 4 hours at 100 °C, cooled to room temperature and cleaned up using an Oasis HLB cartridge. The analytes are eluted with methanol (10 mL), evaporated to 5 mL under nitrogen at 40 °C and diluted with water to 20 mL prior to analysis.

For *N*-des-Me-DFPA, an aliquot of the combined extract is hydrolysed with 6 M hydrochloric acid for 6 hours at 100 °C and diluted to 15 mL with water. The extract is cleaned up with a Chem Elut cartridge, eluted with ethyl acetate (4 × 25 mL) and evaporated to dryness under vacuum at 40 °C and reconstituted in water/methanol (3:1) with sonication before being made up to 10 mL with water/methanol (3:1). All samples are analysed by HPLC-MS/MS. The mass transitions employed in methods SUM-1601V are summarised in Table 92.

Table 92 Mass transitions for analytes determined with the method SUM-1601V

Analyte	Ion Mode	Mass transition (m/z)	Quantification/Confirmation
inpyrfluxam	ESI^+	334 → 294	Quantification
	ESI^+	334 → 238	Confirmation
DFPA-$CONH_2$	ESI^+	176 → 136	Quantification
	ESI^+	176 → 156	Confirmation
3'-OH-S-2840	ESI^-	348 → 175	Quantification
	ESI^-	348 → 131	Confirmation
N-des-Me-DFPA	ESI^-	161 → 141	Quantification

Analyte	Ion Mode	Mass transition (m/z)	Quantification/Confirmation
	ESI^-	161 → 66	Confirmation
DFPA	ESI^+	177 → 137	Quantification
	ESI^-	175 → 91	Confirmation
	ESI^+	177 → 137	Confirmation
1'-COOH-S-2840-A & B	ESI^+	364 → 278	Quantification
	ESI^+	364 → 318	Confirmation
	ESI^-	362 → 318	Confirmation
1'-CH_2OH-S-2840-A & B	ESI^+	350 → 292	Quantification
	ESI^+	350 → 312	Confirmation
	ESI^+	350 → 262	Confirmation

Notes:
ESI+: Electron spray ionization mode in positive mode. ESI-: electron spray ionization mode in negative mode

The method was validated by fortification with inpyrfluxam, 3'-OH-S-2840, DFPA-$CONH_2$, *N*-des-Me-DFPA and DFPA at nominal concentrations of 0.02 mg/kg (LOQ) and 0.10 mg/kg and with 1'-COOH-S-2840-A&B and 1'-CH_2OH-S-2840-A&B at nominal concentrations of 0.005 mg/kg (LOQ) and 0.10 mg/kg.

For the determination of *N*-des-Me-S-2840 residues in wheat (whole plant), wheat (grain), potato (tubers), grapes, soya bean (seeds), lettuces (w/o roots), carrot (roots) and carrots (leaves + top) the method SUM-1701V was used for data generation.

Samples were homogenised with acetonitrile/water (1:1) and mechanically shaken for 30 minutes. The extracts are filtered through filter paper and Celite (40 g suspended is methanol (80 mL) in a Buchner funnel. The extraction/filtration process is repeated twice more and the extracts combined and made up to 200 mL with acetonitrile/water (1:1). For *N*-des-Me-S-2840, an aliquot is transferred to a test tube, evaporated to dryness with nitrogen at 40 °C then reconstituted in water/methanol (3:1) prior to analysis. Samples are analysed by HPLC-MS/MS. The method was validated by fortification with *N*-des-Me-S-2840 at nominal concentrations of 0.01 mg/kg (LOQ) and 0.10 mg/kg. The mass transitions employed in methods SUM-1701V are summarised in Table 93.

Table 93 Mass transitions for analytes determined with the method SUM-1701V

Analyte	Ion Mode	Mass transition (m/z)	Quantification/Confirmation
N-des-Me-S-2840	ESI^-	318 > 278	Quantification
	ESI^+	320 > 280	Confirmation

Notes:
ESI+: Electron spray ionization mode in positive mode. ESI-: electron spray ionization mode in negative mode

An additional method JP2015C239 was used for the determination of inpyrfluxam, 3'-OH-S-2840, 1'-CH_2OH-S-2840-A, 1'-CH_2OH-S-2840-B, DFPA-$CONH_2$ and *N*-des-Me-DFPA in apples in studies JP2015C239, JP2016C334 and JP2014C288.

In brief, the homogenised samples were extracted with acetonitrile/water (1:1). For the analysis of inpyrfluxam and 3'-OH-S-2840, an aliquot of the extract was purified with a pre-conditioned HLB mini-column and then quantified by HPLC-MS/MS. For DFPA-$CONH_2$ an aliquot was purified with a graphite carbon mini-column and then quantified using HPLC-MS/MS. The metabolites 1'-CH_2OH-S-2840-A and 1'-CH_2OH-S-2840-B were hydrolysed with alkali and enzymes or 4 M hydrochloric acid for 4 hours at 100 °C followed by purification with a pre-conditioned HLB mini-column and then quantified using HPLC-MS/MS. For the extraction of the metabolite *N*-des-Me-DFPA, samples were refluxed with hydrochloric acid (6

hours, 105 °C) followed by purification with a macroporous diatomaceous earth column and cation exchange mini-column and then quantified by using HPLC-MS/MS.

The method was validated by fortification with inpyrfluxam, 3'-OH-S-2840, DFPA-$CONH_2$and 1'-CH_2OH-S-2840 (sum of 1'-CH_2OH-S-2840-A and 1'-CH_2OH-S-2840-B), at nominal concentrations of 0.01 mg/kg (LOQ) and 0.1 mg/kg and 1'-CH_2OH-S-2840-A and 1'-CH_2OH-S-2840-B at nominal concentrations of 0.005 mg/kg and 0.1 mg/kg. The mass transitions employed in method JP2015C239 are summarised in Table 94.

Table 94 Mass transitions for analytes determined with the method JP2015C239

Analyte	Ion Mode	Mass transition (m/z)
Inpyrfluxam	ESI^-	332 → 91
3'-OH-S-2840	ESI^-	348 → 175
DFPA-$CONH_2$	ESI^+	176 → 156
1'-CH_2OH-S-2840-A and -B	ESI^+	350 → 292
N-des-Me-DFPA	ESI^-	161 → 141

Notes:
ESI+: Electron spray ionization mode in positive mode. ESI-: electron spray ionization mode in negative mode.

In all methods, the mean recoveries were within the range of 70–120 percent and relative standard deviations (RSD) were less than 20 percent for all analytes tested. In all cases, the analytical procedures have been successfully validated in terms of specificity, linearity, precision, accuracy, and LOQ. A summary of method validation recovery data is presented in Table 95.

For enforcement, the multi-residue QuEChERS method using liquid chromatography coupled with tandem mass spectrum detection (LC-MS/MS) has been validated, in the study TPA-0027, at the LOQ of 0.01 mg/kg for determining inpyrfluxam in wheat (grain), cucumber, soya bean (seeds) and grapes. An independent laboratory validation was carried out and reported in TPA-0048.

Homogenised samples (5 g wheat grain or soya bean seeds, 10 g cucumber or grapes) were combined with water (*ca.* 10 mL; wheat grain and soya bean seeds only) and the samples were allowed to soak for 20 minutes at room temperature. All the samples were extracted with acetonitrile (*ca.* 10 mL) on a platform shaker for 15 minutes before the addition of magnesium sulfate (4.0 g), sodium chloride (1.0 g), trisodium citrate dihydrate (1.0 g) and disodium hydrogen citrate sesquihydrate (0.5 g). The samples were shaken by hand for approximately 1 minute followed by centrifugation.

For wheat grain and soya bean seed samples, after complete phase separation, aliquots of the upper acetonitrile phase were centrifuged and the supernatant separated. For all matrices, aliquots of acetonitrile phase (1.5 mL) were combined with 40 mg of primary secondary amine and 225 mg of magnesium sulfate. The samples were vortex mixed, shaken by hand for 30 seconds and centrifuged. Aliquots of the extracts were diluted to 10 mL with acetonitrile/0.1 percent formic acid (7:3).

The samples were analysed by HPLC-MS/MS in positive ion mode. The limit of quantification (LOQ) for inpyrfluxam, defined as the lowest fortification level at which acceptable recovery and repeatability data were obtained, was demonstrated to be 0.01 mg/kg. Quantification was performed using external standards. The ion transition m/z 334 → 258 $gmol^{-1}$ was used for quantification and the ion transition m/z 334 → 238 $gmol^{-1}$ was used for confirmation.

Mean recoveries were within the range of 70-120 percent and relative standard deviations (RSD) were less than 20 percent for all analytes tested. In all cases, the analytical procedures have been successfully validated in terms of specificity, linearity, precision, accuracy, and LOQ. A summary of method validation recovery data is presented in Table 95.

Animal matrices

The analytical method TPR-0013 analyses inpyrfluxam and its metabolites 1'-CH_2OH-S-2840-A, 1'-CH_2OH-S-2840-B, 1'-COOH-S-2840-A and 1'-COOH-S-2840-B in samples of poultry egg, muscle, liver and fat. Milk/skim/cream samples were extracted with acetone, liver/kidney/muscle samples with acetonitrile/water (1:1) and fat samples were extracted with hexane/acetone (4:1).

The extraction was repeated twice more, firstly for milk/skim/cream/fat samples with acetone and for liver/kidney/muscle samples with acetonitrile/water (1:1). The final extraction was carried out for milk/skim/cream samples with acetone/water (1:1), for liver/kidney/muscle samples with acetonitrile or fat with acetone. The samples were centrifuged after each partition to remove and combine the supernatants. The "initial extract" is then used to prepare two separate final extracts, one for analysis of inpyrfluxam, 1'-COOH-S-2840-A and -B residues and another for analysis of 1'-CH_2OH-S-2840-A and -B residues.

For the determination of residues of inpyrfluxam, 1'-COOH-S-2840-A and -B in all matrices except fat, an aliquot of the "initial extract" was diluted with methanol/water (1:1) then filtered. For fat, an aliquot of the "initial extract" was diluted with hexane and partitioned twice with acetonitrile. The acetonitrile layers were combined and concentrated to near dryness before being reconstituted in methanol/water (1:1) prior to analysis.

For the determination of 1'-CH_2OH-S-2840-A and -B residues in all matrices except fat, an aliquot of the "initial extract" was acidified (1 M HCl) and hydrolysed for 4 hours at 100 °C to release free forms of 1'-CH_2OH-S-2840-A and -B metabolites from potential conjugates. For fat extracts, an aliquot of the "initial extract" is first concentrated to near dryness, then reconstituted with acetonitrile/water (1:1) prior to acidification and hydrolysis as above. For all matrices, the resulting hydrolysed extract is cleaned up using a Waters Oasis HLB solid phase extraction (SPE) cartridge. Samples are analysed by HPLC-MS/MS

in both positive and negative modes. Quantification is performed using external standards. The LOQ was determined to be 0.01 mg/kg for inpyrfluxam and 0.005 mg/kg for metabolites 1'-COOH-S-2840-A/-B and 1'-CH_2OH-S-2840-A/-B. The following mass transitions were employed:

Analyte	Ion Mode	Mass transition (m/z)	Quantification/Confirmation
inpyrfluxam	ESI^+	334 → 238	Quantification
	ESI^+	334 → 258	Confirmation
1'-COOH-S-2840-A and -B	ESI^-	362 → 318	Quantification
	ESI^-	362 → 131	Confirmation
1'-CH_2OH-S-2840-A and -B	ESI^+	350 → 292	Quantification
	ESI^+	350 → 312	Confirmation

Notes:
ESI+: Electron spray ionization mode in positive mode. ESI-: electron spray ionization mode in negative mode.

An additional analytical method (TPR-0015) was used for analysis of inpyrfluxam and its metabolites 1'-CH_2OH-S-2840-A, 1'-CH_2OH-S-2840-B, 1'-COOH-S-2840-A and 1'-COOH-S-2840-B in samples of bovine milk, liver, fat, muscle and kidney for data generation.

Homogenised tissue samples (muscle, liver, fat or egg) were extracted using vigorous mechanical shaking with different extraction solvents. Egg/white/yolk samples were extracted with hexane/acetone (1:1), while liver/muscle samples were extracted with acetonitrile/water (1:1) and fat was extracted with hexane/acetone (4:1). The extractions were repeated a further two times on the pellet with egg/white/yolk/fat samples using acetone and acetonitrile/water (1:1) for muscle/liver samples. The samples were then centrifuged each time to remove and combined supernatants. The "initial extract" was used to prepare two separate final extracts, one for analysis of inpyrfluxam, 1'-COOH-S-2840-A and B residues and another for analysis of 1'-CH_2OH-S-2840-A and B residues.

For the determination of residues of inpyrfluxam, 1'-COOH-S-2840-A and -B in eggs and fat samples, an aliquot of the "initial extract" was diluted with hexane then partitioned twice with acetonitrile. The acetonitrile layers were combined and concentrated to near dryness. The resulting concentrate was reconstituted in methanol/water (1:1) before being further diluted/filtered as necessary and presented for analysis.

For the determination of 1'-CH_2OH-S-2840-A and B residues in eggs and fat samples, an aliquot of the "initial extract" was first concentrated to near dryness, before being reconstituted with acetonitrile/water (1:1), acidified (1 M HCl) and then hydrolysed for 4 hours at 100 °C to release 1'-CH_2OH-S-2840-A and -B metabolites from potential conjugates.

For muscle and liver extracts, an aliquot of the "initial extract" is directly acidified (without concentration), then hydrolysed as above. For all matrices, the resulting hydrolysed extract is purified using a Waters Oasis HLB solid phase extraction (SPE) cartridge. The resulting final extract is presented for analysis.

Samples are analysed by HPLC-MS/MS in both positive and negative ion modes. Quantification is performed using external standards. Analyte identity was confirmed by comparison of the retention time of the analyte with that of a reference standard. The following mass transitions were the same as shown previously.

In both methods, the mean recoveries were within the range of 70–120 percent and relative standard deviations (RSD) were less than 20 percent for all analytes tested in most cases. An exception was observed in the method TPR-0015 for 1'-COOH-S-2840-A at the 0.005 mg/kg level where the mean recovery was marginally outside these levels in egg and muscle matrices. In principle, the analytical

procedures have been successfully validated in terms of specificity, linearity, precision, accuracy, and LOQ. A summary of method validation recovery data for inpyrfluxam is presented in Table 96.

For enforcement, the multi-residue QuEChERS method using LC-MS/MS has been validated, in the study TPA-0049, at the LOQ of 0.01 mg/kg for determining inpyrfluxam in bovine whole milk, poultry eggs, bovine fat, bovine muscle meat and bovine liver. In addition, this method was validated at an LOQ of 0.01 mg/L in bovine blood and urine. An ILV (TPA-0061) of the method TPA-0049 was also provided in which an LOQ for inpyrfluxam was demonstrated to be 0.01 mg/kg in bovine fat and bovine liver.

For bovine whole milk, poultry eggs, bovine muscle, bovine liver, bovine fat (5 g) and bovine blood (5 mL), water (*ca.* 6-10 mL) and acetonitrile (*ca.* 10 mL) were added. For urine, only acetonitrile (*ca.* 10 mL) was added. The samples were shaken for 15 minutes on a platform shaker (with heating in a water bath at 60 °C for bovine fat). The contents of QuEChERS Bekolut Citrate Kit 01 (magnesium sulfate (4.0 g), sodium chloride (1.0 g), trisodium citrate dehydrate (1.0 g) and disodium hydrogen citrate sesquihydrate (0.5 g)) were added and the samples shaken by hand vigorously for 1 minute; all samples were then centrifuged.

An aliquot of the acetonitrile extract (*ca.* 1 mL) was purified using an PSA-KIT-03 (Bekolut) containing PSA (primary secondary amine, 25 mg), C18 (25 mg) and magnesium sulfate (150 mg). The tubes were vortex mixed, shaken by hand for 30 seconds and centrifuged. Aliquots of the final extract were diluted with acetonitrile/0.1 percent formic acid (1:1).

The samples were analysed by LC-MS/MS in positive ion mode. Quantification was performed using external standards. The LOQ was determined to be 0.01 mg/kg for inpyrfluxam and 0.005 mg/kg for metabolites 1'-COOH-S-2840-A and -B and 1'-CH_2OH-S-2840-A and -B. A summary of method validation recovery data is presented in Table 96.

Table 96 Summary of method validation recovery data for inpyrfluxam and metabolites in animal matrices (n=5)

Soil

The analytical methods in studies TPA-0028, TPA-0043 and TPA-0070 are being proposed for analysis of inpyrfluxam and and its metabolites (3'-OH-S-2840, 1'-COOH-S-2840-A and 1'-COOH-S-2840-B) in soil for data generation.

In methods RM-50S (TPA-0028 and TPA-0070), soil samples (10.0 g) are weighted and 25 mL acetone/water (4:1) is added. The samples are shaken for 30 minutes and centrifuged for 5 minutes at 2000 rpm. The extraction step is repeated, combining the extracts in graduated cylinders (100 mL). 25 mL

acetone/0.5M HCl (4:1 v/v) is added and the samples shaken for 30 minutes and centrifuged for 5 minutes. The extracts are combined with the first two in the graduated cylinder, 0.5 M sodium acetate solution (2 mL) is added, and the samples mixed. The residues are partitioned into dichloromethane, the solvent evaporated and the residues dissolved in methanol/water (1:1). The samples are analysed by high performance liquid chromatography with tandem mass detection (HPLC-MS/MS) in both positive and negative ion modes using an C_8 column..

In method TPA-0043, soil samples (5.0 g) are weighed and acetone/water (80:20, 12.5 mL) is added. The samples are mechanically shaken for 10 minutes, centrifuged at 4000 rpm for 5 minutes and the supernatant is transferred to a fresh centrifuge tube (50 mL). The extraction process is repeated again and the supernatants combined. Acetone/0.5 M HCl (80:20, 12.5 mL) is added and the samples mechanically shaken for 10 minutes. 5 M sodium hydroxide (1mL) is added and the samples are shaken briefly by hand. The supernatants are filtered through filter paper covered in small amounts of celite and the combined supernatants adjusted to 50 mL with acetone/water (80:20). Aliquots (10 mL) are transferred to Schott bottles (100 mL) and ethyl acetate (32 mL) is added. The samples are agitated for 10 minutes on a horizontal flatbed shaker, before solid NaCl is added and the samples shaken for a further 2 minutes. Following addition of sodium sulphate, the samples are shaken further for 2 minutes. Aliquots of the supernatant (20 mL) are transferred to pear-shaped flasks and evaporated to dryness on a rotary evaporator at 40°C. The dried residues are reconstituted with methanol (0.125 mL) followed by water (0.375 mL) with the assistance of sonication. The samples are analysed by high performance liquid chromatography with tandem mass selective detection (HPLC-MS/MS) in positive and negative ionisation modes, using a C_{18} column.

A summary of the validation data for both methods are presented in Table 97.

In study TPA-0062, the extraction efficiency of radioactivity and inpyrfluxam from various crops (rice grain, rice straw, soya bean pods, apple) using a modified QuEChERS analytical method (TPA-0027) was compared to the results from the original analyses performed in the corresponding metabolism studies. The test systems used for the extraction efficiency experiment are rice samples from study TPM-0014, soya bean samples from study TPM-0015 and apples from study TPM-0013.

In the metabolism studies, soya bean pods and apple fruit were rinsed with acetonitrile. Rice grain and rice straw were not rinsed. A portion of rinsed apple fruit was further separated into peel and pulp. Rinsed matrices and unrinsed rice grain and rice straw were processed to a fine consistency in food processors in the presence of dry ice.

As all apples and mature soya bean pods were rinsed during the metabolism studies, rinsed whole apples and mature soya bean pods were used for the QuEChERS analytical method. Rinsed whole apples treated with [phenyl-U-^{14}C]inpyrfluxam were processed in a food processor to a fine consistency in the presence of dry ice. The dry ice was allowed to sublime overnight in a freezer. The rinses and extracts were radio-assayed directly by LSC in triplicate aliquots. The processed samples were combusted to determine the residue levels present.

In the original metabolism studies, aliquots of processed rice grain, rice straw, apple peel, apple fruit pulp (20–50 g) and mature soya bean pods (20–30 g) were extracted using a neutral solvent mixture of acetonitrile and water. Rice grain, rice straw and mature soya bean pod matrices were extracted twice with acetonitrile/water (1:1) and once with acetonitrile. Apple peel and pulp were extracted once with acetonitrile/water (1:1) and once with acetonitrile. For each extraction, the solution was mechanically shaken for *ca.* 30 minutes. The mixture was centrifuged and the supernatant was measured and aliquots were analysed by LSC. No further extractions were performed on apple pulp or peel. Soybean and rice matrices were further extracted with other solvents.

For the QuEChERS extraction method, aliquots of processed rice grain (*ca.* 5 g), rice straw (*ca.* 2 g), mature soya bean pod (*ca.* 2 g) or whole apple (*ca.* 10 g) were used and the amount of moisture in each aliquot was calculated. To rice grain, water was added to result in a total moisture content of 10 mL and acetonitrile (10 mL) was added to give a 1:1 solution. To rice straw (*ca.* 2 g), water was added to result in a total moisture content of 15 mL and acetonitrile (15 mL) was added to give a 1:1 solution. To mature soya bean pods (*ca.* 2 g) water was added to result in a total moisture content of 15 mL and acetonitrile (15 mL) was added to give a 1:1 solution. To whole processed apple, water was added to result in a total moisture content of 10 mL and acetonitrile (10 mL) was added to give a 1:1 solution.

Rice grain, rice straw and soya bean samples were left to soak for 20 minutes at room temperature between the addition of water and acetonitrile. Acetonitrile was added to apple samples

directly after the addition of water. Samples were shaken vigorously for 15 minutes. Samples were centrifuged, the supernatant volume was measured and aliquots were analysed by LSC.

The post-extraction solid residues (PES) from the modified QuEChERS method were analysed by combustion of the dried samples. The TRR for treated plant matrices was determined as the sum of QuEChERS extraction and PES. In the original studies, the TRR was determined by the sum of rinses (if any), acetonitrile/water extracts and PES.

In the original apple metabolism study, fruit peel and pulp were extracted separately. In order to compare the data obtained by modified QuEChERS extraction of whole fruit to the original data, the original peel and pulp TRR were determined by normalizing the weights of peel and pulp to the calculated weight of whole fruit. Analysis of the samples was performed by HPLC-UV. For apple, rice grain and soya bean the LOQ was determined as 0.002 mg/kg, while for rice straw the LOQ was determined to be 0.003 mg/kg.

For rice grain, the original metabolism method extracted somewhat more radioactivity than the QuEChERS method (95.9 and 74.5 percent of TRR, respectively). For rice straw, the multiple acetonitrile/water extractions removed more radioactivity than the modified QuEChERS method (81.4 and 56.1 percent of TRR, respectively). For mature soya bean pod, the combination of the acetonitrile rinse and acetonitrile/water extraction removed more radioactivity than the modified QuEChERS method (58.8 and 44.0 percent of TRR, respectively). For whole apple fruit, multiple acetonitrile/water extractions of peel and peeled fruit removed more radioactivity than the QuEChERS method applied to whole fruit (90.5 and 53.2 percent of TRR, respectively).

HPLC analysis of extracts showed similar profiles for the two methods. inpyrfluxam was the largest component and comparing the results from the original metabolism method to the modified QuEChERS method, inpyrfluxam was present in similar concentrations. The level of inpyrfluxam extracted (mg/kg and/or percent TRR) by the modified QuEChERS method was similar to the level extracted by the original metabolism method. A summary of the percent TRR and distribution of residues (mg/kg eq) is presented in Table 99.

Based on these results it was concluded that the extraction procedure based on the QuEChERS method is suitable for the extraction of a large fraction of the total radioactive residues and determination of residues of inpyrfluxam in foodstuffs of plant origin.

Table 99 Summary percent TRR and distribution of residues (mg/kg eq) between the QuEChERS method (TPA-0027) and the metabolism studies in apples (TPM-0013), rice (TPM-0014) and soybeans (TPM-0015)

Notes:
[a] TRR determined by sum of fractions.
[b] inpyrfluxam value from the extract stability analysis after 21 months storage.
[c] TRR in mature pods (including rinses) was 0.742 mg/kg. Rinses accounted for 0.055 mg/kg (7.4% TRR), of which 0.046 mg/kg (6.2% TRR) was inpyrfluxam. Extracts of rinsed pods accounted for 0.436 mg/kg (58.8% TRR), of which 0.170 mg/kg (23.0% TRR) was inpyrfluxam.
[d] Apple pulp and peel values were normalized to the weight of whole apple.
%TRR = mg/kg (Extraction or PES or inpyrfluxam) ÷ TRR * 100.

In study TPA-0030 the extraction efficiency of the method RM-50C-1 was evaluated. Rice straw and radish tops were extracted by two separate methods. In the case of rice straw, the 1st method, extraction was performed in the same manner as in the metabolism studies (TPM-0016 and TPM-0047) and the 2nd method extraction was performed in accordance with the residue method RM-50C-1 (201700135).

In the case of mature radish tops in the 1st method, extraction was performed in the same manner as in the confined rotational crop study (TPM-0047) while in the 2nd method, extraction was performed in accordance with the residue method RM-50C-1 (201700135).

Extraction efficiencies of inpyrfluxam and its metabolites in rice straw and radish tops were determined for the residue method RM-50C-1. The residue method extractions of rice straw and radish tops solubilized 69.5 and 88.4 percent TRR, respectively, compared to 64.6 percent and 90.4 percent of TRR in the metabolism method extracts. The metabolism and the residue method showed equivalent extraction efficiency and equivalent hydrolysis effectiveness for generating the aglycones. A summary of the percent TRR and distribution of residues (mg/kg eq) is presented in Table 100.

Table 100 Summary percent TRR and distribution of residues (mg/kg eq) between the RM-50C-1 method (201700135) and the metabolism studies in rice straw (TPM-0016 and TPM-0047) and mature radish tops (TPM-0047)

In study TPA-0054 the extraction efficiency of the method TPR-0013 was investigated. The method was to determine the residues of metabolites in select tissues from TPM-0024 (lactating goat) and TPM-0025 (laying hens) metabolism studies.

Extraction efficiency was comparable between the metabolism study extraction and the residue method extraction based on total extracted residue or Percent TRR extracted. For all tissues, the percent relative recovery (percent TRR extracted using residue method / percent TRR extracted using metabolism method × 100) ranged from 84.2 to 105 percent. The results are shown in Table 101.

Table 101 Summary percent TRR and distribution of residues (mg/kg eq) between the TPR-0013 method and the metabolism studies TPM-0024 (lactating goat) and TPM-0025 (laying hens)

n/a: Not applicable.
[a] Combined mg/kg residues of skim milk and milk fat.
[b] Calculated values, based on ratios of omental, subcutaneous and renal fats.
[c] Extract mg/kg ÷ (extract mg/kg + combustion mg/kg).

Last, in study TPA-0063 the extraction efficiency of the method TPA-0049 (QuEChERS) for measurement for extractable radioactivity and determination of inpyrfluxam in animal matrices has been evaluated. The samples investigated were obtained from metabolism studies for goats (TPM-0024) and hens (TPM-0025). The test systems used for the extraction efficiency experiment were goat fat, goat liver and goat milk samples from study TPM-0024. Hen egg and hen muscle samples were from study TPM-0025.

Inpyrfluxam was detected in extracts from goat liver, hen muscle and hen egg. The levels of inpyrfluxam extracted (mg/kg and/or percent TRR) by the QuEChERS method was comparable to the levels extracted by the original metabolism method in goat liver, hen muscle and hen egg. Inpyrfluxam was not detected in extracts from goat fat or goat milk.

Based on these results, it was concluded that the extraction procedure based on the QuEChERS method is suitable for the extraction of a large fraction of the total radioactive residues and determination of residues of inpyrfluxam in goat liver, hen muscle and hen egg. These investigations are not conclusive for goat fat or milk as, whilst comparable amounts of the total radioactive residues were extracted by the QuEChERs method, the amount of inpyrfluxam in each matrix was below the detection limit of the

method. A summary of the percent TRR and distribution of residues (mg/kg eq) is presented in Table 102 and Table 103.

Notes:

ND: Not detected (≤0.001 mg/kg).

[a] %TRR and mg/kg for inpyrfluxam from the initial analysis (TPM-0024; goat metabolism study). Following storage for 14 months at -17 °C, inpyrfluxam accounted for 0.007 mg/kg (2.2 %TRR) which is comparable with the results from the present study based on analysis performed after 45-46 months of frozen storage.

[b] %TRR values were from original metabolism reports.

[c] %TRR for inpyrfluxam in milk fat from original study taken from original data.

STABILITY OF PESTICIDE RESIDUES IN STORED ANALYTICAL SAMPLES

The Meeting received studies investigating the stability of residues of inpyrfluxam and its metabolites 3'-OH-S-2840, DFPA, DFPA-$CONH_2$, *N*-des-Me-DFPA, *N*-des-Me-S-2840, *N*-des-Me-1'-CH_2OH-S-2840 (determined separately as *N*-des-Me-1'-CH_2OH-S-2840A and B), 1'-COOH-S-2840 (determined separately as 1'-COOH-S-2840A and B) and 1'-CH_2OH-S-2840 (determined separately as 1'-CH_2OH-S-2840A and B) in various matrices (Arndt, 2016; TPR-0013) and soil (TPR-0064; TPR-0088). The maximum storage periods of inpyrfluxam and metabolites per commodity and per commodity groups are summarized in Table 104.

Table 104 Maximum storage stability periods of inpyrfluxam and metabolites per commodity

Group per content	Commodity	inpyrfluxam	3'-OH-S-2840	DFPA	DFPA-CONH2	N-des-Me-DFPA	1'-COOH-S-2840A	1'-COOH-S-2840B

	Soil	540	540	-	-	-	-	-

For all matrices, control samples were fortified with an individual standard of each analyte. Fortified samples were stored frozen (at -15 to -22 °C) and residues were analysed using either SUM-1701V or Method RM-50C-1 or JP2015C239. Inpyrfluxam and its metabolites was shown to be stable under frozen storage conditions as presented in Table 105 to Table 111.

Notes:
P: Parent; D: DFPA
[a] Day 0 recoveries were not determined, the average of the freshly fortified sample recoveries across all intervals are reported as surrogates.
[b] Average of 6 replicates.
[c] The storage stability was investigated using each test site sample (FS: Fukushima-Shoku, AS: Aomori-Shoku test sites). When the storage intervals are different among the test sites, the test site names are presented for clarification.
[d] The storage stability was investigated using each test site sample (A: Aomori, I: Iwate, F: Fukushima and N: Nagano test sites). When the storage intervals are different among the test sites, the test site names are presented for clarification.

Notes:
D: DFPA; N: *N*-des-Me-DFPA.
a Considered an outlier since result at 3 month interval fell within the acceptance criteria.
b Average of 6 replicates.
c The storage stability was investigated using each test site sample (A: Aomori, AS: Aomori-Shoku, F: Fukushima, FS: Fukushima-Shoku, I: Iwate, N: Nagano, test sites). When the storage intervals are different among the test sites, the test site names are presented for clarification.

Notes:

[a] Samples were re-analysed after 50 days of storage; results are displayed in brackets. Therefore, an additional procedural recovery experiment was conducted. The average recovery takes into account all four recovery values.

USE PATTERN

Inpyrfluxam is registered for use on numerous crops in multiple countries. Inpyrfluxam can be used a seed treatment with a flowable concentrate (FS) formulation, or foliar application with a suspension concentrate (SC) formulation. Information on registered uses that was provided to the meeting is summarized in Table 113.

Table 113 Summary of registered use patterns for inpyrfluxam. For all uses, application timing, coincides with threshold pest pressure Adjuvants permitted to be used for foliar applications unless specified

Crop	Country	Formulation		Application						PHI (days)	Remarks
		Name	Active ingredient (%)	Method	No.	Rate (g ai/ha)	Timing	Interval (days)	Seasonal max. (g ai/ha)		
Apple	United States	2.84 SC	31	Foliar	2	100	Between green tip and petal fall (BBCH 69)	10	200	n.a.	Do not use adjuvants

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received data from supervised residue trials on apples, soya beans, sugar beets, rice corn and peanuts.

The field trial reports included method validation data, as recoveries from spiked samples at levels reflecting those observed in the field trial samples, dates from critical events during the study, including application, harvest, storage, and analysis; as well as detailed information on the field site and treatment parameters. Analytical reports were sufficiently detailed and included example chromatograms and example calculations. Samples were analysed by the methods described above. Unless otherwise noted in the tables below, harvested commodities were maintained whole in the field and not cut or homogenized until they reached the analytical laboratory.

The field trial study designs included control plots. For most crops measured residues from control plots were < 0.01 mg/kg (i< LOQ) and are not included in the summary tables in this evaluation. Cases where quantifiable residues were found in control matrices are noted in the Table 114 to Table 123.

In the summary tables, values used for making maximum residue level recommendations are underlined and highest individual values for estimating dietary intake are bolded. Trial locations that the Meeting has determined are not independent are grouped by a heavy cell border in the tables. A summary of supervised trials for inpyrfluxam per crop group and commodity is shown below

Commodity	Study No	Table No
Apple (FP 0226)	201700036, 201700086, JP2014C288, JP2015C239, JP2016C334	Table 114

Apple

Nineteen field trials were conducted in Canada and the United States during 2014 -2015 growing seasons (201700036 and 201700086), inpyrfluxam was applied as a SC formulation, twice as a foliar spray, at full bloom and petal fall growth stages, at a rate of 100 g ai/ha per treatment and with a PHI of 111–185 days. In trial V-38516-Q a second plot was treated with two applications of 500 g ai/ha (5× rate) as to obtain apples for processing and trials V-38516-F, V-38516-L in which sampling dates were varied to evaluate the effect of harvest timing.

Fruits in the US and Canadian trials were analysed for residues of inpyrfluxam and its metabolites 3'-OH-S-2840, 1'-CH_2OH-S-2840 (analysed separately as 1'-CH_2OH-S-2840A and 1'-CH_2OH-S-2840B) and DFPA-$CONH_2$ using validated method RM-50C-1, with a LOQ of 0.01 mg/kg for each analyte. Overall, concurrent recovery samples for inpyrfluxam and its metabolites 3'-OH-S-2840, 1'-CH_2OH-S-2840A, 1'-CH_2OH-S-2840B and DFPA-$CONH_2$ in apples, gave results ranging from 67 to 108 percent recovery, with relative standard deviations up to 4 percent. Results from the trials are summarized in Table 114.

In addition eight trials were conducted in Japan during 2014, 2015 and 2016 growing seasons. Inpyrfluxam, was applied as an SC formulation, three times (6–7 days interval) as a foliar spray to apple trees between the fruit colouring stage to the beginning of harvest, at a nominal rate of 429 and 450 g ai/ha and with a PHI of 1 days. Apples were harvested at 1, 3, 7, 14 and 21 days after the last application.

Fruits in the Japanese trials (JP2014C288, JP2015C239 and JP2016C334) were analysed for residues of inpyrfluxam and its metabolites 3'-OH-S-2840, 1'-CH_2OH-S-2840A, 1'-CH_2OH-S-2840B, *N*-des-Me-DFPA and DFPA-$CONH_2$ using a validated LC-MS/MS method (JP2015C239) with an LOQ of 0.01 mg/kg for each analyte. Overall, concurrent recovery samples for inpyrfluxam and its metabolites 3'-OH-S-2840, 1'-CH_2OH-S-2840A, 1'-CH_2OH-S-2840B, DFPA-$CONH_2$ and *N*-des-Me-DFPA in apples, gave results ranging from 67 to 107 percent recovery, with RSD up to 10 percent.

Samples were stored for a maximum of 505 days prior to extraction and analysis. This period is covered by the available storage stability study (514 days in apple). Results from the trials are summarized in Table 114.

Notes:
DALA: days of the last application
[a] Free and conjugated, sum of A and B isomers

Soya bean, dry

Twenty one residue trials were conducted on soya bean in the United States in 2014–2015 growing season (Foster, 2017; 201700156). Soya bean seeds were treated with inpyrfluxam as a FS formulation, at a rate of 10 g ai/100 kg seed, 14 days prior to the R5 growth stage (visible seed in pod of upper four nodes) and with two foliar application as an SC formulation at a rate of 100 g ai/ha (on a 10–21 interval) at the BBCH 75. Adjuvant (non-ionic surfactant (NIS), crop oil concentrate (COC) or silicone) was added. Soil type was not reported.

In trial V-38537-O the sampling dates varied as to evaluate the effect of harvest timing in trial. In V-38537-H an additional plot was treated at an exaggerated rate of 2× the GAP rate for each formulation, in trials V-38537-I, R and U an additional plot was treated at 5× the GAP rate, and in trial V-38537-U soya bean seeds were processed into hulls, meal and refined oil.

Dry seed samples were collected at normal commercial harvest, 26–84 days after the last application for harvest trials and 31–43 days after last application for the decline trials.

Samples were analysed for inpyrfluxam and its major metabolites 3'-OH-S-2840, 1'-CH_2OH-S-2840 (analysed as 1'-CH_2OH-S-2840A and B), DFPA-$CONH_2$ and conjugated forms of metabolites analysed as aglycones (1'-COOH-S-2840 and 1'-CH_2OH-S-2840) using the validated method RM-50C-1. The LOQ was 0.01 mg/kg for each analyte. The combined LOQ for l'-CH_2OH-S-2840 (A and B) or 1'-COOH-S-2840 (A and B) was 0.02 mg/kg (sum of the individual LOQs). For the determination of *N*-des-Me-DFPA, method RM-50C-2a was used, with a LOQ of 0.02 mg/kg. Overall, concurrent recovery samples for inpyrfluxam and its metabolites 3'-OH-S-2840, 1'-CH_2OH-S-2840A, 1'-CH_2OH-S-2840B, 1'-COOH-S-2840 and *N*-des-Me-DFPA in seeds, gave results ranging from 67 to 115 percent recovery, with RSD up to 11 percent.

Samples of dry soya bean seed were stored frozen for up to 587 days prior to the extraction and analysis. This period is covered by the available storage stability study (683 days in dry for soya bean seed). Results from the trials are summarized in Table 115.

Table 115 Inpyrfluxam residues in dry soya bean seeds resulting from a seed treatment followed by two foliar treatments in supervised trials in the United States of America (Study 201700156)

Sugar beet

Twenty residue trials were conducted on sugar beets in Canada and the United States in 2014 and 2015 growing seasons (Bitter, 2016; 201700065, Bitter, 2017; 201700098), from which fifteen are considered independent. In each trial, sugar beet seeds were treated with a FS formulation, at a rate of 0.1 g ai/100,000 seeds. Following planting at 71 and 50 days before harvest, two foliar applications of inpyrfluxam as an SC were performed at a rate of 100 g ai/ha per treatment. Adjuvant (non-ionic surfactant (NIS), crop oil concentrate (COC) or silicone) was added. Sugar beet roots were collected at normal commercial harvest, 50–51 days after the last application. Residues in sugar beet tops were not investigated. Soil type was not reported.

In trials V-38533-E and L an additional plot was treated at an exaggerated (5×) rate. In trial V-38533-N, sugar beet roots were processed into sugar, dried pulp and molasses. Seeds were treated at nominal rate of 0.5 g ai/100,000 seeds. Application intervals were the same as those in the associated 1× plot. In trial V-38533-B and -K the sampling dates varied as to evaluate the effect of harvest timing.

Samples of roots were analysed for residues of inpyrfluxam and its metabolites 3'-OH-S-2840, 1'-CH_2OH-S-2840 (analysed separately as 1'-CH_2OH-S-2840A and B), DFPA-$CONH_2$ and conjugated forms of metabolites analysed as aglycones (1'-COOH-S-2840 and 1'-CH_2OH-S-2840) using the validated method RM-50C-1. The LOQ was 0.01 mg/kg for each analyte. The combined LOQ for l'-CH_2OH-S-2840 (A and B) or 1'-COOH-S-2840 (A and B) was 0.02 mg/kg or 0.023 mg/kg respectively (sum of the individual LOQs). Samples were not analysed for N-des-Me-DFPA. Overall, concurrent recovery samples for inpyrfluxam and its metabolites 3'-OH-S-2840, 1'-CH_2OH-S-2840A, 1'-CH_2OH-S-2840B, DFPA-$CONH_2$, 1'-COOH-S-2840A, 1'-COOH-S-2840B, and *N*-des-Me-DFPA in roots, gave results ranging from 70 to 121 percent recovery, with RSD up to 20 percent. The samples of sugar beet obtained at harvest were frozen for a maximum of 607 days before extraction and analysis. This period is covered by the available storage stability study (610 days in potatoes). Results from the trials are summarized in Table 116.

Rice

Seventeen residue trials were conducted on rice (Irrigated paddies) in the United States in 2014, 2015 and 2017 growing season [Bitter, 2017; 201700341), from which fourteen are considered independent. In each trial, rice grains were treated with inpyrfluxam as a FS formulation, at a rate of 10 g ai/100 kg seed. Treated seeds were planted 0–55 days after receipt and we stored at approximately 14 ºC prior to planting.

At the late boot stage, a single foliar application of 96.5–106.7 g ai/ha was made using inpyrfluxam as a formulation. Adjuvant (non-ionic surfactant (NIS), crop oil concentrate (COC) or silicone) added. Rice was collected at normal commercial harvest, 35-71 days after the last application for harvest trials and 35–50 days after last application for the decline trial (V-38528-N). Soil type was not reported.

In trial V-38528-N, seeds in the second plot were treated at 5× rate (50 g ai/100 kg seed), in three trials (V-38528-K, V-38528-N and V-38528-M), an additional plot was also treated at 5× rate (500–501 g ai/ha) as to investigate the effect of exaggerated application rates on residues. In trial V-38528-N the sampling dates varied as to evaluate the effect of harvest timing and in trial V-38528-L grains were processed into hulls, bran and polished rice.

Grain samples were analysed for residues of inpyrfluxam and its metabolites 3'-OH-S-2840, 1'-CH_2OH-S-2840 (analysed separately as 1'-CH_2OH-S-2840A and B), DFPA-$CONH_2$ and conjugated forms of metabolites analysed as aglycones (1'-COOH-S-2840 and 1'-CH_2OH-S-2840) using the validated method RM-50C-1. The LOQ was 0.01 mg/kg for each analyte. The combined LOQ for l'-CH_2OH-S-2840 (A and B) or 1'-COOH-S-2840 (A and B) was 0.02 mg/kg (sum of the individual LOQs). Overall, concurrent recovery samples for inpyrfluxam and its metabolites 3'-OH-S-2840, 1'-CH_2OH-S-2840A, 1'-CH_2OH-S-2840B, DFPA-$CONH_2$, 1'-COOH-S-2840A (agly), 1'-COOH-S-2840B (agly) in seeds, gave results ranging from 70 to 121 percent recovery, with RSD up to 20 percent.

The samples of grain (husked rice) obtained at harvest were frozen for a maximum of 609 days before extraction and analysis. This period is covered by the available storage stability study (616 days in rice grain). Results from the trials are summarized in Table 117.

Sweet corn

Seventeen residue trials were conducted on sweet corn in the United States in 2015 and 2016 growing season (Fosster, 2017; 201700217). In each trial, seeds were treated with inpyrfluxam as a FS formulation containing at a rate of 0.014 mg ai/seed inpyrfluxam, planted at a seeding rate and row spacing typical for the selected locations followed by an in furrow (spray treatment) as a SC formulation at a rate of 50 g ai/ha. (at BBCH 00). In addition, in trials V-38939-AF and -AG, an additional plot was treated at an exaggerated rate (5× the GAP) at nominally 0.070 mg ai/seed and 250 g ai/ha, respectively. In trial V-38939-AD, and –AE, the sampling dates varied as to evaluate the effect of harvest timing.

The raw agricultural commodity (RAC) samples of sweet corn were harvested at the milk stage (BBCH 75). Samples were analysed for residues of inpyrfluxam and its metabolites 3'-OH-S-2840, 1'-CH_2OH-S-2840 (analysed separately as 1'-CH_2OH-S-2840A and B), DFPA-$CONH_2$ and conjugated forms of metabolites analysed as aglycones (1'-COOH-S-2840 and 1'-CH_2OH-S-2840) using the validated method RM-50C-1. LOQs were 0.01 mg/kg for each analyte. The combined LOQ for l'-CH_2OH-S-2840 (A and B) or 1'-COOH-S-2840 (A and B) was 0.02 mg/kg (sum of the individual LOQs). The metabolite, *N*-des-Me-DFPA was also analysed using method RM-50C-2a, with a LOQ of 0.02 mg/kg. Overall, concurrent recovery samples for inpyrfluxam and its metabolites 3'-OH-S-2840, 1'-CH_2OH-S-2840A, 1'-CH_2OH-S-2840B, DFPA-$CONH_2$, 1'-COOH-S-2840A, 1'-COOH-S-2840B and *N*-des-Me-DFPA in sweet corn gave mean recoveries ranging from 79.7-93.4 percent, with RSD up to 13 percent. Samples of sweet corn were stored for up to 642 days prior to analysis, whici is covered by the storage stability study (681 days in wheat grain). Results from the trials are summarized in Table 118.

Table 118 Inpyrfluxam residues in sweet corn resulting from supervised trials in the United States using seed treatment (FS formulation) followed by in furrow treatment at BBCH 00 (SC formulation) (Study 20170021)

Maize

Twenty-nine residue trials were conducted on maize in the United States in 2015 and 2016 growing season (201700217). In each trial, seeds were treated with inpyrfluxam as a FS formulation containing at a rate of 0.014 mg ai/seed inpyrfluxam, planted at a seeding rate and row spacing typical for the selected locations followed by an in furrow (spray treatment) as a SC formulation at a rate of 50 g ai/ha. (at BBCH 00). In trial V-38939-V an adjuvant (crop oil concentrate (COC)) was used. In addition, in trials V-38939-V, -AF and -AG, an additional plot was treated at an exaggerated rate (5× or 10× the GAP) for a sample processing trial at nominally 0.070 mg ai/seed and 250 or 500 g ai/ha, respectively. In trial V-38939-B, and -E, the sampling dates of forage varied as to evaluate the effect of harvest timing.

The samples of maize grains were harvested at the milk stage (BBCH 75). Cut samples of the whole aerial portion of the plant (forage) were harvested at the late dough/early dent stage (BBCH 85–86). Mature corn kernels removed from cob, with a maximum of 25 percent moisture (grain) and mature dried stalks from which the whole ear (cob and grain) had been removed, containing 80–85 percent dry matter (stover) were harvested after the BBCH 95 growth stage.

Samples were analysed for residues of inpyrfluxam and its metabolites 3'-OH-S-2840, 1'-CH_2OH-S-2840 (analysed separately as 1'-CH_2OH-S-2840A and B), DFPA-$CONH_2$ and conjugated forms of metabolites analysed as aglycones (1'-COOH-S-2840 and 1'-CH_2OH-S-2840) using the validated RM-50C-1. The LOQs were 0.01 mg/kg for each analyte. For the method RM-50C-1 for forage and stover, the LOQ was 0.02 mg/kg. The combined LOQ for l'-CH_2OH-S-2840 (A and B) or 1'-COOH-S-2840 (A and B) was 0.02 mg/kg (sum of the individual LOQs) in all matrices. The metabolite, *N*-des-Me-DFPA was also analysed using method RM-50C-2a, with a LOQ of 0.02 mg/kg in all matrices. Overall, concurrent recovery samples for inpyrfluxam and its metabolites 3'-OH-S-2840, 1'-CH_2OH-S-2840A, 1'-CH_2OH-S-2840B, DFPA-

$CONH_2$, 1'-COOH-S-2840A, 1'-COOH-S-2840B and *N*-des-Me-DFPA in grain, forage and stover g and RSD up to 18 percent.

Samples of corn were stored for up to 642 days prior to analysis. This period is covered by the available storage stability study (679 days in wheat grain). Samples of forage and stover were stored for up to 563 and 560 days prior to analysis, respectively, with the except of one sample of forage (B-17, analysed by method 2a) which was stored for 591 days. This period is covered by the available storage stability study (591 days in forage and 587 in stover). Results from the trials are summarized in Table 119 to Table 121.

Table 119 Inpyrfluxam residues in maize grain resulting from supervised trials in the United States of America using seed treatment (FS formulation) followed by in furrow treatment at BBCH 00 (SC formulation) (Study 201700217).

Peanut

Thirteen residue trials were conducted on peanuts in the United States in 2015 growing season (Bietter, 2017: 201700318) In each trial, peanuts were treated with two foliar applications of inpyrfluxam as a SC formulation at a rate of 99–104 g ai/ha per application. The first application was made at approximately 61 days before normal harvest (DBH) and the second at 40 DBH. Adjuvant (non-ionic surfactant (NIS), crop oil concentrate (COC) or silicone) added at nominally 0.063–0.50 percent.

In trials TPR-0066-D and -L two additional plots were treated at 5× and 7.5× the GAP rate. In trials TPR-0066-C and -H, the sampling dates varied as to evaluate the effect of harvest timing.

Peanut samples were collected at normal commercial harvest, 21–42 days after the last application for harvest trials and 29–46 days after last application for the decline trial. Peanuts (nutmeat and hulls) were dug and hay was cut at normal harvest (39–42 days after the last application), and allowed to dry in the field for 0–16 days, as needed, before sample collection. The peanuts (nutmeat and hulls) were collected from at least 24 plants and allowed to dry in the field until commercially acceptable (BBCH 29). The hulls (shell) were removed from the nutmeat (nutmeat), and only the nutmeat was collected for analysis. Samples were analysed for inpyrfluxam and its major metabolites 3'-OH-S-2840, 1'-CH_2OH-S-2840 (analysed as 1'-CH_2OH-S-2840A and B), DFPA-$CONH_2$ and conjugated forms of metabolites analysed as the aglycones of 1'-COOH-S-2840 and 1'-CH_2OH-S-2840 using the validated method RM-50C-1. The LOQ was 0.01 mg/kg for each analyte except for 1'-COOH-S-2840-A (for which LOQ was 0.013 mg/kg). The combined LOQ for l'-CH_2OH-S-2840 (A and B) or 1'-COOH-S-2840 (A and B) was 0.02 mg/kg or 0.023 mg/kg respectively (sum of the individual LOQs). For the determination of *N*-des-Me-

DFPA, method RM-50C-2a was used, with a LOQ of 0.02 mg/kg. Overall, concurrent recovery samples for inpyrfluxam and its metabolites 3'-OH-S-2840, 1'-CH_2OH-S-2840A, 1'-CH_2OH-S-2840B, DFPA-$CONH_2$, 1'-COOH-S-2840A (agly), 1'-COOH-S-2840B (agly) and *N*-des-Me-DFPA in nutmeat and hay gave results ranging from 64 to 117 percent recovery, with relative standard deviations up to 17 percent. Only for the metabolite 1'-CH_2OH-S-2840A recoveries ranged from 99 to 136 percent, however mean recovery of 13 samples was 114 percent with RSD of 8 percent, thus the results can be considered valid.

Samples of peanut nutmeat and hay were stored for up to 465 days prior to analysis. This period is covered by the available storage stability study (683 days in soya bean). Results from the trials are summarized in Table 122 and Table 123.

FATE OF RESIDUES IN STORAGE AND PROCESSING

In Storage

Inpyrfluxam is not intended for use in stored products.

Nature of the residue during processing

The Meeting received three high temperature hydrolysis studies of inpyrfluxam and its metabolites 3'-OH-S-2840 and 1'-CH_2OH-S-2840. In all studies the spiked buffer solutions were put into conditions simulating pasteurisation (90 °C, pH 4, 20 minutes); baking, brewing, boiling (100 °C, pH 5, 60 minutes); and sterilisation (120 °C, pH 6, 20 minutes). Prior to and after processing, an aliquot from each sample was collected and analysed by LSC for total radioactivity, by radio-HPLC for determination of hydrolysis products and chiral chromatography for the determination of R/S isomers.

High-temperature hydrolysis of inpyrfluxam was investigated by Freelander (2016, TPM-0022). In the study, [Pyrazolyl-4-^{14}C]inpyrfluxam was spiked, in duplicate, into buffered solutions at a target concentration of 1 mg/L. Mass balance of radioactivity after processing was 100.5, 103.2, and 100.7 percent for 90 °C/pH 4, 100 °C/pH 5, and 120 °C/pH 6, respectively. [^{14}C]inpyrfluxam did not degrade over the incubation period thus, inpyrfluxam is considered to be stable under high-temperature hydrolysis conditions. Chiral analysis showed the *R*-isomer to account for 100 percent of the residue at all time points (Table 124).

Table 124 High-temperature hydrolysis radio-HPLC results for inpyrfluxam

Process represented	Test conditions	Analyte	Total Recovery[a] (% of applied dose)		Mass balance (%)[b]
			Before incubation	After incubation	
Pasteurisation	pH 4, 90 °C, 20 minutes	inpyrfluxam (*R*-isomer)	97.1, 97.7 (97.4)	97.5, 98.2 (97.9)	100.5
		S-2940 (*S*-isomer)	-	-	n.a.
Baking/brewing/boiling	pH 5, 100 °C, 60 minutes	inpyrfluxam (*R*-isomer)	93.9, 95.9 (94.9)	97.1, 98.7 (97.9)	103.2
		S-2940 (*S*-isomer)	-	-	n.a.
Sterilisation	pH 6, 120 °C, 20 minutes	inpyrfluxam (*R*-isomer)	94.9, 98.9 (96.9)	97.4, 97.7 (97.6)	100.7
		S-2940 (*S*-isomer)	-	-	n.a.

Notes:
Value in parentheses = average of two determinations.

n.a. = Not applicable.
[a] %AR (all residues comprised the *R*-isomer of inpyrfluxam).
[b] Compared to 'time zero'.

High-temperature hydrolysis of 3'-OH-S-2840 was investigated by Lamond (2018, TPM-0054). In the study, [Pyrazolyl-4-^{14}C] 3'-OH-S-2840 was spiked, in duplicate, into buffered solutions at a target concentration of 1 mg/L. 3'-OH-S-2840 degraded to form 3'-OH-S-2840 dehydrate at an average of 13.0 percent TRR (0.133 mg/kg) under pasteurization, 9.0 percent TRR (0.092 mg/kg) under brewing, baking and boiling and 1.7 percent TRR (0.017 mg/kg) under sterilisation. In all processed a small number of minor degradation products were also observed in HPLC and TLC analyses (Table 125).

Table 125 High-temperature hydrolysis radio-HPLC results for 3'-OH-S-2840

Process represented	Test conditions	Analyte	Total Recovery [a] % of applied dose (mg/L)	
			Before incubation	After incubation
Pasteurisation	pH 4, 90 °C, 20 minutes	3'-OH-S-2840	97.8 (0.999)	82.8 (0.846)
		3'-OH-S-2840 dehydrate	ND	13.0 (0.133)
		Unknown [c]	1.4 (0.015)	2.9 (0.029)
Baking/brewing/boiling	pH 5, 100 °C, 60 minutes	3'-OH-S-2840	98.5 (1.005)	87.6 (0.895)
		3'-OH-S-2840 dehydrate	ND	9.0 (0.092)
		Unknown [d]	1.0 (0.005)	2.9 (0.030)
Sterilisation	pH 6, 120 °C, 20 minutes	3'-OH-S-2840	99.0 (1.011)	96.7 (0.987)
		3'-OH-S-2840 dehydrate	ND	1.7 (0.017)
		Unknown [e]	0.2 (0.002)	1.0 (0.010)

Notes:
ND: Not detected (<0.21% TRR).

[c] Unknown degradants were maximally comprised of 8 components in which the largest peak was quantified to be 1.9% TRR (0.019 mg/L).
[d] Unknown degradants were maximally comprised of 6 components in which the largest peak was quantified to be 2.8% TRR (0.029 mg/L).
[e] Unknown degradants were maximally comprised of 2 components in which the largest peak was quantified to be 1.0% TRR (0.010 mg/L).

High-temperature hydrolysis of 1'-CH_2OH-S-2840 was investigated by Gilbert (2017, TPM-0055). In the study, [Pyrazolyl-4-^{14}C]1'-CH_2OH-S-2840 (supplied as isomers A and B) was spiked, in duplicate, into buffered solutions at a target concentration of 1 mg/L. Degradation products were not detected in any buffer samples, thus 1'-CH_2OH-S-2840 (isomers A and B) are considered to be stable under high-temperature hydrolysis conditions (Table 126).

Table 126 High-temperature hydrolysis radio-HPLC results for 1'-CH_2OH-S-2840

Process represented	Test conditions	Analyte	Total Recovery [a] % of applied dose (mg/L)	
			Before incubation	After incubation

Residues after processing

Apple

A single sample of apples from a residue trial (V-38516-R) conducted at an exaggerated rate and described above was used to investigate the effect of juicing process on inpyrfluxam residues. In the study by Bitter (2017, 201700086 or TPR-0022) apple samples were washed and reduced to apple pulp using a fruit press. The pulp was then transferred to a steam-jacketed kettle and heated with low pressure steam to approximately 50 °C before pectic enzyme was added. After 2 hours, the treated pulp was pressed, and the wet pomace and juice were collected. The juice was filtered to remove solids. A pasteurization step was not included.

Samples were homogenized in the presence of dry ice and analysed for residues of inpyrfluxam and its metabolites 3'-OH-S-2840, 1'-CH_2OH-S-2840 (analysed separately as 1'-CH_2OH-S-2840A and 1'-CH_2OH-S-2840B) and DFPA-$CONH_2$ using Method RM-50C-1. Concurrent recoveries ranged from 68 to 95 percent with a maximum RSD of 14 percent. Samples were stored frozen (-20 °C) for up to 155 days before analysis, which is covered by the storage stability study (514 days in apples).

Results from the trials are summarized in Table 127. Residues of inpyrfluxam, concentrated in wet pomace (PF = 2.7) but were diluted in fresh juice (PF = 0.125).

Soya bean

A single sample of soya bean from a residue trial (V-38537-V) conducted at an exaggerated rate was used to investigate the effect of oil production process on inpyrfluxam residues. In the study by Foster (2017,

201700156), soya bean seeds processed into hulls, meal and refined oil in a manner reflecting commercial production. For the production of hulls, whole soybeans were fed into a roller mill and were separated using an aspirator and screen cleaner into hulls and kernels. For meal production, kernel material was heated and flaked using a flaking roll. The flakes were extruded and converted into collets by direct steam injection and compression. The collets were then ground in a disc mill and dried before being placed in a batch extractor for repeated extraction with hexane at 49–60 °C. The extracted ground collets were toasted by direct steam injection and the meal was collected after sieving.

For the refined oil production, crude oil and hexane (collected from the extrusion and extraction procedures) were separated *in vacuo.* The crude oil fraction was filtered and neutralised with 14° Baumé sodium hydroxide. The neutralised oil was centrifuged and alkaline refined oil removed and filtered. The refined oil was then bleached before deodorisation under vacuum at 220–230 °C in a steam bath. On cooling, a 0.5 percent citric acid solution was added and the deodorised oil (refined oil) was collected for analysis.

Samples were homogenised in the presence of dry ice and analysed for residues of inpyrfluxam and its metabolites 3'-OH-S-2840 and 1'-CH_2OH-S-2840 (analysed separately as 1'-CH_2OH-S-2840A and 1'-CH_2OH-S-2840B) using Method RM-50C-1 and *N*-des-Me-DFPA using Method RM-50C-2a. Concurrent recoveries across all matrices (meal, hulls, oil), analytes and fortification levels ranged from 67 to 126 percent with a maximum relative standard deviation of 9 percent. Samples were stored at -20 °C for up to 303 days before analysis. This period is covered by the available storage stability study (683 days in soya bean).

Results from the trials are summarized in Table 128. Residues in in refined oil were 0.012 mg/kg, but as no residues of inpyrfluxam was detected in the seed (< 0.01 mg/kg), no processing factors can be derived.

Table 128 Inpyrfluxam residues in soya bean and processed commodities resulting from trial V-38537-V in the United States of America (Report 2017000156)

Sugar beet

As single sample of sugar beets from a residue trial (V-38533-N) conducted at an exaggerated rate was used to investigate the effect of sugar and molasses production process on inpyrfluxam residues. In the study by Bitter (2017, 201700098) beets were sliced and sugar was extracted in steam-jacketed kettles using a mixture of water and pulp press water at 60–65 °C. The extracted pulp was pressed to recover the sugar solution and a portion of the solution was returned to the kettles. The pressed pulp was dried and milled before storage (dried pulp). Raw juice was purified in a steam-jacketed kettle using lime and

carbon dioxide and the precipitates were coagulated using settling aid. Following filtration, the clarified thin juice was concentrated to thick juice and filtered before returning to the kettles, filtering again and storing the molasses for analysis. The washed sugar was removed from the filter and dried using hot air before storage.

Samples were homogenised in the presence of dry ice and analysed for residues of inpyrfluxam and its metabolites 3'-OH-S-2840, 1'-CH_2OH-S-2840 (analysed separately as 1'-CH_2OH-S-2840A and B), DFPA-$CONH_2$ and conjugated forms of metabolites analysed as aglycones (1'-COOH-S-2840 and 1'-CH_2OH-S-2840) using the validated LC-MS/MS method RM-50C-1. The LOQ was 0.01 mg/kg for each analyte. Concurrent recoveries across all matrices (sugar, dried pulp, molasses), analytes and fortification levels ranged from 73 to 126 percent with a maximum relative standard deviation of 13 percent. Samples were stored frozen (-20 °C) for up to 361 days before analysis. This period is covered by the available storage stability study (681 days in cucumbers).

Results from the trials are summarized in Table 129. Residues of inpyrfluxam were detected in dried pulp and molasses (0.02-0.03 mg/kg), but as residues in the roots were < 0.01 mg/kg, no processing factors can be derived.

Maize

A single sample of maize grain from the residue trial (V-15-38939) conducted at an exaggerated rate was used to investigate the effect of flour, grits, meal, starch and oil (wet and dry milled) production process on inpyrfluxam residues.

In the study by Foster (2017, TPR-0059) corn grains were cleaned by aspiration and screening and went through a dry and wet milling process.

In the dry milling process, grain was fed into a disc mill to crack the kernel. The corn stock was dried and screened to separate the bran, germ and large grits from the grits, meal and flour. These three fractions were further screened by sieving. The bran, germ and large grits were screened again and material above the screen was aspirated to separate the hull from germ with attached hull and endosperm. The germ fraction was milled and screened and the material above the screen was aspirated to remove hull from germ. The material that passed through the screen (large grits and detached germ) was passed over a gravity separator to separate the germ from large grits. The grits, meal and flour fractions were collected for frozen storage and the germ material was flaked in a flaking roll. Flaked kernel material was extracted three times with hexane in a batch extractor at 49–60 °C. After each extraction, the crude oil/hexane and germ flakes were collected. The oil and hexane were separated *in vacuo* and the oil was filtered before alkaline refining with 16° Baumé sodium hydroxide. The neutralised

oil was isolated via centrifugation and filtered before bleaching under vacuum at 85–100 °C and further filtration. The bleached oil was deodorised in a steam bath at 220–230 °C under vacuum and cooled, with addition of 0.5 percent citric acid. The refined oil was then collected for analysis.

In the wet milling process, the grain was steeped in water containing 0.1–0.2 percent sulphur dioxide at 49–54 °C for 22–48 hours. The whole corn was milled and the germ and hull removed using a hydroclone. The germ and hull were then dried and separated using aspiration and screening. The cornstock remaining after milling was screened and the process water was separated into starch and gluten via centrifugation. The starch fraction was dried prior to collection for analysis and the germ samples were heated, flaked and pressed in an expeller to generate presscake (containing residual crude oil) and crude oil. The presscake was extracted three times with hexane in the same manner as for the dry milling process to generate crude oil/hexane and germ cake fractions. The crude oil was collected by vacuum evaporation and heated to evaporate the remaining hexane. The crude oil fractions were filtered, alkali refined, bleached and deodorised using the same method as used for the dry milling procedure.

Samples were homogenised in the presence of dry ice and analysed for residues of inpyrfluxam and its metabolites 3'-OH-S-2840, 1'-CH2OH-S-2840 (analysed separately as 1'-CH2OH-S-2840A and B), DFPA-CONH2 and conjugated forms of metabolites analysed as aglycones (1'-COOH-S-2840 and 1'-CH2OH-S-2840) using the validated LC-MS/MS method RM-50C-1. The LOQ was 0.01 mg/kg for each analyte. Concurrent recoveries across all matrices (flour, grits, meal, starch and oil), analytes and fortification levels ranged from 72 to 123 percent with a maximum RSD of 13 percent. Samples were stored frozen (-20 °C) for up to 319 days before analysis. This period is covered by the available storage stability study in maize grain.

Results are summarized in Table 130. As residues of parent were not detected in the RAC and all processed samples of corn, no processing factors can be derived.

Rice

As single sample of rice from a residue trial (V-38528) conducted at an exaggerated rate was used to investigate the effect of polished rice production process on inpyrfluxam residues. In the study by Bitter

(2017, 201700341), rough rice grain samples were cleaned by aspiration and screening. The rough rice was milled, grains were hulled and the hulls were separated from the brown rice by aspiration before being placed into frozen storage. The brown rice was then milled into white milled rice (polished rice) and bran by friction. The bran was then separated from the milled rice using air injected into the milling chamber and was sieved to remove rice and hull particulates.

Samples were homogenised in the presence of dry ice and analysed for residues of inpyrfluxam and its metabolites 3'-OH-S-2840 and 1'-CH_2OH-S-2840 (analysed separately as 1'-CH_2OH-S-2840A and B), using the validated Valent LC-MS/MS method RM-50C-1. Concurrent recoveries across all matrices (sugar, dried pulp, molasses), analytes and fortification levels ranged from 73 to 124 percent with a maximum relative standard deviation of 21 percent. Samples were stored frozen (-20 °C) for up to 174 days before analysis. This period is covered by the available storage stability study (679 days in wheat grain).

Results from the trials are summarized in Table 131. Residues of inpyrfluxam were found in hussl and bran, but residues in grain were <LOQ, no processing factors can be derived.

Table 131 Inpyrfluxam residues in rice grain and processed commodities resulting from trial V-38528-Q in the United States of America (Study 201700341)

Peanut

A single sample of peanuts from a residue trial (V-38942-M) conducted in an exaggerated rate was used to investigate the effect of oil production process on inpyrfluxam residues. In the study by Bitter (2017, 201700318) nutmeats were heated and pressed to liberate a portion of crude oil from the presscake. The presscake was then ground in a disc mill to remove the remaining oil before being extracted three times with hexane in a batch extractor at 49–60 °C. Following extraction, the meal was collected for analysis and the crude oil and hexane fraction separated *in vacuo*. Crude oil fractions were filtered and combined before alkali refinement using 16° Baumé sodium hydroxide. The homogenized oil was then filtered and bleached under vacuum before further filtration. The bleached oil was homogenize in a steam bath at 220–230 °C under vacuum before citric acid solution was added on cooling. The resulting oil was collected for analysis.

Samples were homogenized in the presence of dry ice and analysed for residues of inpyrfluxam and its metabolites 3'-OH-S-2840, 1'-CH_2OH-S-2840 (analysed as 1'-CH_2OH-S-2840A and B) and DFPA-$CONH_2$ using the validated LC-MS/MS method RM-50C-1. For the determination of *N*-des-Me-DFPA, Valent method RM-50C-2a was used. The LOQ was 0.01 mg/kg for each analyte. Concurrent recoveries across all matrices (peanuts. Meal and refined oil), analytes and fortification levels ranged from 73 to 126 percent with a maximum RSD of 13 percent. Samples were stored frozen (-20 °C) for up to 361 days before analysis. This period is covered by the available storage stability study (683 days in soya bean).

Results from the trials are summarized in Table 132. Residues of inpyrfluxam are <LOQ in all samples thus no processing factors can be derived.

RESIDUES IN ANIMAL COMMODITIES

The Meeting received a feeding study conducted in lactating cows and in laying hens.

Ruminants

In the cow feeding study (Arndt, and Van Middlesworth, 2016, TPR-0013) lactating Holstein cows were dosed for 29 consecutive days via gelatine capsule using a balling gun at levels equivalent to ca. 2 (3 cows), 6 (3 cows) and 20 (6 cows) ppm in their feed (dry-weight basis) per day for 28 consecutive days (mean mg/kg bw: 0.07, 0.20 and 0.61, respectively). Milk was collected twice daily and composited (evening milking with the next morning milking). Extra milk from days 14 and 28 was separated into cream and skimmed milk for cows from each group. Milk samples were held frozen prior to transport to the analytical facility.

After administration of the final dose, the animals were slaughtered (within 24h) and samples of liver, kidneys, fat and muscle were collected and weighed. After collection, the liver, kidney, and muscle samples were cubed and frozen. Samples were stored for the following a maximum period prior to analysis: milk: 75 days, cream: 67 days, skim milk: 16 days, liver and kidney: 19 days, muscle: 21 days, fat: 30 days. With the exception of cream, all samples were analysed within the periods where storage stability was demonstrated (milk: at least 75 days, meat, liver and kidney 29 days, fat: 31 days).

Tissue and milk samples were analysed for inpyrfluxam and metabolites 1'-COOH-S-2840 (A and B) and 1'-CH2OH-S-2840 (A and B) by method TPR-0013. Concurrent recoveries across all analytes and matrices ranged from 71 to 114 percent with a maximum RSD of 18.1 percent. Residues in milk, muscle and fat were <LOQ in all sampling periods and for all dosing levels. Residues were only detected in liver and kidney at levels above the LOQ and the results are summarized in Table 133.

Residues detected at or above the LOQ were of the metabolite 1'-CH2OH-S-2840 in day 28 liver at the 20 ppm diet dose level and kidney samples at the 6 mg/kg diet and 20 ppm diet dose levels. The average residue level of 1'-CH2OH-S-2840 in liver was 0.014 mg/kg at the 20 ppm diet dose level, in kidney was 0.013 mg/kg for the 6 ppm diet dose level and 0.022 mg/kg for the 20 ppm diet dose level on the first day after cessation of dosing. Residue levels returned to below the LOQ within 3 days. All other matrices (milk, skimmed milk, cream, muscle and fat) had no residues at or above the LOQ for parent, 1'-COOH-S-2840 and 1'-CH2OH-S-2840 throughout the dosing period and for the two week depuration phase.

The results of this study indicate that there is no transfer of residues of inpyrfluxam or its main metabolites (at ≥ 0.01 mg/kg) to milk, skimmed milk or cream during or up to two weeks after 28 days of consecutive dosing. There were no appreciable residues found even at an exaggerated rate of dosing. Similarly, there was no appreciable residue transfer (≥ 0.01 mg/kg) or preferential accumulation to bovine muscle or fat. For liver and kidney, the only residues detected were of 1'-CH2OH-S-2840 and were found only on the first day after cessation of dosing and only from cows administered at the 6 mg/kg diet and 20 mg/kg diet dosing levels for kidney and at the 20 ppm diet dosing level for liver, demonstrating rapid withdrawal from tissue.

The results are summarized in Table 133 and Table 134.

Poultry

In the poultry feeding study (Van Middlesworth, 2017, TPR-0015) ISA Brown laying hens were dosed for 28 consecutive days *via* gelatine capsules at levels equivalent to at 1 (12 hens), 3 (12 hens) and 10 (24 hens) ppm feed (DM) per day (mean: 0.058, 0.164 or 0.547 mg/kg bw, respectively). Eggs were collected twice daily (morning and evening) and pooled. Hens were sacrificed on 28th day within 6 hours of the receipt of the final dose. After dosing was stopped, selected hens from the high dose group were kept alive for further 3–14 days in order to investigate the depuration of inpyrfluxam and metabolites in eggs and tissues after the end of application. Samples of muscle (thigh and breast combined), liver and fat (subcutaneous and abdominal combined) were taken and stored frozen prior to analysis. Samples were stored prior to analysis for up to: eggs: 85 days, egg yolk: 44 days, egg white: 24 days, liver: 37 days, muscle: 35 days, fat: 45 days. Stability was demonstrated for at least: eggs: 90 days, liver and muscle: 40 days, fat: 49 days.

Tissue and egg samples were analysed for inpyrfluxam and metabolites 1'-COOH-S-2840 (A and B) and 1'-CH_2OH-S-2840 (A and B) by method TPR-0015. Concurrent recoveries across all analytes and matrices ranged from 70 to 108 percent with a RSD of 7.7 percent.

Residues detected at or above the LOQ were inpyrfluxam and 1'- CH_2OH -S-2840 in day 28 fat and liver from the 10 ppm, respectively. 1'-CH_2OH-S-2840 was identified in day 28 liver at the 3 ppm and 10 ppm dose levels. The average concentration of inpyrfluxam in fat for the 10 ppm was 0.017 mg/kg. In liver, 1'-CH_2OH-S-2840 averaged 0.017 mg/kg at the 10 ppm less than a day after cessation of dosing. However, each of these residues in the liver and fat were <LOQ within 3 days.

No residues of inpyrfluxam or its metabolites were found in whole egg and egg white. Egg yolk contained residues of 1'-CH_2OH-S-2840 in the 10 ppm samples on day 28. The average total of 1'-CH_2OH-S-2840 in egg yolk at the 10 ppm on day 28 was 0.012 mg/kg (Table 135). No discernible plateau of residues was observed because of the low levels of residues in all samples.

Table 135 Residues (mg/kg) of inpyrfluxam in egg yolk from the 1, 3 and 10 ppm dose group during the 28-day hen study

Day	1 ppm			3 ppm			10 ppm		
	Inpyrfluxam	1'-COOH-S2840	1'-CH_2OH-S-2840	Inpyrfluxam	1'-COOH-S2840	1'-CH_2OH-S-2840	Inpyrfluxam	1'-COOH-S2840	1'-CH_2OH-S-2840
14	<0.01 (3)	<0.01 (3)	<0.01 (3)	-	-	-	<0.01 (3)	<0.01 (3)	<0.01 (3)

Samples of muscle had no residues at or above the LOQ throughout the dosing period. No residues were found in muscle, liver or fat in the 10 ppm group up two weeks after cessation of dosing, suggesting limited transfer from feed to tissues. The results for liver and fat are summarized in Table 136.

APPRAISAL

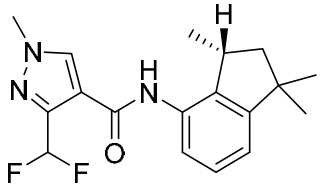
Inpyrfluxam is a broad spectrum fungicide belonging to the succinate dehydrogenase inhibitor (SDHI) group of fungicides, which mode of action involves inhibition of energy production processes in pathogenic fungi.

Inpyrfluxam has not previously been evaluated by JMPR and was scheduled at the Fifty-first Session of the CCPR (2019) for toxicology and residue evaluation as a new compound by the 2022 JMPR.

The Meeting received information on identity, physical-chemical properties, plant and animal metabolism, analytical methods, storage stability, use patterns, residues resulting from supervised trials, fate of residues in succeeding crops, fate of residues during processing and livestock feeding studies.

All critical studies contained statements of compliance with GLP and were conducted in accordance with relevant national or international test guidelines, unless otherwise specified.

Inpyrfluxam (S-2399) is the ISO-approved common name for 3-(Difluoromethyl)-1-methyl-*N*-[(3*R*)-1,1,3-trimethyl-2,3-dihydro-1*H*-inden-4-yl]-1*H*-pyrazole-4-carboxamide with the CAS number 1352994-67-2.



The abbreviations, chemical names, and structures discussed in the appraisal are summarized in Table 137.

Table 137 Abbreviations for the relevant compounds referred to in this document

Compound code (other names)	Name and matrix	Structure

Physical chemical properties

Inpyrfluxam is not soluble in water (0.0164 g/L at 20 °C), but is soluble in acetone (621 g/L), methanol (368 g/L) and ethyl acetate 396 g/L). Inpyrfluxam is hydrolytically and photolytically stable. The compound has a LogPow of 3.65 suggesting potential accumulation in fat and a vapour pressure of 1.2×10^{-7} Pa at 25 °C suggesting that the compound in not volatile.

Plant metabolism

The Meeting received plant metabolism studies for inpyrfluxam in apple (fruit), soya bean and rapeseed (pulse and oilseed crops), maize, sorghum and rice (cereal crops) and potato (root crop). Inpyrfluxam was applied using either [pyrazolyl-4-^{14}C]-inpyrfluxam or [phenyl-U-^{14}C]-inpyrfluxam (Table 138). In metabolism studies, total radioactive residues (TRR) are expressed in mg inpyrfluxam equivalents/kg.

Table 138 Labels used in the plant metabolism studies

	[Pyrazolyl-4-^{14}C]-inpyrfluxam used in all primary metabolism studies.	[Phenyl-U-^{14}C]-inpyrfluxam used in all primary metabolism studies.

The use patterns received include foliar application (apples, soya, sugar beet, rice, peanut), broadcast granular application (rice) and seed treatment (soya, sugar beet, rice, maize).

Apple

The metabolic fate of [pyrazolyl-4-^{14}C]-inpyrfluxam and [phenyl-U-^{14}C]-inpyrfluxam was investigated in apples following three foliar applications with approximate 10-day intervals 35, 24 and 14 days before harvest (BBCH stage not specified in the report) at an actual rate of 214–221 g ai/ha each.

Samples of apple fruits were collected 14 days after the final application.. Fruits were rinsed with acetonitrile and separated into peel and flesh before homogenisation. Processed samples were extracted twice with acetonitrile:water (1:1) and once with acetonitrile.

Extracted radioactivity was similar in both labels ranging between 95.9–96.3 percent TRR (0.25–0.3 mg eq/kg) in whole fruit (including apple rinse). The PES accounted for 3.6–4 percent TRR (0.01–0.011 mg eq/kg) and were not further analysed. The majority of radioactivity was recovered in the fruit rinse (58–64 percent TRR, (0.14–0.19 mg eq/kg) and peel (17–22 percent TRR, 0.052–0.055 mg eq/kg). Radioactivity in the flesh was markedly lower than in the peel for both treatment groups.

The major component identified was inpyrfluxam, representing 78–79 percent of the TRR (0.19–0.24 mg /kg). Minor metabolites identified were 3'-OH-S-2840 (11.5 percent TRR, 0.035 mg eq/kg) and 1-CH_2OH-S-2840 (5.6 percent TRR, 0.014 mg eq/kg).

Soya bean

The metabolic fate of [pyrazolyl-4-14C]-inpyrfluxam and [phenyl-U-14C]-inpyrfluxam was investigated in outdoor soya beans following two foliar applications with a 36-day interval (at BBCH 60 and 75) at actual rates 107–113 g ai/ha each.

Samples of soya bean forage and hay were collected 20 and 33 days after the final application as follows:

Forage was harvested at BBCH 75 and left to dry to soya bean hay, immature pods were taken at BBCH 77 and mature pods were taken at BBCH 89. Samples were separated into pods and seeds and a portion of mature bean pods were rinsed (with acetonitrile) before homogenisation.

Homogenized samples were extracted twice with acetonitrile:water, and once with acetonitrile. The post-extraction solids (PES) were further submitted to either acidic or alkaline hydrolysis to release plant natural components (e.g. pectin (lignin, hemicellulose and cellulose).

Extracted radioactivity was similar in both labels being 100 percent TRR (1.71–2.37 mg eq/kg) in hay ranging between 99.8–99.9 percent TRR (1.39–1.5 mg eq/kg) in forage, 72.7–96.35 percent TRR (0.016–0.1 mg eq/kg) in immature seed, 100 percent TRR (0.61–0.71 mg eq/kg) in immature seed, 65.8–95.4 percent TRR (0.023–0.2 mg eq/kg) in mature pods and 92.5–94.6 percent TRR (0.59–1.04 mg eq/kg) in mature seeds.

Unextracted residues after hydrolysis accounted for 4.1–36.8 percent TRR (0.009–0.014 mg eq/kg) only for mature seeds and were not further characterized.

Parent inpyrfluxam was extensively metabolised in soya beans accounting for the major part of the residue in forage samples (40.3–50.5 percent TRR, 0.56–0.79 mg /kg) but declined as the plant matured. Residues of inpyrfluxam in hay were between 0.42–0.49 mg/kg (17.8–22.1 percent TRR), in immature pods levels ranged from 0.24–0.41 mg/kg (34–65.2 percent TRR) and in mature pods levels ranged from 0.13–0.22 mg/kg (10.9–29.2 percent TRR), including the surface rinse fraction. Only trace levels of inpyrfluxam residues were detected in the soya bean seeds.

In <u>forage</u>, 3'-OH-S-2840 was present at the highest levels (15.3–22.1 percent TRR, 0.24–0.31 mg eq/kg), whilst 1'-CH_2OH-S-2840 was identified but in low levels below 3.7 percent TRR (0.058 mg eq/kg).

In <u>hay</u>, 3'-OH-S-2840 was present at the highest levels (14.3–14.7 percent TRR, 0.32–0.35 mg eq/kg), whilst *N*-des-Me-S-2840 was detected at low levels (≤ 2.4 percent TRR, 0.05 mg eq/kg).

Also the metabolites 1'-CH_2OH-S-2840 (free and conjugated) and Glc-NDM-inpyrfluxam, were detected at minor levels.

In immature pods, metabolites 3'-OH-S-2840, *N*-des-Me-S-2840 and 1'-CH_2OH-S-2840 were found below 10 percent TRR but at levels up to 0.065 mg eq/kg, 0.042 mg eq/kg and 0.026 mg eq/kg respectively.

In immature seeds, N-DesMet-pyrazole carboxylic acid and *N*-des-Me-S-2840 were detected at levels below 10 percent TRR (< 0.01 mg eq/kg). The majority of the residue (61.6 percent TRR, 0.067 mg eq/kg) was characterised as multiple polar components with a single component representing 4.6 percent TRR (0.005 mg eq/kg).

In mature pods, 3'-OH-S-2840 was identified as the most dominant metabolite at 11.6 percent TRR (0.086 mg eq/kg), whilst *N*-des-Me-S-2840 (3.9 percent TRR; up to 0.029 mg eq/kg) and 1'-CH_2OH-S-2840 (2.8 percent TRR; up to 0.021 mg eq/kg) were also characterized at lower levels. In the [pyrazolyl-^{14}C] label, polar components were present at high levels (48.9 percent TRR, 0.59 mg eq/kg), with the highest component being no greater than 2.1 percent TRR (up to 0.032 mg eq/kg).

In mature seed, N-DesMet-pyrazole carboxylic acid (conjugated), was detected (17.5 percent TRR, 0.038 mg eq/kg). Metabolites 3'-OH-S-2840, Glc-NDM-inpyrfluxam and 1'-CH_2OH-S-2840 were detected at low levels (< 10 percent TRR; ≤ 0.001 mg eq/kg). The major fraction contained unretained polar components (11.7–63.8 percent TRR, 0.004–0.140 mg eq/kg).

Rice–foliar treatment

The metabolic fate of [pyrazolyl-4-^{14}C] inpyrfluxam and [phenyl-U-^{14}C]inpyrfluxam was investigated in outdoor rice following one foliar applications at actual rates 95–108.1 g ai/ha, 28 days (at BBCH 77) before normal commercial harvest.

Samples of the immature whole plant (BBCH not specified) were taken for analysis 14 days after application. Samples of rice heads and straw were collected 28 days after application (at normal commercial harvest). Rice heads were separated into husked rice and hulls.

Homogenised samples were extracted twice with acetonitrile:water and once with acetonitrile. The PES were further submitted to either acidic or alkaline hydrolysis.

Extracted radioactivity was similar in both labels, ranging between 99.3–99.7 percent TRR (0.29–0.37 mg eq/kg) in immature rice, 97.4–99.3 percent TRR (0.84–1.44 mg eq/kg) in straw, 96.9–98 percent TRR (1.4–1.5 mg eq/kg) in hulls and 95.3–95.9 percent TRR (0.063–0.047 mg eq/kg) in husked rice.

Unextracted residues after hydrolysis accounted for 0.6–3.2 percent TRR (0.002–0.054 mg eq/kg).

In immature rice plants, the only major component for both radiolabels detected in the neutral extract was parent inpyrfluxam, present at 81.2–86.7 percent TRR (0.25–0.31 mg/kg). The metabolite, 3'-OH-S2480 was detected between 5.6–7.1 percent TRR (0.016–0.027 mg eq/kg), with trace levels of *N*-des-Me-S-2840 and 1'-CH_2OH-S-2840 (two isomers) also detected in both labelled extracts. The acidic acetonitrile extracts for both labels contained predominantly parent (2.5–3.4 percent TRR, 0.007–0.013 mg/kg).

In husked rice, inpyrfluxam accounted for 60.6–78.6 percent TRR (0.038–0.039 mg/kg). Metabolites 3'-OH-S-2840 and Gly-1'-CH_2OH-S-2840 were also detected but at ≤ 0.01 mg eq/kg (up to 16 percent TRR).

In straw, inpyrfluxam was present as the major residue (67.7–77.8 percent TRR, 0.58–0.72 mg/kg). Metabolites 3'-OH-S-2840 (up to 12 percent TRR; 0.102 mg eq/kg), Gly-1'-CH_2OH-S-2840 (5.2 percent TRR; 0.040 mg eq/kg) and DFPA-$CONH_2$ (4.6 percent TRR; 0.039 mg eq/kg) were also present.

In rice hulls, residues were characterized as a mixture of inpyrfluxam at 52.5–41.8 percent TRR (0.64–0.88 mg/kg), 1'-CH_2OH-S-2840 at 18–33.9 percent TRR (0.52–0.28 mg eq/kg) and 3'-OH-S-2840 at 6–12 percent TRR (0.055–0.1 mg eq/kg) respectively.

Rice–granular treatment

The metabolic fate of [pyrazolyl-4-^{14}C] inpyrfluxam and [phenyl-U-^{14}C]inpyrfluxam was also investigated in rice grown in trays and transplanted at the 4 leaf stage of growth in outdoor plots. Inpyrfluxam was applied following one granular treatment at BBCH 13-14 at actual rate 400 g ai/ha.

Immature rice plants were harvested 30 days after treatment (BBCH 30) and mature rice plants were harvested 132 days after treatment (BBCH 89) and were separated into straw, hulls and husked rice.

Homogenised samples were extracted twice with acetonitrile:water and once with acetonitrileand PES were further submitted to either acidic or alkaline hydrolysis.

Extracted radioactivity was similar in both labels, being 100 percent TRR (1.9–3.9 mg eq/kg) in immature rice, 100 percent TRR (1.07–1.58 mg eq/kg) in straw, ranging from 91.1–93.2 percent TRR (0.14–0.16 mg eq/kg) in hulls and 40.4–55.6 percent TRR (0,005–0.006 mg eq/kg). Unextracted residues after hydrolysis accounted for 6.9 percent TRR (0.012 mg eq/kg) in hulls and 60 percent TRR (0.009 mg eq/kg) in husked rice but were not further identified.

In immature rice plants, parent inpyrfluxam accounted for a large proportion of the residues at 20–38.2 percent TRR (0.72–0.78 mg/kg). In addition, 1'-CH_2OH-S-2480 (5.8-6.2 percent TRR, 0.11–0.24 mg eq/kg), 3'-OH-S-2840 (1.2–3.6 percent TRR, 0.023-0.14 mg eq/kg) and DFPA-$CONH_2$ (2.2 percent TRR, 0.086 mg eq/kg) were identified. Glycosidic derivative of 1'-CH_2OH-S-2840, was present at 16.8–26.0 percent TRR (0.32–1.01 mg eq/kg).

In straw, parent inpyrfluxam accounted for 1.9–2.8 percent TRR (0.03 mg eq/kg). The major part of the residue was metabolite 1'-CH_2OH-S-2840 and its glycosidic derivatives (57.4–61.6 percent TRR (0.77–0.66 mg/kg), whilst metabolites *N*-des-Me-S-2840 (1.6 percent TRR, 0.025 mg eq/kg) and DFPA-$CONH_2$ (2.1 percent TRR, 0.034 mg eq/kg) in lower levels.

In rice hulls, parent inpyrfluxam was not detectable. Metabolite 1'-CH_2OH-S-2840 and its glycosidic conjugates (40.1–60.2 percent TRR, 0.031–0.085 mg eq/kg) were the main residues, followed by DFPA-$CONH_2$ (17.5 percent TRR, 0.031 mg eq/kg) and N-DesMet-pyrazole carboxylic acid (5.3 percent TRR, 0.009 mg eq/kg).

In husked rice, parent inpyrfluxam was not detectable. Metabolites DFPA, N-DesMet-pyrazole carboxylic acid and 1'-CH_2OH-S-2840 were detected at ≤ 0.002 mg eq/kg (up to 23.1 percent TRR).

Seed treatment

Maize

The metabolic fate of [pyrazolyl-4-^{14}C] inpyrfluxam and [phenyl-U-^{14}C]inpyrfluxam was investigated in outdoor maize following seed treatment at actual rates 22.1 g ai/tonne seeds and planted after 3–4 days.

Maize forage was sampled at late dough/early dent stage, sweet corn (kernels plus cob with husks removed at the milk/succulent stage, approximately 95 days after planting) whilst stover and

grains were harvested at maturity. Grain was separated from the cob (approximately 126 days after planting) and grain-free mature cobs and stalks were processed as maize stover.

In all samples from both labels, TRR were not found above the LOQ (0.005 mg/kg), as a result no metabolite identification was attempted.

Sorghum

The metabolic fate of [pyrazolyl-4-^{14}C] inpyrfluxam and [phenyl-U-^{14}C]inpyrfluxam was investigated in outdoor sorghum following seed treatment at actual rates 50 g ai/tonne seeds.

Sorghum forage samples were collected at the soft dough to hard dough stage. The remaining plants were harvested at maturity and separated into grain and stover. In all samples from both labels, TRR were not found above the LOQ (0.005 mg/kg), thus no metabolite identification was attempted.

Rapeseed

The metabolic fate of [pyrazolyl-4-^{14}C] inpyrfluxam and [phenyl-U-^{14}C]inpyrfluxam was investigated in outdoor rapeseed following seed treatment at actual rates 5 g ai/tonne seeds and planted after 7 days.

Samples of mature seeds of rapeseed, were harvested after 4 months from individual plots at BBCH 97–99 (approximately 161 days after planting).

In all samples from both labels, TRR were not found above the LOQ (0.005 mg/kg), thus no metabolite identification was attempted.

Potatoes

The metabolic fate of [pyrazolyl-4-^{14}C] inpyrfluxam and [phenyl-U-^{14}C]inpyrfluxam was investigated in potato following seed piece treatment at actual rates 50 g ai/tonne seeds and planted in outdoor plots at the same day.

Samples of the mature tubers were harvested at the appropriate growth stage (BBCH 49; 84–85 days from treatment and planting) and samples of foliage (collected at BBCH 48; 71–72 days from treatment and planting) were also taken from the plots.

Surface radioactivity was extracted into acetone and homogenised tuber samples were extracted twice with acetone and twice with acetone:water. To identify conjugates in tuber samples, the acetone extract was evaporated to dryness and dissolved in acetonitrile:water before being subjected to acid hydrolysis.

Extracted radioactivity was similar in both labels ranging between 87.9–93.4 percent TRR (0.011–0.039 mg eq/kg) in potato tubers. The PES accounted for 6.6–12.1 percent TRR (0.001–0.003 mg eq/kg).

In tubers, parent accounted for 5.8–15 percent TRR (0.002 mg eq/kg). Metabolite 1'-COOH-S-2840 accounted for 14.5–22.3 percent TRR (0.006–0.009 mg eq kg). Metabolites 1'-CH_2OH-S-2840, 3'-OH-S-2840, DFPA and N-DesMet-pyrazole carboxylic acid were also detected but individually accounted for ≤ 0.004 mg eq/kg (≤ 10.2 percent TRR).

Low TRR values in tubers, in both labels, indicated that the uptake of inpyrfluxam from the treated seed pieces was low. Inpyrfluxam metabolised into a number of metabolites, none of which were present at levels above ≥ 0.01 mg/kg in the tuber tissue. Inpyrfluxam was shown to metabolise via the routes of oxidation, amide bond cleavage and conjugation in potato tubers.

Summary of plant metabolism

Plant metabolism studies were conducted in apple and soya bean (foliar spray), rice (foliar and granular treatments) and maize, sorghum rapeseed and potato (seed treatment) at rates that accommodate the anticipated maximum total seasonal GAP application rates.

Uptake and transport of inpyrfluxam in the maize, sorghum, oilseed and potato studies, after seed treatment was low. Metabolism in soya bean, rice and apple proceeds via oxidation to form the hydroxylated components, 3'-OH-S-2840 and 1'-CH_2OH-S-2840 the latter forming multiple glycoside conjugates. The glycoside conjugates of 1'-CH_2OH-S-2840 are further transformed into plant constituents. DFPA-$CONH_2$ can be also formed from the degradation of 3'-OH-S-2840 and 1'-CH_2OH-S-2840, which is further metabolised into plant components. Additional minor pathways include the demethylation of inpyrfluxam or cleavage of the amide bond to DFPA which is rapidly demethylated to N-DesMet-pyrazole carboxylic acid followed by sugar conjugation and metabolism into multiple high polarity components.

Environmental fate

The Meeting received information on hydrolysis, aqueous photolysis, aerobic degradation in soil under laboratory conditions, soil field dissipation, confined and field rotational crops.

Hydrolysis

[Pyrazolyl-4-^{14}C] inpyrfluxam incubated in the dark in sterile aqueous buffered solutions at pH 4, 7 and 9 for 5 days at 50 °C remained stable. No degradation products were detected and no change in ratio between the R- and S-isomers was observed. The results indicate that inpyrfluxam is hydrolytically stable at environmental conditions and hydrolysis is not considered a significant route of degradation.

Photochemical degradation

In an aqueous photolysis study, inpyrfluxam was minimally degraded under simulated sunlight in sterilized aqueous phosphate buffer pH 7 and in sterilized natural water. The formation of metabolites 3'-OH-S-2840 and DFPA-$CONH_2$ was observed below < 10 percent AR (applied radioactivity. The DT_{50} values ranged from 36–88 days (69–579 sunlight days).

In a soil photodegradation study, the main degradation product was 3-'OH-S-2840 (mean maximum of 8.3 percent AR at day 13) and soil bound residues represented less than 3 percent AR. Isomerization from inpyrfluxam R-isomer to its S-isomer was not observed.

Based on the above, photolysis is not considered a significant route of degradation in water or the soil surface.

Soil metabolism

DT_{50} values for inpyrfluxam in aerobic soil under laboratory conditions ranged from 101–1720 days with a geomean DT_{50} of 348 days, indicating moderate persistence to persistence in soil resulting in the formation of two major metabolites (3'-OH-S-2840 and 1'-COOH-S-2840) and many minor metabolites.

Using the best fit kinetics for the parent molecule, calculated DT_{50} values for 3'-OH-S-2840 ranged from 78–843 (> 10,000 at Atwater soil) days and for 1'-COOH-S-2840 ranged from 34.2–669 (> 10,000 at Penn soil) days. However since the duration of the studies was short (120–182 days) and metabolites did not show significant decline during the incubation, there is significant uncertainty in the study, thus the Meeting concluded that the calculated DT_{50} are not reliable.

Soil field dissipation studies

The field soil dissipation of inpyrfluxam has been studied in Europe and the United States with DT_{50} values ranging from 78.1–419 days and 14.6–113 days, respectively, with an overall geomean DT_{50} of 117 days (n = 9). The DT_{50} values of the metabolites were assessed only in Europe, however residues below the LOQ were observed thus the Meeting concluded that the reliable DT_{50} could not be calculated.

Water/sediment degradation in the field

Inpyrfluxam degraded slowly under anaerobic (DT_{50} of 3537 and 3498 days) or aerobic (DT_{50} of 154 to 704 days depending on the study) aquatic conditions. Degradation was primarily to form 1′-COOH-S-2840 (0.9–13.1 percent AR) and 3′-OH-S-2840 (2.9–6.8 percent AR). In natural surface water, no significant degradation of inpyrfluxam was observed (DT_{50} ≥ 1.540 days).

The dissipation, mobility and degradation of inpyrfluxam and its transformation products was investigated in an aquatic field dissipation study following planting of treated rice seed. Inpyrfluxam was applied at 10 g ai/100 kg seed or at 10 g ai/100 kg seed followed by foliar application 77 days after sowing at 100 g ai/ha. In the seed treatment only, inpyrfluxam was observed in the sediment and soil phases at very low concentrations up to 0.027 mg/kg, with no transformation product residues observed (<LOQ) at any sampling event. Formation of 1'-COOH-S-2840 in the water phase was observed at low concentrations up to 5. 1µg/L. In the seed treatment/foliar application study, inpyrfluxam was observed in the sediment and soil phases at very low concentrations up to 0.027 mg/kg, and no degradants were observed in the water, sediment or soil. Inpyrfluxam, dissipated rapidly from the system as a whole (paddy water and sediment) with a calculated DT_{50} of 0.064–0.87 days.

Confined rotational crop studies

[Phenyl-^{14}C] inpyrfluxam and [pyrazolyl-^{14}C] inpyrfluxam were applied to bare soil at a rate of approximately 235 g ai/ha. Lettuce, radish and sorghum were grown as rotational crops 30, 120 and 365 days after treatment, i.e., plant back intervals (PBI), and harvested according to normal agricultural practice.

TRR levels were lower in lettuce and radish samples at the 365 days PBI compared to the levels at 30 and 120 days PBI. The highest AR was observed in sorghum stover samples, with TRR of 0.69–0.7 mg eq/kg at 30 days PBI and 0.94–1.07 mg eq/kg at 120 days PBI, decreasing to 0.13–0.24 mg eq/kg at 365 days PBI. The sorghum forage contained considerably lower residue levels than the stover samples at all planting intervals.

Inpyrfluxam and its primary oxidation product 3'-OH-S-2840 (free and conjugated) was found in all crops except for sorghum grain. Inpyrfluxam was found in lettuce (up to 17.4 percent TRR; 0.011 mg/kg), radish tops (up to 12.3 percent TRR; 0.025 mg/kg), radish roots (up to 57.8 percent TRR; 0.045 mg/kg), sorghum forage (up to 3.4 percent TRR; 0.007 mg/kg) and sorghum stover (up to 1.8 percent TRR; 0.02 mg/kg). The major portion of metabolite 3'-OH-S-2840 was present in conjugated form accounting for up to 17.6 percent in lettuce (0.012 mg eq/kg), for up to 13.3 percent TRR in radish tops (0.017 mg eq/kg) and for up to 12.1 percent TRR sorghum stover (0.017 mg eq/kg). 1'-COOH-S-284, mostly conjugated, was found in lettuce (up to 14.6 percent TRR; 0.045 mg eq/kg), radish tops (up to 25.6 percent; 0.021 mg eq/kg), radish roots (up to 25.7 percent TRR; 0.06 mg eq/kg) and potatoes (up to 19.1 percent TRR; 0.005 mg eq/kg). 1'-CH_2OH-S-2840, mostly conjugated, was found in lettuce (up to 24.8 percent TRR; 0.024 mg eq/kg) and sorghum stover (15.5 percent TRR; 0.008 mg eq/kg). N-des-Me-S-2840, mostly in free form, was found in radish immature (up to 15.1 percent TRR; 0.027 mg eq/kg) and mature tops (up to 12.8 percent TRR; 0.039 mg eq/kg). N-des-Me-1'-CH_2OH-S-2840, mostly conjugated,

was found in radish immature (14.7 percent TRR; 0.017 mg eq/kg) and mature tops (15 percent TRR; 0.056 mg eq/kg).

Field rotational crop studies

Inpyrfluxam and its metabolites are persistent in the environment and may contribute to residues in follow/rotational crops through uptake from soil. In assessing the potential uptake of residues, excluding apples, the maximal season rate was 200 g ai/ha for peanut, i.e., the highest seasonal application rate of the uses evaluated by the Meeting. The use pattern of inpyrfluxam in the United States of America for apple, maize, peanut, rice, soya bean and sugar beet includes a rotational interval of 9 months (120 days) and a restriction for livestock grazing (soya bean use). Five field rotational crop studies were conducted in Canada (1), Europe (1), and the United States (3).

In the European study inpyrfluxam was applied at a single rate of 240 g ai/ha on winter and spring barley. The crops were destroyed and incorporated in the soil whilst preparing the soil for rotational crops within 13–14 days of application. Follow-up crops lettuce, carrot and wheat or barley were planted at PBIs of 28, 120 and 350 days. Residues of inpyrfluxam and its metabolites were < 0.01 mg/kg in all rotated crop matrices at all PBIs except for cereal straw on 30 days PBI, residues were up to 0.017 mg eq/kg for 3'-OH-S-2840, up to 0.019 mg eq/kg for 1'-COOH-S-2840, up to 0.023 mg eq/kg for 1'-CH_2OH-S-2840 and up to 0.1 mg eq/kg for DFPA.

In the Canadian and one US study, inpyrfluxam was applied at a single rate of 100–120 g ai/ha on wheat. The crops, after growth to maturity, the wheat was harvested and either destroyed (Canadian study) or tilled into the ground near the treated plot (US study). In the Canadian study, wheat, field peas and rapeseed were planted at PBIs of 328, 328 and 339 days and in the US study, wheat and rapeseed were planted at PBIs of 328 and 312 days. In two additional US studies inpyrfluxam was applied twice at a rate of 105–110 g ai/ha on soya bean. After growth to maturity the crops were tilled into the ground near the treated plot and sorghum and cotton planted at PBIs of 273–267 days. Residues of inpyrfluxam and its metabolites were < 0.01 mg/kg in all rotated crop matrices at all PBIs.

Summary of environmental fate

Inpyrfluxam is hydrolytically stable, does not photodegrade in aqueous buffered solutions or on the surface of soil. Aerobic degradation studies under laboratory conditions indicated a DT_{50} of 101–331days of inpyrfluxam in various soils, indicating moderate persistence to persistence in soil. Field dissipation studies confirmed the results, with DT_{50} for inpyrfluxam residues ranging from 41.6 to 419 days (geometric mean of 117 days) in European Union and United States soils. 3'-OH-S-2840 and 1'-COOH-S-2840 were identified in soil, but reliable DT_{50} values could not be calculated.

In the aquatic field dissipation studies, inpyrfluxam was observed in the sediment and soil phases at very low concentrations, as well as 1'-COOH-S-2840 in the water phase. Decline in the total aquatic system was very quick (<1 day DT_{50}). Based on the available studies, a soil plateau level estimation is not required as to address the residues in rotational crops.

Confined rotational crop studies indicate that inpyrfluxam was extensively metabolized into a large number of metabolites, but the residues were < 0.01 mg/kg in all rotated crop matrices at all PBI, except wheat straw were 3'-OH-S-2840, 1'-COOH-S-2840, 1'-CO_2OH-S-2840 and DFPA were detected at quantitative levels.

In conclusion, no residues of inpyrfluxam are expected in rotated crops under the conditions investigated in the studies provided to the Meeting. Should a more cGAP or additional uses received in the future, the expectation of residues of inpyrfluxam in rotational crops may need to be re-evaluated.

Animal metabolism

The meeting received information on the fate of orally-dosed inpyrfluxam in rat, lactating goats and laying hens.

Laboratory animals

Metabolism in laboratory animals was summarized and evaluated by the WHO panel of the current Meeting.

Lactating goats

The metabolic fate of inpyrfluxam was investigated in lactating goats using [pyrazolyl-^{14}C] inpyrfluxam and [phenyl-^{14}C] inpyrfluxam. The compound was administered orally once daily (after morning milking) for five consecutive days at 0.51 mg/kg body weight/day (13.74 ppm feed per day) for [pyrazolyl-^{14}C] inpyrfluxam and at 0.64 mg/kg body weight/day (15.74 ppm feed per day) for the [phenyl-^{14}C]inpyrfluxam. Milk was collected twice daily during the dosing period and the goat was sacrificed ca. 6-7 hours after the final dose.

Muscle, liver and kidney samples were extracted twice with acetonitrile:water, once with acetonitrile and for liver and kidney, extracts were further characterized by enzyme hydrolysis using β-glucuronidase. Milk fat was extracted twice with hexane:acetone and once with acetone, while skimmed milk was extracted once with acetone. Fat samples were extracted once with hexane:acetone and twice with acetone.

The majority of the radioactive dose (≥ 76.5 percent of the administered dose (AD)) was found in excreta whilst the highest tissue radioactivity was in liver (up to 0.26 percent AD; 0.35 mg eq/kg) and kidney (up to 0.02 percent AD; 0.17 mg eq/kg). Radioactivity was qualitatively lower in the muscle (up to ≤ 0.01 percent AD; up to 0.024 mg eq/kg) and fat (up to ≤ 0.01 percent AD; up to 0.040 mg eq/kg). In whole milk, the radioactive residues ranged between 0.09–0.12 percent AD for both labels. Residue levels reached a plateau after the first dose (1st day) and very low levels (0.09–0.12 percent AD) were excreted in whole milk. Residues in milk fat were found at 0.011–0.042 mg eq/kg and in skimmed milk at 0.014–0.041 mg eq/kg.

The extraction efficiency was high in liver (up to 91.1 percent TRR; 0.31 mg eq/kg), kidney (up to 98.2 percent TRR; 0.17 mg eq/kg), muscle (up to 100 percent TRR; up to 0.021 mg eq/kg) and fat (up to 96.6 percent TRR ; up to 0.041 mg eq/kg). The PES accounted between 1.9–28.6 percent TRR (≤ 0.001–0.033 mg eq/kg) and were further characterized by β-glucuronidase.

Inpyrfluxam was only quantified at low levels in liver (up to 5.9 percent TRR; 0.019 mg/kg), milk fat (9.1 percent TRR; 0.002 mg/kg) and fat (up to 15.8 percent TRR; 0.004 mg/kg). The major metabolites in the tissue samples were 1'-COOH-S-2840 (up to 49.7 percent TRR; 0.13 mg eq/kg) and 1'-CH_2OH-S-2840 (up to 45.8 percent TRR; 0.079 mg eq/kg) As minor metabolites 3'-OH-S-2840 (up to 3.1 percent TRR; 0.005 mg eq/kg) and DFPA-$CONH_2$ (up to 11.2 percent TRR; 0.008 mg eq/kg) were also detected.

Residues of 1'-COOH-S-2840 were found in fat (up to 46.4 percent TRR; 0.018 mg eq/kg) and skimmed milk (up to 15.9 percent TRR; 0.006 mg eq/kg) and 1'-CH_2OH-S-2840 in fat (up to 35.6 percent TRR; 0.005 mg eq/kg).

Laying hens

The metabolic fate of inpyrfluxam was investigated in laying hens using [pyrazolyl-^{14}C] inpyrfluxam and [phenyl-^{14}C] inpyrfluxam. The compound was administered orally once daily for seven consecutive days at

12.44 ppm feed per day for [pyrazolyl-^{14}C] inpyrfluxam and at 13.13 ppm feed per day for the [phenyl-^{14}C]inpyrfluxam. Eggs and excreta were collected twice daily. The hens were sacrificed approximately 6 hours after the last dose administration.

Excreta, egg, liver, thigh and breast muscle samples were extracted twice with acetonitrile:water once with acetonitrile. Residues in liver extracts were further subjected to enzyme or chemical hydrolysis. Fat samples were extracted once with hexane:acetone and twice with acetone.

The majority of the radioactivity (80.3–81.7 percent AD) was found in excreta whilst the highest tissue radioactivity was found in liver (up to 0.22 percent AD; 0.526 mg eq/kg), in the gastrointestinal tract (up to 1.1 percent AD; 2.48 mg eq/kg) and less than 0.1 percent AD (up to 0.11 mg eq/kg) in the other tissues and eggs. In eggs, levels increased over the 7 day dosing period and plateau levels reached for both radiolabels by the end of day 7. The maximum radioactivity in egg was 0.033 mg/kg (0.01 percent AD).

TRR in eggs were 90–91.3 percent (0.023–0.02 mg eq/kg), with major residues being inpyrfluxam (11.5–11.9 percent TRR, 0.002 mg/kg) and 1'-CH_2OH-S-2840 (29.8–31.6 percent TRR, 0.006–0.008 mg eq/kg). Sulfate conjugates of 1'-CH_2OH-S-2840, 1'-COOH-S-2840, 3'-OH-S-2840 and *N*-des-Me-S-2840 were present at ≤ 9.2 percent TRR (≤ 0.002 mg/kg).

TRR in liver was between 91.4–94.3 percent (0.25–0.32 mg eq/kg), with sulphate conjugates of 1'-CH_2OH-S-2840) the major residue (up to 51.7 percent TRR; up to 0.16 mg eq/kg. Other metabolites identified (free and conjugated) were *N*-des-Me-S-2840 (up to 9.5 percent TRR; up to 0.024 mg eq/kg) and 1'-COOH-S-2840 (up to 11 percent TRR; up to 0.028 mg eq/kg).

TRR in fat (abdominal and subcutaneous) ranged between 96.8–99 percent (0.064–0.102 mg eq/kg), with inpyrfluxam accounting for up to 80.7 percent TRR (0.045–0.075 mg/kg), and sulphate conjugates of 1'-CH_2OH-S-2840 with up to 16.9 percent TRR (up to 0.014 mg eq/kg).

TRR in muscle (thigh and breast) were between 80–92.3 percent (0.012–0.023 mg/kg), with several metabolites identified, with sulphate conjugates of 1'-CH_2OH-S-2840 accounting for 47.7 percent TRR, but at low levels (≤ 0.011 mg/kg).

Summary of animal metabolism

The metabolism of inpyrfluxam in poultry and ruminants demonstrates a comparable metabolite profile. The majority of the administered dose was rapidly excreted and parent was extensively metabolised in several metabolites, proceeding via two main pathways: (a) Oxidation to form 1'-CH_2OH-S-2840 isomers, which is further transformed by conjugation to sulphate or glucuronic acid, or by oxidation to form 1'-COOH-S-2840 isomers and to 1',1'-bis-(CH_2OH)-S-2840. (b) *N*-demethylation to form *N*-des-Me-S-2840, amide cleavage to form DFPA-$CONH_2$ or oxidation to 3'-OH-S-2840.

Methods of analysis

Several analytical methods with minor modifications were available for the determination of inpyrfluxam and its metabolites (3'-OH-S-2840, 1'-CH_2OH-S-2840-A and B, DFPA-$CONH_2$ and 1'-COOH-S-2840-A and B, and N-DesMet-pyrazole carboxylic acid) in plant commodities (apple, maize grain, maize stover, maize forage, soya bean, wheat plant and grain, potato tubers, grapes, soya bean seeds, lettuce, carrot roots and tops). The methods (including RM-50C-1) involve extraction with acetonitrile/water, the extracts partitioned into hexane/ethyl acetate and purified with SPE. The extract was hydrolysed with HCl to release the conjugates before analysis. In method SUM-1701V used only for the determination of *N*-des-Me-S-2840, acetonitrile/water was used for the extraction and no clean-up step was performed. In all

methods, residues were determined by LC-MS/MS with LOQs ranging from 0.005 to 0.02 mg/kg depending on the analyte and the matrix.

For animal commodities, the analytes were extracted with hexane/acetone (1:1) from egg/white/yolk, with hexane/acetone (4:1) from fat and with acetonitrile/water from liver/muscle. In muscle and liver, conjugates were hydrolyzed with HCl and cleaned up with SPE (methods TPR-013 and TPR-015). Final quantification is by LC-MS/MS, with LOQs of 0.01 mg/kg for inpyrfluxam and 0.005 mg/kg for metabolites 1'-COOH-S-2840-A and -B and 1'-CH2OH-S-2840 (A and B).

The extraction efficient of the enforcement QuEChERS method for the analysis of inpyrfluxam in plant and animal commodities, and methods RM-50C-1 and TPR-0013 used for data generation was evaluated. The QuEChERS method was investigated in rice grain, rice straw, soya bean pods and apples, muscle, liver, fat and milk, the RM-50C-1 in rice straw and radish tops and the TPR-0013 in milk, egg, muscle, liver and fat. The level of inpyrfluxam and metabolites extracted with the methods was similar to the level extracted by the original metabolism methods in all matrices.

In conclusion, the provided analytical methods are suitable for the analysis of inpyrfluxam and metabolites 3'-OH-S-2840, 1'-CH_2OH-S-2840 (A and B isomers), DFPA-$CONH_2$, N-DesMet-pyrazole carboxylic acid and 1'-COOH-S-2840 (A and B isomers) in plants and/or animal commodities.

Stability of pesticide residues in stored analytical samples

The Meeting received freezer storage stability data for inpyrfluxam and its metabolites (3'-OH-S-2840, DFPA, DFPA-CONH2, N-DesMet-pyrazole carboxylic acid, N-des-Me-S-2840, N-des-Me-1'-CH2OH-S-2840 (determined separately as A and B isomers), 1'-COOH-S-2840 (determined separately as A and B isomers) and 1'-CH2OH-S-2840 (determined separately as A and B isomers)) in various plant and processing commodities. Samples were fortified with each analyte at 0.05 to 0.5 mg/kg levels.

Residues of inpyrfluxam and metabolites were stable for at least 679 days in high acid content (grapes), 683 days in high oil content (soya bean, maize oil), 672 days in high protein content (field bean), 681 days in high water content (cucumber, apple, maize forage and stover) and 679 days in high starch content (maize grain, corn starch, polished rice, potato starch, potato tuber, wheat grain and flour) crops.

This period covers the storage period of the samples from the supervised and processing studies.

Residues of inpyrfluxam, 1'-COOH-S-2840 (determined separately as A and B isomers), 1'-CH_2OH-S-2840 (determined separately as A and B isomers) in animal matrices (milk, muscle, liver, kidney and fat), with samples fortified with each analyte at 0.1 or 0.5 mg/kg levels. The analytes were shown to be stable for at least 75 day in milk, 29 days in muscle, liver and kidney and 31 days in fat, when stored under frozen conditions. This period covers the storage period of the samples from the feeding studies.

Definition of the residue

Plant commodities

The metabolism of inpyrfluxam was assessed in apple, potatoes, soya bean and rice and found to be similar in all crops. The metabolism in rotational crops was similar to the metabolism observed in primary crops and the processing of inpyrfluxam is not expected to modify the nature of residues.

Inpyrfluxam was the predominant residue in apple (up to 79 percent TRR; 0.24 mg/kg), mature rice grain (up to 78.6 percent TRR; 0.039 mg /kg) and potato tubers (up to 15 percent TRR; 0.002 mg/kg), but was only found at very low concentrations in mature soya seed (up to 2 percent TRR; < 0.001 mg/kg). In feed commodities, parent was detected in soya bean forage (up to 50.5 percent TRR; 0.79 mg /kg),

soya bean hay (up to 22.1 percent TRR; 0.5 mg/kg), immature pods (up to 65.2 percent TRR; 0.41 mg/kg), rice straw (up to 77.8 percent TRR; 0.72 mg/kg) and rice hulls (up to 52.5 percent TRR; 0.88 mg/kg). In the confined rotational crops study, parent was detected in mature lettuce (up to 26.9 percent; 0.027 mg/kg) and radish immature and mature roots (up to 58.9 percent; 0.045 mg/kg) at 30 to 365 days PBI.

Suitable analytical methods for enforcement are available for inpyrfluxam in plant matrices. The Meeting concluded that inpyrfluxam only should be considered as a suitable marker compound for enforcement purposes.

In deciding which compounds should be included in the residue definition for dietary risk assessment, the Meeting considered the likely occurrence of the compounds and the toxicological properties of the candidates 3'-OH-S-2840, 1'-CH_2OH-S-2840, 1'-COOH-S-2840, DFPA, N-DesMet-pyrazole carboxylic acid, DFPA-$CONH_2$ and *N*-des-Me-1'-CH_2OH-S-2840.

3'-OH-S-2840 was not found at significant levels in primary or rotational crop metabolism studies or field rotational crop studies. In residue trials, 3'-OH-S-2840 was detected in apple fruits at a maximum concentration of 0.08 mg/kg, In most trials, parent residues were at least 10–90 times higher compared to 3'-OH-S-2840.

1'-CH_2OH-S-2840 (free or conjugated), was not found in any food commodities at significant levels in primary crop metabolism studies, residue trials or field rotation crops studies. In the confined rotational crops study 1'-CH_2OH-S-2840 (free or conjugated) was detected only in lettuce (24.8 percent TRR; 0.024 mg/kg).

1'-COOH-S-2840 (free or conjugated) was not found in any food commodities at significant levels in primary crop metabolism studies or field rotation crops studies. In the confined rotational crops study, 1'-COOH-S-2840 (free or conjugated) was detected in lettuce (14.6 percent TRR; 0.045 mg/kg) and radish immature or mature tops (22.1 percent TRR; 0.026 mg/kg). In residue trials, the metabolite was found only in sugar beets root at a maximum of 0.028 mg/kg.

The toxicity of these metabolites is covered by the toxicological properties of the parent compound. The Meeting concluded that residues are low compared to inpyrfluxam, do not contribute significantly to the consumer exposure based on parent residues and decided that an inclusion into the residue definition for exposure purposes is unnecessary.

Metabolites DFPA (free and conjugated) and N-DesMet-pyrazole carboxylic acid (free and conjugated) are not covered by the health based reference values for inpyrfluxam, thus the Meeting assessed the relevance of these metabolites against the TTC Cramer Class III (0.0015 mg/kg bw per day).

N-DesMet-pyrazole carboxylic acid (free and conjugated) was found in the metabolism study in soya bean seeds (17.5 percent TRR; 0.038 mg eq/kg) and in residue trials was the only compound detected in soyabean seeds at levels < 0.02 to 0.19 mg/kg (median residue: 0.026 mg/kg). In the confined rotational crops study, the metabolite was detected in radish tops (13.6 percent TRR; 0.015 mg/kg) but not detected in the field rotation crop studies. This metabolite is also a metabolite formed after use of other active substances, such as bixafen, fluxapyroxad, benzovindiflupyr, and fluindapyr. In the absence of overall information on the uses of all active substances and considering the lack of a specific health based reference value, the Meeting decided there was insufficient information to perform a combined risk assessment for residues resulting from use with all active substances leading to formation of N-DesMet-pyrazole carboxylic acid. The Meeting concluded that N-DesMet-pyrazole carboxylic acid could be assessed by TTC approach against the Cramer Class III and that the exposure should be based on the anticipated residues following use of each active substance, separately.

DFPA (free and conjugated) was not found in any food commodities at significant levels in primary crop metabolism studies, residue trials or field rotational crops studies. In the confined rotational crops study, DFPA (free or conjugated) was detected in immature lettuce and mature lettuce (29.1 percent TRR; 0.028 mg/kg).

In summary, the Meeting agreed that the residue definition for dietary risk assessment should be *inpyrfluxam*.

Animal commodities

Inpyrfluxam was observed in poultry fat (up to 81 percent TRR; 0.075 mg eq/kg), goat fat (up to 15.8 percent TRR; 0.004 mg eq/kg) and eggs (up to 11 percent TRR; 0.002 mg eq/kg). In the feeding studies, parent was only present at 0.017 mg/kg in poultry fat from the highest dose group but not in any other animal tissue, milk or eggs.

DFPA-$CONH_2$ was observed in poultry muscle (up to 15 percent TRR; 0.001 mg eq/kg) but was not found in the feeding studies.

1'-COOH-S-2840 (free and conjugates) was observed in poultry liver (up to 11 percent TRR; 0.028 mg eq/kg), poultry muscle (up to 14 percent TRR; 0.003 mg eq/kg), skimmed milk (up to 16 percent TRR; 0.006 mg eq/kg), goat liver (up to 42 percent TRR; 0.13 mg eq/kg), goat kidney (up to 50 percent TRR; 0.08 mg eq/kg), goat muscle (up to 32 percent TRR; 0.007 mg eq/kg) and goat fat (up to 39.7 percent TRR; 0.018 mg eq/kg). In the feeding studies, residues were present only at 0.01 mg/kg in poultry liver.

1'-CH_2OH-S-2840 (free or conjugated) was observed in poultry liver (up to 52 percent TRR; 0.164 mg eq/kg), poultry muscle (up to 51 percent TRR; 0.012 mg eq/kg), fat (up to 17 percent TRR; 0.014 mg eq/kg), eggs (up to 39 percent TRR; 0.009 mg eq/kg), goat liver (up to 25 percent TRR; 0.088 mg eq/kg), goat kidney (up to 37 percent TRR; 0.063 mg eq/kg) and goat muscle (up to 32 percent TRR; 0.007 mg eq/kg). In the feeding studies, residues were present at 0.012 mg/kg in egg yolk, 0.017 mg/kg in poultry liver, 0.014 mg/kg in goat liver and at 0.022 mg/kg in goat kidney.

3'-OH-S-2840 and *N*-des-Me- S-2840 were not found in any food commodities at levels > LOQ nor were residues found in the feeding studies.

Besides parent inpyrfluxam, 1'-CH_2OH-S-2840 (free or conjugated) was a major residue in most animal matrices and the predominant residue found in the livestock feeding studies. Suitable analytical methods for enforcement are available for inpyrfluxam and 1'-CH_2OH-S-2840 (free or conjugated) in animal matrices. The Meeting decided that the sum of both compounds represents a suitable marker for enforcement purposes in animal matrices.

For dietary exposure purposes, the only other metabolite found in feeding studies at quantified levels was 1'-COOH-S-2840 (free and conjugates) in poultry liver (0.01 mg/kg). Given its low occurrence and that its toxicity is covered by the health-based guidance values for parent inpyrfluxam, the Meeting decided that no inclusion into the residue definition is necessary.

Parent inpyrfluxam has an octanol-water partition coefficient of 3.65, suggesting potential accumulation in fat.

Parent and 1'-CH_2OH-S-2840 residues were predominantly found in liver and kidney commodities. In goats, concentrations between fat and muscle were close to the LOQ without clear tendency for accumulation in the fat. In poultry metabolism studies, fat contained approximately 30x higher residue concentrations compared to muscle. However, no accumulation was observed in milk fat or egg yolk, In

the feeding studies, residues were generally low, not allowing estimation of ratios between fatty and non-fatty tissues. The Meeting decided that the residue is not fat-soluble

In summary, the Meeting agreed that the residue definition for compliance with the MRL and dietary risk assessment for animal commodities should be: *inpyrfluxam and 1'-CH_2OH-S-2840 (free or conjugated) expressed as inpyrfluxam*.

The residue is not fat-soluble.

In deciding which compounds should be taken into consideration for estimation of livestock dietary burdens, the Meeting decided that inpyrfluxam and 1'-CH2OH-S-2840 (free or conjugated) expressed as inpyrfluxam, should be taken into consideration for estimation of livestock dietary burden calculations since they are included in the residue definition for animal commodities and are found in feed commodities in metabolism (soya bean forage, soya bean hay, rice straw, rice hulls, sorghum forage, sorghum stover) and field studies (wheat straw, peanut hay) in primary and rotational crops.

Conclusion

Based on the above the Meeting recommended the following residue definitions:

Residue definition for compliance with the MRL and dietary exposure for plant commodities: *inpyrfluxam*.

Residue definition for compliance with the MRL and dietary exposure for animal commodities is *inpyrfluxam and 1'-CH_2OH-S-2840 (free or conjugated) expressed as inpyrfluxam*.

Residues to be included in the livestock dietary burden calculations: *inpyrfluxam and 1'-CH_2OH-S-2840 (free or conjugated) expressed as inpyrfluxam*.

Results of supervised residue trials on crops

The Meeting received supervised residue trial data for seed treatments and foliar applications of inpyrfluxam on apples, soya beans, maize, peanuts, sugar beets and rice.

In this appraisal, the following residue summaries are given:

- *Inpyrfluxam:* For maximum residue level estimation in plant commodities and dietary exposure calculations.
- *Inpyrfluxam and 1'-CH_2OH-S-2840 (free or conjugated) expressed as inpyrfluxam*: For dietary burden calculations. When the residues of the metabolite was <LOQ (0.02 mg/kg) then it was not taken into consideration in the animal dietary burden calculations
- *N-DesMet-pyrazole carboxylic acid*: For dietary exposure calculations based on TTC approach.

Apples

The critical GAP for inpyrfluxam on apples is from Japan, and consists of a maximum of three foliar applications at a rate of 9.25 g ai/hL with a re-treatment interval of 7 days and a PHI of 1 day.

Trials performed on apples from Japan matching this GAP were available. Residue levels in fruits in ranked order were (n = 8): 0.52, 0.72, 0.78, 0.84, 0.98, 1.23, 1.42, 1.88 mg/kg.

The Meeting estimated a maximum residue level of 4 mg/kg, an STMR of 0.91 mg/kg and an HR of 1.88 mg/kg for apples. Residues of metabolite 1'-CH_2OH-S-2840 were < 0.02 mg/kg in all trials.

Soya bean

The critical GAP for inpyrfluxam on soya beans is from the United States and consists of a seed treatment up to 5 g ai/100 kg seeds and two foliar application at a rate of 75 g ai/ha (not before BBCH 14 or after BBCH 75–76) with an retreatment interval of 14 days and a PHI covered by the growth stage of the crop with a livestock grazing restriction: do not graze treated fields or feed treated hay to livestock.

In trials performed on soya beans in the United States, the seeds were treated at 10 g ai/100 kg, followed by two applications at 100 g ai/ha (one at 200 g ai/ha) at BBCH above 75 and, in most cases. Residue levels in dry seeds were (n = 21): < 0.01 (21) mg/kg.

Since residues of inpyrfluxam were not detected in any overdosed trials, the Meeting estimated a maximum residue level of 0.01(*) mg/kg and an STMR of 0 mg/kg for soya bean (dry).

Residue levels of metabolite N-des-Me-DFPA in dry seeds were (n = 21): < 0.02 (7), 0.02, 0.023, 0.024, 0.026, 0.028, 0.032, 0.036, 0.037, 0.051, 0.062, 0.095, 0.13, 0.16, 0.19 mg/kg. Residues of metabolite 1'-CH_2OH-S-2840 were < 0.02 mg/kg in all trials.

Sugar beet

The critical GAP for inpyrfluxam on sugar beet is in the United States and consists of a seed treatment up to 0.1 g ai/100,000 seeds and up to two foliar applications at a rate of 50g ai/ha with a maximum seasonal rate of 100 g ai/ha (BBCH 12–18), an retreatment interval of 21 days and a PHI of 50 days.

In trials performed on sugar beets, the plant received two foliar application at 100 g ai/ha after the seed treatment. Residue levels in roots were (n = 15): < 0.01 (15) mg/kg.

Since residues of inpyrfluxam were not detected in any overdosed trials, the Meeting estimated a maximum residue level of 0.01(*) mg/kg, an STMR and HR of 0 for beet root. Residues of metabolite 1'-CH_2OH-S-2840 were < 0.02 mg/kg in all trials.

Rice

The critical GAP for inpyrfluxam on rice is from the United States and consists of a seed treatment up to 10 g ai/100 kg seeds and one foliar application at a rate of 100 g ai/ha with a maximum seasonal rate of 100 g ai/ha (approximately 25–30 days after the permanent flood has been established) and PHI covered by the growth stage.

Trials performed on rice, according to this GAP, gave residue levels in husked rice of (n = 14): < 0.01 (15) mg/kg. Three trials conducted at approximately 500 g ai/ha gave the same results.

Since residues of inpyrfluxam were not detected in any trial, including the overdosed trials, the Meeting estimated a maximum residue level of 0.01(*) mg/kg, an STMR of 0 for husked rice. Residues of metabolite 1'-CH_2OH-S-2840 were < 0.02 mg/kg in all trials.

Sweet corn (Corn-on-the-cob)

The critical GAP for inpyrfluxam on maize is from the United States and consists of a seed treatment up to 0.014 mg ai/seed and one in furrow application at a rate of 50 g ai/ha at planting and PHI covered by the growth stage.

Fourteen trials performed on maize in the United States matching this GAP and three additional trials at exaggerated rates of 100–260 g ai/ha were also available. Residue levels in kernels plus corn without husks in all trials were (n = 17):< 0.01 (17) mg/kg.

Since residues of inpyrfluxam were not detected in the trials including the overdosed trials and in primary plant metabolism studies, uptake and transport of inpyrfluxam in the maize, sorghum, oilseed and potato studies, where the seed was treated, was low, the Meeting estimated a maximum residue level of 0.01(*) mg/kg, an STMR and HR of 0 mg/kg for sweet corn. Residues of metabolite 1'-CH_2OH-S-2840 were < 0.02 mg/kg in all trials.

Peanut

The critical GAP for inpyrfluxam on peanuts is in the United States and consists of a maximum of four foliar applications at a rate of 100 g ai/ha (no earlier than 30 days after planting) with a maximum seasonal rate of 200 g ai/ha, an retreatment interval of 14–28 days and a PHI of 40 days.

Trials performed on peanuts from the United States according to GAP (2 × 100 g ai/ha) were available. Residue levels in nutmeal were (n = 13): < 0.01 (13) mg/kg.

The Meeting estimated a maximum residue level of 0.01(*) mg/kg, an STMR and HR of 0.01 mg/kg for peanuts. Residues of metabolite 1'-CH_2OH-S-2840 were < 0.02 mg/kg in all trials.

Maize

The critical GAP for inpyrfluxam on maize is from the United States and consists of a seed treatment up to 0.014 mg ai/seed and one in furrow application at a rate of 50 g ai/ha at planting and PHI covered by the growth stage.

Fourteen trials performed on maize from the United States matching the GAP and three trials at exaggerated rates of 100–260 g ai/ha were also available. Residue levels in all trials were (n = 27): < 0.01 (27) mg/kg.

Since residues of inpyrfluxam or the metabolites were not detected in the trials including the overdosed trials and in primary plant metabolism studies, uptake and transport of inpyrfluxam in the maize, sorghum, oilseed and potato studies, where the seed was treated, was low, the Meeting estimated a maximum residue level of 0.01(*) mg/kg, an STMR of 0 mg/kg for maize and popcorn, Residues of metabolite 1'-CH_2OH-S-2840 were < 0.02 mg/kg in all trials.

Animal Feed commodities

The total residue for estimating the median and highest residues in feed was inpyrfluxam **+** 1'-CH_2OH-S-2840 (free or conjugated)**,** expressed as inpyrfluxam**.**

When the metabolite concentration was < 0.04 mg/kg, it was considered to be 0 in the calculation.

Maize forage-40 percent dry matter

The critical GAP for inpyrfluxam on maize is from the United States and consists of a seed treatment up to 0.014 mg ai/seed and one in furrow application at a rate of 50 g ai/ha at planting and PHI covered by the growth stage.

Trials performed on maize from the United States matching the US GAP were available. Residue levels in forage were (n = 27): < 0.01 (4), < 0.02 (23) mg/kg.

Residues of metabolite *1'-CH_2OH-S-2840,* were < 0.04 mg/kg in all trials.

The Meeting estimated a highest residue of 0.02 mg/kg (as received) for inpyrfluxam in maize forage.

Maize stover–83 percent dry matter

The critical GAP for inpyrfluxam on maize is from the United States and consists of a seed treatment up to 0.014 mg ai/seed and one in furrow application at a rate of 50 g ai/ha at planting and PHI covered by the growth stage.

Trials performed on maize from the United States matching the US GAP were available. Residue levels in fodder were (n = 27): < 0.01 (4),< 0.02 (23) mg/kg. Residues of metabolite 1'-CH_2OH-S-2840 were < 0.04 mg/kg in all trials.

The Meeting estimated a maximum residue level of 0.02(*) mg/kg (based on a dry matter content of 83 percent), a median and highest residue of 0.02 mg/kg for inpyrfluxam in maize fodder (as received).

Peanut hay

The critical GAP for inpyrfluxam on peanuts is in the United States and consists of a maximum of four foliar applications at a rate of 100 g ai/ha (no earlier than 30 days after planting) with a maximum seasonal rate of 200 g ai/ha, an retreatment interval of 14–28 days and a PHI of 40 days.

Trials performed on peanuts from the United States matching GAP were available. Residue levels in hay were (n = 12): 0.083, 0.096, 0.134, 0.217, 0.218, 0.252, 0.338, 0.412, 0.422, 0.526, 0.731, and1.23 mg/kg.

The Meeting estimated a maximum residue level of 3 mg/kg (as received), an median of 0.35 mg/kg and highest residue of 2 mg/kg for peanut hay (as received).

Levels of metabolite 1'-CH_2OH-S-2840 were (n = 12): 0.1, 0.12, 0.20, 0.24, 0.25, 0.32, 0.38, 0.44, 0.57, 0.94, 1.12 and 2 mg/kg.

Since metabolite 1'-CH2OH-S-2840 is included in the residue definition for dietary risk assessment in animal commodities, residues of this metabolite (CF to parent = 1.1) were also taken into consideration as to estimate the median and highest residue for inpyrfluxam and 1'-CH2OH-S-2840 (, free or conjugated) expressed as inpyrfluxam in peanut hay. Total residue levels were (n = 12): 0.1, 0.12, 0.20, 0.24, 0.25, 0.32, 0.38, 0.44, 0.57, 0.94, 1.12, 2 mg/kg.

The Meeting also estimated a median of 0.35 mg/kg and highest residue of 2 mg/kg for peanut hay (as received).

Fates of residues during processing

High temperature hydrolysis

The degradation of [Pyrazolyl-4-^{14}C] inpyrfluxam and its metabolites [Pyrazolyl-4-^{14}C] 3'-OH-S-2840 and [Pyrazolyl-4-^{14}C] 1'-CH_2OH-S-2840 were studied under hydrolytic conditions at high temperatures in sterile aqueous buffers at pH 4, 5 and 6 for periods up to 60 minutes (20 minutes for pH 4 and 6) so as to simulate common processing practice (pasteurisation, baking/brewing/boiling and sterilisation). Degradation of inpyrfluxam, 3'-OH-S-2840 and 1'-CH_2OH-S-2840 was not observed at any investigated condition. Chiral analysis showed the *R*-isomer of inpyrfluxam to account for 100 percent of the residue at all time points confirming no isomerization occurred. The Meeting concluded that inpyrfluxam, is stable under hydrolytic conditions.

Residues in processed commodities

The fate of inpyrfluxam residues after processing has been examined in apple, soya bean, sugar beet, rice, maize and peanut.

For soya bean, sugar beet, rice, maize and peanut processed fractions no reliable PFs can be calculated, since the RAC and the processed commodities contained residues <LOQ. In rice, residues in RAC were also <LOQ however quantitative residues were observed in hulls and bran indicating that residues concentrated in the final processed commodities.

One study was conducted in rice and one study in apple. Maximum residue levels in processed commodities are only estimated when processing factor was higher than 1. The Meeting concluded that the processing factors based on apple data can be extrapolated to other processed pome commodities (pome fruit juice and wet pomace). The results are shown in Tables 140 and 141.

Table 140 Processing factors and median and highest residue values for inpyrfluxam used for estimation of maximum residue levels including livestock dietary burdens

Processed commodity	Raw commodity [median] mg/kg	Individual processing factors	Median residue-P (mg/kg)
Apple wet pomace	0.91	2.7	2.4
Rice Hulls	0	4.3	0
Rice bran (husked)	0	1.3	0

Table 141 Processing factors and STMR value for inpyrfluxam in apple juice

Processed commodity	Raw commodity [STMR]	Individual processing factors	Median or best estimate processing factor	STMR-P = STMRRAC × PF (mg/kg)
Apple juice	0.91	0.125	0.125	0.114

The Meeting estimated a maximum residue level of 0.01(*) mg/kg for inpyrfluxam in rice hulls

Residues in animal commodities

In a feeding study in lactating cows, inpyrfluxam was fed via the diet, to three to six cows per dose group, for 29 consecutive days. The animals received equivalents of 2, 6, or 20 ppm of inpyrfluxam in the diet (DM). Residues of inpyrfluxam and metabolites 1'-COOH-S-2840 (A and B) and 1'-CH_2OH-S-2840 (A and B) were determined.

There was no transfer of residues of inpyrfluxam or its main metabolites (1'-COOH-S-2840 and 1'-CH_2OH-S-2840) at levels above the LOQ (0.01 mg/kg) in milk, skimmed milk or cream during or up to two weeks after 28 days at any dose. Similarly, there were no residues above the LOQ (0.01 mg/kg) or preferential accumulation to bovine muscle or fat. Only residues of metabolite 1'-CH_2OH-S-2840 in liver at the 20 ppm DM (0.014 mg/kg) and in kidney at the 6 ppm DM (0.013 mg/kg) and 20 ppm DM (0.022 mg/kg) were detected.

In a feeding study in laying hens twelve to twenty-four hens/treatment group were dosed with inpyrfluxam for 28 days, at feeding levels equivalent to 1, 3, and 10 ppm of inpyrfluxam in the diet (DM). Residues of inpyrfluxam and metabolites 1'-COOH-S-2840 (A and B) and 1'-CH_2OH-S-2840 (A and B) were determined.

Inpyrfluxam and 1'-CH_2OH-S-2840 were found in liver at 0.01/0.017 mg/kg at the 3/10 ppm levels and in fat and egg yolk at 0.017 mg/kg 0.012 mg/kg, respectively, at the 10 ppm. No discernible plateau of residues was observed because of the low levels of residues in all samples. Samples of muscle had no residues at or above the LOQ throughout the dosing period and for two weeks after cessation of dosing, suggesting limited transfer from feed to tissues.

Farm animal dietary burden

Dietary burdens were calculated for beef cattle, dairy cattle, broilers and laying poultry based on feed items evaluated by the JMPR by the current Meeting including processed and forage commodities. Those commodities are included in Table 142.

Table 142 Processed and forage commodities used in estimating livestock dietary burdens

Codex classification	Commodity	Median residue (-P) (mg/kg)	Highest residue (-P) (mg/kg)
AL 3352	Peanut hay	0.35 [a]	2 [a]
GC 0649	Rice grain	0	n.a
AB 1230	Apple pomace, wet	2.4	n.a
AM3599	Sugar beet, pulp, dry	0	n.a
DM 0596	Sugar beet molasses	0	n.a
AS 3570	Rice, hulls	0	n.a
CF 0649	Rice bran, processed	0	n.a
GC 0645	Maize	0	n.a
AS 0645	Maize, forage (40% DM)	0.02	n.a
GC 0656	Popcorn	0.02	n.a
AS 3558	Maize stover (83% DM)	0.02	0.02
VD 0541	Soya bean	0	n.a

Note:
a residues are calculated as inpyrfluxam and 1'-CH_2OH-S-2840 (free or conjugated) expressed as inpyrfluxam.

The dietary burdens, estimated using the 2018 OECD Feed diets listed in Appendix XIV Electronic attachments to the 2016 edition of the FAO manual[1], are presented in Annex 6 and summarized below in Table 143.

Table 6143 Estimated maximum and minimum dietary burdens of farm animals

	Animal dietary burden: parent ppm of dry matter diet							
	United States-Canada		European Union		Australia		Japan	
	max	mean	max	mean	max	mean	max	mean
Beef cattle	0.008	0.008	1.24	1.24	2.62❶	1.46❷	0	0
Dairy cattle	0.98	0.68	0.63	0.63	2.03	0.86	0.025	0.025
Poultry–broiler	0	0	0	0	0	0	0	0
Poultry–layer	0	0	0	0	0	0	0	0

Notes:
❶Highest maximum beef or dairy cattle dietary burden suitable for maximum residue level estimates for mammalian tissues
❷Highest mean beef or dairy cattle dietary burden suitable for STMR estimates for mammalian tissues and milk.

The Meeting used the calculated beef and dairy cattle maximum and mean dry weight dietary burdens of 2.62 ppm and 1.46 ppm for estimating residue levels in milk and ruminant tissues.

For poultry commodities, no feed items were applicable thus the calculated dry weight maximum and mean dietary burden and is 0 ppm dry weight in feed.

Animal commodity maximum residue levels

Ruminants

The calculations used to estimate maximum residue levels, STMR and HR values for cattle matrices are shown in Table 144.

Table 144 Anticipated residues of inpyrfluxam and 1'-CH_2OH-S-2840 (free or conjugated) expressed as inpyrfluxam in cattle commodities

	Feed Level (ppm) for milk residues	Total residues (mg eq/kg) in milk	Feed Level (ppm) for tissue residues	Total residues (mg eq/kg)			
				Muscle	Liver	Kidney	Fat
HR Determination (beef or dairy cattle)–Parent							
Feeding Study	2	0.02*	2	0.02*	0.02*	0.02*	0.02*
	6	0.02*	6	0.02*	0.02*	0.02*	0.02*
Dietary burden and estimate of highest residue	2.6	0.02*	2.6	0.02*	0.02*	0.02*	0.02*
STMR Determination (beef or dairy cattle)–Parent							
Feeding Study	2	0.02*	2	0.02*	0.02*	0.02*	0.02*
	6	0.02*	6	0.02*	0.02*	0.02*	0.02*
Dietary burden and estimate of highest residue	1.46	0.02*	1.46	0.02*	0.02*	0.02*	0.02*
MRL Determination (beef or dairy cattle)–Parent							
Feeding Study	2	0.01*	2	0.02*	0.02*	0.02*	0.02*
	6	0.01*	6	0.02*	0.02*	0.02*	0.02*
Dietary burden and estimate of highest residue	2.6	0.01*	2.6	0.02*	0.02*	0.02*	0.02*

The Meeting estimated maximum residue levels of 0.02(*) mg/kg in milk, meat (mammalian except marine mammals), mammalian fats, and edible offal.

The Meeting also estimated a STMR of 0 mg/kg for edible offal, muscle, kidney, fat and milk, and a HR of 0 mg/kg for edible offal, muscle, edible offal and fat.

Poultry

As the mean and maximum dietary burden for poultry is 0, no residues are expected in poultry commodities.

The Meeting estimated maximum residue levels of 0.02(*) mg/kg in poultry meat (muscle), poultry fat, poultry edible offal, and eggs. The Meeting also estimated a HR and STMR of 0 mg/kg for poultry edible offal, muscle, fat and eggs.

Recommendations

On the basis of the data from supervised trials, processing studies, storage stability studies and feeding studies the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessments.

The residue definition for compliance with the MRL for plant commodities is *inpyrfluxam*.

The residue definition for dietary exposure for plant commodities is *inpyrfluxam.*

The residue definition for compliance with the MRL and dietary exposure for animal commodities is *inpyrfluxam and 1'-CH_2OH-S-2840 (free or conjugated) expressed as inpyrfluxam*.

The residue is not fat soluble.

CCN	Commodity name	Recommended Maximum residue level (mg/kg)		STMR or STMR-P mg/kg	HR or HR-P mg/kg
		New	Previous		
FP 0226	Apples	4	-	0.91	1.88
JF 0226	Apple, juice		-	0.114	
MO 0105	Edible offal (mammalian)	0.02*	-	0	0

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The ADI for inpyrfluxam is 0–0.06 mg/kg bw. The International Estimated Daily Intakes (IEDIs) for fenpicoxamid were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the JMPR. The results are shown in Annex 3 of the 2022 JMPR Report.

The IEDIs ranged from 0–5 percent of the maximum ADI. The Meeting concluded that long-term dietary exposure to residues of inpyrfluxam from uses considered by the JMPR is unlikely to present a public health concern.

Acute dietary exposure

The ARfD for inpyrfluxam is 0.3 mg/kg bw The International Estimate of Short Term Intakes (IESTIs) for spiropidion were calculated for the food commodities and their processed commodities for which HRs/HR-Ps or STMRs/STMR-Ps were estimated by the present Meeting and for which consumption data were available. The results are shown in Annex 4 of the 2022 JMPR Report.

The IESTIs varied from 0–40 percent of the ARfD for children and 0–10 percent of the ARfD for the general population. The Meeting concluded that acute dietary exposure to residues of inpyrfluxam from uses considered by the present Meeting is unlikely to present a public health concern.

Threshold of toxicological concern (TTC) consideration for metabolites

The metabolite N-DesMet-pyrazole carboxylic acid found in soya bean seeds (STMR of 0.026 mg/kg) was assessed using the TTC approach (Cramer Class III threshold of 1.5 µg/kg bw per day). The estimated a dietary exposure for metabolite N-DesMet-pyrazole carboxylic acid of 0.096 µg/kg bw for the uses of bixafen, fluxapyoxad, fluindapyr and benzovindiflupyr (Report 2022–fluindapyr).

The Meeting concluded that the estimated dietary exposure to residues of N-DesMet-pyrazole carboxylic acid from uses considered by the current JMPR is below the TTC for Cramer Class III compounds and is unlikely to present a public health concern. Should further uses be considered in the future, these conclusions may need to be re-evaluated.

ISOFLUCYPRAM (330)

First draft prepared by J Giordano, Environmental Protection Agency, United States of America

EXPLANATION

Isoflucypram is a broad-spectrum fungicide of the chemical class of N-cyclopropyl-N-benzyl-pyrazole-carboxamides. Isoflucypram is a succinate dehydrogenase (SDH) inhibitor assigned to the Fungicide Resistance Action Committee (FRAC) resistance Group 7.

Isoflucypram was scheduled at the Fifty-first Session of the CCPR for evaluation as a new compound in 2020 and rescheduled to the 2022 JMPR. All relevant information in terms of chemical identity, physical and chemical properties, metabolism and environmental fate, methods of residue analysis, storage stability, intended use patterns, supervised residue trials, fate of residues upon processing, and farm animal feeding studies were submitted for evaluation by the 2022 JMPR.

IDENTITY

Information on the chemical identity of isoflucypram is summarised below.

ISO common name:	Isoflucypram
IUPAC name:	N-(5-chloro-2-isopropylbenzyl)-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide
CA name:	N-[[5-chloro-2-(1-methylethyl)phenyl]methyl]-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide
CAS No.:	1255734-28-1
CIPAC No.:	Not allocated
Manufacturer's experimental name:	BCS-CN88460
Structural formula:	Molecular formula:	$C_{19}H_{21}ClF_3N_3O$
Molecular weight:	399.84 g/mol

Physical and Chemical Properties

Property	Results	Test material purity and specification	Reference
Appearance	White powder	Pure (99.1 %)	PA14/031
	Light beige powder	Technical (98.6 %)	PA17/054
Odour	Odourless	Pure (99.1 %)	PA14/031
	Weak odour, not characteristic	Pure (98.6 %)	PA17/054
Melting point	108.8 °C	Pure (99.1 %)	20140107.01
Boiling point	No endothermic effect was observed between the melting of the test item and its decomposition starting at 215 °C (thermal stability). Therefore the test item has no boiling point at atmospheric conditions.	Pure (99.1 %)	20140107.01

Property	Results	Test material purity and specification	Reference
Thermal Stability	Pure: The test item showed an endothermic effect in the temperature range 105-130 °C. The endothermic effect was followed by an exothermic effect in the temperature range 215-395 °C with an energy of 1239 J/g and 1040 J/g, respectively. No further endothermic or exothermic effects were observed up to the final temperature (400°C), with a decomposition energy greater than -380 J/g. Technical compound: The test item showed an endothermic effect in the temperature range 100-120 °C. The endothermic effect was followed by an exothermic effect in the temperature range 360-440 °C, with a decomposition energy greater than -1110 J/g.	Pure (99.1 %) Technical (98.6 %)	20140107.01, CSL-14-0428.01, CSL-17-1436.01
Flammability	No flammability properties	Technical (98.6 %)	PS20170460-2
Auto-flammability	No self-heating properties	Technical (98.6 %)	PS20170460-3
Explosive properties	No explosive properties	Technical (98.6 %)	CSL-17-1436.01
Oxidising properties	No oxidising properties	Technical (98.6 %)	M-612014-01-1
Surface tension	68.2 mN/m at 20 °C	Pure (99.1 %)	PA14/059
Relative density	D_4^{20} = 1.22	Pure (99.1 %)	PA14/035
	D_4^{20} = 1.31	Technical (98.6 %)	PA17/051
Vapour pressure	Vapour pressure values extrapolated (vapour pressure balance method): 1.2×10^{-7} Pa at 20 °C 2.8×10^{-7} Pa at 25 °C 1.5×10^{-5} Pa at 50 °C	Pure (99.1 %)	CSL-14-0428.01
Henry's law constant	2.7×10^{-5} Pa m^3 mol^{-1} at 20 °C	Pure (99.1 %)	AF14/022
Solubility in water	1.8 mg/L at 20 °C	Pure (99.1 %)	PA14/030
Solubility in organic solvents	At 20 °C: Heptane 1.2 g/L Toluene > 260 g/L Dichloromethane > 260 g/L Methanol 97 g/L Acetone > 260 g/L Ethyl acetate > 260 g/L Dimethyl sulfoxide > 260 g/L	Pure (99.1 %)	PA14/060
Octanol/water partition coefficient	At 25 °C Pow log Pow pH 4 10000 4.0 pH 7 10000 4.0 pH 9 10000 4.0	Pure (99.1 %)	PA14/029
Hydrolysis rate at pH 4, 7,and 9	At 70 °C: stable at all pH values, therefore no DT_{50} and DT_{90} values were calculated.	Radiochemical purity: >98 % Chemical purity: >98 %	EnSa-14-1032
Direct photo-transformation	At 24.5 °C and pH 7: Experimental DT_{50}: 150 days Environmental DT_{50}: -484 solar summer days at Phoenix (Arizona, USA) -750 solar summer days at Athens (Greece)	Radiochemical purity: >98 % Chemical purity: >99 %	EnSa-14-1033

Property	Results	Test material purity and specification	Reference
Quantum yield of direct transformation	Mean Φ = 0.00077	Radiochemical purity: >99 % Chemical purity: >99 %	EnSa-13-0236
Dissociation constant	No dissociation constant (pKa) was determined in aqueous solution of isoflucypram in the pH range of 1<pH<12. Isoflucypram shows no acidic or basic properties in the range of 1<pKa<12.	Pure (99.1 %)	PA14/048

METABOLISM AND ENVIRONMENTAL FATE

The studies for plant metabolism, animal metabolism, rotational crops, and environmental degradation were conducted with isoflucypram radiolabelled in either the pyrazole or phenyl moiety, as shown below. (*) indicates the position of ^{14}C-radiolabel. The metabolites or degradates found in metabolism and environmental fate studies are shown in Table 1.

Pyrazole label	Phenyl label
	[pyrazole-4-^{14}C]isoflucypram	[phenyl-UL-^{14}C]isoflucypram

Table 1 Isoflucypram and metabolites/degradates found in metabolism and environmental fate studies

Number Name Identity (IUPAC)	Structure	Identified in:
Isoflucypram BCS-CN88460 CAS: 1255734-28-1 N-(5-chloro-2-isopropylbenzyl)-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide		Animal: Rat (faeces, liver, kidney); hen (eggs, muscle leg, fat); goat (milk, muscle, fat, liver, kidney, faeces) sunfish (edible parts, viscera) Plant: Soya bean (forage, hay, straw, seed); wheat (hay, straw, grain); CRC (wheat forage, Swiss chard, turnip leaves); oilseed rape (intermediate harvest, mature plants, seeds), tomatoes, potato (tubers, leaves) Soil: Aerobic & anaerobic, field dissipation, photolysis Water: Hydrolysis, photolysis, water-sediment

Number Name Identity (IUPAC)	Structure	Identified in:
M01 Isoflucypram-propanol N-[5-chloro-2-(1-hydroxypropan-2-yl)benzyl]-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide		Animal: Rat (faeces); hen (eggs, muscle, fat, liver, excreta); goat (muscle, fat, liver, kidney, faeces, urine); sunfish (edible parts, viscera) Plant: Wheat (hay, straw)
M02 Isoflucypram-2-propanol 2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]-carbonyl}amino)-methyl]phenyl}propan-2-yl		Animal: Rat (faeces); goat (milk, muscle, fat, liver, kidney, faeces, urine)
M03 Isoflucypram-1,2-propandiol N-[5-chloro-2-(1,2-dihydroxypropan-2-yl)benzyl]-N-cyclopropyl-3-(difluoro-methyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide		Animal: Hen (excreta)
M04 Isoflucypram-hydroxyphenyl N-(5-chloro-4-hydroxy-2-isopropylbenzyl)-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide		Animal: Goat (urine)
M05 Isoflucypram-olefine 1H-Pyrazole-4-carboxamide, N-[[5-chloro-2-(1-methylethenyl)phenyl]methyl]-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl- [CA] N-[5-chloro-2-(prop-1-en-2-yl)benzyl]-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide		Animal: Rat (faeces, bile)

Number Name Identity (IUPAC)	Structure	Identified in:
M06 Isoflucypram-desmethyl-propanol N-[5-chloro-2-(1-hydroxypropan-2-yl)benzyl]-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1H-pyrazole-4-carboxamide		Animal: Rat (faeces, bile); hen (eggs, muscle, fat, liver, excreta); goat (milk, muscle, fat, liver, kidney, faeces, urine); sunfish (edible parts, viscera) Plant: Wheat (straw)
M07 Isoflucypram-desmethyl-1,2-propandiol N-[5-chloro-2-(1,2-dihydroxypropan-2-yl)benzyl]-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1H-pyrazole-4-carboxamide		Animal: Hen (eggs, muscle, fat, liver, excreta)
M08 Isoflucypram-desmethyl-diOH (isomers)		Animal: Rat (faeces)
M09 Isoflucypram-desmethyl-lactic acid 2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1H-pyrazol-4-yl]carbonyl}amino)methyl]phenyl}-2-hydroxypropanoic acid		Animal: Rat (faeces, plasma, liver, kidney, bile)
M10 Isoflucypram-lactic acid 2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]carbonyl}amino)methyl]phenyl}-2-hydroxypropanoic acid		Animal: Rat (faeces, plasma, liver, kidney, bile); goat (liver, kidney, faeces, urine) Plant: - Soil: met., aerobic

Number Name Identity (IUPAC)	Structure	Identified in:
M11 Isoflucypram-desmethyl-carboxylic acid 2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1H-pyrazol-4-yl]carbonyl}amino)methyl]phenyl}propanoic acid		Animal: Rat (urine, faeces, plasma, liver, kidney, bile); hen (muscle, fat, liver, excreta); goat (liver, kidney, faeces, urine) Soil: Met., aerobic
M12 Isoflucypram-carboxylic acid 2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]-carbonyl}amino)-methyl]phenyl}-propanoic acid		Animal: Rat (urine, faeces, plasma, liver, kidney, bile); hen (eggs, muscle, fat, liver, excreta); goat (muscle, fat, liver, kidney, faeces, urine) Soil: met., aerobic Water: met., aerobic
M13 Isoflucypram-desmethyl N-(5-chloro-2-isopropylbenzyl)-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1H-pyrazole-4-carboxamide		Animal: Rat (faeces, plasma, liver, kidney); sunfish (edible parts, viscera)
M14 Isoflucypram-desmethyl-hydroxyphenyl-2-propanol N-[5-chloro-4-hydroxy-2-(2-hydroxypropan-2-yl)benzyl]-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1H-pyrazole-4-carboxamide		Animal: Rat (urine, faeces, liver, bile)
M15 Isoflucypram-desmethyl-hydroxyphenyl-1,2-propandiol N-[5-chloro-2-(1,2-dihydroxypropan-2-yl)-4-hydroxybenzyl]-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1H-pyrazole-4-carboxamide		Animal: Rat (faeces)

Number Name Identity (IUPAC)	Structure	Identified in:
M16 Isoflucypram-desmethyl-hydroxymethyl-carboxylic acid 2-{4-chloro-2-[(cyclopropyl{[5-fluoro-3-(hydroxymethyl)-1H-pyrazol-4-yl]carbonyl}amino)methyl]phenyl}propanoic acid		Animal: Rat (urine, faeces)
M17 Isoflucypram-desmethyl-hydroxymethyl-diOH		Animal: Rat (faeces, bile)
M18 Isoflucypram-propanol-Glyc N-{5-chloro-2-[1-(hexopyranosyloxy)propan-2-yl]benzyl}-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide		Plant: Wheat (hay, straw)
M19 Isoflucypram-propanol-GlucA (isomer 1 and 2) 2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]-carbonyl}amino)methyl]phenyl}propyl glucopyranosiduronic acid		Animal: Rat (faeces, bile); goat (milk, muscle, liver, kidney, faeces, urine); sunfish (edible parts, viscera)
M20 Isoflucypram-2-propanol-GlucA 2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]carbonyl}amino)methyl]phenyl}propan-2-yl beta-D-glucopyranosiduronic acid		Animal: Goat (liver, kidney, faeces, urine)
M21 Isoflucypram-propanol-Glyc-MA 2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]-carbonyl}amino)methyl]phenyl}propyl 6-O-(carboxyacetyl)hexopyranoside		Plant: Wheat (hay, straw); oilseed rape (intermediate harvest, mature plants)

Number Name Identity (IUPAC)	Structure	Identified in:
M22 Isoflucypram-2-propanol-Glyc-MA 2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]-carbonyl}amino)-methyl]phenyl}propan-2-yl 6-O-(carboxy-acetyl)hexopyranoside		Plant: Oilseed rape (intermediate harvest, mature plants); potato (leaves)
M23 Isoflucypram-hydroxyphenyl-Gluc-MA 2-chloro-4-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]-carbonyl}amino)-methyl]-5-isopropyl-phenyl 6-O-(carboxyacetyl)-beta-D-glucopyranoside		Plant: Oilseed rape (intermediate harvest, mature plants)
M23a Isoflucypram-OH-phenyl-Glyc-MA		Plant: Potato (leaves)
M24 Isoflucypram-hydroxyphenyl-Glyc-MA 2-chloro-4-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]-carbonyl}amino)-methyl]-5-isopropyl-phenyl 6-O-(carboxyacetyl)-hexopyranoside		Plant: Oilseed rape (intermediate harvest, mature plants)
M25 Isoflucypram-propenol-GlucA 2-{4-chloro-2-[(cycloprop yl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]carbonyl}amino)methyl]phenyl}prop-2-en-1-yl beta-D-glucopyranosiduronic acid		Animal: Goat (kidney, urine)
M26 Isoflucypram-propanol-SA 2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]carbonyl}amino)methyl]phenyl}propyl hydrogen sulfate		Animal: Hen (liver, excreta)

Number Name Identity (IUPAC)	Structure	Identified in:
M27 Isoflucypram-1,2-propandiol-SA		Animal: Hen (excreta)
M28 Isoflucypram-carboxylic acid-GlucA		Animal: Rat (bile)
M29 Isoflucypram-diOH-GlucA (isomer 1 and 2)		Animal: Rat (urine, faeces, bile)
M30 Isoflucypram-oxo-GlucA		Animal: Rat (faeces, bile)

PLANT METABOLISM

The Meeting received studies describing the metabolism of isoflucypram in tomatoes, wheat, soya bean plants and oilseed rape following foliar application and in potatoes following seed treatment.

Tomato

Report Nos. EnSa-16-0959 and EnSa-16-0960.

The metabolism of isoflucypram in tomato fruits was investigated following foliar application of either [pyrazole-4-^{14}C] isoflucypram or [phenyl-UL-^{14}C] isoflucypram (Lamshoeft, M.; 2017). For both tests, radiolabelled isoflucypram was formulated as an emulsifiable concentrate (EC) 200. For the pyrazole study, one foliar application was made at growth stage BBCH 14–15 at 79 g ai/ha and a second foliar application was made at growth stage BBCH 85–86 at 89 g ai/ha, corresponding with the end of fruit ripening. The timing between applications was 99 days. The total application rate was 168 g ai/ha based on a plant density of 12,000 tomato plants/ha. For the phenyl study, one foliar application was made at growth stage BBCH 14–15 at 78 g ai/ha and a second foliar application was made at growth stage BBCH 85–87 at 78 g ai/ha, corresponding with the end of fruit ripening. The timing between applications was 97 days. The total application rate was 156 g ai/ha based on a plant density of 12,000 tomato plants/ha.

Tomato fruits were harvested 14 days after the last application. After surface washing with DCM, tomatoes were conventionally extracted three times with acetonitrile (ACN)/water (8:2). The combined extracts were subjected to solid-phase extraction (SPE) followed by rinsing with ACN/water (8:2) for both labels and either methanol/dichloromethane (DCM) (1:1) for the pyrazole label or tetrahydrofuran (THF)/methanol (1:1) for the phenyl label. The surface wash solution and the purified SPE fractions were analysed by high performance liquid chromatography (HPLC).

The radioactivity in the extracts and the post extraction solids (PES) was determined by combustion/liquid scintillation counting (LSC). Total radioactive residue (TRR) was calculated by summing the radioactivity in the surface wash, the extract, and the PES. Parent compound was identified by spectroscopic methods and co-chromatography with reference compound. Extraction and quantification of four minor metabolites and parent compound was completed within six months (storage temperature ≤-18 °C); no storage stability investigations were conducted.

TRR was 0.170 mg eq/kg for the pyrazole label and 0.095 mg eq/kg for the phenyl label. The main portion of the radioactivity was recovered in the surface wash, comprising 73.6 percent TRR (0.125 mg eq/kg) for the pyrazole label and 74.6 percent TRR (0.071 mg eq/kg) for the phenyl label. Residues in tomato fruits were efficiently extracted using ACN/water (8:2) and amounted to 26.1 percent TRR (0.045 mg eq/kg) in the pyrazole study and 25.1 percent TRR (0.024 mg eq/kg) in the phenyl study. The PES amounted to 0.2 percent TRR (<0.001 mg eq/kg) in both studies. There were no losses during the sample preparation and no radioactivity was observed in the distillate of the concentration procedures.

Isoflucypram was the only metabolite observed, comprising 96.7 percent TRR (0.165 mg/kg) in the pyrazole study and 98.2 percent TRR (0.094 mg/kg) in the phenyl study. Up to four minor unknown peaks were isolated, each comprising ≤ 1.6 percent TRR (≤ 0.003 mg eq/kg). The results are shown in Tables 2 and 3.

Wheat

Report Nos. S14-01087 and S14-01086.

The metabolism of isoflucypram in wheat commodities was investigated following foliar application of [pyrazole-4-^{14}C] isoflucypram or [phenyl-UL-^{14}C] isoflucypram (Traub, M.; 2018). Isoflucypram was formulated as an EC 50 and applied at BBCH growth stage 30 at 64–69 g ai/ha and reapplied at BBCH growth stage 69 at 66–67 g ai/ha for a total application rate of 130–136 g ai/ha. The interval between applications was 28 days or 33 days for the pyrazole and phenyl studies, respectively.

Wheat hay was harvested 1 day prior to the second application (BBCH 69) and allowed to dry for four days. Wheat straw and grain were harvested at maturity (BBCH 89) corresponding to 17–18 days between application and harvest. Samples were subjected to conventional and exhaustive extraction and acid hydrolysis.

Conventional extraction and clean-up

Homogenised samples of wheat hay, straw, and grain were conventionally extracted three times with ACN/water (8:2). Individual extracts were filtered and the solids were rinsed with the solvent mixture used for extraction. The solids were dried and subjected to combustion.

The extracts were combined and cleaned-up by SPE which was rinsed with methanol and water and conditioned with ACN/water (8:2). The percolate was collected and the cartridge was rinsed with ACN/water (8:2). The percolate and rinse fractions were combined. Less polar fractions on the cartridge were eluted by rinsing the cartridge with methanol/THF (1:1). Each combined percolate/rinse solution was mixed with emulsifier and evaporated to the aqueous remainder. The purified conventional extracts were then analysed by HPLC.

Exhaustive extraction and clean-up

In the pyrazole study, solids from the conventional extraction of wheat straw were exhaustively extracted twice with ACN/water/formic acid (50:50:1) with microwave assistance. The microwave extracts were cooled down at room temperature and combined by rotary evaporation. Aliquots of the extracts were

centrifuged. The pellet was dissolved in ACN/water. Both the supernatant and extract were analysed HPLC.

Hydrolysis of conventional extracts

For both labels, hydrolysis experiments in acidic medium were conducted with conventional extract of wheat hay and straw to further characterise the residues. Aliquots of the purified conventional extract of wheat hay and straw were incubated with 1 mol/L hydrochloric acid (HCl) and 5 percent ACN at 100 °C for 1 hour prior to centrifugation. For wheat straw, the supernatant was removed and the pellet was dissolved in ACN/water (1:1) whereas no pellet was formed during processing of wheat hay. Aliquots of the extracts were analysed by HPLC.

The radioactivity in extracts and the PES was determined by combustion/LSC. The TRR was calculated by summing the radioactivity of the combined extracts and the PES.Parent compound and major metabolites were identified by spectroscopic methods and co-chromatography with reference compounds.

For the pyrazole study, grain and hay were stored for a maximum period of one month and wheat straw was stored for a maximum of 13 months (≤-18 °C). A reanalysis of extract after 14 months demonstrated a stable metabolite profile.

For the phenyl study, samples of wheat hay were extracted within one month of being placed in frozen storage (-18 °C). Samples of wheat grain and straw were extracted within 30 months of frozen storage (-18 °C). Stored extract of wheat straw and grain were analysed after 28 and 15 months of storage, respectively, demonstrating stability of the metabolite profile. The results are showing in Tables 4 and 5.

Table 4 Distribution of radioactivity in the extracts of wheat commodities following foliar application of [Pyrazole-4-^{14}C] Isoflucypram (S14-01087)

Notes:
[1] Losses during clean up, concentration, centrifugation, etc.

In the conventional extract from wheat hay, 66.0 percent TRR (2.659 mg eq/kg) [pyrazole] and 66.3 percent TRR (2.015 mg eq/kg) [phenyl] was identified. Parent isoflucypram was the major component representing 50.0 percent (2.016 mg/kg) [pyrazole] and 54.7 percent TRR (1.661 mg/kg) [phenyl]. Remaining major metabolites included isoflucypram-propanol-Glyc accounting for 0.096 mg eq/kg (2.4 percent TRR) [pyrazole] and 0.023 mg eq/kg (0.8 percent TRR) [phenyl], isoflucyrpam-desmethyl-propanol-Glyc-MA accounting for 0.103 mg eq/kg (2.5 percent TRR) [pyrazole] and 0.081 mg eq/kg (2.7 percent TRR) [phenyl], isoflucypram-propanol-Glyc-MA accounting for 0.414 mg eq/kg (10.3 percent TRR) [pyrazole] and 0.229 mg eq/kg (7.5 percent TRR) [phenyl], and isoflucypram-propanol accounting for 0.029 mg eq/kg (0.7 percent TRR) [pyrazole] and 0.021 mg eq/kg (0.7 percent TRR) [phenyl]. In wheat hay, up to 23 unknown metabolites were characterised in the extracts by their chromatographic behaviour, individually accounting for ≤3.1 percent TRR (≤ 0.127 mg eq/kg).

In the conventional extract from wheat straw, 77.1 percent TRR (11.969 mg eq/kg) [pyrazole] and 72.6 percent TRR (11.640 mg eq/kg) [phenyl] was identified. Parent isoflucypram was the major component representing 62.9 percent TRR (9.761 mg/kg) [pyrazole] and 62.1 percent TRR (9.954 mg/kg) [phenyl]. Other major metabolites included isoflucypram-propanol-Glyc accounting for 0.383 mg eq/kg (2.5 percent TRR) [pyrazole] and 0.373 mg eq/kg (2.3 percent TRR) [phenyl], isoflucypram-desmethyl-propanol-Glyc-MA accounting for 0.448 mg eq/kg (2.9 percent TRR) [pyrazole] and 0.306 mg eq/kg (1.9 percent TRR) [phenyl], isoflucypram-propanol-Glyc-MA accounting for 1.042 mg eq/kg (6.7 percent TRR) [pyrazole] and 0.808 mg eq/kg (5.0 percent TRR) [phenyl], isoflucypram-desmethyl-propanol accounting for 0.116 mg eq/kg (0.7 percent TRR) [pyrazole] and 0.052 mg eq/kg (0.3 percent TRR) [phenyl], and isoflucypram-propanol accounting for 0.209 mg eq/kg (1.4 percent TRR) [pyrazole] and 0.147 mg eq/kg (0.9 percent TRR) [phenyl].

In the exhaustive extract of pyrazole-labelled wheat straw, 3.0 percent TRR (0.453 mg eq/kg) were further identified, consisting of parent isoflucypram, isoflucypram-propanol-Glyc, isoflucypram-desmethyl-propanol, and isoflucypram-propanol, representing 1.1, 1.2, 0.4, and 0.3 percent TRR, corresponding to 0.172, 0.178, 0.055, and 0.048 mg eq/kg, respectively. In total, 80.0 percent (12.422 mg eq/kg) of the TRR was identified in the conventional and exhaustive extracts of pyrazole-labelled wheat straw. Between both studies, up to 39 unknown metabolites were characterised in the extracts by their chromatographic behaviour, individually accounting for ≤ 2.1 percent TRR (≤ 0.345 mg eq/kg).

Conventional extract from wheat grain contained only parent isoflucypram, representing 92.0 percent TRR (0.354 mg/kg) [pyrazole] and 92.7 percent TRR (0.264 mg/kg) [phenyl]. The results are shown in Tables 6 to 8.

Notes:
ND: Not detected.

Conventional extracts of wheat hay and straw were subjected to acid hydrolysis in an attempt to release possible hydrolysable conjugates.

In hydrolysed extract of wheat hay, 90.3 percent TRR (3.640 mg eq/kg) [pyrazole] and 95.2 percent TRR (2.893 mg eq/kg) [phenyl] was analysed. Parent isoflucypram was the major component representing 44.4 percent TRR (1.791 mg/kg) [pyrazole] and 49.6 percent TRR (1.508 mg/kg) [phenyl]. Other major metabolites included isoflucypram-propanol-Glyc accounting for 0.031 mg eq/kg (0.8 percent TRR) [pyrazole] and 0.019 mg eq/kg (0.6 percent TRR) [phenyl], isoflucypram-propanol accounting for 0.901 mg eq/kg (22.3 percent TRR) [pyrazole] and 0.642 mg eq/kg (21.1 percent TRR) [phenyl], isoflucypram-desmethyl-propanol accounting for 0.277 mg eq/kg (6.9 percent TRR) [pyrazole] and 0.204 mg eq/kg (6.7 percent TRR) [phenyl], and isoflucypram-propanol-Glyc-MA accounting for 0.036 mg eq/kg (0.9 percent TRR) [pyrazole only].

In the hydrolysed extract of wheat straw, 92.5 percent TRR (14.372 mg eq/kg) [pyrazole] and 92.5 percent TRR (14.832 mg eq/kg) [phenyl] were analysed. Parent isoflucypram was the major component, representing 67.0 percent TRR (10.397 mg/kg) [pyrazole] and 60.8 percent TRR (9.751 mg/kg) [phenyl]. Other major metabolites included isoflucypram-propanol-Glyc accounting for 0.2 percent TRR (0.024 mg eq/kg) [pyrazole] and 0.3 percent TRR (0.053 mg eq/kg) [phenyl], isoflucypram-propanol-Glyc-MA accounting for 0.3 percent TRR (0.054 mg eq/kg) [pyrazole] and 0.1 percent TRR (0.022 mg eq/kg) [phenyl], isoflucypram-propanol accounting for 10.5 percent TRR (1.625 mg eq/kg) [pyrazole] and

12.7 percent TRR (2.046 mg eq/kg), isoflucypram-desmethyl-propanol accounting for 3.6 percent TRR (0.564 mg eq/kg) [pyrazole] and 4.0 percent TRR (0.644 mg eq/kg) [phenyl], and isoflucypram-desmethyl-propanol-Glyc-MA accounting for 0.3 percent TRR (0.054 mg eq/kg) [phenyl only]. In contrast to hydrolysis of the hay extract, a pellet was formed during hydrolysis of the straw extract. Therefore values of analysed residues are given as sum of supernatant and dissolved pellet.

In the pyrazole study, identification rates after hydrolytic treatment increased from 66.0 percent TRR (2.659 mg eq/kg) before hydrolysis to 75.3 percent TRR (3.035 mg eq/kg) after hydrolysis for wheat hay and from 77.1 percent TRR (11.969 mg eq/kg) before hydrolysis to 81.6 percent TRR (12.666 mg eq/kg) after hydrolysis for wheat straw. In the phenyl study, identification rates after hydrolytic treatment increased from 66.3 percent TRR (2.015 mg eq/kg) before hydrolysis to 78.0 percent TRR (2.373 mg eq/kg) for wheat hay after hydrolysis and from 72.6 percent TRR (11.640 mg eq/kg) before hydrolysis to 78.2 percent TRR (12.570 mg eq/kg) for wheat straw after hydrolysis. Two major metabolites were formed after acidic hydrolysis as a result of de-conjugation of residues: isoflucypram-desmethyl-propanol and isoflucypram-propanol. Isoflucypram-desmethyl-propanol accounted for 6.9 percent TRR (0.277 mg eq/kg) [pyrazole] and 6.7 percent TRR (0.204 mg eq/kg) [phenyl] in wheat hay and 3.6 percent TRR (0.564 mg eq/kg) [pyrazole] and 4.0 percent TRR (0.644 mg eq/kg) in wheat straw. Isoflucypram-propanol was detected in hydrolysed extract accounting for 22.3 percent TRR (0.901 mg eq/kg) [pyrazole] and 21.1 percent TRR (0.642 mg eq/kg) [phenyl] in wheat hay and 10.5 percent TRR (1.625 mg eq/kg) [pyrazole] and 12.7 percent TRR (2.046 mg eq/kg) [phenyl] in wheat straw. The results are shown in Tables 9 and 10.

A significant amount of conjugated residues in the conventional extracts of hay and straw hydrolyse to isoflucypram-desmethyl-propanol and isoflucypram-propanol.

Figure 1 shows the proposed metabolic pathway of isoflucypram in wheat

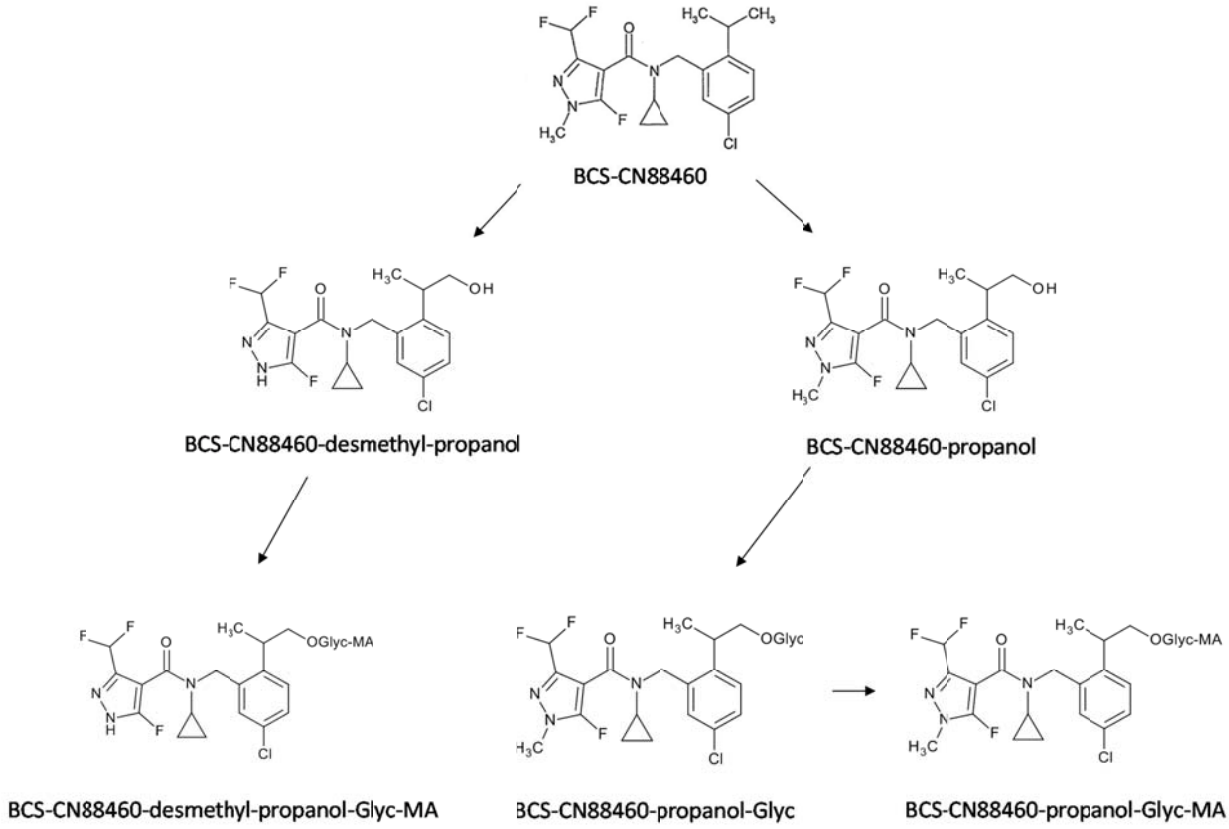

Figure 1 Proposed metabolic pathway of isoflucypram (BCS-CN88460) in wheat

Soya bean

Report Nos. S14-01089 and S14-01090.

The metabolism of isoflucypram was investigated in soya bean commodities after three foliar-directed post-emergent spray applications of [pyrazole-4-^{14}C] and [phenyl-UL-^{14}C] isoflucypram (Traub, M.; 2017). Isoflucypram was formulated as an EC 50. The first application was made at BBCH growth stage 14 at

54–59 g ai/ha, the second application was made at BBCH 51 at 56–57 g ai/ha, and the third application was made at BBCH growth stage 84–85 at 65–66 g ai/ha, for a total application rate of 176–181 g ai/ha. Application timing was 6–8 days between applications one and two, and 62–69 days between applications two and three.

Soya bean forage was harvested at BBCH 49, corresponding to 5–6 days after the first application. Hay was harvested at BBCH 77, corresponding to 38–39 days after the second application, and allowed to dry for four days. Straw and seed were harvested at BBCH 96, corresponding to 21 days after the third application. Samples were subjected to conventional and exhaustive extraction.

Conventional extraction and clean-up

Homogenised samples of soya bean forage, hay, straw, and seed were extracted three times with ACN/water (8:2). Individual extracts were filtered and the solids were rinsed with the solvent mixture used for extraction. The solids were dried and aliquots were subjected to combustion.

The extracts were combined and cleaned-up step by SPE which was rinsed with methanol and water and conditioned with ACN/water (8:2). The percolate was collected and the cartridge was rinsed with ACN/water (8:2). The percolate and the rinse were combined. Less polar fractions on the cartridge were eluted by rinsing the cartridge with methanol/THF (1:1). Each combined percolate/rinse solution obtained from SPE purification was evaporated to the aqueous remainder. The purified conventional extracts were analysed by HPLC.

Exhaustive extraction and clean-up

Solids from the conventional extraction of soya bean forage, hay, and straw were exhaustively extracted twice with ACN/water/formic acid (50:50:1:v) with microwave assistance.

For forage and hay, the individual extracts were combined and cleaned-up step by SPE which was rinsed with methanol and water and conditioned with ACN/water (8:2). The percolate was collected and the cartridge was rinsed with ACN/water (8:2). The percolate and the rinse were combined. Less polar fractions on the cartridge were eluted by rinsing the cartridge with methanol/THF (1:1). Each combined percolate/rinse solution obtained from SPE purification was mixed with emulsifier and evaporated to the aqueous remainder. The exhaustive extracts of straw were directly concentrated by evaporation to the aqueous remainder. The final exhaustive extracts of forage and straw were analysed by HPLC.

Characterisation of residues by partitioning

Radioactivity released from soya bean hay by exhaustive extraction with microwave assistance was characterised by partitioning with water and ethyl acetate. The radioactivity in extracts and the PES was determined by combustion/LSC. The total radioactive residue TRR was calculated by summing the radioactivity of the combined extracts and the PES. Pyrazole labelled soya bean forage and seed were stored for a maximum of five months (-18 °C). Soya bean hay and straw were stored for a maximum of 10 and 16 months, respectively (-18 °C).

Parent compound and major metabolites were identified by spectroscopic methods and co-chromatography with reference compounds. Phenyl labelled soya bean forage and seed were stored for a maximum of four months (-18 °C). Soya bean hay and straw were stored for a maximum of 18 and seven months, respectively (-18 °C). A comparison of the metabolic profile via HPLC after 18 and 27 months for soya bean hay and straw, respectively, shows stability of the metabolic profile over the period of frozen storage. The results are shown in Tables 11 and 12.

Notes:

[1] Losses during clean up, concentration, degreasing, centrifugation, etc.

NQ: Not quantified.

In the conventional extract from soya bean forage, 64.5 percent TRR (2.817 mg eq/kg) [pyrazole] and 69.4 percent TRR (2.729 mg eq/kg) [phenyl] was identified. Parent isoflucypram accounted for 17.6 percent (0.770 mg/kg) [pyrazole] and 17.9 percent TRR (0.703 mg/kg) [phenyl]. Remaining major metabolites included isoflucypram-desfluoro-homoGSH accounting for 21.9 percent TRR (0.955 mg eq/kg) [pyrazole] and 19.6 percent TRR (0.770 mg eq/kg) [phenyl], isoflucypram-desfluoro-mercapto-lactic acid-propyl-OH-Glyc accounting for 3.4 percent TRR (0.147 mg eq/kg) [pyrazole] and 4.8 percent TRR (0.187 mg eq/kg) [phenyl], isoflucypram-desfluoro-mercapto-lactic acid-OH accounting for

9.5 percent TRR (0.415 mg eq/kg) [pyrazole] and 16.7 percent TRR (0.658 mg eq/kg) [phenyl], isoflucypram-desfluoro-mercapto-lactic acid-Glyc accounting for 3.0 percent TRR (0.129 mg eq/kg) [pyrazole] and 2.7 percent TRR (0.107 mg eq/kg) [phenyl], and isoflucypram-desfluoro-Cys-MA accounting for 9.2 percent TRR (0.400 mg eq/kg) [pyrazole] and 7.7 percent TRR (0.304 mg eq/kg) [phenyl].

In the exhaustive extract from soya bean forage, 2.1 percent TRR (0.091 mg eq/kg) [pyrazole] and 2.8 percent TRR (0.108 mg eq/kg) [phenyl] was further identified. Parent isoflucypram accounted for 1.1 percent TRR (0.049 mg/kg) [pyrazole] and 1.3 percent TRR (0.053 mg/kg) [phenyl]. Remaining major metabolites included isoflucypram-desfluoro-homoGSH accounting for 1.0 percent TRR (0.042 mg eq/kg) [pyrazole] and 0.6 percent TRR (0.023 mg eq/kg) [phenyl], isoflucypram-desfluoro-mercapto-lactic acid-OH accounting for 0.3 percent TRR (0.014 mg eq/kg) [phenyl, only], and isoflucypram-desfluoro-Cys-MA accounting for 0.5 percent TRR (0.019 mg eq/kg) [phenyl, only]. In soya bean forage, up to 17 unknown metabolites were characterised in the extract by chromatographic behaviour, individually accounting for ≤3.9 percent TRR (0.171 mg eq/kg).

In the conventional extract from soya bean hay, 63.2 percent TRR (2.958 mg eq/kg) [pyrazole] and 69.8 percent TRR (0.974 mg eq/kg) [phenyl] was identified. Parent isoflucypram accounted for 10.4 percent TRR (0.487 mg/kg) [pyrazole] and 10.3 percent TRR (0.144 mg/kg) [phenyl]. Remaining metabolites included isoflucypram-desfluoro-mercapto-lactic acid-propyl-OH-Glyc accounting for 15.2 percent TRR (0.711 mg eq/kg) [pyrazole] and 17.6 percent TRR (0.246 mg eq/kg) [phenyl], isoflucypram-desfluoro-mercapto-lactic acid-Glyc accounting for 11.1 percent TRR (0.520 mg eq/kg) and 10.7 percent TRR (0.150 mg eq/kg), isoflucypram-desfluoro-Cys-MA accounting for 15.4 percent TRR (0.723 mg eq/kg) [pyrazole] and 20.5 percent TRR (0.286 mg eq/kg) [phenyl], isoflucypram-desfluoro-homoGSH accounting for 7.8 percent TRR (0.366 mg eq/kg) [pyrazole] and 7.8 percent TRR (0.109 mg eq/kg) [phenyl], and isoflucypram-desfluoro-mercapto-lactic acid-OH accounting for 3.2 percent TRR (0.151 mg eq/kg) and 2.8 percent TRR (0.040 mg eq/kg).

Residues in the exhaustive extract of soya bean hay were characterised by partitioning using ethyl acetate. Complete radioactivity of the exhaustive extract was found in the ethyl acetate phase after partitioning. In the phenyl study, radioactivity in the concentrated ethyl acetate phase was analysed by HPLC but no peak was detected above the limit of detection due to low radioactivity concentration and high matrix content of the sample. In soya bean hay, up to 13 unknown metabolites were characterised in the extracts by their chromatographic behaviour, individually accounting for ≤ 6.1 percent TRR (≤ 0.208 mg eq/kg).

In the conventional extract from soya bean straw, 81.2 percent TRR (14.380 mg eq/kg) [pyrazole] and 83.3 percent TRR (7.107 mg eq/kg) [phenyl] was identified. Parent isoflucypram was the major component representing 63.6 percent TRR (11.262 mg/kg) [pyrazole] and 69.6 percent TRR (5.934 mg/kg) [phenyl]. Remaining major metabolites included isoflucypram-desfluoro-mercapto-lactic acid-propyl-OH-Glyc accounting for 3.8 percent TRR (0.667 mg eq/kg) [pyrazole] and 2.1 percent TRR (0.177 mg eq/kg) [phenyl], isoflucypram-desfluoro-homoGSH accounting for 4.8 percent TRR (0.857 mg eq/kg) [pyrazole] and 2.5 percent TRR (0.211 mg eq/kg) [phenyl], isoflucypram-desfluoro-mercapto-lactic acid-OH accounting for 1.5 percent TRR (0.272 mg eq/kg) [pyrazole] and 2.4 percent TRR (0.206 mg eq/kg) [phenyl], isoflucypram-desfluoro-mercapto-lactic acid-Glyc accounting for 3.0 percent TRR (0.533 mg eq/kg) [pyrazole] and 2.7 percent TRR (0.228 mg eq/kg) [phenyl], and isoflucypram-desfluoro-Cys-MA accounting for 4.4 percent TRR (0.788 mg eq/kg) [pyrazole] and 4.1 percent TRR (0.350 mg eq/kg) [phenyl].

In the exhaustive extract from soya bean straw, a further 1.6 percent TRR (0.288 mg eq/kg) [pyrazole] and 3.1 percent TRR (0.264 mg eq/kg) [phenyl] was identified. Parent isoflucypram accounted for 0.9 percent TRR (0.162 mg/kg) [pyrazole] and 0.6 percent TRR (0.049 mg/kg) [phenyl]. Remaining

major metabolites included isoflucypram-desfluoro-mercapto-lactic acid-propyl-OH-Glyc accounting for 0.1 percent TRR (0.023 mg eq/kg) [pyrazole only], isoflucypram-desfluoro-mercapto-lactic acid-OH accounting for 0.4 percent TRR (0.065 mg eq/kg) [pyrazole] and 0.1 percent TRR (0.009 mg eq/kg) [phenyl], isoflucypram-desfluoro-Cys-MA accounting for 0.2 percent TRR (0.040 mg eq/kg) [pyrazole] and 0.2 percent TRR (0.020 mg eq/kg) [phenyl], and isoflucypram-homoGSH accounting for 0.3 percent TRR (0.024 mg eq/kg) [phenyl only]. In soya bean straw, 20 unknown metabolites were characterised in the extracts by their chromatographic behaviour, individually accounting for ≤2.8 percent TRR (≤ 0.329 mg eq/kg).

Conventional extract from soya bean seed contained only parent isoflucypram, representing 76.6 percent TRR (0.027 mg/kg) [pyrazole] and 69.8 percent TRR (0.011 mg/kg) [phenyl]. The results are shown in Tables 13 to 16.

Notes:

[1] For hay and straw, microwave extraction was only performed in the course of a second extraction and values given for exhaustive extraction after first conventional extraction were obtained by conversion. Microwave extract of hay was analysed by HPLC but no peak above the detection limit was detected due to low radioactivity and high matrix content.

Figure 2 Metabolic pathway of isoflucypram (BCS-CN88460) in soya bean

Oilseed Rape

Report Nos. S16-01038 and S16-01044.

The metabolism of isoflucypram in oilseed rape plants was investigated following foliar application of [pyrazole-4-^{14}C] and [phenyl-UL-^{14}C] isoflucypram (Botterweck, J.; 2017). Isoflucypram was formulated as an EC 50. The first application was made at BBCH growth stage 14 at 63–64 g ai/ha and the second application was made at BBCH growth stage 77 at 62–63 g ai/ha, for a total application rate of 126 g ai/ha. The timing between applications was 84 days.

Oilseed rape was harvested at BBCH 30 for intermediate harvest, corresponding to two days after the first application. Oilseed rape forage was harvested at BBCH 55, corresponding to 40 days after the first application. Oilseed rape plants and seed were harvested at maturity (BBCH 89), corresponding to 21 days after the second application.

Samples were subjected to conventional and exhaustive extraction and enzyme/acid treatment.

Conventional extraction and clean-up

Homogenised samples of oilseed rape intermediate harvest, forage, mature plants, and seed were extracted three times with ACN/water (8:2). Individual extracts were filtered and the solids were rinsed with the solvent mixture used for extraction. The solids were dried and aliquots were subjected to combustion.

The extracts were combined and cleaned-up step by SPE which was rinsed with methanol and water and conditioned with ACN/water (8:2). The percolate was collected and the cartridge was rinsed with ACN/water (8:2). The percolate and the rinse were combined. Less polar fractions on the cartridge were eluted by rinsing the cartridge with methanol/THF (1:1). Each combined percolate/rinse solution obtained from SPE purification was mixed with emulsifier and evaporated to the aqueous remainder. The purified conventional extracts were analysed by HPLC.

Exhaustive extraction and clean-up

Solids from the conventional extraction of oilseed rape seeds were exhaustively extracted twice with ACN/water/formic acid (50:50:1:v) with microwave assistance. The microwave extracts were cooled down at room temperature and combined. Aliquots of the extracts were cleaned-up step by SPE which was rinsed with methanol and water beforehand. The percolate was collected and the cartridge was rinsed with ACN/water (8:2). Less polar fractions on the cartridge were eluted by rinsing the cartridge with methanol/THF (1:1).

The percolate and the rinse obtained from SPE purification were combined and mixed with emulsifier and evaporated to the aqueous remainder. The final exhaustive extract was analysed by HPLC.

Release of residues upon enzymatic digestion

Solids of oilseed rape seed remaining following exhaustive extraction were incubated with cellulase in sodium acetate buffer (0.1 mol/L) to release additional radioactive residues. The solids were autoclaved (121 °C, 2 bar vapour pressure) in buffer (set to pH 5 using acetic acid) for 2 hours. The solution was mixed with cellulose (100 mg), incubated for 24 hours in a water bath at 37 °C, and centrifuged.

Solids of oilseed rape seed remaining after cellulase treatment were further incubated with amylase in sodium acetate buffer (0.1 mol/L) to release radioactive residues assimilated to carbohydrates. The solids were autoclaved (121 °C, 2 bar) in buffer (set to pH 5 using acetic acid) for 2 hours. The solution was mixed with amylase (50 mg), incubated for 24 hours in a water bath at 37 °C, and centrifuged.

Release of residues upon acidic extraction with HCl

Solids of oilseed rape seed remaining following enzymatic digestion with cellulase and amylase were further extracted with 5 mol/L HCl to release radioactive residues. After addition of HCl the mixture was incubated for 60 minutes at 120 °C with microwave assistance.

Residues in the acid-hydrolysed extracts were characterised by partitioning. The complete extract was neutralised by addition of 10 mol/L NaOH and mixed with ethyl acetate (1:1). The ethyl acetate and water phases were separated, the water phase was again mixed with ethyl acetate (1:1), and the procedure was repeated.

Hydrolysis of the conventional extracts from oilseed rape intermediate harvest

The final purified extract for oilseed rape intermediate harvest was mixed with 10 mol/L HCl and incubated at 100 °C for 1 hour. The mixture was subsequently adjusted to pH 7 with 10 mol/L NaOH and analysed by HPLC.

The radioactivity in extracts and the PES was determined by combustion/LSC. TRR was calculated by summing the radioactivity of the combined extracts and the PES.

Parent compound and major metabolites were identified by spectroscopic methods and co-chromatography with reference compounds. In both radiolabel studies, samples were stored frozen for less than three months at -18 °C. The results are in Tables 17 to 20 and Figure 3 shows the proposed metabolic pathway of isoflucypram in oilseed rape.

Notes:
NQ: Not quantified.
[1] No individual peak above detection limit was observed in the HPLC chromatogram of the exhaustive extract of seeds.

In the conventional extract from intermediate harvest, 92.3 percent TRR (4.384 mg eq/kg) [pyrazole] and 94.0 percent TRR (3.096 mg eq/kg) [phenyl] was identified. Parent isoflucypram was the major component representing 81.9 percent TRR (3.890 mg/kg) [pyrazole] and 84.1 percent TRR (2.770 mg/kg) [phenyl]. Remaining major metabolites included isoflucypram-hydroxyphenyl-Gluc-MA accounting for 2.3 percent TRR (0.109 mg eq/kg) [pyrazole] and 2.3 percent TRR (0.077 mg eq/kg) [phenyl], isoflucypram-2-propanol-Glyc-MA accounting for 2.2 percent TRR (0.106 mg eq/kg) [pyrazole] and 1.6 percent TRR (0.052 mg eq/kg) [phenyl], isoflucypram-propanol-Glyc-MA accounting for 2.8 percent TRR (0.131 mg eq/kg) [pyrazole] and 2.2 percent TRR (0.071 mg eq/kg) [phenyl], and isoflucypram-hydroxyphenyl-Glyc-MA accounting for 3.1 percent TRR (0.148 mg eq/kg) [pyrazole] and 3.8 percent TRR (0.126 mg eq/kg) [phenyl]. In the conventional extract of intermediate harvest, up to 23 unknown metabolites were characterised, individually accounting for ≤ 1.5 percent TRR (≤ 0.072 mg eq/kg).

Comparison of metabolic profiles before and after acid hydrolysis of intermediate harvest indicated cleavage of isoflucypram-hydroxyphenyl-Gluc-MA, isoflucypram-2-propanol-Glyc-MA, isoflucypram-propanol-Glyc-MA, and isoflucypram-hydroxyphenyl-Glyc-MA to less polar compounds.

In the conventional extract from forage, 85.4 percent TRR (0.010 mg eq/kg) [pyrazole] and 77.3 percent TRR (0.006 mg eq/kg) [phenyl] was analysed. No individual peak was above the background noise due to low radioactivity.

In the conventional extract from mature plants, 91.3 percent TRR (3.719 mg eq/kg) [pyrazole] and 84.4 percent TRR (3.318 mg eq/kg) [phenyl] was identified in total. The parent compound was the major component representing 88.1 percent TRR (3.589 mg/kg) [pyrazole] and 72.0 percent TRR (2.831 mg/kg) [phenyl]. Remaining major metabolites included isoflucypram-hydroxyphenyl-Gluc-MA accounting for 0.7 percent TRR (0.027 mg eq/kg) [pyrazole] and 2.2 percent TRR (0.087 mg eq/kg) [phenyl], isoflucypram-2-propanol-Glyc-MA accounting for 0.9 percent TRR (0.038 mg eq/kg) [pyrazole] and 4.6 percent TRR (0.181 mg eq/kg) [phenyl], isoflucypram-propanol-Glyc-MA accounting for 0.6 percent TRR (0.025 mg eq/kg) [pyrazole] and 2.5 percent TRR (0.097 mg eq/kg) [phenyl], and isoflucypram-hydroxyphenyl-Glyc-MA accounting for 1.0 percent TRR (0.040 mg eq/kg) [pyrazole] and 3.1 percent TRR (0.122 mg eq/kg) [phenyl]. In the conventional extract in mature plants, up to 39 unknown metabolites were characterised, individually accounting for ≤1.3 percent TRR (≤ 0.054 mg eq/kg).

In the conventional extract from seeds, 71.0 percent TRR (0.070 mg eq/kg) [pyrazole] and 73.6 percent TRR (0.093 mg eq/kg) [phenyl] was identified. Parent isoflucypram was the only component, representing 71.0 percent TRR (0.070 mg/kg) [pyrazole] and 73.6 percent TRR (0.093 mg/kg) [phenyl].

Exhaustive extraction of seeds released a further 9.8 percent TRR (0.010 mg eq/kg) [pyrazole] and 10.6 percent TRR (0.013 mg eq/kg) [phenyl], of which and 7.6 percent TRR (0.008 mg eq/kg) [pyrazole] and 9.6 percent TRR (0.012 mg eq/kg) [phenyl] was analysed by HPLC. No individual peak was above the background noise due to low radioactivity.

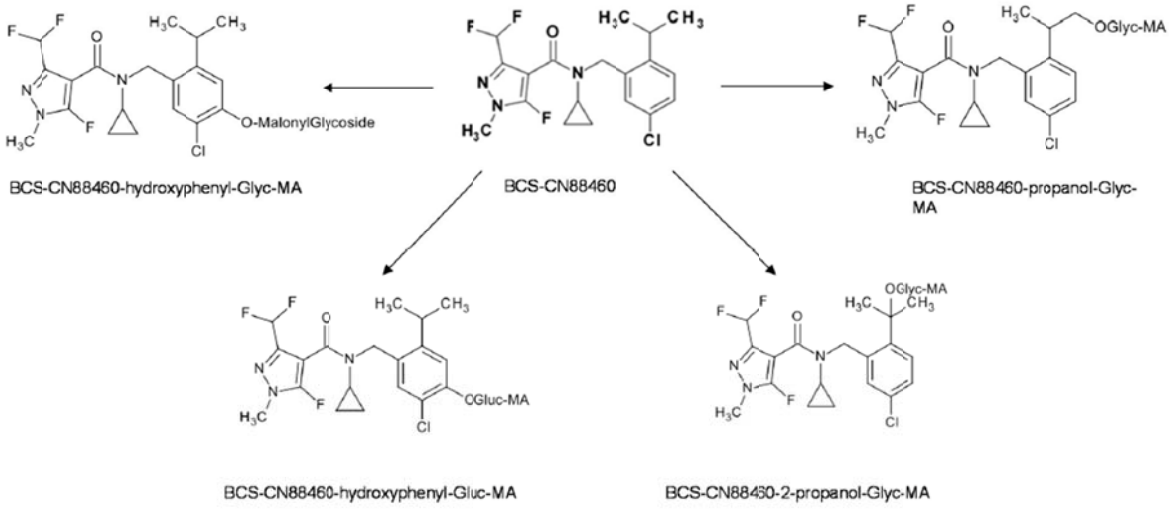

Figure 3 Metabolic pathway isoflucypram (BCS-CN88460) in oilseed rape

Potato Seed Treatment

Report Nos. S17-01394 and S17-01392.

The metabolism of isoflucypram in potatoes was investigated following seed treatment application of [pyrazole-4-^{14}C] and [phenyl-UL-^{14}C] isoflucypram (Botterweck, J.; 2018). Isoflucypram was formulated as an EC 200 and applied to potato tubers prior to planting. Potato seeds were treated at 28 g ai/ha (0.55 mg ai/ tuber and 50,000 plants/ha) for a low dose experiment and 274–280 g ai/ha (5.5 mg ai/tuber and 50,000 plants/ha) for a high dose experiment.

Potato tubers and leaves were harvested at BBCH growth stage 97, corresponding to 119 days after planting. Samples were subjected to conventional and exhaustive extraction.

Conventional extraction and clean-up

Due to the low radioactivity of tubers following the low dose application, no extraction was performed. For conventional extraction of tubers in the high dose experiment and leaves for both dose levels, homogenised samples were extracted three times with ACN/water (8:2). Individual extracts were filtered and the solids were rinsed with the solvent mixture used for extraction. The solids were dried and aliquots were subjected to combustion analysis.

The extracts were combined and cleaned-up by SPE. The percolate was collected and the cartridge was rinsed with ACN/water (8:2). The percolate and the rinse were combined. Less polar fractions on the cartridge were eluted by rinsing the cartridge with methanol/THF (1:1).

Each combined percolate/rinse solution obtained from SPE purification was evaporated to the aqueous remainder and mixed with emulsifier beforehand. The purified conventional extracts were analysed by HPLC.

Exhaustive extraction and clean-up

Solids from the conventional extraction of potato leaves in the low dose pyrazole experiment and potato tubers in the high dose phenyl experiment were exhaustively extracted twice with ACN/water/formic acid (50:50:1:v) with microwave assistance at 120 °C. The microwave extracts were combined and cleaned-up by SPE. The combined fractions from SPE purification were evaporated to the aqueous remainder.

The radioactivity in extracts and the PES was determined by combustion/LSC. The total radioactive residue TRR was calculated by summing the radioactivity of the combined extracts and the PES.

Isoflucypram and the major metabolites were identified by spectroscopic methods and use of co-chromatography with reference compounds.

In the pyrazole study, potato tubers were stored frozen for a maximum of two months at -18 °C. Potato leaves were stored for a maximum of 10 months at -18 °C. Comparison of the metabolite profile in extract stored after 10 months of storage at -18°C demonstrated that the residue profile was stable for at least 10 months.

In the phenyl study, potato tubers and leaves were stored frozen for a maximum of three months at ≤-18 °C.

Notes:

[1] No individual peak above detection limit was observed in the HPLC chromatogram of the exhaustive extract of tubers for the overdose experiment.

Low dose experiment

No extraction/profiling was performed in tubers due to low radioactivity (0.002–0.009 mg eq/kg).

In the conventional extract of potato leaves, 88.6 percent TRR (0.331 mg eq/kg) [pyrazole] and 92.6 percent TRR (0.046 mg eq/kg) [phenyl] was released. Parent isoflucypram was a minor component of the residue accounting for 2.0 percent TRR (0.007 mg/kg) [pyrazole] and 7.3 percent TRR (0.004 mg/kg) [phenyl]. Major metabolites identified included isoflucypram-OH-phenyl-Glyc-MA accounting for 6.6 percent TRR (0.025 mg eq/kg) [pyrazole] and 23.4 percent TRR (0.012 mg eq/kg) [phenyl], isoflucypram-2-propanol-Glyc-MA accounting for 14.3 percent TRR (0.053 mg eq/kg) [pyrazole] and 29.0 percent TRR (0.014 mg eq/kg) [phenyl], and isoflucypram-cyclopropyl-pyrazole-carboxamide accounting for 10.7 percent TRR (0.040 mg eq/kg) [pyrazole, only]. Up to 17 unknown metabolites were characterised, individually accounting for ≤19.9 percent TRR (≤ 0.024 mg eq/kg).

Exhaustive extraction released an additional 7.5 percent TRR (0.028 mg eq/kg) [pyrazole]. No detectable peaks were observed in the exhaustive extract. The results are shown in Table 23

Table 23 Summary of characterisation and identification of TRR in potato leaves following low dose seed treatment application of [Pyrazole-4-^{14}C] (Study S17-01394) and [Phenyl-UL-^{14}C] Isoflucypram (Study S17-01392)

Notes:

[1] No individual peak above detection limit was observed in the HPLC chromatogram of the exhaustive extract of leaves.

High dose experiment

In the conventional extract for potato tubers, 97.7 percent TRR (0.063 mg eq/kg) [pyrazole] and 82.2 percent TRR (0.034 mg eq/kg) [phenyl] was released. Isoflucypram represented the main residue component at 86.4 percent TRR (0.056 mg/kg) [pyrazole] and 69.2 percent TRR (0.029 mg/kg) [phenyl]. The only other identified compound was isoflucypram-cyclopropyl-pyrazole-carboxamide accounting for 11.1 percent TRR (0.007 mg eq/kg) [pyrazole only]. Up to one unidentified metabolite was characterized accounting for 13.0 percent TRR (0.005 mg eq/kg).

In the potato tuber pyrazole study, and additional 12.9 percent TRR (0.005 mg eq/kg) was released in the exhaustive extract. No single peak was identified above the limit of detection.

In the conventional extract for potato leaves, 93.2 percent TRR (0.998 mg eq/kg) [pyrazole] and 93.8 percent TRR (0.645 mg eq/kg) [phenyl] was released. Isoflucypram accounted for 2.5 percent TRR (0.027 mg/kg) [pyrazole] and 4.0 percent TRR (0.027 mg/kg) [phenyl]. Remaining major metabolites included isoflucypram-cyclopropyl-pyrazole-carboxamide accounting for 7.2 percent TRR (0.077 mg eq/kg) [pyrazole only], isoflucypram-OH-phenyl-Glyc-MA accounting for 9.9 percent TRR (0.105 mg eq/kg) [pyrazole] and 15.0 percent TRR (0.103 mg eq/kg) [phenyl], and isoflucypram-2-propanol-Glyc-MA accounting for 13.9 percent TRR (0.148 mg eq/kg) [pyrazole] and 15.0 percent TRR (0.103 mg eq/kg) [phenyl]. In leaves, up to 34 unknown metabolites were characterised, individually

accounting for ≤8.6 percent TRR (≤ 0.064 mg eq/kg). The results are shown in Tables 24 and 25 and the proposed metabolic pathways in Figures 4 and 5.

Confined rotational crops

Report Nos. EnSa-16-945 and EnSa-17-0128.

Confined rotational crop studies were submitted with [pyrarazol-4-^{14}C] isoflucypram and [phenyl-UL-^{14}C] isoflucypram (Lamshoeft, M., *et al*., 2017). The experimental design and sample work-up was the same for both studies, except as noted below. The test substance was applied to bare sandy loam soil as a single spray application at a rate of 198–210 g ai/ha. Turnips, Swiss chard, and wheat were sown into the treated soil with 30-, 140-, and 287-day plant-back intervals (PBIs). Immature samples of Swiss chard (BBCH 45), wheat forage (BBCH 29), and wheat hay (BBCH 75–83) and mature samples of turnip roots, turnip tops, Swiss chard, wheat straw, and wheat grain were harvested and analysed for residues. The TRRs are shown in Table 26.

Table 26 TRR (mg eq/kg) in confined rotational crops following treatment with label isoflucypram

Notes:

[1] Determined by combustion and LSC. Samples were not extracted due to low levels of radioactivity

TRR was determined by combustion and LSC. For all matrices with adequate radioactivity, samples were extracted using ACN/water (4:1). The following matrices were not extracted for analysis due to low levels of radioactivity: turnip roots (all PBIs for the pyrazole label), turnip roots and tops (all PBIs for the phenyl label), and wheat grain (30-day PBI for the pyrazole label and all PBIs for the phenyl label).

PES for wheat hay (all PBIs), wheat straw (all PBIs), and wheat grain (140- and 287-day PBIs) were further extracted using ACN/water/formic acid (50:50:1) with microwave assistance and SPE. Following microwave extraction, solids from pyrazole-label wheat hay and wheat straw were subjected to a second microwave extraction using dioxane and 5 mol/L HCl. Extracts were analysed by HPLC using radiometric and ultraviolet (UV) detection.

For the phenyl label only, extracts of wheat straw and Swiss chard from the 30-day PBI were hydrolysed for 1 hour in 1 mol/L HCl at 100 °C to investigate conjugated residues of parent compound and metabolites.

Compound identification was accomplished by comparison of HPLC profile for the parent compound and by spectroscopic methods with comparison of chromatographic profiles for metabolites.

All samples were stored frozen for a maximum of 41 days. Within a maximum of one month after extraction, the earliest metabolite profiles (used for quantitation of metabolites) were obtained by HPLC-analysis. Therefore, it was concluded that the results of this study were not negatively influenced by storage effects.

In pyrazole-labelled rotational turnip tops, 92.3–93.1 percent TRR (0.017–0.029 mg eq/kg) was extracted. Parent isoflucypram was a minor residue representing 4.8 percent TRR (0.001 mg/kg) at the first PBI and was not detected at longer PBIs. All other identified components retained only the pyrazole moiety and were minor with concentrations ≤ 0.006 mg eq/kg. Up to nine unknown peaks were characterised, each accounting for ≤ 9.5 percent TRR (≤ 0.003 mg eq/kg). The results are in Table 27

In rotational immature Swiss chard, a total of 94.4–97.2 percent TRR (0.030-0.060 mg eq/kg) [pyrazole] and 96.2–97.7 percent TRR (0.015–0.028 mg eq/kg) [phenyl] was extracted. Parent isoflucypram was a minor component in the pyrazole and phenyl studies representing ≤ 6 percent TRR (≤ 0.002 mg/kg). All remaining identified metabolites retained only the pyrazole moiety. Isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-GSH was a major metabolite accounting for 23.0–26.9 percent TRR (0.008–0.016 mg eq/kg). All other metabolites were minor components accounting for ≤ 0.007 mg eq/kg. Up to 19 unknown peaks were characterised based on chromatographic behaviour, each accounting for ≤ 25.4 percent TRR (≤ 0.009 mg eq/kg).

In the hydrolysed extract of phenyl-labelled immature Swiss chard at the 30-day PBI, isoflucypram was identified at 7.4 percent TRR (0.002 mg/kg), isoflucypram-propanol was identified at 10.9 percent TRR (0.003 mg eq/kg), and isoflucypram-carboxylic acid was identified at 37.2 percent TRR (0.011 mg eq/kg). The results are shown in Tables 28 and 29.

In rotational mature Swiss chard, a total of 92.4–96.0 percent TRR (0.025–0.058 mg eq/kg) [pyrazole] and 95.6–97.7 percent TRR (0.015–0.024 mg eq/kg) [phenyl] was extracted. Parent isoflucypram was a minor component in the pyrazole and phenyl studies representing ≤ 6.1 percent TRR (0.001 mg/kg). All remaining identified metabolites retained only the pyrazole moiety. Isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-Cys was a major metabolite accounting for 16.4–34.2 percent TRR (0.009–0.011 mg eq/kg). All other metabolites were minor components accounting for ≤ 0.006 mg eq/kg. Up to 22 unknown peaks were characterised based on chromatographic behaviour, each accounting for ≤ 28.3 percent TRR (≤ 0.007 mg eq/kg).

In the hydrolysed extract of phenyl-labelled mature Swiss chard at the 30-day PBI, isoflucypram was identified at 16.8 TRR (0.003 mg/kg), isoflucypram-propanol was identified at 17.4 percent TRR (0.004 mg eq/kg), and isoflucypram-carboxylic acid was identified at 40.5 percent TRR (0.008 mg eq/kg). The results are shown in Tables 30 and 31.

In rotational wheat forage, a total of 91.0–92.9 percent TRR (0.038–0.071 mg eq/kg) [pyrazole] and 90.1–94.8 percent TRR (0.014–0.021 mg eq/kg) [phenyl] was extracted. Parent isoflucypram was a minor component in the pyrazole and phenyl studies representing ≤17 percent TRR (≤ 0.004 mg/kg). All remaining identified metabolites retained only the pyrazole moiety. Isoflucypram-cyclopropyl-pyrazole-carboxamide-Ala was a major metabolite accounting for 15.4–25.6 percent TRR (0.009–0.020 mg eq/kg). All other metabolites were minor components accounting for ≤ 0.008 mg eq/kg. Up to 12 unknown peaks were characterised based on chromatographic behaviour, each accounting for ≤30.6 percent TRR (≤ 0.007 mg eq/kg). The results are shown in Tables 32 and 33.

In rotational wheat hay, a total of 83.6–85.7 percent TRR (0.098–0.184 mg eq/kg) [pyrazole] and 82.0–86.3 percent TRR (0.030–0.053 mg eq/kg) [phenyl] was released in the conventional extract. Parent isoflucypram was not recovered in the pyrazole study and a minor component of the residue (≤1.1 percent TRR; ≤ 0.001 mg/kg) in the phenyl study. All remaining identified metabolites retained only the pyrazole moiety. Major metabolites included isoflucypram-cyclopropyl-pyrazole-carboxamide-Ala accounting for 7.9 percent–13.9 percent TRR (0.014–0.031 mg eq/kg), isoflucypram-cyclopropyl-pyrazole-carboxamide-Glyc (isomer 2) accounting for 3.8–5.8 percent TRR (0.007–0.013 mg eq/kg), isoflucypram-cyclopropyl-pyrazole-carboxamide-OH-lactic acid (isomer 2) accounting for 3.2–9.0 percent TRR (0.007–0.016 mg eq/kg), isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-Cys accounting for 5.7–7.0 percent TRR (0.012–0.013 mg eq/kg), isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-GSH accounting for 1.8–6.5 percent TRR (0.003–0.014 mg eq/kg), and isoflucypram-desfluoro-cyclopropyl-pyrazole-carboxamide-Ala accounting for 2.2–4.8 percent TRR (0.004–0.011 mg eq/kg). All other metabolites were minor components accounting for ≤ 0.009 mg eq/kg. Up to 17 unknown peaks were characterised based on chromatographic behaviour, each accounting for ≤17.3 percent TRR (≤ 0.013 mg eq/kg).

An additional 10.5–12.5 percent TRR (0.012–0.027 mg eq/kg) [pyrazole] and 5.5–6.7 percent TRR (0.002–0.003 mg eq/kg) [phenyl] was released in the exhaustive extract. The resuls are shown in Tables 34 and 35.

In rotational wheat straw, a total of 78.5–83.7 percent TRR (0.103–0.284 mg eq/kg) [pyrazole] and 78.4–82.9 percent TRR (0.040–0.058 mg eq/kg) [phenyl] was released in the conventional extract. Parent isoflucypram was not recovered in either study. All remaining identified metabolites retained only the pyrazole moiety. Major metabolites included BCS-CR60082 (Isoflucypram-N-methyl-cyclopropyl-pyrazole-carboxamide) accounting for 2.8–7.0 percent TRR (0.007–0.020 mg eq/kg), isoflucypram-cyclopropyl-pyrazole-carboxamide-Ala accounting for 2.6 percent–9.1 percent TRR (0.003–0.022 mg eq/kg), isoflucypram-cyclopropyl-pyrazole-carboxamide-Glyc (isomer 1) accounting for 2.3–3.6 percent TRR (0.003–0.011 mg eq/kg), isoflucypram-cyclopropyl-pyrazole-carboxamide-Glyc (isomer 2) accounting for 3.3–3.5 percent TRR (0.005–0.011 mg eq/kg), isoflucypram-cyclopropyl-pyrazole-carboxamide-OH-lactic acid (isomer 2) accounting for 5.9–11.9 percent TRR (0.015–0.029 mg eq/kg), isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-Cys accounting for 2.6–7.6 percent TRR (0.003–0.026 mg eq/kg), isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-GSH accounting for 2.6–6.6 percent TRR (0.009–0.014 mg eq/kg), and isoflucypram-desfuloro-N-methyl-cyclopropyl-pyrazole-carboamide-mercapto-Glyc-MA accounting for 2.9–5.5 percent TRR (0.007–0.010 mg eq/kg). All other metabolites were minor components accounting for

≤ 0.009 mg eq/kg. Up to 18 unknown peaks were characterised based on chromatographic behaviour, each accounting for ≤16 percent TRR (≤ 0.021 mg eq/kg).

An additional 12.1–15.1 percent TRR (0.020–0.041 mg eq/kg) [pyrazole] and 7.6–10.8 percent TRR (0.005–0.006 mg eq/kg) [phenyl] was released in the exhaustive extract.

In the hydrolysed extract of phenyl-labelled wheat straw at the 30-day PBI, isoflucypram-propanol was identified at 5.5 percent TRR (0.003 mg eq/kg) and isoflucypram-carboxylic acid was identified at 10.8 percent TRR (0.006 mg eq/kg). The results are shown in Tables 36 and 37.

In pyrazole labelled rotational wheat grain, a total of 52.9–53.7 percent TRR (0.006–0.009 mg eq/kg) was released in the conventional extract. Parent isoflucypram was not recovered. All identified metabolites retained only the pyrazole moiety. All metabolites were minor components accounting for ≤ 0.002 mg eq/kg. Three unknown peaks were characterised based on chromatographic behaviour, each accounting for ≤ 22.4 percent TRR (≤ 0.004 mg eq/kg). An additional 27.6–31.5 percent TRR (0.003–0.005 mg eq/kg) was released in the exhaustive extract (Table 38).

A proposed metabolic pathway of isoflucypram in confined rotational crops is shown in Figure 6

Magnitude of the residue in rotational crops and soil

Report No. 15-2502.

The Meeting received four independent rotational crop trials, one each from Germany, the Netherlands, France, and Italy in 2015 following one broadcast application of an EC formulation containing 50 g ai/L (Freitag, T., *et al.,* 2017). The application rate was 0.18 kg ai/ha. Rotational crops of barley, carrot or turnips, and lettuce were planted in treated plots at PBIs of 20–34 days, 100–201 days, and 299–370 days and analysed for isoflucypram and BCS-CR60082. Additionally, soil samples (from 0–30 cm) were taken at from each plot at each PBI and analysed for isoflucypram and isoflucypram-carboxylic acid. No adjuvants were added to the solution at any trial. The soil characteristics in each trial are shown in Table 39.

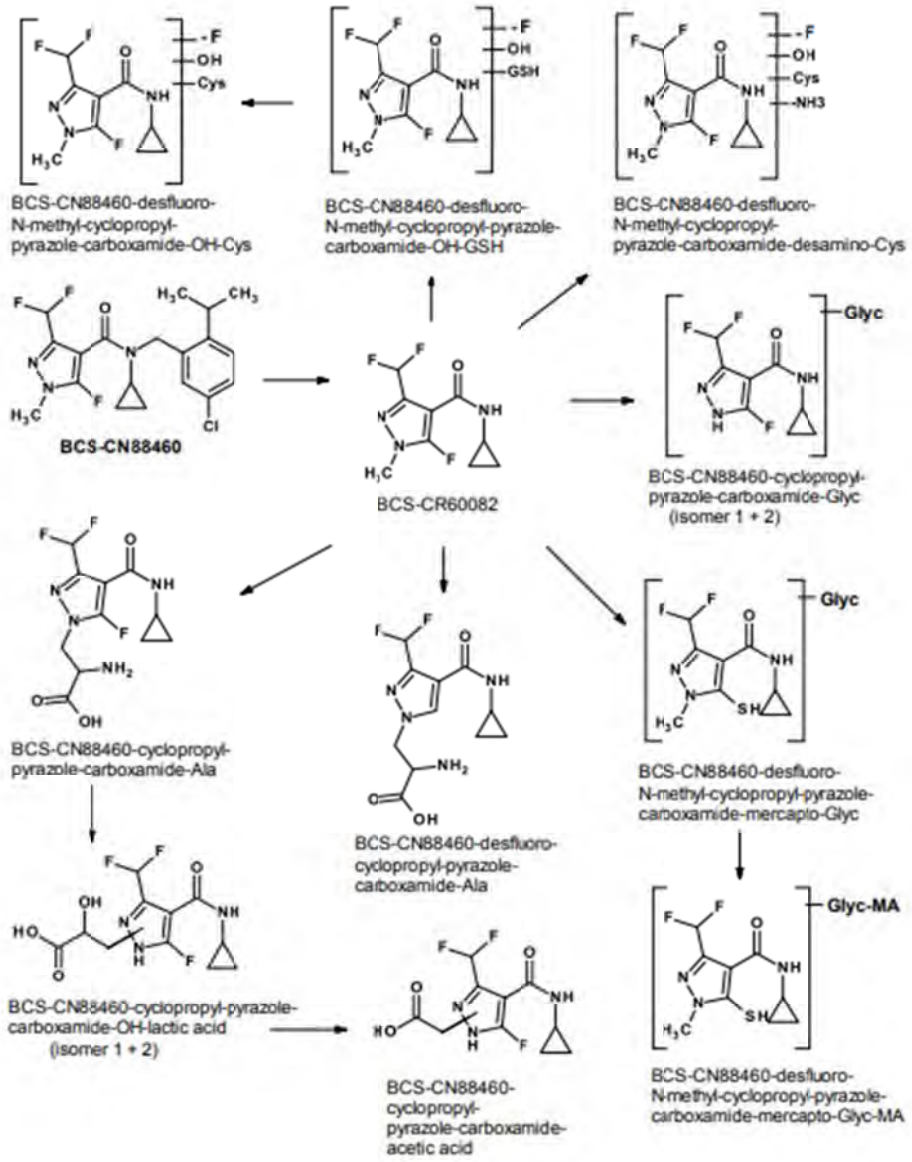

Figure 6 Metabolic pathway in pyrazole-labelled isoflucypram (BCS-CN88460) in confined rotational crops

Table 39 Soil Characteristics (0–30 cm) in the field rotational crops conducted in Europe in 2015

Trial Number (Country)	Classification (USDA)	Clay (%)	Silt (%)	Sand (%)	CEC (meq/100 g)	$CaCO_3$ Content (%)	pH in KCl	Organic Content (%)	WHCmax (g/100g)
15-2502-01 (Germany)	Silt Loam	16.4	76.4	7.2	15.3	<0.1	6.47	1.74	48.3
15-2502-02 (Netherlands)	Loam	15.4	47.1	37.5	31.3	2.1	7.4	2.5	58.1
15-2502-03 (France)	Silt Loam	13.3	65.2	21.5	20.0	41.0	7.97	0.77	39.7
15-2502-04 (Italy)	Silt Loam	16.0	53.1	30.9	24.3	13.4	7.60	1.14	46.9

Irrigation was used at Trials 15-2502-02, 15-2502-03, 15-2502-04. A minimum of 2.02 and 2.08 kg of carrot/turnip leaf and carrot/turnip root were collected from treated plots, respectively; 1.29 kg of lettuce was collected from treated plots; 1.58, 1.07, and 0.600 kg of barley green material, grain, and straw were collected from treated plots, respectively; and 2.70 kg of soil sample was collected from treated plots (however, soil weights were not reported in Trial 15-2502-04). Treated and control samples were frozen within 24 hours after sampling and during shipment to the Laboratory for Sampling (Bayer AG, Monheim am Rhein, Germany). Samples were shredded and homogenized with dry ice and shipped frozen to the analytical laboratory (Bayer S.A.S., Lyon, France).

The maximum storage duration between harvest and extraction for analysis was 299 days for carrot/turnip tops, 300 days for carrot/turnip roots, 341 days for lettuce, 259 days for barley green material, 96 days for barley grain, 103 days for barley straw, and 320 days for soil.

Residues levels of isoflucypram and BCS-CR60082 (isoflucypram-N-methyl-cyclopropyl-pyrazole-carboxamide) were determined in plants by Method 01475. Residue levels of isoflucypram and isoflucypram-carboxylic acid were determined in soil according to Method 01432. There were no residues in control samples. Therefore, residues in treated samples were not corrected for residues in controls.

Average residues of BCS-CR60082 were below the limit of quantitation (LOQ; <0.01 mg eq/kg) in all samples. Average residues of isoflucypram were below the LOQ (<0.01 mg/kg) in all samples except carrot tops at one trial at the 106-day PBI (average residue of 0.066 mg/kg). According to the study report, this plot was close to the barley plot which received an application five days prior to harvest of carrot tops. There was no buffer zone or structure preventing spray drift and a slight wind in the direction of the carrot field. Therefore, the Meeting considers this residue point an outlier and potentially resulting from drift rather than uptake in the field. The results of the residues in the rotational cropos are shown in Table 40 and the residues in the soil in Table 41

Environmental degradation

The Meeting received studies investigating the aerobic metabolism/degradation in soil, hydrolytic degradation, photolytic transformation, and theoretical photodegradation in water and environmental half-life.

Aerobic Metabolism/Degradation in Soil

Report No. EnSa-13-1043.

The route and rate of degradation of [pyrazole-4-^{14}C] isoflucypram was studied in four soils (Hellpointner, E., *et. al.*; 2014). Samples were maintained under aerobic conditions in the dark in the laboratory for 120 days at 20.0 °C. Samples were maintained at a moisture content of 53.1 percent of the maximum water holding capacity. The application rate of was 75 g ai/ha, corresponding to 200 µg ai/kg soil dry weight. Soil was collected from the top 20 cm and sieved to a particle size of ≤ 2 mm. The four soils represent different geographical origin and properties (Table 42).

Table 42 Soil properties for aerobic metabolism study for isoflucypram (EnSa-13-1043)

Designation	Source	Texture (USDA)	pH[1]	% organic content
Hanscheider Hof	Burscheid, Germany	Loam	5.7	2.9
Laacher Hof AXXa	Monheim, Germany	Loamy sand	6.3	2.0
Hoefchen Am Hohenseh	Burscheid, Germany	Silt loam	6.6	1.9
Dollendorf II	Blankenheim, Germany	Loam	7.4	5.2

Notes:
[1] pH values were derived from aqueous 0.01M $CaCl_2$ suspensions.

Tests were performed in incubation vessels with 100 g soil (dry weight equivalents) equipped with oxygen-permeable polyurethane (PU) and soda lime traps for volatile organic compounds (VOCs) and CO_2, respectively.

Water loss from evaporation was determined by weighing test systems at the start of the study and after 37, 76, and 107 days of incubation. No significant losses of moisture were observed throughout the study. Determinations of microbial biomass were performed on day after treatment (DAT)-0, DAT50 and DAT120 and demonstrated that the used soils were microbially viable.

Ten sampling intervals were distributed over the incubation period of 120 days. Duplicate samples were processed and analysed on DAT 0, 2, 6, 15, 28, 50, 62, 84, 104, and 120. Prior to processing of soil, possible volatiles were purged into the trap attachment and the trap attachment was removed. CO_2 was released from the soda lime with HCl and re-absorbed to a scintillation cocktail for LSC. VOCs were released with ethyl acetate. No chromatographic analyses were performed for VOCs due to low radioactivity (≤ 0.1 percent applied radioactivity [AR]).

The entire soil of each test vessel was extracted three times under ambient conditions with ACN/water (1:1) followed by one extraction with ACN/water (1:1) with microwave assistance at 70 °C, followed by one extraction with MeOH/water (1:1) with microwave assistance at 50 °C. The radioactivity content was determined by LSC. Non-extracted residues (NER) were determined by combustion/LSC.

The trap attachments containing soda lime and PU foam were stored for a maximum of six days. The first analysis of soil extracts with the primary chromatographic method was usually done within one day after sampling. After analysis, soil extracts were stored at <-18 °C in the dark. Soil extracts of DAT120 samples were re-analysed with the confirmatory method with a maximum sample storage period was four weeks. The exhaustive extracted soils were stored at ambient temperature in the laboratory for a maximum period of two weeks.

Mean material balances were ranged from 97.7–100.3 percent AR. The complete material balances found at all sampling intervals for all soils demonstrated that there was no significant loss of radioactivity from the test systems or during sample processing. The resuts of the degradation study in different soils are shown in Table 43.

Table 43 Degradation of isoflucypram in soil under aerobic conditions, in percent of applied radioactivity (mean ± SD)

Notes:

[1] ROI: Region of interest.

Isoflucypram was evaluated according to the FOCUS guidance document on degradation kinetics using the software KinGUI 2. Three different kinetic models were tested in order to determine the best-fit

kinetic model: single first order (SFO), first order multi-component (FOMC), and double first-order in parallel (DFOP). The best-fit kinetic model was selected on the basis of the chi^2 scaled-error criterion and visual assessment of the goodness of fit. DT_{50} and DT_{90} values were calculated from the resulting kinetic parameters.

The degradation of isoflucypram was best fit with SFO kinetics in all soils according to the lowest chi^2 error values and visual assessments. The calculated DT_{50} and DT_{90} are shown in Table 44.

Table 44 Best fit results of the DT_{50} and DT_{90} calculations for isoflucypram

Soil (Texture)	Best Fit Kinetic Model[1,2]	DT_{50} (Days)	DT_{90} (Days)	Chi^2 Error (%)	Visual Assessment
Hanscheider Hof (loam)	SFO	458	>1,000	0.7	Good

The metabolic/degradation pathway of isoflucypram (BCS-CN88460) in soil in shown in Figure 7.

Report No. MELNN013.

The route and rate of degradation of [pyrazole-4-1^4C] isoflucypram was studied in two United States soils (Gabbert, D., *et. al.*; 2017). Samples were maintained under aerobic conditions in the dark in the laboratory for 123 days at 20.4 °C. Samples were maintained at moisture content of between pF 2.0 and 2.5. The application rate was 75 g ai/ha, corresponding to a concentration of 200 µg ai/kg soil dry weight. In order to bridge to a higher rate, additional test systems were treated at 430 µg ai/kg soil dry weight (equivalent to ca. 150 g ai/ha) which were additionally used for metabolite identification. Soil was collected from the top 20 cm and sieved to a particle size of ≤ 2 mm. The two soils represent different geographical origin and properties.

Table 45 Soil Properties for aerobic metabolism study for isoflucypram

Designation	Source	Texture (USDA)	pH	% organic content
CA Soil	Sanger, CA	Sandy loam	6.3	0.77
NE Soil	Louisville, NE	Silty clay loam	6.3	2.0

Notes:
[1] pH values were derived from aqueous 0.01M $CaCl_2$ suspensions.

The test was performed with a flow-through system consisting of cylindrical bottles each containing 75 g soil (dry weight equivalents). The bottles were attached to a series of traps for collection of VOCs and CO_2.

Water loss from evaporation was determined by weighing all test systems at study start and the respective each sampling interval. No significant losses of moisture were observed throughout the study. Determinations of microbial biomass were performed on DAT0 and DAT123 and demonstrated that the soils were microbially viable. The CA soil showed a significant decline in activity at the end of the study. Under the conditions of a laboratory experiment a decrease of microbial biological activity is inevitable due to the absence of any further amendment of nutrients.

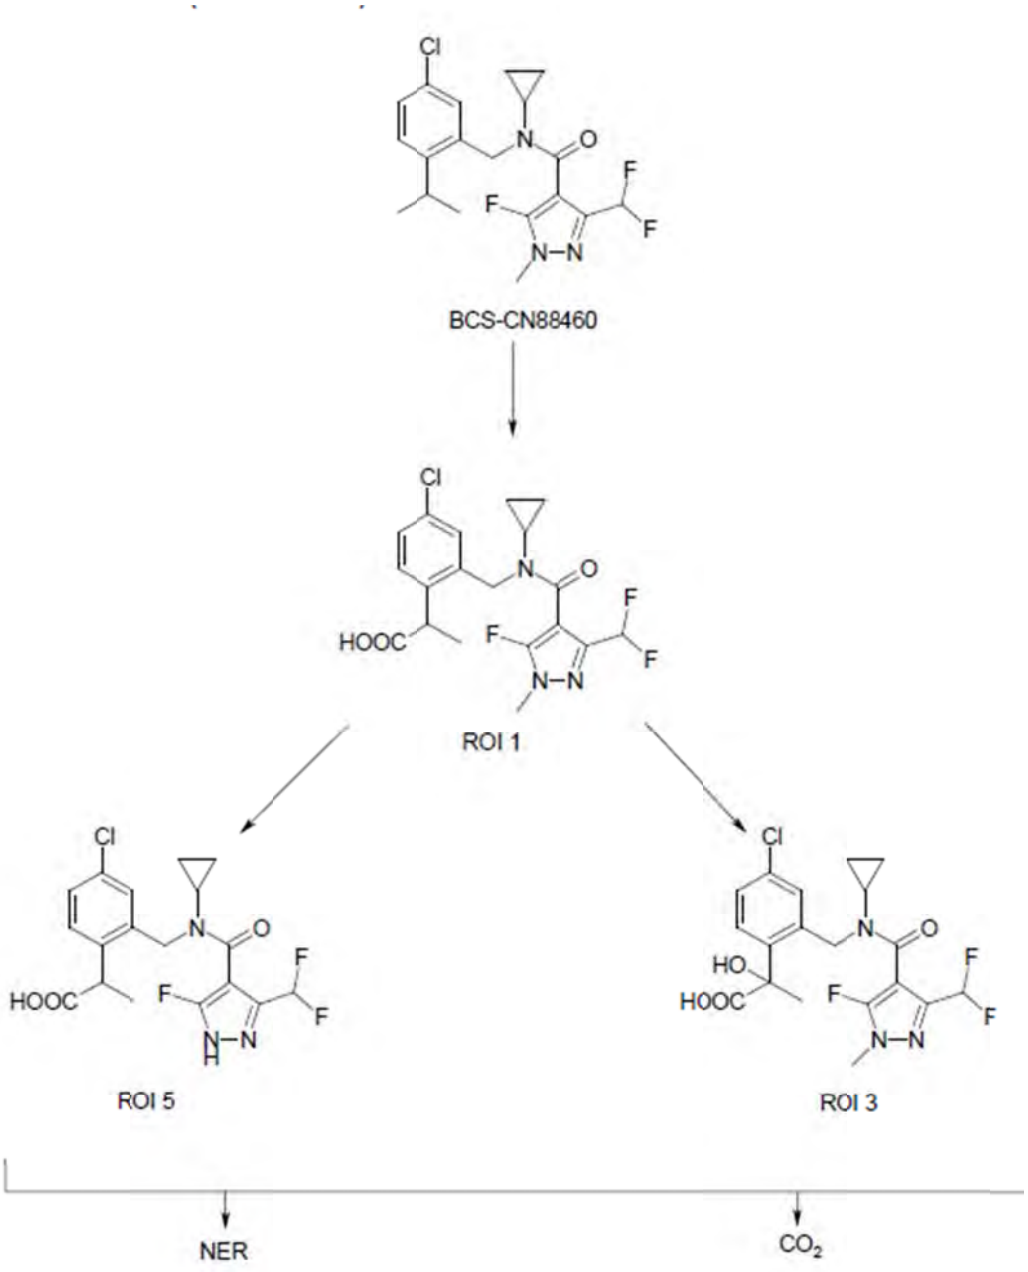

Figure 7 Metabolic/degradation pathway of isoflucypram (BCS-CN88460) in soil

Replicate samples were collected for analysis on DAT0, 6, 14, 21, 28, 60, 88, and 123. The exaggerated application soil samples were collected for analysis on DAT76, 88, and 123. Prior to processing of soil, possible volatiles were purged into the trap attachment and the trap attachment was removed. VOCs and CO_2 were extracted with ethylene glycol and potassium hydroxide, respectively, and

radioactivity was determined by LSC. No chromatographic analyses were performed for VOCs due to low radioactivity (≤ 3.3 percent AR).

At each sampling interval, soil was extracted three times at ambient temperature: once using ACN and additional two times using ACN/water (4:1). Furthermore, two microwave-accelerated extraction steps were performed using ACN/water (4:1) at 70°C and MeOH/water (9:1; v;v) at 50 °C, respectively. The amounts of test substance and degradation products in soil extracts were determined by LSC and by HPLC/radiodetection analysis. The amounts of volatiles and non-extracted residues were determined by LSC and combustion/LSC, respectively.

The test substance and degradation products were identified by LC/ESI-MS and comparison with reference standards. Further, on DAT123, samples were extracted as described above with an additional two ambient extraction steps, first with ethyl acetate and second with hexane. Radioactivity of the combined extracts was determined by LSC and found to be ≤ 0.9 percent AR for the CA soil and ≤ 2.1 percent for NE soil, demonstrating that the principal extraction method was effective at determining extracted residues. Parent and metabolite peaks from these samples were analysed for identification by LC/ESI-MS.

Soil extracts were stored for a maximum of two days at -10°C. Soil NER were stored for a maximum of four days under refrigerated conditions.

Mean material balances were 97.0 percent AR for CA soil and 96.8 percent AR for NE soil. Extracted residues decreased from 94.7 percent AR at DAT0 to 92.3 percent AR at DAT123 in CA soil and from 94.8 percent at DAT0 to 83.0 percent AR DAT123 in NE soil. NER increased from 0.2 percent at DAT0 to 3.4 percent AR at DAT123 in CA soil and from 0.3 percent at DAT0 to 10.7 percent AR at DAT123 in NE soil. Formation of carbon dioxide was ≤ 3.2 percent AR and other VOCs was ≤ 0.1 percent AR in both soil samples.

Trials showed similar trends at both application rates. The results are shown in Tables 46 and 47.

Isoflucypram was evaluated according to the FOCUS guidance document on degradation kinetics using the software KinGUI 2. Three different kinetic models were tested in order to determine the best-fit kinetic model (SFO, FOMC, and DFOP). The best-fit kinetic model was selected on the basis of the chi^2 scaled-error criterion and visual assessment of the goodness of fit. DT_{50}, DT_{75}, and DT_{90} values were calculated from the resulting kinetic parameters.

The degradation of isoflucypram was best fit with SFO kinetics in all soils according to the lowest chi^2 error values and visual assessments (Table 48). Another proposal of degradation of isoflucypuram in soil is shown in Figure 8.

Table 48 Summary of the kinetic evaluation (for trigger values according to FOCUS) of the degradation of isoflucypram in soils under aerobic conditions

Soil Texture (USDA)	Kinetic Model[1]	DT_{50} (Days)	DT_{75} (Days)	DT_{90} (Days)	Chi^2 Error[2] (percent)	Visual Assessment

[2] Best fit highlighted in bold font.

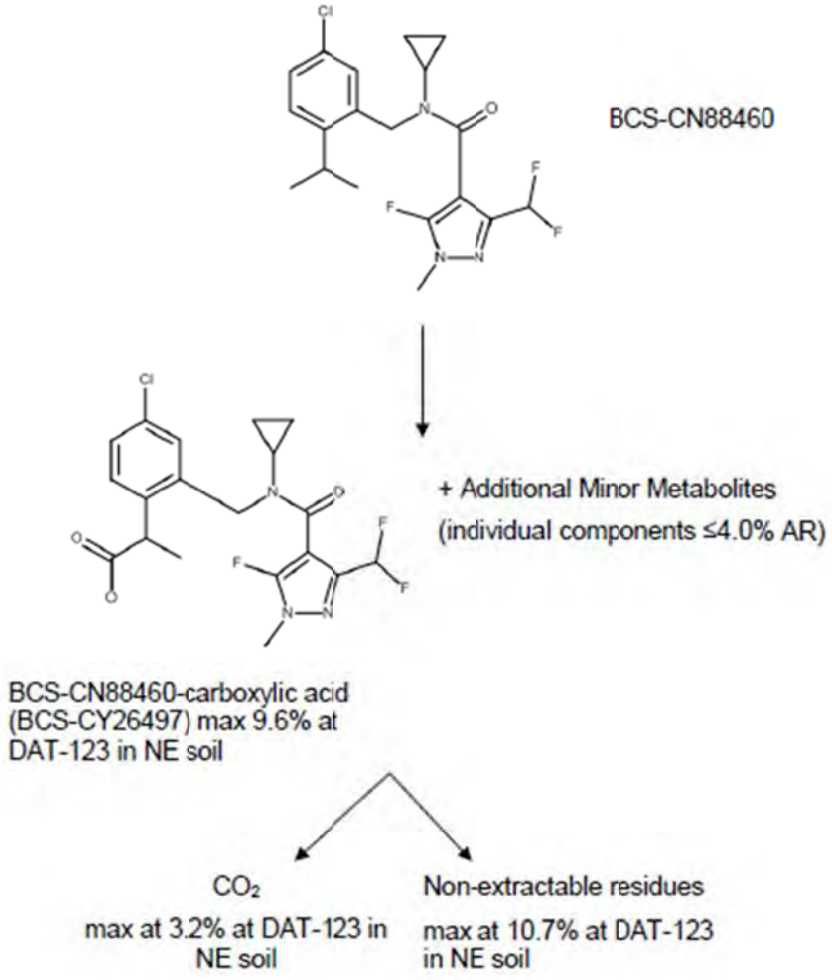

Figure 8 Metabolic/degradation pathway of isoflucypram (BCS-CN88460) in soil

Report No. EnSa-16-0986.

The route and rate of degradation including the radiolabelled testing of the simplified extraction method of [phenyl-UL-^{14}C] isoflucypram were studied (Heinemann, O., *et. al.*, 2017). Samples were maintained under aerobic conditions in the dark in the laboratory for 125 days at 20 °C. Samples were maintained at 55 percent of the maximum water holding capacity. The application rate was 75 g ai/ha, corresponding to

a concentration of 18.8 µg ai/kg soil dry weight. Soil was collected from the top 20 cm and sieved to a particle size of ≤ 2 mm (Table 49.

Table 49 Soil properties for aerobic metabolism study for isoflucypram

Soil	Source	Texture	pH[1]	OC (percent)
Laacher Hof AXXa	Monheim, Germany	Loamy sand	5.8	1.6

Notes:

[1] pH value was derived from aqueous 0.01M $CaCl_2$ suspension.

Tests were performed in incubation vessels with 100 g soil (dry weight equivalents) equipped with oxygen-permeable PU and soda lime traps for VOCs and CO_2, respectively. Water loss from evaporation was determined by weighing all test systems at study start and each sampling interval from DAT14 onwards. The evaporated portion was replaced accordingly by addition of de-ionized water after 28, 50, and 85 days of incubation. No significant losses of moisture were observed throughout the study. Determinations of microbial biomass were performed on DAT0, 65, and 125 and demonstrated that the used soil was microbially viable. Duplicate samples were processed and analysed on DAT0, 2, 6, 14, 28, 50, 65, 85, 100, and 125.

Prior to processing of soil, possible volatiles were purged into the trap attachment and the trap attachment was removed. CO_2 was released from the soda lime with HCl and re-absorbed to a scintillation cocktail for LSC. VOCs were released with ethyl acetate. No chromatographic analyses were performed for VOCs due to low radioactivity (≤ 0.1 percent AR).

At each sampling interval, the soil was extracted three times at ambient temperature using ACN/water (1:1). Furthermore, two microwave-assisted extraction steps were performed using ACN/water (1:1) at 70 °C and MeOH/water (1:1) at 50 °C. The amounts of test item and degradation products in soil extracts were determined by LSC and by HPLC/radiodetection analysis. The amounts of volatiles and non-extracted residues were determined by LSC and combustion/LSC, respectively.

Test item identity was confirmed by HPLC-MS(/MS) including accurate mass determination and degradation products were identified by co-chromatography with reference items. Additionally, samples were processed and analysed on DAT0, 65, and 125 using a simplified extraction method and compared to the exhaustive extraction method (Table 50). The simplified extraction method involved ACN:water:acetic acid (400:100:3) for LSC. The simplified extraction process was not used for sample analysis.

Table 50 Extraction efficiencies of the simplified and exhaustive extraction methods in soils Laacher Hof AXXa and Dollendorf II, in percent of applied radioactivity (mean ± SD)

Difference: 18.9		Difference: 25.7		Difference: 18.5	

Soil samples were stored for a maximum of three days in the dark. Soda lime and PU were stored for a maximum of 22 days. Soil NER were stored for a maximum of three days in the dark.

The material balances ranged from 101 to 105 percent AR. The maximum amount of CO_2 was 5.2 percent AR at study end (DAT125). Formation of VOCs was insignificant as demonstrated by values of ≤ 0.1 percent AR at all sampling intervals. Extracted residues decreased from DAT0 to DAT125 from 100 to 92.0 percent AR. NER increased from DAT0 to DAT125 from 0.7 to 6.4 percent AR. The amount of isoflucypram in the soil extracts decreased from DAT0 to DAT125 from 100 to 75.5 percent AR (Table 51).

Aerobic degradation and time-dependent sorption

Report No. EnSa-19-0236

The Meeting received a study investigating the degradation and time-dependence of sorption of [phenyl-UL-^{14}C] isoflucypram (Hellpointner, E., *et. al.*; 2019). Isoflucypram was studied in six soils under aerobic conditions in the laboratory in the dark at 20 °C for 120 days. Samples were maintained at 55 percent of the maximum water holding capacity. The application rate was 75 g ai/ha, corresponding to a

concentration of 204.8 µg ai/kg soil dry weight. Soil was collected from the top 20 cm and sieved to a particle size of ≤ 2 mm (Table 53).

Table 53 Soil properties

Soil	Source	Texture (USDA)	pH[1]	% organic content
Laacher Hof AXXa	Monheim, Germany	Sandy loam	6.9	1.7
Hoefchen am Hohenseh 4a	Burscheid, Germany	Silt loam	5.8	2.3

Frankenforst	Vinxel, Germany	Silt loam	6.9	3.3

Notes:

[1] pH values were derived from aqueous 0.01 mol/L $CaCl_2$ suspensions.

Tests were performed in incubation vessels with 100 g soil (dry weight equivalents) equipped with oxygen-permeable PU and soda lime traps for VOCs and CO_2, respectively.

Water loss from evaporation was determined by weighing test systems DAT64 and DAT98. The evaporated portion was replaced accordingly by addition of de-ionized water. No significant losses of moisture were observed throughout the study.

Determinations of microbial biomass were performed on DAT0 demonstrated that the soil was microbially viable. Duplicate samples were processed and analysed on DAT0, 3, 7, 14, 28, 49, 70, 84, 98, and 120.

Prior to processing of soil, possible volatiles were purged into the trap attachment and the trap attachment was removed. CO_2 was released from the soda lime with HCl and re-absorbed to a scintillation cocktail for LSC. VOCs were released with ethyl acetate. No chromatographic analyses were performed for VOCs due to low radioactivity (≤ 0.1 percent AR).

At each sampling interval, the soil was extracted three times at ambient temperature; first with 0.01 mol/L $CaCl_2$ followed by two extractions with ACN/water (1:1). Furthermore, two microwave-assisted extraction steps were performed using ACN/water (1:1) at 70°C and MeOH at 50 °C. The amounts of test item and degradation products in soil extracts were determined by LSC and by HPLC/radiodetection analysis. The amounts of volatiles and non-extracted residues were determined by LSC and combustion/LSC, respectively.

Test item identity and degradation products were confirmed by HPLC-MS(/MS) including accurate mass determination.

Mean material balances were 97.9 percent AR for soil Laacher Hof AXXa, 98.8 percent AR for soil Hoefchen am Hohenseh 4a, 98.8 percent AR for soil Hanscheider Hof, 98.1 AR for soil Dollendorf II, 98.1 percent AR for soil Wurmwiese, and 98.1 percent for soil Frankenforst.

Desorbable residues in aqueous 0.01 mol/L $CaCl_2$ solution slightly increased from DAT0 to DAT120 from 15.6 percent to 16.0 percent AR in soil Laacher Hof AXXa, from 4.7 percent to 7.0 percent in soil Dollendorf, from 7.5 percent to 9.8 percent AR in soil Frankenforst, and decreased from 10.5 percent to 9.5 percent AR in soil Hoefchen am Hohenseh 4a, from 5.7 percent to 3.8 percent AR in soil Hanscheider Hof, and from 11.8 percent to 9.5 percent AR in soil Wurmwiese. The results for all soils are shown in Table 54.

Notes:

[1] Replicate 2 of DAT28 is an outlier and was therefore excluded from the evaluation as reanalysis of the soil extracts gave the same results as the first analysis.

Isoflucypram was evaluated according to the FOCUS guidance document on degradation kinetics using the software KinGUI 2. Three different kinetic models were tested in order to determine the best-fit kinetic model (SFO, FOMC, and DFOP). The best-fit kinetic model was selected on the basis of the chi^2 scaled-error criterion and visual assessment of the goodness of fit. DT_{50} and DT_{90} values were calculated from the resulting kinetic parameters (Table 56).

The degradation of isoflucypram was best fit with SFO kinetics in all soils according to the lowest chi^2 error values and visual assessments.

Table 56 Summary of kinetic evaluation (for trigger values according to FOCUS) of the degradation of isoflucypram in soil under aerobic conditions

Soil	Kinetic Model[1,2]	DT_{50}	DT_{90}	Chi^2 Error	Visual Assessment

Aerobic metabolism/degradation in soil: isoflucypram-carboxylic acid

Report No. S19-22674.

The Meeting received a study investigating the degradation of the isoflucypram-carboxylic acid in laboratory soil (Schwarzkopf, A.; 2020). The degradation of the test item was investigated in five different soils (Laacher Hof AXXa, Dollendorf II, Hoefchen Am Hohenseh 4a, Laacher Hof Wurmwiese, and Hanscheider Hof) under aerobic conditions at 20 °C in the dark. The five soils were chosen to represent diverse agricultural soils. The nominal application rate was 4.12 µg test item/100 g dry soil (actual application rate = 4.68 µg test item/100 g dry soil). This rate was selected based on 2× the value of expected test item in the field based on the application rate for isoflucypram to cereal grains (0.075 kg ai/ha) and maximum formation rate of the degradate based on radiolabelled aerobic soil metabolism studies (9.6 percent AR). This calculation accounted for metabolite weight conversion (1.07×) and assumed homogenous distribution in soil to a depth of 2.5 cm and a soil density of 1.5 g/cm^3. Samples were analysed for isoflucypram-carboxylic acid at various intervals for a period up to DAT120.

Table 57 Summary of soil characteristics

Soil	Soil ID	Source Location	Texture (USDA)	pH: $CaCl_2$ (0.01 M)	% organic content
Laacher Hof AXXa	AX	Monheim, Germany	Sandy loam	6.8	1.6
Dollendorf II	DD	Blankenheim, Germany	Loam	7.4	3.8
Hofchen am Hohenseh	HH	Burscheid, Germany	Silt loam	5.8	2.0
Wurmweise	WW	Monheim, Germany	Loam	5.1	2.0
Hanscheider Hof	HN	Burscheid, Germany	Silt loam	5.4	2.9

Soil in the field was collected from 0–20 cm, passed through a 2mm sieve, and shipped under ambient conditions. For the test systems, 100 g soil (dry weight basis) were used. The average soil moisture content was maintained at approximately 55 percent of the maximum water holding capacity (MWHC) over the entire period of the study.

The biological activity was checked directly after arrival at the test facility, at the start, after 30 days, after 60 days, and at the end of incubation. Soil microbial activity ranged from 25.1–104.7 mg C/100g DS. Flasks were closed with a PU plug with passive diffusion of oxygen. Duplicate test vessels were sampled on DAT0, 1, 3, 7, 14, 30, 60, and 120.

Samples were stored for a maximum of 108 days at -18 °C. The entire soil per flask was extracted three times with ACN:water (1:1) at ambient temperature, followed by an extraction with ACN:water (1:1) at 70°C, followed by an extraction with MeOH:water (1:1) at 50 °C. Each extraction step was followed with centrifugation and all extracts were combined. Internal standard was added and samples were analysed by LC-MS/MS. The LOQ was 0.060 ng/mL (0.0023 mg/kg). Calibration curves were established with coefficients of correlation >0.99. Method validation was performed successfully within the study. In addition, the extraction efficiency during the study was demonstrated by concurrent recovery samples. Successful recoveries were observed at the LOQ and at 22× LOQ.

Blank samples were taken from Laacher Hof AXXa and analysed alongside concurrent recovery samples. No residues above the limit of detection (LOD) were observed in black samples. Residues of isoflucypram-carboxylic acid during in dark soil is shown in Table 58.

Table 58 Residues of isoflucypram-carboxylic acid at multiple time points in dark soil at 20 °C

Notes:
[1] Average of 2-3 analyses.

Dissipation kinetics were modelled with the KinGUII software under the FOCUS Guideline. The degradation pathways evaluated were SFO, DFOP, FOMC, and Hockey Stick. The best representative model was chosen based on chi^2 error and goodness of fit (Table 59.

Table 59 Kinetic modelling for isoflucypram-carboxylic acid in dark soil at 20 °C

Soil Sample	Kinetic Model[1,2]	DT_{50} (Days)	DT_{90} (Days)	Chi^2 Error (%)	Visual Assessment
Laacher Hof AXXa	SFO	27.15	90.19	1.457	Good
	FOMC	26.5	95.07	1.334	Good
	DFOP	26.52	93.9	1.331	Good
	HS	27.15	90.19	1.679	Good
Dollendorf II	SFO	17.67	58.71	2.37	Good
	FOMC	16.78	65	1.797	Good
	DFOP	16.82	63.23	1.358	Good
	HS	17.18	61.5	1.584	Good
Hofchen am Hohenseh	SFO	33.03	109.7	7.411	Satisfactory
	FOMC	24.71	275.47	2.293	Good
	DFOP	24.48	197.3	2.756	Good
	HS	30.3	130.6	5.467	Satisfactory
Wurmweise	SFO	39.75	132	11.97	Satisfactory
	FOMC	21.08	>1,000	1.393	Good
	DFOP	20.17	265.4	1.327	Good
	HS	24.77	227.3	2.724	Good
Hanscheider Hof	SFO	39.42	130.9	10.07	Satisfactory
	FOMC	24.01	806.2	3.085	Good
	DFOP	25.16	218.3	3.478	Good
	HS	32.48	173.2	4.943	Good

Notes:
[1] SFO = single first order. FOMC = first order multicomponent. DFOP = double first order in parallel. HS = hockey stick.
[2] Best fit written with bold.

Terrestrial Field Dissipation

The Meeting received several terrestrial field dissipation studies evaluating the rate of degradation of isoflucypram and the rate of formation of the metabolite isoflucypram-carboxylic acid. Analytical reports included chromatograms showing defined symmetrical peaks.

Report No. 14-2750 (Germany)

Dissipation of isoflucypram was studied under aerobic field conditions (Heinemann, *et al.,* 2017). Field dissipation was examined in four replicate plots following application of an isoflucypram & prothioconazole EC 200 (50 g isoflucypram/ha) formulation to bare soil at one site in Burscheid, Germany. The application was made at a rate of 100 g isoflucypram/ha. Soil samples were collected prior to treatment and at various intervals after treatment up to a final sampling interval of DAT713. Rainfall was supplemented with irrigation as needed. The monthly mean air temperatures during the study were representative of average monthly mean temperatures. The plots did not have a slope and therefore run-off was not assessed. Soil characterisation samples were taken prior to application to a depth of 100 cm and sent under ambient conditions for analysis (Table 60).

Table 60 Summary of soil characteristics

Trial Number (Location)	Soil Depth (cm)	Type of Soil (USDA)	pH ($CaCl_2$)	pH (H_2O)	Organic Carbon (percent)
14-2750-01 (Bursheid, Germany)	0-30	Silt loam	5.3	5.4	1.0
	30-50	Silt loam	5.5	5.9	0.2
	50-75	Loam	5.7	6.0	0.1
	75-100	Sandy loam	5.9	6.2	0.0

At all sampling intervals, 16 soil cores were collected from the plots. Treated soil samples were collected to a depth of 10 cm on DAT0; to a depth of 40 cm on DAT3, 7, 13, 28, 70, and 91; and to a depth of 60 cm on DAT110, 160, 209, 370, 538, and 713. Control samples were taken on DAT0, 370, and 713.

Samples were frozen (-18 °C) within 24 hours of collection. Treated samples were stored for a maximum of 530 days. Each sample was separated into 10 cm horizons and homogenized. Samples were analysed according to Method 01432.

Two soil trays were laid out per plot for verification. Soil tray recoveries were in the range of 85-122 percent of the applied amount. Additionally, spray broth analysis resulted in recoveries of 93-102 percent of the intended amount. No quantifiable residues were observed in control samples. The results are shown in Table 61

Notes:

[1] Samples were also analysed for isoflucypram-carboxylic acid at segment depth 10-20 cm and isoflucypram and isoflucypram-carboxylic acid at segment depths 20-30, 30-40 cm, 40-50 cm, and 50-60 cm at select sampling intervals but were not reported due to residues <LOQ.

[2] Range from four replicate trials.

[3] Expressed in parent equivalents.

NA: Not analysed.

Report No. 14-2750 (United Kingdom).

Dissipation of isoflucypram was studied under aerobic field conditions (Heinemann, O., *et al.,*2017). Field dissipation was examined in four replicate plots following application of an isoflucypram & prothioconazole EC 200 (50 g isoflucypram/ha) formulation to bare soil at one site in Great Chishill, United Kingdom. The application was made at a rate of 100 g isoflucypram/ha. Soil samples were collected prior to treatment and at various intervals after treatment up to a final sampling interval of DAT749. Rainfall was supplemented with irrigation as needed. The monthly mean air temperatures during the study were representative of average monthly mean temperatures. The plots did not have a slope and therefore run-off was not assessed. Soil characterisation samples were taken prior to application to a depth of 100 cm and sent under ambient conditions for analysis (Table 62).

Table 62 Summary of soil characteristics

Trial Number (Location)	Soil Depth (cm)	Type of Soil (USDA)	pH ($CaCl_2$)	pH (H_2O)	Organic Carbon (percent)
14-2750-02 (Great Chishill, UK)	0-30	Clay loam	7.0	7.0	2.0
	30-50	Clay	7.5	7.7	0.2
	50-75	Clay	7.6	7.9	1.5
	75-100	Clay	7.6	7.8	1.9

At all sampling intervals, 16 soil cores were collected from the plots. Treated soil samples were collected to a depth of 10 cm on DAT0; to a depth of 40 cm on DAT4, 7, 14, 27, 67, and 111; and to a depth of 60 cm on DAT140, 168, 278, 402, 560, and 749. Control samples were taken on DAT -0 (prior to application) and DAT 402.

Samples were frozen (-18 °C) within 24 hours of collection. Treated samples were stored for a maximum of 597 days. Each sample was separated into 10 cm horizons and homogenized. Samples were analysed according to Method 01432. Two soil trays per plot were laid out for verification. Soil tray recoveries were in the range of 70–105 percent of the applied amount. Additionally, spray broth analysis resulted in recoveries of 91–102 percent of the intended amount. No quantifiable residues were observed in control samples (Table 63)

Report No. 14-2750 (Spain).

Dissipation of isoflucypram was studied under aerobic field conditions (Heinemann, O., *et al.,*2017). Field dissipation was examined in four replicate plots following application of an isoflucypram & prothioconazole EC 200 (50 g isoflucypram/ha) formulation to bare soil at one site in Vilobi d'Onyar, Spain. The application was made at a rate of 100 g isoflucypram/ha. Soil samples were collected prior to treatment and at various intervals after treatment up to a final sampling interval of DAT714. Rainfall was supplemented with irrigation as needed. The monthly mean air temperatures during the study were representative of average monthly mean temperatures. The plots did not have a slope and therefore run-off was not assessed. Soil characterisation samples were taken prior to application to a depth of 100 cm and sent under ambient conditions for analysis (Table 64).

Table 64 Summary of Soil Characteristics

Trial Number (Location)	Soil Depth (cm)	Type of Soil (USDA)	pH ($CaCl_2$)	pH (H_2O)	Organic Carbon (percent)
14-2750-06 (17185 Vilobi d'Onyar, Spain)	0-30	Loam	5.8	6.1	0.7
	30-50	Sandy clay loam	6.0	6.3	0.4
	50-75	Sandy clay loam	6.5	6.9	0.1
	75-100	Sandy clay loam	6.5	6.8	0.1

At all sampling intervals, 16 soil cores were collected from the plots. Treated soil samples were collected to a depth of 10 cm on DAT0; to a depth of 40 cm on DAT3, 7, 15, 30, 57, and 99; and to a depth of 60 cm on DAT120, 158, 224, 345, 533, and 714. Control samples were taken on DAT -0 (prior to application), 345, and 714.

Samples were frozen (-18 °C) within 24 hours of collection. Treated samples were stored for a maximum of 595 days. Each sample was separated into 10 cm horizons and homogenized. Samples were analysed according to Method 01432. Two soil trays per plot were laid out for verification. Soil tray recoveries were in the range of 62–101 percent of the applied amount. Additionally, spray broth analysis resulted in recoveries of 87–102 percent of the intended amount. No quantifiable residues were observed in control samples (Table 65).

Report No. 14-2750 (Italy).

Dissipation of isoflucypram was studied under aerobic field conditions (Heinemann, O., *et al.,* 2017). Field dissipation was examined in four replicate plots following application of an isoflucypram & prothioconazole EC 200 (50 g isoflucypram/ha) formulation to bare soil at one site in Albaro di Ronco all Adige, Italy. The application was made at a rate of 100 g isoflucypram/ha. Soil samples were collected prior to treatment and at various intervals after treatment up to a final sampling interval of DAT728. Rainfall was supplemented with irrigation as needed. The monthly mean air temperatures during the study were representative of average monthly mean temperatures. The plots did not have a slope and therefore run-off was not assessed. Soil characterisation samples were taken prior to application to a depth of 100 cm and sent under ambient conditions for analysis (Table 66).

Table 66 Summary of soil characteristics

Trial Number (Location)	Soil Depth (cm)	Type of Soil (USDA)	pH ($CaCl_2$)	pH (H_2O)	Organic Carbon (%)
14-2750-05 (Albaro di Ronco all Adige, Italy)	0-30	Clay	7.0	7.2	2.1
	30-50	Clay	7.1	7.3	1.6
	50-75	Clay	7.3	7.5	0.7
	75-100	Clay loam	7.2	7.6	0.6

At all sampling intervals, 16 soil cores were collected from the plots. Treated soil samples were collected to a depth of 10 cm on DAT0; to a depth of 40 cm on DAT3, 7, 14, 28, 62, and 89; and to a depth of 60 cm on DAT122, 157, 209, 369, 531, and 728. Control samples were taken on DAT -0 (prior to application), 359, and 728.

Samples were frozen (-18 °C) within 24 hours of collection. Treated samples were stored for a maximum of 272 days. Each sample was separated into 10 cm horizons and homogenized. Samples were analysed according to Method 01432.

Two soil trays per plot were laid out for verification. Soil tray recoveries were in the range of 83–99 percent of the applied amount. Additionally, spray broth analysis resulted in recoveries of 89–103 percent of the intended amount. No quantifiable residues were observed in control samples. The results are shown in Table 67.

Report No. 14-2750 (North France).

Dissipation of isoflucypram was studied under aerobic field conditions (Heinemann, O., *et al.,*2017). Field dissipation was examined in four replicate plots following application of an isoflucypram & prothioconazole EC 200 (50 g isoflucypram/ha) formulation to bare soil at one site in Parcay Meslay, France. The application was made at a rate of 100 g isoflucypram/ha. Soil samples were collected prior to treatment and at various intervals after treatment up to a final sampling interval of DAT701. Rainfall was supplemented with irrigation as needed. The monthly mean air temperatures during the study were representative of average monthly mean temperatures. The plots did not have a slope and therefore run-off was not assessed. Soil characterisation samples were taken prior to application to a depth of 100 cm and sent under ambient conditions for analysis (Table 70).

Table 70 Summary of Soil Characteristics

Trial Number (Location)	Soil Depth (cm)	Type of Soil (USDA)	pH ($CaCl_2$)	pH (H_2O)	Organic Carbon (%)
14-2750-03 (37210 Parcay Meslay, France)[1]	0-30	Loam	5.9	6.3	1.2
	30-50	Loam	6.1	6.5	0.5
	50-75	Clay loam	6.5	6.9	0.2
	75-100	Clay loam	6.4	6.8	0.2

Notes:

[1] The trials from Northern and Southern France are separated by approximately 325 miles and application dates are separated by 35 days and are therefore considered independent.

At all sampling intervals, 16 soil cores were collected from the plots. Treated soil samples were collected to a depth of 10 cm on DAT0; to a depth of 40 cm on DAT3, 7, 14, 29, 63, and 88; and to a depth of 60 cm on DAT121, 143, 210, 357, 519, and 701. Control samples were taken on DAT -0 (prior to application) and 357.

Samples were frozen (-18 °C) within 24 hours of collection. Treated samples were stored for a maximum of 532 days. Each sample was separated into 10 cm horizons and homogenized. Samples were analysed according to Method 01432.

Two soil trays per plot were laid out for verification. Soil tray recoveries were in the range of 63–119 of the applied amount. Additionally, spray broth analysis resulted in recoveries of 84–95 percent of the intended amount. No quantifiable residues were observed in control samples. The results are shown in Table 71.

Notes:

[1] Samples were also analysed for isoflucypram-carboxylic acid at segment depth 10-20 and isoflucypram and isoflucypram-carboxylic acid at segment depths 20-30 cm, 30-40 cm, and 50-60 cm.
[2] Range from four replicate trials.
[3] Expressed as parent equivalents.
NA: Not analysed.

Report No. 14-2750 (Kinetics).

Samples from trials 14-2750-01/02/03/04/05/06 were analysed for rate of degradation. Degradation kinetics were calculated using the FOCUS kinetics model. The model tested SFO, FOMC, and DFOP. DFOP was selected based on chi^2 and visual inspection. Degradation showed biphasic characteristics (Table 72).

Table 72 Kinetic modelling for isoflucypram in soil

Notes:
[1] SFO: Single First Order. FOMC: First Order Multicompartment. DFOP: Double First Order in Parallel.
[2] Best fits highlighted in bold.
[3] The trials from Northern and Southern France are separated by approximately 325 miles and application dates are separated by 35 days and are therefore considered independent.

Report No. MELNN203.

Dissipation of isoflucypram and isoflucypram-carboxylic acid were studied under aerobic field conditions (Harbin, A., 2019). Field dissipation was examined following broadcast applications of an isoflucypram EC 50 (50 g ai/L) formulation to bare soil at one site in Rosthern, Saskatchewan, Canada. The application was made at a nominal application rate of 150 g ai/ha (actual rate = 148 g ai/ha). Soil samples were collected prior to treatment and at various intervals after treatment up to a final sampling interval of DAT705. Rainfall was supplemented with irrigation as needed. The monthly mean air temperatures during the study were representative of average monthly mean temperatures. The plots did not have a slope and therefore run-off was not assessed. Soil characterisation samples were taken for control and treated plots to a depth of 105 cm, sectioned into 15 cm segments (Table 73).

Table 73 Soil properties for study MELNN203

Soil cores were collected from the treated plots on 0-DAT to a depth of 15 cm and at all other intervals (DAT -2 [prior to application], 6, 12, 27, 60, 96, 120, 336, 371, 434, 490, and 705) to a depth of 105 cm, which were subsequently split into 15 cm horizons. Samples for control analysis were collected at the control plot on DAT -2 (prior to application). Samples for the control plot were also collected on DAT0, 120, and 371, fortified in the field, shipped frozen to the analytical laboratory, and analysed for isoflucypram at all three intervals and for isoflucypram-carboxylic acid on DAT371.

Soil was frozen after sampling. Treated samples were stored for a maximum of 686 days. Analysis for verification pads was accomplished through Method LN-001-F15-01. Soil pans and treated samples were analysed according to Method 01432. An average of 91.3 percent (n=6) and 90.2 percent (n=3) of the expected active ingredient was recovered from solvent saturation pad monitors and soil pan application monitors, respectively. It is noted that 0.15 percent AR was recovered in the control for pan recovery. For both verification pads and pans, the soil was allowed to dry after application and shipped frozen for analysis. No quantifiable residues were observed in control samples. The results are shown in Table 74.

Notes:

[1] Samples were also analysed for isoflucypram-carboxylic acid at segment depth 15-30 cm and isoflucypram and isoflucypram-carboxylic acid at segment depths 30-45 and 45-60 cm but results were not reported due to residues <LOQ.

[2] Average of three samples.

The kinetics of isoflucypram degradation was evaluated using kinetic modelling (KinGUII2.1 under FOCUS guidance). Goodness of fit was determined by chi^2, visual assessment, and R^2. The FOMC model best fit the data. The DT_{50} value was 260 days, the DT_{75} was 776 days, and the DT_{90} was >1,000 days. Leaching was not a significant degradation pathway as residues were mainly found in the top 15 cm throughout the course of the study (Table 75).

Table 75 Kinetic modelling for isoflucypram in soil

Model[1,2]	DT_{50}	DT_{75}	DT_{90}	Chi^2	R^2	Visual Assessment
SFO	312	624	>1,000	15.87	0.497	Satisfactory
DFOP	254	586	>1,000	16.31	0.5096	Satisfactory
FOMC	259.5	776	>1,000	15.71[3]	0.5079[3]	Satisfactory

Notes:

[1] SFO: Single First Order. FOMC: First Order Multicompartment. DFOP: Double First Order in Parallel.

[2] Best fit highlighted in bold.

[3] Regarded as unreliable due to high Chi^2 and low R^2.

Report No. AUS-0032.

Dissipation of isoflucypram and isoflucypram-carboxylic acid were studied under aerobic field conditions (White, J., *et al.,*2018). Field dissipation was examined following broadcast application of an isoflucypram EC 50 (50 g ai/L) formulation to bare soil at one site in Richland, Iowa, United States. The application was made at a nominal/actual application rate of 150 g ai/ha. Soil samples were collected prior to treatment and at various intervals after treatment up to a final sampling interval of DAT518. Rainfall was supplemented with irrigation as needed. The monthly mean air temperatures during the study were representative of average monthly mean temperatures. The plots had a 0.5 percent slope and therefore run-off was not assessed. Disturbed soil characterisation samples were taken from treated plots to a depth of 120 cm, sectioned into 15 cm segments, and combined. Two disturbed soil cores were taken, one for bulk density and water holding capacity and one for morphology. Soil characteristics are shown in Table 76.

Notes:

[1] Samples were also analysed for isoflucypram-carboxylic acid at segment depths 15-30 cm and isoflucypram and isoflucypram-carboxylic acid at segment depths 30-45 cm and 45-60 cm but results were not reported due to residues <LOQ.

[2] Average of three samples.

NA = Not analysed.

The kinetics of isoflucypram degradation was evaluated using kinetic modelling (KinGUII2.1 under FOCUS guidance). Goodness of fit was determined by chi^2, visual assessment, and R^2. The FOMC model best fit the data. The DT_{50} value was 31 days, the DT_{75} was 114 days, and the DT_{90} was 471 days. Leaching was not a significant degradation pathway as residues were mainly found in the top 15 cm throughout the course of the study (Table 84).

Table 84 Kinetic modelling for isoflucypram in soil

Model[1,2]	DT_{50}	DT_{75}	DT_{90}	Chi^2	R^2	Visual Assessment
SFO	50.12	100.2	166.5	24.40	0.7964	Satisfactory
DFOP	30.96	108.3	495.6	8.793	0.8289	Good
FOMC	30.78	113.8	470.8	9.311	0.8267	Good

Notes:

[2] Best fit highlighted in bold.

Report No. AUS-0034.

Dissipation of isoflucypram and isoflucypram-carboxylic acid were studied under aerobic field conditions (White, J., *et al.,* 2018). Field dissipation was examined following two broadcast applications of an isoflucypram EC 50 (50 g ai/L) formulation to bare soil and turf grass at one site in Chula, Georgia, United States. The first application was made at a nominal application rate of 350 g ai/ha (actual application rate = 347 g ai/ha). The second application was made 120 days after the first application at a nominal application rate of 150 g ai/ha (actual application rate = 154–155 g ai/ha). Soil samples were collected prior to the first treatment and at various intervals following the first and second applications. The final sampling interval was DAT1-635 (DAT2-515). Rainfall was supplemented with irrigation as needed. The monthly mean air temperatures during the study were representative of average monthly mean temperatures. The plots had a slope of ~2 percent and therefore run-off was not assessed. Disturbed soil characterisation samples were taken from both treated plots to a depth of 120 cm, sectioned into 15 cm segments, and combined. Two disturbed soil cores were taken from each treated plot, one for bulk density and water holding capacity and one for morphology. Soil characterisation is shown in Table 85

Soil cores were collected from the treated plots on DAT1-0 and 120 (i.e., DAT2-0) to a depth of 15 cm. Samples at all other intervals (DAT1 -5 [prior to application], 0, 7, 14, 29, 62, 90, 119, 120, 127, 134, 148, 181, 211, 244, 301, 391, 401, 490, 566, 587, and 635) were collected to a depth of 120 cm. Samples from the bare soil plot were split into 15 cm horizons. Samples from turf plot were split into a 0-7.5 cm horizon, a 7.5-15 cm horizon, and 15 cm horizons for the remainder of the sample. Samples for control analysis were collected at the control plot on DAT1 -5 (prior to application), 0, and 120.

Soil was frozen after sampling. Treated samples were stored for a maximum of 514 days. Analysis for verification pads was accomplished through Method LN-001-F15-01. Soil pans and treated samples were analysed according to Method 01432.

The theoretical application rate for the spray solution calibration was 99.3 percent for the first application and 103.3 percent for the second application. For application pads, an average of 101.3 percent (n=6) and 93.5 percent (n=6) of the expected active ingredient was recovered from both treated plots following application one and two, respectively. For application pans, an average of 95.9 percent (n=6) and 95.0 percent (n=6) of the expected active ingredient was recovered from both treated plots following application one and two, respectively. Soil was allowed to dry after application before analysed. There were no quantifiable residues in control samples. The results are shown in Tables 86 and 87.

The kinetics of isoflucypram degradation was evaluated in both soil and turf grass using kinetic modelling (KinGUII2.1 under FOCUS guidance). Goodness of fit was determined by chi^2, visual assessment, and R^2. For the bare soil plot, SFO most closely matched the first application and FOMC most closely matched the second application. For the turf plot, SFO most closely matched following the first application and DFOP most closely matched following the second application. Leaching was not a significant degradation pathway as residues were mainly found in the top 15 cm throughout the course of the study (Table 88).

Report No. AUS-0033.

Dissipation of isoflucypram and isoflucypram-carboxylic acid were studied under aerobic field conditions (White, J., *et al.,* 2018). Field dissipation was examined following two broadcast applications of an isoflucypram EC 50 (50 g ai/L) formulation to bare soil and turf grass at one site in North Rose, New York, United States. The first application was made at a nominal application rate of 350 g ai/ha (actual application rate = 360 [bare soil] and 345 [turf] g ai/ha). The second application was made 121 days after the first application at a nominal application rate of 150 g ai/ha (actual application rate = 148–149 g ai/ha). Soil samples were collected prior to the first treatment and at various intervals after the first and second treatments. The final collection interval was DAT1-832 (DAT2-707). Rainfall was supplemented with irrigation as needed. The monthly mean air temperatures during the study were representative of average monthly mean temperatures. The plots had a slope of ≤1 percent and therefore run-off was not assessed. Three disturbed soil characterisation samples were taken from each treated plot to a depth of 120 cm, sectioned into 15 cm segments, and combined. Two disturbed soil cores were taken from each treated plot, one for bulk density and water holding capacity and one for morphology. Soil characterisation is shown in Table 89.

Soil cores were collected from the treated plots on DAT1-0 and 120 (i.e., DAT2-0) to a depth of 15 cm. Samples at all other intervals (DAT1 -4 [prior to application], 0, 7, 14, 28, 59, 90, 120, 121, 128, 135, 149, 181, 211, 241, 301, 392, 487, 570, 662, and 828 DAT1) were collected to a depth of 120 cm. Samples from the bare soil plot were split into 15 cm horizons and samples from turf plot were split into a 0–7.5 cm horizon, a 7.5–15 cm horizon, and 15 cm horizons for the remainder of the samples. Samples for control analysis were collected at the control plot on DAT1 -4 (prior to application), 0, and 121.

Soil was frozen after sampling. Treated samples were stored for a maximum of 509 days. Analysis for verification pads was accomplished through Method LN-001-F15-01. Soil pans and treated samples were analysed according to Method 01432.

The theoretical application rate for the spray solution calibration was 100 percent for the first application and 99 percent for the second application. For application pads, an average of 101.3 percent (n=6) and 72.2 percent (n=6) of the expected active ingredient was recovered from both treated plots following application one and two, respectively. For application pans, an average of 37.5 percent (n=6) and 34.7 percent (n=6) of the expected active ingredient was recovered from both treated plots following application one and two, respectively. The soil was allowed to dry after application before analysed analysis. There were no quantifiable residues in control samples. The results are shown in Tables 90 and 91.

The kinetics of isoflucypram degradation was evaluated in both soils using kinetic modelling (KinGUII2.1 under FOCUS guidance). Goodness of fit was determined by chi^2, visual assessment, and R^2. For both plots and applications, the kinetic modelling followed SFO most closely. Leaching was not a significant degradation pathway as residues were mainly found in the top soil segments throughout the course of the study. The results are shown in Table 92.

ANIMAL METABOLISM

The Meeting received studies describing the metabolism of isoflucypram in lactating goats and laying hens. Additionally, a brief summary of the WHO's review of metabolism of isoflucypram in laboratory rats is given.

Laboratory Rats

The WHO received studies investigating the absorption, distribution, metabolism, and excretion (ADME) of isoflucypram in rats. One study evaluated a single dose of [pyrazole-4-^{14}C] isoflucypram at 2 or 200 mg/kg bw and a single 2 mg/kg bw dose after bile duct cannulation by oral gavage. A second study evaluated a single dose of [phenyl-UL-^{14}C] isoflucypram at 2 mg/kg bw. Additionally, whole-body autoradiography studies were conducted with both radiolabels.

The absorption of [pyrazole-4-^{14}C] and [phenyl-UL-^{14}C] isoflucypram started immediately after administration, demonstrated by the observed maximum plasma concentration (Cmax) within 1 hour (tmax) our administration for the low dose experiments and within 2/4 hours (male/female) for the pyrazole high dose experiment. Radioactivity could be detected in all plasma samples until 72 hours after dosing, the latest time of plasma sampling, with values ≤ 3.1 percent of the maximum plasma concentration measured, indicating quick elimination. Low dose pyrazole studies with bile-duct cannulated rats showed that 74 percent/82 percent (male/female) of the dose was detected in the bile.

Isoflucypram-cyclopropyl-pyrazole-carboxamide (M58) and isoflucypram-desmethyl-carboxylic acid (M11) were observed at much higher concentrations than isoflucypram. Other metabolites measured in rats were observed at similar or higher concentrations than the parent compound in plasma.

In the pyrazole study, the low dose female rats showed lower organ concentrations compared to male rats, whereas In the phenyl study, radioactivity in organs and tissues of male and female rats was in the same order of magnitude. Radioactivity in bodies (excluding the gastrointestinal tract) amounted to 0.152–0.365 percent of the administered dose in the pyrazole studies and 0.234–0.290 percent of the administered dose in the phenyl studies. The highest concentration of radioactivity was detected in the liver, followed by blood cells, followed by other tissues.

The whole-body autoradiography studies demonstrated that radioactivity was widely distributed among tissues immediately after dosing. Radioactivity was observed predominantly in the liver and kidney. Absorbed radioactivity was quickly and efficiently eliminated within 72 hours after administration.

Excretion was almost completed 72 hours after administration. The main excretion route was faeces, with less radioactivity eliminated through urine. In bile-duct cannulated rats, radioactivity was observed primarily in bile, followed by faeces, followed by urine, indicating that the major elimination route is faeces through bile. An observed lower urinary excretion rate in the high dose pyrazole studies indicates lower absorption of isoflucypram at higher dose rates.

A high number of metabolites were identified in urine, faeces, and bile, suggesting thorough metabolism in rats. Metabolites and conjugates identified at levels >10 percent of the absorbed dose were:

- Isoflucypram-carboxylic acid;
- Isoflucypram-desmethyl;
- Isoflucypram-desmethyl-propanol;
- Isoflucypram-desmethyl-carboxylic acid;
- Isoflucypram-desmethyl-hydroxyphenyl-1,2-propandiol;
- Isoflucypram-desmethyl-hydroxymethyl-carboxylic acid;
- Isoflucypram-propanol-GlucA (isomer 1);
- Isoflucypram-desmethyl-GlucA (isomer 1 and 2);
- Isoflucypram-desmethyl-OH-GlucA (isomer 2);
- Isoflucypram-desmethyl-diOH-GlucA (group of isomers).

Lactating Goats

Report Nos. EnSa-17-0309 and EnSa-17-0308.

The metabolism and excretion of [pyrazole-4-1^{4}C] Isoflucypram and [phenyl-UL-^{14}C] Isoflucypram were investigated in lactating goats (Bongartz *et al*., 2017). The test compounds were orally administered in gelatine capsules at a dose level of 1 mg/kg bw/day to two goats, corresponding to 45.19 ppm and 20.57 ppm in dry feed per day for the pyrazole and phenyl labels, respectively. The goats were dosed once daily (morning) for five consecutive days and were sacrificed approximately six hours after the final dosing. The goats were milked in the morning immediately prior to each dose administration, about eight hours later in the afternoon, and approximately one hour before sacrifice. TRR was determined in each milk sample, as well as liver, kidney, muscle (pooled round and loin), and fat (pooled perirenal and omental; pyrazole only). Additionally, the total radioactivity (percent of total administered dose) was determined in each urine and faeces sample. The phenyl label goat did not have fat for analysis. The goat was healthy according to veterinarian investigation during acclimation and testing period and did not show any abnormality with regard to feed consumption, weight, and common behaviour.

All fractions were minced (if necessary) and measured for radioactivity by LSC. The overall recovery accounted for 64 percent and 51 percent of the administered dose for pyrazole and phenyl labels, respectively. The remaining amount of radioactivity was postulated to still be present in the non-edible part of the animal body and especially in the gastrointestinal tract at sacrifice due to the short time period between last administration and sacrifice. At the time of sacrifice, a cumulative total of 6.94/9.8 percent (pyrazole/phenyl) and 56.09/40.08 percent (pyrazole/phenyl) of the administered dose was excreted in urine and faeces, respectively, with an observed linear increase following one (pyrazole) or

three (phenyl) days after the first dose. Approximately 0.03 percent (pyrazole) and 0.06 percent (phenyl) of the administered dose was secreted with milk, correlating to TRRs ranging from 0.009–0.021 mg eq/kg (pyrazole) and 0.008–0.016 mg eq/kg (phenyl) per individual sample. Per-day pooled milk samples (evening sample plus following day pre-dose sample) reached a plateau after three days. At sacrifice, the sum of radioactive residues in edible fractions was 0.72 percent (pyrazole) and 0.27 percent (phenyl) of the administered dose (AD), correlating to TRRs of 0.717 mg eq/kg (pyrazole) and 0.348 mg eq/kg (phenyl) in liver, 0.189 mg eq/kg (pyrazole) and 0.183 mg eq/kg (phenyl) in kidney, 0.038 mg eq/kg (pyrazole) and 0.011 (phenyl) mg eq/kg for muscle, and 0.102 mg eq/kg in fat (pyrazole only; no fat analysed in phenyl study). The results are shown in Table 93.

Table 93 TRR for lactating goats dosed with isoflucypram

	[Pyrazole-4-^{14}C][1]		[Phenyl-UL-^{14}C]	
Sample	% AD	TRR (mg eq/kg)	% AD	TRR (mg eq/kg)

Notes:

[1] Pyrazole reference: EnSa-17-0309. Phenyl reference: EnSa-17-0308.

[2] Per-day pooled milk samples from Day 1-4 consists of combined milking eight hours and 24-hours post-dose. The day five milk sample consists of one sample collected approximately five hours post-dose, just before slaughter.

NA = not analysed

Samples for all matrices except urine were extracted 2–3× with ACN/water (8/2). In the pyrazole study, milk was additionally extracted once with THF (3/7) and ACN/water (3/7). Conventional extraction released 89.2–98.7 percent (pyrazole) and 88.3–100.0 percent (phenyl) TRR. All samples from the pyrazole study and liver and kidney extracts from the phenyl study were partitioned against n-heptane. The extracts of milk and muscle were purified with SPE cartridges and a subsequent phase separation with NaCl. In edible fractions, very low amounts of radioactivity were detected in the n-heptane organic phase (≤1.4 percent; ≤ 0.002 mg eq/kg). In edible fractions, concentration of the aqueous phases caused minor losses of radioactivity (≤6.3 percent TRR; ≤ 0.009 mg eq/kg).

In muscle from the pyrazole study and liver from both labels, the solids after conventional extraction were exhaustively extracted using ACN/water, microwave assistance, and HCl in the extract of liver from the pyrazole study. Exhaustive extraction in these matrices released an additional 4.3–4.9 percent TRR (pyrazole) and 3.5 percent TRR (phenyl). In all matrices, up to 7.8 percent TRR (0.036 mg eq/kg) [pyrazole] and 8.2 percent TRR (0.029 mg eq/kg) [phenyl] remained in the PES.

The conventional liver and kidney extract were incubated, separately, for 20 hours at 37 °C with β-glucuronidase and arylsulfatase and analysed by HPLC for comparison of the metabolite profile with the pre-hydrolysis extract. Additionally, aliquots of isoflucypram-propenol-GlucA and isoflucypram-propanol-GlucA (isomer 1 and 2) isolated from goat urine [24–48 hours] from the phenyl study were incubated with

ß-glucuronidase and arylsulfatase for four or 20 hours, respectively, at 37 °C. After purification the digested metabolites were analysed by HPLC.

Residue components of the conventional and exhaustive extracts were analysed by HPLC and thin-layer chromatography (TLC), respectively. Compounds were identified and by co-chromatography with reference standards.

Samples were stored for a maximum of three months in the pyrazole study. Comparison of initial extract with extract stored 13 and 14 months in liver and kidney, respectively, showed no degradation. Also, repeat analysis of muscle, fat, and kidney after 25, nine, and nine months, respectively, demonstrated stability of peaks.

Samples were stored for a maximum of four months in the phenyl study. Comparison of initial extract with extract stored 11 months (liver) showed no degradation. Also, repeat analysis of muscle, liver, and kidney after 16, six, and 20 months, respectively, demonstrated stability of peaks.

In milk samples pooled from 32–101 hours post first dose (correlating with the plateau level), parent isoflucypram was the predominant residue at 33.4 percent TRR (0.005 mg/kg) [pyrazole] and 33.9 percent TRR (0.004 mg/kg) [phenyl]. Isoflucypram-2-propanol was observed at 20.3 percent TRR (0.003 mg eq/kg) [pyrazole] and 5.0 percent TRR (0.001 mg eq/kg) [phenyl]. Isoflucypram-desmethyl-propanol and isoflucypram-propanol-GlucA (isomers 1 and 2) were minor metabolites, each accounting for ≤ 6.7 percent TRR (≤ 0.001 mg eq/kg) in the phenyl study and not detected in the pyrazole study. Up to three peaks each accounting for ≤ 38.6 percent TRR (≤ 0.005 mg eq/kg) were characterized based on chromatographic behaviour. When separated between cream and skim fractions, the majority of the radioactivity (approximately 87 percent TRR) remained in the skimmed milk fraction in the pyrazole study, whereas the radioactivity was essentially evenly distributed between the two fractions in the phenyl study, as determined by TLC. Figure 9 shows the TRRs in milk thought the study and Tables 94 and 95 the identification and characterization of the residues

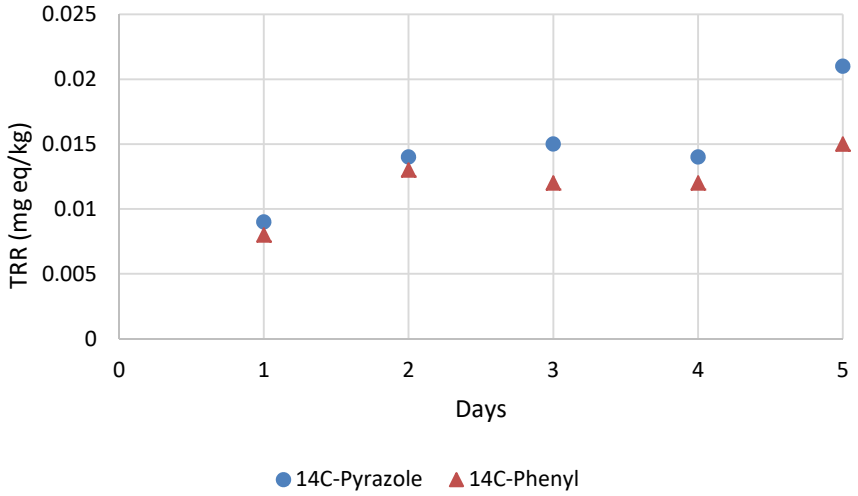

Figure 9 Concentration of TRR in milk following dosing with radiolabelled isoflucypram.

Notes:
* Residues are the average of samples from the evening and following morning, except Day 5, which are only from the evening sample.

In pooled muscle, isoflucypram was the predominant residue at 22.3 percent TRR (0.008 mg/kg) [pyrazole] and 21.5 percent TRR (0.002 mg eq/kg) [phenyl]. Other major metabolites included isoflucypram-2-propanol accounting for 17.9 percent TRR (0.006 mg eq/kg) [pyrazole] and 14.2 percent YTT (0.002 mg eq/kg) [phenyl] and isoflucypram-propanol accounting for 10.2 percent TRR (0.004 mg eq/kg) [pyrazole] and 9.0 percent TRR (0.001 mg eq/kg) [phenyl].

Minor metabolites included isoflucypram-carboxylic acid, isoflucypram-propanol-GlucA (isomer 2), and isoflucypram-desmethyl-propanol (≤9.0 percent TRR; ≤ 0.003 percent mg eq/kg). Up to five peaks (≤ 25 percent TRR; ≤ 0.003 mg eq/kg) were characterised based on the chromatographic behaviour in the conventional extract. In the pyrazole exhaustive ACN/water extract, five minor compounds (≤ 1.6 percent TRR; ≤ 0.001 mg eq/kg) were characterised based on the chromatographic behaviour using TLC (Table 95).

In pooled fat, isoflucypram was the predominant residue at 58.7 percent TRR (0.061 mg/kg). Isoflucypram-2-propanol was a major metabolite accounting for 0.017 mg eq/kg (16.8 percent TRR). Minor metabolites included isoflucypram-carboxylic acid and isoflucypram-propanol (≤ 0.003 mg eq/kg; ≤ 3.3 percent TRR). Four minor peaks (≤ 0.008 mg eq/kg; ≤ 7.5 percent TRR) were characterised based on the chromatographic behaviour using HPLC (Table 97).

In liver, isoflucypram accounted for 3.5 percent TRR (0.025 mg/kg) [pyrazole] and 5.3 percent TRR (0.018 mg/kg) [phenyl]. In the conventional extract, major metabolites included isoflucypram-2-propanol-GlucA accounting for 13.8 percent TRR (0.099 mg eq/kg) [pyrazole] and 13.0 percent TRR (0.045 mg eq/kg) [phenyl], isoflucypram-propanol-GlucA (isomer 1) accounting for 13.1 percent TRR

(0.094 mg eq/kg) [pyrazole] and 8.8 percent TRR (0.031 mg eq/kg) [phenyl], isoflucypram-propanol-GlucA (isomer 2) accounting for 7.7 percent TRR (0.055 mg eq/kg) [pyrazole] and 5.9 percent TRR (0.021 mg eq/kg) [phenyl], isoflucypram-carboxylic acid accounting for 8.9 percent TRR (0.064 mg eq/kg) [pyrazole] and 4.2 percent TRR (0.015 mg eq/kg) [phenyl], isoflucypram-propanol accounting for 5.8 percent TRR (0.042 mg eq/kg) [pyrazole] and 4.9 percent TRR (0.017 mg eq/kg) [phenyl], isoflucypram-2-propanol accounting for 2.6 percent TRR (0.019 mg eq/kg) [pyrazole] and 2.8 percent TRR (0.010 mg eq/kg) [phenyl], and isoflucypram-lactic acid accounting 1.6 percent TRR (0.011 mg eq/kg) [pyrazole] and 1.3 percent TRR (0.005 mg eq/kg) [phenyl]. The minor metabolites isoflucypram-desmethyl-carboxylic acid and isoflucypram-desmethyl-propanol accounted for ≤ 0.9 percent TRR (≤ 0.007 mg eq/kg).

Up to eighteen peaks, each accounting for ≤ 6.7 percent TRR (≤ 0.029 mg eq/kg), were characterised based on chromatographic behaviour using HPLC. In the exhaustive ACN/water extract, up to 11 minor compounds each accounting for ≤ 1.7 percent TRR (≤ 0.007 mg eq/kg), and in the exhaustive HCl extract, four peaks each accounting for ≤ 2.3 percent TRR (≤ 0.017 mg eq/kg) of the TRR), were characterised based on the chromatographic behaviour using TLC.

The extract enzymatically cleaved with ß-glucuronidase and arylsulfatase resulted in significantly decreased or absent concentrations of isoflucypram-2-propanol-GlucA and isoflucypram-propanol-GlucA (both isomer 1 and 2), whereas their aglycones isoflucypram-2-propanol and isoflucypram-propanol increased. The cleavage of some unknown conjugates resulted in higher amounts of aglycones. Unknown compounds following cleavage accounted for ≤ 9.9 percent TRR (≤ 0.069 mg eq/kg) (Table 98).

Notes:
[1] Pyrazole reference: EnSa-17-0309. Phenyl reference: EnSa-17-0308.

In kidney, isoflucypram was a minor compound accounting for 2.7 percent TRR (0.005 mg/kg) [pyrazole] and 1.6 percent TRR (0.003 mg/kg) [phenyl]. Major metabolites included isoflucypram-carboxylic acid accounting for 18.0 percent TRR (0.034 mg eq/kg) [pyrazole] and 6.8 percent TRR (0.012 mg eq/kg) [phenyl], isoflucypram-lactic acid accounting for 6.1 percent TRR (0.012 mg eq/kg) [pyrazole] and 4.2 percent TRR (0.008 mg eq/kg) [phenyl], isoflucypram-propanol-GlucA (isomer 2) accounting for 7.0 percent TRR (0.013 mg eq/kg) [pyrazole] and 8.6 percent TRR (0.016 mg eq/kg) [phenyl], isoflucypram-propanol accounting for 5.6 percent TRR (0.011 mg eq/kg) [pyrazole] and 2.5 percent TRR (0.004 mg eq/kg) [phenyl], isoflucypram-propenol-GlucA accounting for 3.6 percent TRR (0.007 mg eq/kg) [pyrazole] and 6.2 percent TRR (0.011 mg eq/kg) [phenyl], and isoflucypram-N-methyl-pyrazole-carboxylic acid accounting for 5.8 percent TRR (0.011 mg eq/kg) [pyrazole; not detected in phenyl study]. Minor metabolites included isoflucypram-2-propanol-GlucA, isoflucypram-propanol-GlucA (isomer 1), isoflucypram-desmethyl-carboxylic acid, and isoflucypram-2-propanol in both studies, as well as isoflucypram-desmethyl-propanol in the pyrazole study, only, at concentrations ≤ 0.008 mg eq/kg (≤ 4.2 mg eq/kg).

The extract of kidney enzymatically cleaved with ß-glucuronidase and arylsulfatase resulted in significant decreased concentrations of isoflucypram-2-propanol-GlucA and isoflucypram-propanol-GlucA (isomer 1 and 2), whereas their aglycones isoflucypram-2-propanol and isoflucypram-propanol increased in concentration. The cleavage of some unknown conjugates resulted in higher amounts of aglycones. Unknown compound concentrations following cleavage accounted ≤ 9.3 percent TRR (≤ 0.018 mg eq/kg) (Table 99).

The proposed metabolism pathway of isoflucypram in goats is shown in Figure 10.

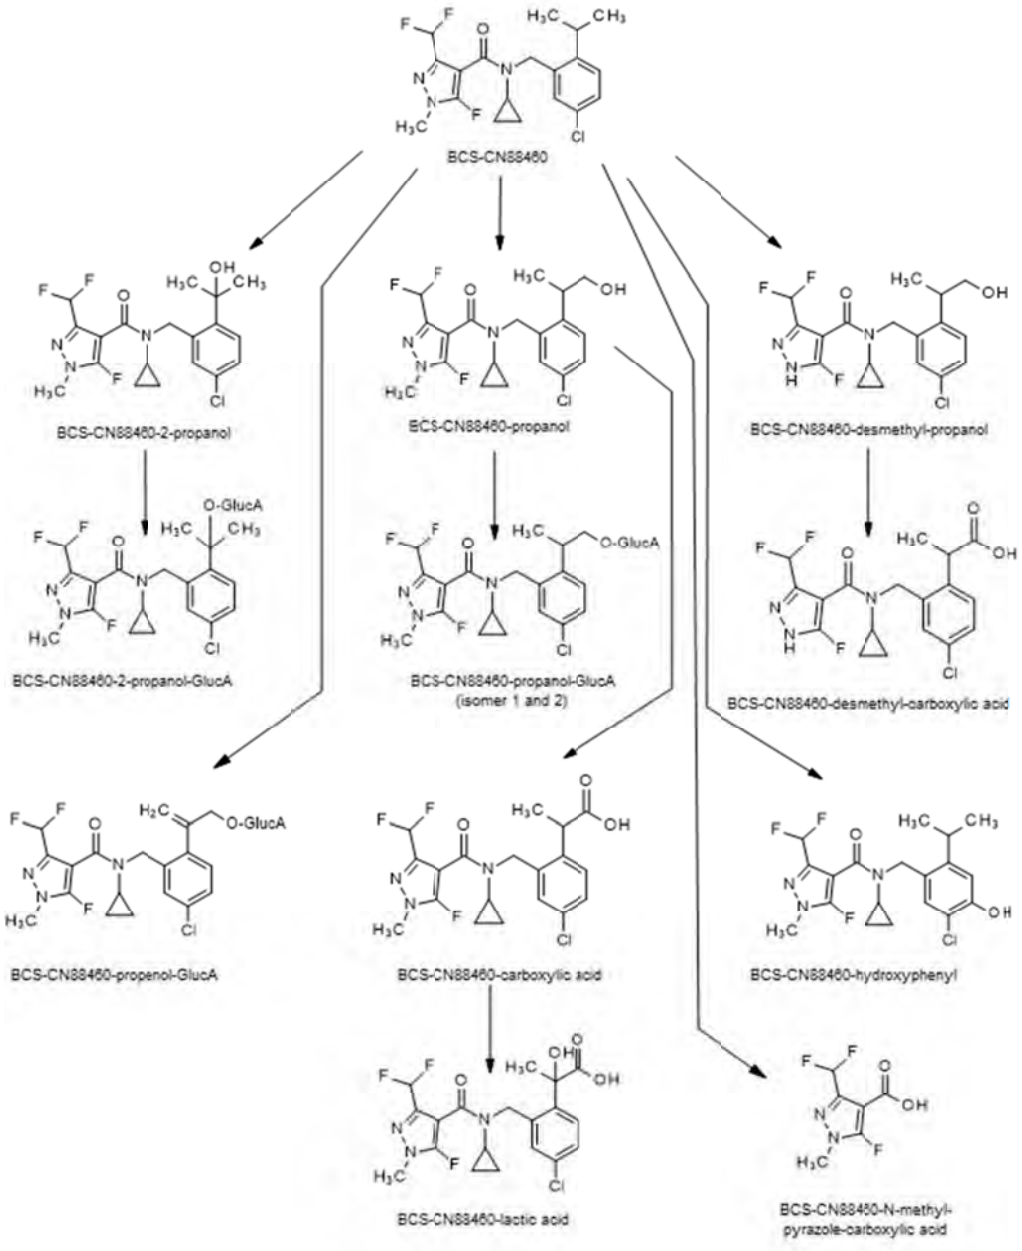

Figure 10 Metabolic pathway in lactating goats

Laying Hen

Report Nos EnSa-17-0307 and EnSa-17-0306.

The metabolism and excretion of [pyrazole-4-^{14}C] Isoflucypram and [phenyl-UL-^{14}C] Isoflucypram was investigated in laying hens as a model for poultry (Bongartz *et al.,* 2017). The test compounds were orally administered to six hens as aqueous 0.5 percent suspensions (via gavage) at **1** mg/kg body weight, corresponding to average doses of 16.57 ppm and 18.12 ppm dry feed per day for the pyrazole and phenyl labels, respectively. The hens received 14 doses at 24-hour intervals in the morning and were sacrificed six hours after the last dosing. Eggs were collected once daily and before sacrifice. Samples were pooled from all hens and TRR was determined in each daily egg sample and in tissues of muscle (leg and thorax),

fat, liver, kidney, skin, and eggs from ovary/oviduct at sacrifice. The percent of the administered dose was determined in each excreta sample.

Solid samples were minced and radioactivity was determined by LSC or combustion/LSC. The overall recovery amounted to approximately 96 percent (pyrazole) and 103.4 percent (phenyl) of the total dose. Approximately 95.8 percent (pyrazole) and 103.0 percent (phenyl) of the total dose was excreted. After the third administration the daily excretion rate was steady at a level ranging from 6.3–7.7 percent (pyrazole) and 7.1–8.8 percent (phenyl). An average of 0.12 percent (pyrazole) and 0.14 percent (phenyl) of the total administered dose was measured in the eggs. At sacrifice, radioactive residues in the tissues were calculated or estimated to be about 0.22 percent (pyrazole) and 0.24 percent (phenyl) of the total administered dose.

TRR in eggs ranged from 0.029 mg eq/kg on day two to 0.057 mg eq/kg at sacrifice in the pyrazole study, and from 0.032 mg eq/kg at day three to 0.066 mg eq/kg at sacrifice in the phenol study. TRR in eggs followed a linear increase until a plateau-level of approximately 0.050 mg eq/kg was reached on the sixth (pyrazole) and fourth day (phenyl). Pooled samples for analysis were collected from Day 6-13 (pyrazole) and 4-13 (phenyl). TRR in tissues amounted to 0.370 mg eq/kg (pyrazole) and 0.373 mg eq/kg (phenyl) in liver, 0.390 mg eq/kg (pyrazole) and 0.360 mg eq/kg (phenyl) in kidney, 0.042 mg eq/kg (pyrazole) and 0.047 mg eq/kg (phenyl) in subcutaneous fat, 0.075 mg eq/kg (pyrazole) and 0.109 mg eq/kg (phenyl) in skin, 0.029 mg eq/kg in leg muscle (both labels), and 0.018 mg eq/kg (pyrazole) and 0.017 mg eq/kg (phenyl) in thorax muscle (Table 100).

Notes:

[1] Pyrazole reference: EnSa-17-0307. Phenyl reference: EnSa-17-0306.

[2] TRR of the eggs collected from the ovary and oviduct at sacrifice (0.076 mg eq/kg [pyrazole] and 0.096 mg eq/kg [phenyl]) were a factor of 1.3X (pyrazole) and 1.5X (phenyl) higher than the laid eggs collected at sacrifice.

A total of 83.9–93.4 percent (pyrazole) and 85.4–93.3 percent (phenyl) was extracted using ACN/water (8/2). For sample preparation, the conventional extracts from eggs, muscle, liver, and excreta

were partitioned against n-heptane. Low amounts of radioactivity were detected in the n-heptane phases (≤1.3 percent TRR; 0.001 mg eq/kg). Concentration procedures caused no losses in radioactivity.

In liver, the remaining solids after conventional extraction underwent exhaustive extraction with ACN/water (8/2) using microwave assistance followed by microwave treatment with 0.1 mol/L HCL, which together released an additional 16.1 percent (pyrazole) and 14.5 percent (phenyl) TRR. In the pyrazole study, up to 8.2 percent TRR (thorax muscle) and 0.003 mg eq/kg (egg and fat) remained in the PES. In the phenyl study, up to 8.2 percent TRR (fat) and 0.004 mg eq/kg (egg and fat) remained in the PES.

Aliquots of the conventional liver extracts were incubated with ß-glucuronidase and arylsulfatase. The suspensions were incubated for 96 hours at 37 °C. After incubation, the enzymatic suspensions were analysed by HPLC and compared with the pre-hydrolysis extract. Additionally, aliquots of isoflucypram-desmethyl-1,2-propandiol-N-GlucA and isoflucypram-desmethyl-1,2-propandiol-SA from pyrazole excreta (Day 1) were incubated with ß-glucuronidase and arylsulfatase for 96 and 24 hours, respectively, at 37 °C. An aliquot of isoflucypram-desmethyl-propanol-N-GlucA from the phenyl study was incubated with ß-glucuronidase and arylsulfatase for 96 hours at 37 °C. After purification the digested metabolites were analysed by HPLC.

Extracts were analysed by HPLC in tandem with mass spectrometry (MS) and/or nuclear magnetic resonance (NMR) using MS-electrospray ionisation (ESI)/NMR spectroscopy for quantitation. Additionally, TLC was used for quantitative analyses of the exhaustive extracts of liver as well as for identification of parent compound in the conventional extract of fat.

Identities were assigned by comparison of HPLC profiles among various tissues and across both radiolabels. The identification was performed in isolated fractions from the extract of eggs and excreta by spectroscopic methods and by enzymatic cleavage of selected conjugates. The identified metabolites and their aglycones in the isolated fractions were used as reference compounds. In addition, parent and metabolites were identified in the extract of fat by TLC co-chromatography using metabolites in the isolated fractions from eggs and excreta.

Metabolites isoflucypram-desmethyl-1,2-propandiol-SA, isofliucypram-1,2-propandiol-SA and isoflucypram-propanol-SA showed an additional peak due to necessary sample preparation resulting in a cleavage of the sulphate group. The respective aglycone was identified based on assignment to the radiolabelled reference compound. In case of the isolated metabolites isoflucypram-desmethyl-propanol and isoflucypram-desmethyl-propanol-N-GlucA, an addition of a formyl group was observed during structure elucidation. An exact structure could not be generated and were only present in minor amounts; therefore, they were not reported.

Samples were stored for a maximum of five months in the pyrazole study. Comparison of liver extract after 20 months of storage demonstrated no degradation of parent or metabolites. Re-extraction 3.5–22 months showed no indication of degradation in all profiles, except fat, which showed slight deviations after 23 months due to high matrix content of the extract according to the report.

Samples were stored for a maximum of three months in the phenyl study, a second conventional extraction of liver following nine months of storage demonstrated no significant degradation. Re-analysis of other extracts 4-15 months after extraction showed no indication of degradation.

In eggs, parent compound comprised 3.7 percent TRR (0.002 mg/kg) [pyrazole] and 6.4 percent TRR (0.003 mg/kg) [phenyl]. Isoflucypram-propanol was the most prominent compound at 35.0 percent TRR (0.018 mg eq/kg) [pyrazole] and 33.9 percent TRR (0.017 mg eq/kg) [phenyl] followed by isoflucypram-desmethyl-propanol at 22.3 percent TRR (0.011 mg eq/kg) [pyrazole] and 22.6 percent TRR (0.011 mg eq/kg) [phenyl]. Isoflucypram-desmethyl-1,2-propandiol and isoflucypram-carboxylic acid were

minor components in both studies accounting for ≤ 7.2 percent TRR (≤ 0.004 mg eq/kg); isoflucypram-desmethyl-propanol-N-GlucA was only observed as a minor component in the phenyl study accounting for 3.0 percent TRR (0.002 mg eq/kg). Up to five minor peaks, each accounting for ≤ 7.7 percent TRR (≤ 0.004 mg eq/kg), were characterised based on the chromatographic behaviour. Small portions of the radioactivity (≤ 1.3 percent TRR; 0.001 mg eq/kg) were observed in the n-heptane phase. Levels of TRR in eggs are shown in Figure 11 and identification and characterization of the residues in Table 101.

Notes:

[1] Pyrazole reference: EnSa-17-0307. Phenyl reference: EnSa-17-0306.

In muscle, parent compound was a minor residue component and was only identified in leg muscle at ≤ 2.9 percent TRR (0.001 mg eq/kg). In both leg and thorax muscle samples, prominent metabolites included isoflucypram-desmethyl-propanol accounting for 20.9–29.7 percent TRR (0.004–0.009 mg eq/kg) [pyrazole] and 20.9–25.8 percent TRR (0.004–0.007 mg eq/kg) [phenyl], isoflucypram-desmethyl-1,2-propandiol accounting for 15.0–17.9 percent TRR (0.003–0.004 mg eq/kg) [pyrazole] and 14.2–22.3 percent TRR (0.004 mg eq/kg) [phenyl], isoflucypram-desmethyl-carboxylic acid accounting for 12.0–12.1 percent TRR (0.002–0.004 mg eq/kg) [pyrazole] and 19.9–20.2 percent TRR (0.003–0.006 mg eq/kg) [phenyl], and isoflucypram-carboxylic acid accounting for 9.1–11.0 percent TRR (0.002–0.003 mg eq/kg) [pyrazole] and 6.6–8.6 percent TRR (0.001–0.002 mg eq/kg) [phenyl]. Isoflucypram-propanol was a minor component accounting for ≤5.9 percent TRR (≤ 0.002 mg eq/kg). Isoflucypram-desmethyl-1,2-propandiol-N-GlucA and isoflucypram-desmethyl-propanol-N-GlucA were only observed in phenyl-label leg muscle and accounted for ≤ 4.1 percent TRR (0.001 mg eq/kg). Up to four peaks, each accounting for ≤ 19.5 percent TRR (0.004 mg eq/kg) were characterised based on the chromatographic behaviour. Although one peak represented 19.5 percent TRR, it only accounted for 0.004 mg eq/kg was therefore not further analysed (Table 102).

Note:
[1] Pyrazole reference: EnSa-17-0307. Phenyl reference: EnSa-17-0306.

In fat, parent was the most prominent compound at 23.6 percent TRR (0.010 mg/kg) [pyrazole] and 20.1 percent TRR (0.009 mg/kg) [phenyl], followed by isoflucypram-propanol at 11.9 percent TRR (0.005 mg eq/kg) [pyrazole] and 6.5 percent TRR (0.003 mg eq/kg) [phenyl] and isoflucypram-desmethyl-propanol at 10.1 percent TRR (0.004 mg eq/kg) [pyrazole] and 8.0 percent TRR (0.004 mg eq/kg) [phenyl].

Minor metabolites included isoflucypram-desmethyl-1,2-propandiol and isoflucypram-carboxylic acid in both labels, and isoflucypram-desmethyl-carboxylic acid in the phenyl label, at concentrations ≤ 7.9 percent TRR (≤ 0.004 mg eq/kg). Up to seven peaks, each accounting for ≤ 11.2 percent TRR (≤ 0.005 mg eq/kg), were characterised based on chromatographic behaviour (Table 103).

Note:
[1] Pyrazole reference: EnSa-17-0307. Phenyl reference: EnSa-17-0306.

Parent compound was not detected in the liver. In the conventional extract, isoflucypram-desmethyl-carboxylic acid was the most prominent compound at 14.4 percent TRR (0.053 mg/kg) [pyrazole] and 12.9 percent TRR (0.082 mg/kg) [phenyl]. Further prominent components were isoflucypram-carboxylic acid accounting for 11.9 percent TRR (0.044 mg eq/kg) [pyrazole] and 5.8 percent TRR (0.022 mg eq/kg) [phenyl], isoflucypram-desmethyl-1,2-propandiol-N-GlucA accounting for 5.4 percent TRR (0.020 mg eq/kg) [pyrazole] and 9.2 percent TRR (0.034 mg eq/kg) [phenyl], isoflucypram-desmethyl-propanol-N-GlucA accounting for 6.1 percent TRR (0.023 mg eq/kg) [pyrazole] and 10.8 percent TRR (0.040 mg eq/kg) [phenyl], isoflucypram-desmethyl-1,2-propandiol accounting for 6.9 percent TRR (0.025 mg eq/kg) [pyrazole] and 5.6 percent TRR (0.021 mg eq/kg) [phenyl], isoflucypram-desmethyl-propanol accounting for 5.3 percent TRR (0.020 mg eq/kg) [pyrazole] and 2.7 percent TRR (0.010 mg eq/kg) [phenyl], and isoflucypram-desmethyl-2-propanol-N-GlucA accounting for 2.5 percent TRR (0.009 mg eq/kg) [pyrazole] and 3.0 percent TRR (0.011 mg eq/kg) [phenyl]. Isoflucypram-propanol (both labels) and isoflucypram-propanol-SA (phenyl label only) were less abundant and accounted for ≤ 1.7 percent TRR (≤ 0.007 mg eq/kg). Up to 18 minor peaks, each accounting for ≤ 8.4 percent TRR (≤ 0.031 mg eq/kg), were characterised based on the chromatographic behaviour using HPLC.

In the exhaustive ACN/water extract, five compounds each accounting for ≤ 2.8 percent TRR (≤ 0.010 mg eq/kg) were characterised based on the chromatographic behaviour using TLC. In the exhaustive 0.1 mol/L HCl extract, four compounds each accounting for ≤ 8.2 percent TRR (≤ 0.031 mg eq/kg) were characterised based on the chromatographic behaviour using TLC.

The enzymatically digested liver extracts were analysed by HPLC. The amount of isoflucypram-desmethyl-1,2-propandiol-N-GlucA, isoflucypram-desmethyl-propanol-N-GlucA, and isoflucypram-desmethyl-2-propanol-N-GlucA decreased in concentration or were absent following 96 hours incubation, whereas their aglycones isoflucypram-desmethyl-1,2-propandiol and isoflucypram-desmethyl-propanol

increased. The cleavage of some unknown conjugates resulted in higher amounts of the aglycones. Unknown compounds following cleavage accounted for ≤ 5.4 percent TRR (≤ 0.020 mg eq/kg) after enzymatic cleavage (Table 104).

The proposed metabolic pathway of isoflucypram in laying hens is shown in Figure 12.

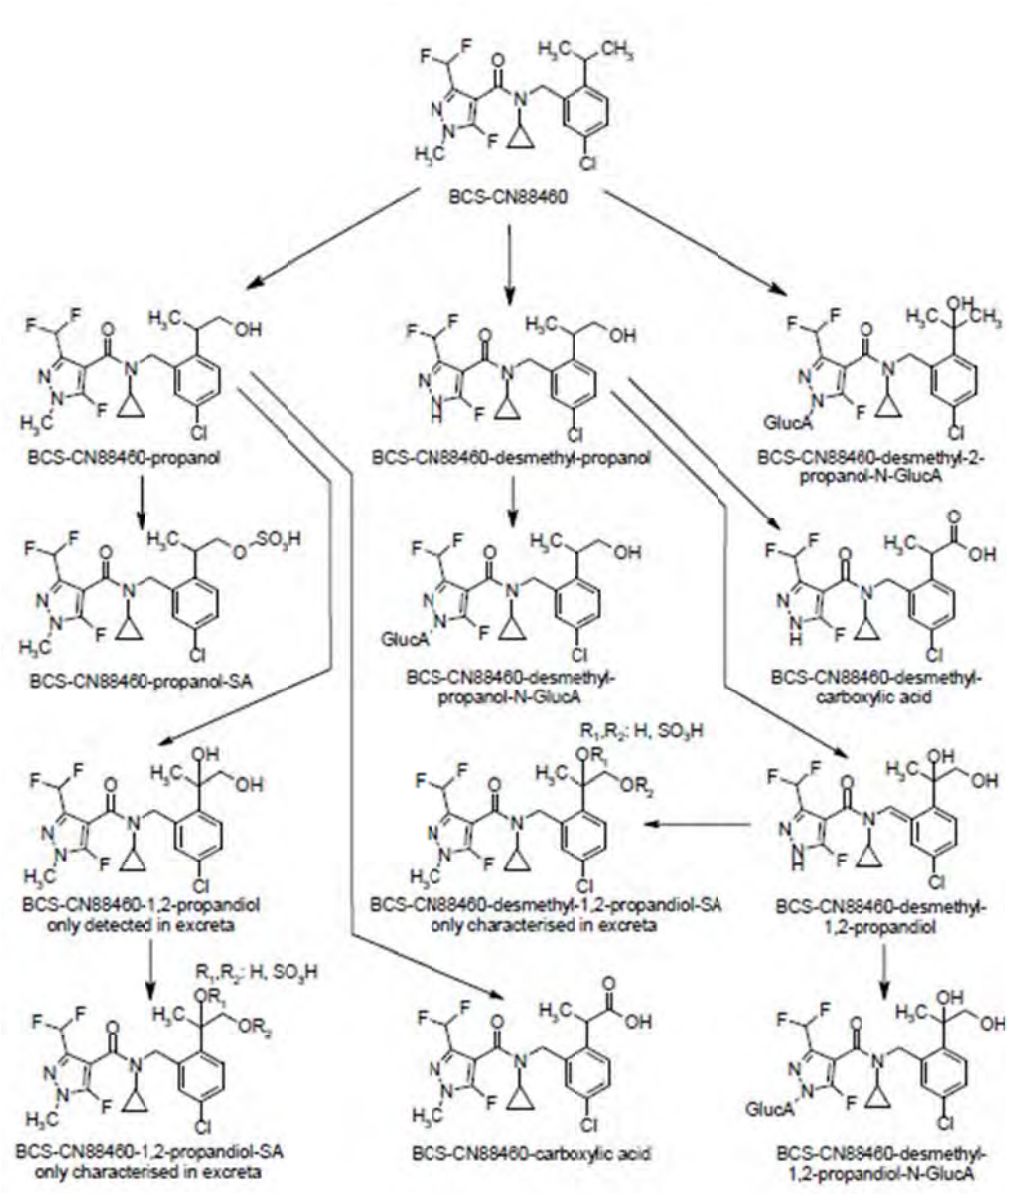

Figure 12 Metabolic pathways in laying hens

METHODS OF RESIDUE ANALYSIS

Plant Matrices

Data Collection Method 01475

Report Nos. MR-16/234, S15-06246, EnSa-16-0204, and EnSa-16-0179.

The Meeting received analytical method descriptions and validation data for the determination of the residues of isoflucypram and its metabolite BCS-CR60082 in/on plant materials by means of HPLC-MS/MS.

Briefly, isoflucypram BCS-CR60082, are extracted from plant material with ACN/water (8:2). The extraction is repeated after blending and centrifugation. The combined extracts are diluted in water and

internal standard is added. The residues are determined by LC-MS/MS using the characteristic m/z 400.2 → 139 (parent) and m/z 234 → 177 (BCS-CR60082) multiple reaction monitoring (MRM) transitions for quantification and m/z 400.2 → 177 (parent) and m/z 234 → 157 (BCS-CR60082) for confirmation using external calibrations with internal standards.

The LOQ for isoflucypram and BCS-CR60082, defined as the lowest validated fortification level, is 0.01 mg/kg in all matrices tested.

The commodities tested for method validation included: tomato fruit (high-water content), orange fruit (high-acid content), rape seed (high-oil content), wheat grain (high-starch content), bean dry seed (high-protein content), and wheat straw (dry). Commodities with low moisture content like wheat grain, rape seed, bean dry seed, and wheat straw are left to soak in water before extraction. Samples were fortified with isoflucypram and BCS-CR60082 at 0.01 and 0.10 mg/kg. Mean recoveries per fortification level were in a range of 70–110 percent, using the quantitation MRM transition with acceptable relative standard deviations (RSDs). Confirmatory procedures for isoflucypram and BCS-CR60082 gave mean recoveries ranging from 82–101 percent for all matrices tested, with acceptable RSD values. Due to a lack of sensitivity and an intercept above 30 percent of the LOQ, it was not possible to determine BCS-CR60082 residues in rape (seed) and bean (dry seed) using a second (confirmatory) MRM transition. The analytical method is fully validated for the accurate and precise determination of residues in crop samples.

For isoflucypram, using the quantification and confirmatory MRM transitions, method linearity was validated over the range of 0.01 to 2.0 µg/mL (internal standard calibration solutions). For isoflucypram, the r values ranged from 0.9997 to 0.9999. For BCS-CR60082, using the quantifier MRM transition, linearity was validated over the range of 0.01 to 1.0 µg/mL (internal standard calibration solutions). For BCS-CR60082, using the confirmatory MRM transition, linearity was validated over the range of 0.01 to 2.0 µg/mL (internal standard calibration solutions). For BCS-CR60082, the r values ranged from 0.9994 to 1.0000. Residues in control samples were <30 percent of the LOQ. The analytical method is fully validated for the accurate and precise determination of residues in crop samples.

The ability of method 01475 to extract incurred residues of isoflucypram and BCS-CR60082 was tested is tomato, wheat, soya bean, oilseed rape, rotational Swiss chard, rotational turnip leaves, and rotational wheat. Extracts of tomato, wheat, soya bean, oilseed rape, Swiss chard, and turnip leaves were stored for approximately 13, 18, 25, 6, 11, and 19 months, respectively, at ≤-18 °C. The stored radioactive residues in samples from primary crop and confined rotational crop studies were analysed according to Method 01475, and the recoveries of the extracted residues were then compared to those in the respective metabolism studies. Method 01475 extracted residues from plant commodities with an efficiency of ≥ 70.8 percent compared to the respective metabolism studies (Table 105). The extraction efficiency of the method is shown in Tables 106 and 107.

Table 105 Recoveries (%) for Method 01475: isoflucypram and BCS-CR60082 in plants (n=5) (MR-16/234)

Swiss chard (3rd rotation)	17.0	0.0045	19.4	0.0051	88.2
Turnip leaves (3rd rotation)	17.6	0.0034	18.4	0.0033	103

Notes:

[1] Calculated by: extracted radioactivity (mg eq/kg) from residue analytical method/extracted radioactivity (mg eq/kg) of method used in the metabolism studies * 100 percent.
[2] Metabolite BCS-CR60082 was not detected in confined rotational crop sample wheat grain.

Method 01475 was also utilized for data gathering in the field rotational crop, storage stability, magnitude of the residue, barley processing study, and to screen feed in the lactating cow and laying hen feeding studies.

For all data gathering, calibration curves were established for each analytical set with at least five concentration levels and an r value >0.99. For rotational crops, the extracts were analysed within 24 hours after extraction. The results are shown in Table 108

Table 108 Concurrent recoveries for rotational crops according to Method 01475 (Ref. 15-2502

For storage stability study MR-17/244, the maximum time between extraction and analysis was 105 hours. For isoflucypram, all concurrent recovery averages were within the acceptable range of 70–110 percent except the storage interval 561 days for bean (dry seed) with an average recovery of 111 percent. The results are shown in Table 109.

Table 109 Summary of concurrent recoveries for isoflucypram and BCS-CR60082 in crops in storage stability study MR-17/244 according to Method 01475

Notes:
[1] Samples stored at -18 °C for ca. 25 months followed by storage at -1 °C for six days.
[2] The recovery was performed with a control sample stored a ca. -18 °C (789 days) because not enough material was available for samples stored at ca. -18 °C followed by storage at -1 °C.
[3] Value not retained.

For barley magnitude of the residue_trials, samples were analysed according to Method 01475. Extracts were analysed within 55 hours of extraction for grain and straw, and within 88 hours of extraction for green material (Table 110).

Data Collection Method LN-002-P16-01

Report Nos. RALN0017 and M-606616-01-1

The Meeting received analytical method descriptions for the residue analytical method LN-002-P16-01, which is an adaptation of the Method 01475 and was developed as a data collection method for the determination of the residues of isoflucypram in/on plant materials using LC-MS/MS.

Briefly, residues of isoflucypram are extracted by two successive extractions with a mixture of ACN/water (4:1). Before the first extraction, crop samples are left to soak for a minimum of 20 minutes in the ACN/water (4:1) extraction solvent mixture prior to blending for two minutes. After filtration, extracts are combined and an isotopic internal standard is added. An aliquot of this sample is diluted with a mixture of ACN/water (1:4) and then subjected to LC-MS/MS. The quantitation MRM transition is m/z

400.2 → 139.2. The LOQ for isoflucypram, defined as the lowest fortification level of an analyte at which an acceptable recovery can be achieved, was 0.01 mg/kg.

The method validation commodities tested included: tomato fruit (high-water content commodity), orange fruit (high-acid content commodity), wheat grain (high starch commodity), soya bean seed, and canola seed (both high-oil content commodities). The accuracy of the method was assessed based on the determined recovery rates. Samples were fortified with isoflucypram at concentrations of 0.01 and 0.10 mg/kg. Mean recoveries per fortification level were in a range of 70–110 percent. Residues in control samples were <30 percent of the LOQ.

Standard solution concentrations ranged from 0.05 ng/mL to 100 ng/mL with R^2 values ≥ 0.998 using at least five concentration levels. The analytical method is fully validated for accuracy, precision, and linearity for determination of isoflucypram residues in crop samples. The results are shown in Table 114.

Data Collection Method 01564

Report Nos. P602186501 and EnSa-18-1075.

The Meeting received analytical method descriptions and validation data for the determination of isoflucypram, isoflucypram-desmethyl-propanol (free and conjugated), and isoflucypram-propanol (free and conjugated) in wheat grain, green material, straw.

Briefly, samples are spiked with an isotopic internal standard of isoflucypram-desmethyl-propanol (1 mg/L), combined with 5 mol/L HCl (15 mL), and heated at 98 °C for 30 minutes. The solution is cooled, combined with water (100 mL), and centrifuged. The supernatant is decanted over a cartridge with a filter frit. The solid pellet is extracted by two successive extractions with ACN/water (4:1). After filtration, extracts are combined with the first supernatant, and isotopic internal standards of isoflucypram and isoflucypram-propanol are added to the sample. An aliquot of this sample is diluted with ACN/water (1:4) and subjected to LC-MS/MS. The quantitation MRM transition for isoflucypram is m/z 400 → 167, for isoflucypram-desmethyl-propanol is m/z 402 → 220, and for isoflucypram-propanol is m/z 416 → 234.

The LOQ for isoflucypram, isoflucypram-desmethyl-propanol, and isoflucypram-propanol was validated at 0.01 mg/kg in wheat grain, green material, and straw. Method validation mean recoveries for each fortification level were within the 70–110 percent range for recoveries at fortification levels of 0.01 mg/kg and 0.10 mg/kg for wheat grain, green material, and straw, expressed as parent equivalents. RSDs were below 20 percent for each analyte in all investigated sample materials.

For each analyte, method linearity was validated over the range of 0.015 to 1.0 µg/L (internal standard calibration solutions) with r values >0.99. Residues in control samples were < 30 percent of the LOQ. The overall performance (extractability and hydrolysis) of the residue analytical Method 01564 was determined for isoflucypram, isoflucypram-desmethyl-propanol (free and conjugated), and isoflucypram-propanol (free and conjugated). Wheat straw and hay extracts were stored for approximately 3.5 years at ≤-18 °C. The stored extracts were analysed using Method 01564 and compared for radioactive residues in the wheat hay and wheat straw primary crop metabolism studies. The extracts contained similar residue profiles prior to hydrolysis.

The extracts underwent the acid hydrolysis step of the analytical method with 5 mol/L HCl at 98 °C for 30 minutes for comparison with the acidic conditions of the metabolism study (1 mol/L HCl at 100 °C for 60 minutes). The extraction efficiencies of the individual compounds and the cleavage of the conjugates were ≥ 83.8 percent. In the metabolism study approximately 5–7 percent of the conjugates were not cleaved to the respective aglycon, which resulted in slightly higher efficiency for the residue analytical method compared to the metabolism study.

The repeatability of the extraction efficiency and hydrolysis yield of the residue analytical method was assessed by five replicates per sample material. The relative standard deviations of the five replicates were low and in the range of 0.4 percent to 4.1 percent which is an indication of the good reproducibility of the extraction procedure as well as the cleavage of the conjugates. Isoflucypram,

isoflucypram-propanol, and isoflucypram-desmethyl-propanol did not show any degradation during acidic hydrolysis (Table 115). Table 116 shows the extraction efficiency of the method for wheat hay and straw.

Notes:

[1] Calculated as concentration (mg eq/kg) from Method 01564 /concentration (mg eq/kg) from the metabolism studies * 100 percent.

Method 01564 was used for data collection in storage stability and magnitude of the residue studies. Calibration curves were established with at least five calibration standards and an r value >0.99

for each analytical set. For storage stability study P642186502, the maximum time between extraction and analysis was 24 hours. The results are shown in Table 117.

Data collection Method 46437, Version 1

Method 46437, version 1 is based on Method 01564. The LOQ was 0.01 mg/kg. Extracts are heated with HCl at 98 °C, extracted twice with ACN:water, combined, and analysed by LC-MS/MS with internal standards.

For barley magnitude of the residue trials GLP658 and S18-07828, samples were analysed by Method 46437, version 1. For each analytical set, a calibration curve was performed with a coefficient of determination (R^2) above 0.99. Samples were analysed on the same day as extraction (Table 120).

Monitoring Method 01520

Report Nos. MR-17/239 and P 4386 G.

The Meeting received analytical method descriptions and validation data for the determination of isoflucypram residues in/on plants using LC-MS/MS Method 01520. Method 01520 uses the same extraction conditions as Method 01475 which was shown capable to extract the residues of isoflucypram from plant samples. Matrix-matched standards are used.

For method validation, samples were extracted from tomato (fruit), orange (fruit), wheat (grain), coffee (green bean), oilseed rape (seed), and bean (dry seed) by two successive extractions using a high-speed blender with a mixture of ACN/water (8:2). Commodities with low moisture content (wheat grain, rape seed, bean dry seed, and coffee green bean) were left for soaking in water before extraction. After centrifugation the combined extracts were adjusted volumetrically, filtered, and diluted with a mixture of ACN/water (17:73) for LC-MS/MS determination. Two MRM transitions were monitored for isoflucypram and each matrix tested m/z 400 → 139 as 1st MRM (quantification) and m/z 400 → 177 as 2nd MRM (confirmation).

Method 01520 was also independently validated for the determination of isoflucypram residues in/on plant using LC-MS/MS. The LOQ for isoflucypram is 0.01 mg/kg in the six tested crop matrix types using both the quantification and the confirmatory MRM transitions. The correlation between the injected amount of substance and the detector response was linear for matrix matched standards ranging from 0.005 µg/L to 2.0 µg/L. with r values > 0.99.

Mean recoveries for each fortification level and the overall mean recovery were within the 70–110 percent range for all matrices with acceptable RSD (Table 122).

Table 122 Recovery results (n=5) from the method validation of Method 01520–Isoflucypram

Multi-Residue Methods

Report Nos. EnSa-17-0483, EnSa-17-0551, and S16-05413.

The extraction efficiency of the QuEChERS analytical method was tested for the determination of isoflucypram in tomatoes, wheat, soya bean, oilseed rape, rotational turnip leaves, rotational Swiss chard, and rotational wheat grain. Extracts of tomato, wheat commodities, soya bean commodities, oilseed rape commodities, turnip leaves, and Swiss chard were stored for a maximum of 13, 25, 26, 6, 19, and 19 months, respectively, at ≤-18 °C. Residues in the stored extracts were analysed using the QuEChERS method and the recoveries were compared to those in the respective metabolism studies Table 123.

Table 123 Isoflucypram - extraction efficiency of the QuEChERS analytical method from representative matrices from plant pyrazole metabolism studies

	QuEChERS Extraction		Extraction in metabolism studies[1]		Extraction efficiency[2]
Sample	% TRR	mg/kg	% TRR	mg/kg	%
Primary crops, S16-05413, EnSa-17-0483					
Tomato fruit	82.3	0.181	96.7	0.165	110
Wheat hay	24.7	0.986	50.0	2.016	48.9
Wheat straw	35.1	5.955	64.0	9.933	60.0
Wheat grain	78.6	0.210	92.0	0.354	59.3
Soya bean forage	8.4	0.354	18.7	0.819	43.2
Soya bean hay	4.5	0.138	10.4	0.487	28.3
Soya bean straw	47.2	8.859	64.5	11.424	77.5
Soya bean seeds	67.1	0.019	76.6	0.027	70.3
OSR intermediate harvest	60.8	2.795	81.9	3.890	71.9
OSR seeds	54.9	0.051	71.0	0.070	72.9
Confined rotational crops[3], EnSa-17-0551					
Turnip leaves (1st rotation)	3.4[4]	0.0006[4]	4.8	0.0009	66.7
Immature Swiss chard (1st rotation)	5.7[4]	0.0020[4]	6.0	0.0019	105

Notes:

[1] Combined conventional and exhaustive extractions, if applicable.

[2] Calculated by: Concentration (mg/kg) from QuEChERS analytical method/concentration (mg/kg) from metabolism studies * 100 percent.

[3] No HPLC analysis of confined rotational wheat grain extracts was performed as isoflucypram was not detected in this matrix in the confined rotational wheat grain metabolism study.

[4] Mean of three replicates.

Animal Matrices

Data Collection Method 01511

Report Nos. P603166029 and M-605551-01-1

The Meeting received analytical method descriptions and validation data for the determination of free residues of isoflucypram, isoflucypram-2-propanol, isoflucypram-carboxylic acid, isoflucypram-propanol, isoflucypram-desmethyl-propanol, isoflucypram-desmethyl-carboxylic acid in/on animal tissues, milk, and eggs by HPLC-MS/MS. Method 01511 also allows the determination of the sum of isoflucypram-propanol and its conjugated residue and the sum of isoflucypram-2-propanol and its conjugated residues in cow liver and kidney and the sum of isoflucypram-desmethyl-propanol and its conjugated residue in hen liver by HPLC-MS/MS.

Briefly, residues are extracted from milk, muscle, kidney and eggs samples with a mixture of ACN/water (4:1). After addition of internal standards, the combined raw extracts (extract A) are diluted and subjected to HPLC-MS/MS for the analysis of free residues of isoflucypram, isoflucypram-2-propanol, isoflucypram-carboxylic acid, isoflucypram-propanol, isoflucypram-desmethyl-propanol, and isoflucypram-desmethyl-carboxylic acid.

For free and conjugated residues of isoflucypram-2-propanol and isoflucypram-propanol, an aliquot of extract is evaporated to dryness at 50 °C, followed by a redissolution in water. The obtained extracts are enzymatically hydrolysed with ß-glucuronidase/arylsulfatase for 20 hours at 37 °C. The extracts are cleaned-up using an Oasis SPE column. The eluted solution is evaporated to dryness at 50 °C and redissolved in a mixture of ACN/water (4:1). The final extract is then subjected to HPLC-MS/MS analysis.

For free and conjugated residues of isoflucypram-desmethyl-propanol, an aliquot of extract A is evaporated to dryness at 50 °C, followed by a redissolution in water. The obtained extracts are enzymatically hydrolysed with ß-glucuronidase/arylsulfatase for 96 hours at 37 °C. The extracts are cleaned-up using an Oasis SPE column. The eluted solution is evaporated to dryness at 50 °C and redissolved in a mixture of ACN/water (4:1). The final extract is then subjected to HPLC-MS/MS for the analysis. The LOQ for all analytes is 0.01 mg/kg except for cattle (milk) for which the LOQ is 0.005 mg/kg. Table 124 shows the MRM transitions monitored in the method

Table 124 MRM transitions were monitored for each matrix tested and for each analyte

Analyte	1st MRM (quantitation)	2nd MRM (confirmation)
Isoflucypram	m/z 400.1 → 167.1	400.1 → 139.1
Isoflucypram-2-propanol	m/z 416.1 → 177.0	416.1 → 398.0
Isoflucypram-carboxylic acid	m/z 430.1 → 177.0	430.1 → 412.1
Isoflucypram-propanol	m/z 416.2[1] → 234.1	416.2 → 177.0
Isoflucypram-desmethyl-propanol	m/z 402.1 → 220.1	402.1 → 58.1
Isoflucypram-desmethyl-carboxylic acid	m/z 416.1 → 236.2	416.1 → 208.2

Notes:

[1] Due to fluctuation in the instrument during the measurement on this study there was a slight shift observed from 416.1 to 416.2 m/z during the course of the study.

The linearity range of the detector used was determined for each analyte using internal standards. The tested concentrations were 0.025 µg/L to 5.0 µg/L with r values >0.99. For method validation, eggs, milk, cattle muscle, cattle fat, cattle liver, cattle kidney, and hen liver were analysed. For each matrix, at least five recovery-tests were conducted at the LOQ and five further recovery-tests were

conducted at 10× LOQ. Using the quantification MRM the mean recoveries per fortification level, matrix and analyte ranged between 87 percent and 113 percent (Table 125).

A waiver for extraction efficiency data was received (Report M-605551-01-1) as samples are extracted with the same conventional conditions and with the same solvent mixture of ACN/water (8:2) as performed in the animal metabolism studies. Based on the metabolism studies, the extraction steps used in Method 01511 release > 91.8 percent TTR in all matrices investigated.

Table 125 Recovery results from the method validation of Method 01511 for isoflucypram and metabolites (Ref. P60316602)

Notes:

[1] These results are considered acceptable because they were not identified as outliers by a Grubbs outlier test with a level of significance of 95 percent.

[2] Due to fluctuation in the instrument during the measurement on this study there was a slight shift observed from 416.1 to 416.2 m/z during the course of the study.

Method 01511 was used for data collection in the lactating cow and laying hen feeding studies. Calibration curves were established with coefficients of correlation >0.99. For the lactating cow study, the maximum time from extraction to analysis was 27 days. The maximum period of demonstrated stability for residues in the extract is 23 days. Due to acceptable concurrent recoveries in cream and whey samples, the additional four days between extraction and analysis beyond the demonstrated period is considered acceptable. The results are shown in Table 126.

Table 126 Concurrent recoveries for isoflucypram and metabolites in cattle matrices according to Method 01511 (Ref. 17-8001)

Monitoring Method 01300/M034

Report Nos. RALN0050, P683176031, and EnSa-17-0647.

The Meeting received analytical method descriptions and validation data for the determination of residues of isoflucypram, isoflucypram-carboxylic acid, isoflucypram-propanol, and isoflucypram-desmethyl-carboxylic acid. The validated matrices are cattle (muscle), cattle (fat), cattle (liver), cattle (kidney), cattle

(milk), hen (muscle), and hen (eggs). The extracts were subjected to HPLC-MS/MS. A further independent laboratory validation study was carried on same matrices.

The residues are extracted from animal matrices according to the QuEChERS multi-residue method. For cow liver, muscle, and milk, a 5.0 g sample aliquot is shaken after the addition of water and ACN. For fat samples, a 5.0 g sample aliquot is shaken after the addition of ACN. QuEChERS salts were added, samples are shaken and centrifuged; and an aliquot is diluted with ACN/water (1:4). Identification and quantitation were performed by LC-MS/MS. The LOQ for all analytes is 0.01 mg/kg except for cattle (milk) for which the LOQ is 0.005 mg/kg. Table 128 shown the monitored MRM transitions

Table 128 MRM transitions were monitored for each matrix tested and for each analyte:

Analyte	1st MRM (quantitation)	2nd MRM (confirmation)
Isoflucypram	m/z 400.1 → 167.0	400.1 → 139.0
Isoflucypram-carboxylic acid	m/z 430.1 → 177.0	430.1 → 412.0
Isoflucypram-propanol	m/z 416.1 → 234.1	416.2 → 177.0
Isoflucypram-desmethyl-carboxylic acid	m/z 416.1 → 236.2	416.1 → 208.1

The linearity range of the detector used was determined for each analyte using matrix-matched standards or internal standards. The correlation between the injected amount of substance and the detector response was linear for concentrations ranging from 0.025 µg/L to 5 µg/L with r values >0.99. For each matrix at least five recovery-tests were conducted at the LOQ and five recovery-tests were conducted at 10× LOQ. Mean recoveries for each fortification level were within the 70–120 percent range for all analyte/matrix combinations and both investigated MRM transitions.

The extraction efficiency of the QuEChERS analytical method was tested for the determination of the TRR, isoflucypram, isoflucypram-desmethyl-carboxylic acid, isoflucypram-propanol, isoflucypram-carboxylic acid, isoflucypram-propanol, and isoflucyrpam-2-propanol in animals. Extracts of eggs, hen muscle (leg and thorax), hen muscle, hen fat, hen liver, goat muscle, goat fat, goat liver, and goat kidney were stored for a maximum of 18 months at ≤-18 °C. Stored extracts were analysed using the QuEChERS method and compared to results of the hen and goat metabolism studies (Table 129). The efficiency of extraction of isoflucypram and metabolites is shown in Table 130.

Table 129 Recovery results from the method validation of method 01300/M034 – isoflucypram and metabolites

Environmental Matrices

Method 01432

Report No. MR-14/077.

The Meeting received analytical method descriptions and validation data for the determination of residues of isoflucypram and isoflucypram-carboxylic acid residues in/on soil and sediment.

Briefly, soil and sediment samples of 20 g were extracted in a microwave extractor with ACN/water/acetic acid (4000:1000:30:v). The extracts were centrifuged to remove fine particles of the soil. Possible matrix effects of isoflucypram and isoflucypram-carboxylic acid are eliminated by using an internal standard solution of isotopically labelled reference items. Identification and quantitation of the active ingredient was done by high performance liquid chromatography using MS/MS detection in the Multiple Reaction Monitoring mode.

The LOQ for each single analyte was 1.0 µg/kg in soil. Two MRM transitions were monitored for each compound and each soil tested m/z 400.1 → 139.0 for quantitation and m/z 400.1 → 167.1 for confirmation of isoflucypram and m/z 430.1 → 177.0 for quantitation and m/z 430.1 → 412.1 for confirmation of isoflucypram-carboxylic acid. Mean recoveries for each fortification level were within the range of 94 -101 percent for isoflucypram and isoflucypram-carboxylic acid.

The correlation between the injected amount of substance and the detector response was linear for standards ranging from 0.1 µg/L to 200 µg/L, equivalent to a concentration ranging from 0.2 µg/kg to 400 µg/kg with r values ranging from 0.9996 to 0.9999. Relative standard deviations were for each fortification level were between 0.5 to 2.8 percent for isoflucypram and isoflucypram-carboxylic acid (Table 131).

Method 01432 was used in the terrestrial field dissipation studies, the soil analysis portion of the limited field rotational crops study, and the soil storage stability study. Calibration curves were established for each analytical set with coefficients of determination > 0.99. Results are shown in Tables 132 and 133.

STABILITY OF PESTICIDE RESIDUES IN STORED ANALYTICAL SAMPLES

The Meeting received three studies investigating various analytes in various commodities under frozen storage conditions. Analytical reports are sufficiently detailed and included chromatograms showing defined symmetrical peaks.

Plants

Report No. MR-17/244.

The Meeting received a study evaluating the stability of isoflucypram and BCS-CR60082 (Isoflucypram-N-methyl-cyclopropyl-pyrazole-carboxamide) during freezer storage (≤-18 °C) for a period of 24–25 months in tomato (fruit), bean (dry seed), wheat (grain), rape (seed), and orange (fruit) (Uceda, L.; 2018). The study also investigated the stability of isoflucypram and BCS-CR60082 following frozen storage for 25–26 months at -18 °C followed by six days of storage at -1 ± 2 °C.

Samples were fortified, separately, with isoflucypram and BCS-CR60082 at 0.20 mg/kg and stored at an average temperature of -18 °C or below. Tomato (fruit), bean (dry seed), wheat (grain), and rape (seed) were analysed at the nominal storage intervals of 0, 3, 8, 13, 18, and 24 months. Samples of orange (fruit) were analysed at the nominal storage intervals of 0 and 6 days, and 1, 3, 8, 13, 18, and 24 months. Additionally, second set of orange (fruit) data were investigated due to high variability of recoveries in orange (fruit) on Day-0. The second set of orange (fruit) was analysed following 0, 5, and 10 months.

After approximately 25 months of storage at -18 °C, some samples of all commodities were transferred to a refrigerator with a temperature of -1 ± 2 °C and stored for six days. After the six additional days of storage, samples were observed to have partially thawed and no fungal formation was observed.

Samples were analysed according to Method 01475. At each storage interval, residues of isoflucypram and BCS-CR60082 in the control samples were below the LOQ. Therefore, treated samples were not corrected for residues in controls.Residues of isoflucypram and BCS-CR60082 were stable (mean recoveries greater than 70 percent) at all sampling intervals. Therefore, isoflucypram and BCS-CR60082 are considered to be stable in diverse crop matrices for a period of 24–25 months at -18 °C, as well as a period of 25–26 months at -18 °C plus six days at approximately 1 °C. The results are shown in Table 134.

Table 134 Storage stability for isoflucypram and BCS-CR60082 ((isoflucypram-N-methyl-cyclopropyl-pyrazole-carboxamide) in crops

Notes:
[1] Samples stored at -18 °C for ca. 25 months followed by storage at -1 °C for six days.
[2] Results confirmed after 782 days with new samples.

Report No. P642186502.

The Meeting received a study investigating the stability of isoflucypram-desmethyl-propanol and isoflucypram-propanol in/on wheat grain, green material, and straw under frozen storage conditions (Stuke, S.; 2021). Isoflucypram-desmethyl-propanol and isoflucypram-propanol were fortified, separately, at 0.1 mg/kg. Samples were stored at <-18 °C and analysed at nominal intervals of ca. 0, 1, 3, 6, 12, 18, 24, and 30 months of storage. It is noted that a power outage occurred, requiring samples to be moved to a separate freezer with a temperature of ca. -26 °C for approximately 53 hours.

Samples were analysed according to Method 01564. Residues in all control samples were below the LOQ. Therefore, residues in treated samples were not corrected for control samples.Residues of isoflucypram-desmethyl-propanol and isoflucypram-propanol were stable (mean recoveries greater than 70 percent) at all sampling intervals. The interim study results demonstrate that the residues of isoflucypram-desmethyl-propanol and isoflucypram-propanol are stable in wheat commodities for at least 18 months under deep-freezer storage conditions (≤-18 °C) (Table 135).

Table 135 Summary of storage stability recoveries for isoflucypram-desmethyl-propanol and isoflucypram-propanol in wheat commodities

Soil

Report No. P641 14 1803.

The Meeting received a study evaluating the stability of isoflucypram and isoflucypram-carboxylic acid in soil under freezer storage conditions (Koch, V.; 2016). Untreated soil samples of soil Höfchen (silt loam) and soil Dollendorf (clay loam) were fortified, separately, with isoflucypram and isoflucypram-carboxylic acid at 10 µg/kg for each analyte. The characteristics of the soils are shown in Table 136

Table 136 Soil Characteristics

	Soil Höfchen	Soil Dollendorf
Description	0-30 cm soil layer	0-20 cm soil layer
pH (in $CaCl_2$ solution)	6.7	7.3
pH (in H_2O)	7.4	7.4
Organic carbon (percent)	0.92	5
Organic matter (percent)[1]	1.58	8.6
Cation exchange capacity (meq/100 g dry soil)	12.4	20.6
Maximum water holding capacity (g/100 g dry soil)	39.5	79.1
Clay (<0.002 mm) (percent)	19.4	31
Silt (0.002-0.050 mm) (percent)	76.3	38

	Soil Höfchen	Soil Dollendorf
Sand (0.050-2.000 mm) (percent)	4.3	31
Soil type	Silt loam	Clay loam

Notes:
[1] Organic matter = Organic carbon X 1.72.

Soil samples were analysed following 0, 93, 194, 308, 363, 539, and 720 days of storage. Samples were generally maintained at ≤-18 °C; however, due to an error on day 235, the temperature rose to an average of -12.2 °C for 5 hours and 55 minutes. This deviation is not expected to have an impact on the study.

Soil samples were analysed according to Method 01432. All control samples were below the LOQ. Therefore, treated samples were not corrected for residues in controls. Residues of isoflucypram and isoflucypram-carboxylic acid were stable (mean recoveries greater than 70 percent) at all sampling intervals. The results demonstrate that residues of isoflucypram and isoflucypram-carboxylic acid are stable in soil for at least 720 days under frozen storage conditions (Table 137).

Table 137 Summary of storage stability for isoflucypram and isoflucypram-carboxylic acid in soil

Analyte/Matrix	Fortification level (µg/kg)	Storage interval (Days)	% remaining	Mean

USE PATTERN

The Meeting received two labels from New Zealand, both for ECs containing 50 g ai/L. The labels included use patterns for isoflucypram on wheat, barley, triticale, and ryegrass seed crop (Table 138).

Table 138 Summary of use patterns for isoflucypram in New Zealand [1,2]

Crop	Maximum Application Rate (kg ai/ha)	Number of Applications	Withholding Period (Days)	Additional Instructions
Wheat	0.075	1	Grain and straw/stubble: 42 Feed/silage: 28	1st appearance of disease or before disease appearance Up to BBCH 69
Barley	0.075	1	Grain and straw/stubble: 56 Forage green feed/silage: 42	1st appearance of disease Up to BBCH 61
Triticale	0.075	1	Grain and straw/stubble: 42 Feed/silage: 28	1st appearance of disease Up to BBCH69

Notes:
[1] Use 100-300 L water/ha for ground applications and 50 L water/ha for air applications.
[2] Neither label specifies PBI for planting rotational crops.

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received several magnitude of the residue studies for isoflucypram on wheat and barley. In many cases, residues of multiple active ingredients were analysed. The following evaluation only addresses data submitted pertaining to isoflucypram, and in some cases, the metabolites isoflucypram-propanol and isoflucypram-desmethyl-propanol.

The field trial reports included dates from critical events during the study, including application, harvest, storage, and analysis, and detailed information on the field site and treatment parameters. Analytical reports were sufficiently detailed and included example chromatograms and example calculations. Chromatogram peaks were clean and symmetrical.

Field trial residues for metabolites are expressed in parent equivalents. Residues below the LOQ were reported as "<0.01 mg/kg" and were calculated at the LOQ (0.01 mg/kg). Several European trials reported percent moisture content and all New Zealand trials report percent dry matter. New Zealand study reports included calculations of residues corrected for percent dry matter; therefore, residues from New Zealand are shown before correction ("as received") and after correction ("dry matter").

In the summary tables, values used for maximum residue level recommendations and dietary burden/intake are underlined. Table 139 summarizes the trials submitted to the Meeting.

Table 139 Supervised trials for isoflucypram

Crop Group	Commodity	Table No
Cereal Grains	Barley (GC 0640)	140
	Wheat (GC 0654)	141
Straw, fodder, and forage of cereal grains	Barley (AS 0640)	142
	Wheat (AS 0654)	13143

Cereal Grains

Barley

The Meeting received 63 supervised residue trials from multiple European countries, New Zealand and the United Kingdom. Trials were conducted with an EC formulation containing 50 g ai/L or 42 g ai/L. Trials were conducted on a variety of spring, winter, and malting barley. Residues were investigated in

forage/green material, grain, and straw. For all trials, a foliar-directed spray application was made at BBCH 61. Grain was harvested at BBCH 89, except where indicated. No adjuvants were used at any of the trials.

Irrigation was conducted at Trials 15-2115-01, 15-2117-03, 15-2066-01, PNZ16414-01, PNZ16414-02, 17-2018-02, BAYERNZ/GLP/16/04/a-03, S17-07998-01, S17-07998-03, and S18-07828-04. In general, a minimum of 1.0 kg was collected for barley grain; however, the minimum sample weight for treated barley grain from Trial 16-2052 was 0.96 kg.

Treated and control samples were frozen within 24 hours after sampling and during shipment to the Laboratory for Sampling. Samples were shredded and homogenized with dry ice and then shipped frozen to the analytical laboratory. Samples were generally stored below -18 °C. There were several exceptions with storage temperatures briefly reaching temperatures up to 10 °C; howeverr, these deviations are not expected to adversely impact the validity of the study results. Frozen storage conditions were not reported for P672186504.

In general, the maximum storage duration for barley grain was 544 days. However, in samples from study P672186504 (amendment to studies 16-2051 and 16-2052), residues of isoflucypram-desmethyl-propanol and isoflucypram-propanol were extracted for analysis after frozen storage of 819–885 days. Additionally, frozen storage duration from study GLP658 (amendment to study S17-07996) were not reported for isoflucypram-desmethyl-propanol and isoflucypram-propanol. The Meeting calculated the maximum duration of frozen storage of 481 days for barley grain based on harvest data and date of extraction for analysis.

Samples were analysed according to Methods 01475 and 46437, version 1. There were no residues in control samples. For samples analysed according to Method 01564, residues of isoflucypram, isoflucypram-propanol, or isoflucypram-desmethyl-propanol were generally below the LOQ in control samples, except for residues of isoflucypram and isoflucypram-desmethyl-propanol were 0.013 and 0.036 mg eq/kg in untreated barley grain from Trial 17-2018-01. The results are shown in Table 140.

Notes:

Dw = dry weight.

[1] DALA = Days after last application.

[2] Application rates are reported as the nominal values if the measured rates were ±5 percent of the planned rates.

[3] Trials 15-2114-01 and 15-2066-01 are not independent.

[4] Trials 15-2114-02, 15-2117-01, and 15-2066-02 are not independent.

[5] For Trials 15-2114-03 and 15-2066-03, applications were made at BBCH 53. Additionally, Trials 15-2114-03 and 15-2066-03 are not independent.

[6] Trials 15-2114-04 and 15-2066-04 are not independent.
[7] Trials 15-2113-01 and 15-2110-01 are not independent.
[8] For Trials 15-2113-02 and 15-2110-02, applications were made at BBCH 59. Additionally, Trials 15-2113-02 and 15-2110-02 are not independent.
[9] Trials 15-2113-03 and 15-2110-03 are not independent.
[10] Trials 15-2113-04 and 15-2110-04 are not independent.
[11] Quantifiable residues in control sample. Residues presented are not corrected for residues in controls.
[12] Isoflucypram applied at BBCH 63.
[13] Grain harvested at BBCH 92.
[14] Trials S17-07996-01/GLP658 and S17-07996-02/GLP658 were accidentally overdosed.
[15] Trials S17-07996-03/GLP658-03 and S17-07996-04/GLP658-04 are not independent.
[16] Trials S18-07828-02 and S18-07828-03 are not independent.
[17] For Trials S18-07828-04 and S18-07828-05, grain was harvested at BBCH 93. Additionally, Trials S18-07828-04 and S18-07828-05 are not independent.

Wheat

The Meeting received 62 supervised residue trials from multiple European countries, the United Kingdom, and New Zealand. Trials were conducted with an EC formulation containing either 50 g ai/L or 42 g ai/L. Trials were conducted on a variety of spring, winter, and durum wheat. Residues were generally investigated in forage/green material, grain, and straw; however, grain and straw were not analysed at Trial 15-2116-03 and Trial 15-2069-03 due to insufficient material harvested. For all trials, isoflucypram was applied as a single foliar-directed application. Grain was harvested at BBCH 89, except where indicated. No adjuvants were added to the solution at any trial.

Irrigation was only conducted at Trials 15-2116-01, 15-2116-04, 15-2069-01, 15-2069-04, 15-2119-02, and S17-07939-02/GLP655-02. In general, a minimum of 1.00 kg of treated grain was collected. However, in Trial S17-07939-02/GLP655-02, a minimum of 0.50 kg of grain was collected; the low collection weight was not addressed in the study report. Additionally, wheat grain from Trial BAYER NZ/GLP/16/04-01 was specified to be below the required amount of 1.0 kg due to poor yield; however, grain was collected from 12 areas adequately representative of the entire plot.

Treated and control samples were frozen within 24 hours after sampling and during shipment to the Laboratory for Sampling. Samples were shredded and homogenized with dry ice and then shipped frozen to the analytical laboratory.

Samples were generally maintained below -18 °C. In several cases, samples were briefly stored at higher temperature which are not generally expected to adversity impact the residue results. Samples from Trial 18-2014-03 were replaced with reserve samples due to an increase to -0.5 °C during transit. Frozen storage conditions were not reported for study P672186504.

In general, the maximum storage duration for wheat grain was 544 days. However, in samples from study P672186504 (amendment to studies 16-2053 and 16-2054), residues of isoflucypram-desmethyl-propanol and isoflucypram-propanol were extracted for analysis after frozen storage for 817–894 days. Additionally, storage durations were not provided for isoflucypram-desmethyl-propanol and isoflucypram-propanol for study GLP655 (amendment to study S17-07939). The Meeting calculated a maximum frozen storage duration of 483 days based on the harvest date and date of extraction for analysis. No residues were observed in control samples. The results are shown in Table 141.

Table 141 Residues of isoflucypram and metabolites (expresses as parent) in wheat grain treated once with EC formulation at 50 or 42 g ai/L

Notes:

dw = dry wight.

[1]DALA = Days after last application.

[2] Application rates are reported as the nominal values if the measured rates were ±5 percent of the planned rates.

[3] Trials 15-2115-01 and 15-2111-01 are not independent.

[4] Trials 15-2115-02, and 15-2111-02 are not independent.

[5] Trials 15-2115-03 and 15-2111-03 are not independent.

[6] Trials 15-2115-04 and 15-2111-04 are not independent.

[7] Trials 15-2116-01 and 15-2069-01 are not independent.

[8] Trials 15-2116-02, 2119-01, and 15-2069-02 are not independent.

[9] Trials 15-2116-04 and 15-2069-04 are not independent.

[10] Average of duplicate analyses.

[11] Samples from Trial 07939-01 were harvested at BBCH 87.

[12] Trials S17-07939-01/GLP655-01 and S17-07939-02/GLP655-02 were accidentally overdosed.

[13] Trials S17-07939-03/GLP655-03 and S17-07939-04/GLP655-04 are not independent.

[14] Trials S18-07829-01 and S18-07829-02 are not independent. Samples were harvested at BBCH 93.

Straw, fodder, and forage or cereal grains

Residue trials for barley and wheat green material and straw matrices are the same as those for barley and wheat grain described above.

Barley

A minimum of 1.0 kg and 0.50 kg of treated sample was collected for barley green material and straw, respectively. In general, the maximum storage duration for barley green material and straw was 544 days which is supported by storage stability data. However, in straw samples from P672186503 (amendment to studies 16-2051 and 16-2052), residues of isoflucypram-desmethyl-propanol and isoflucypram-propanol were extracted for analysis after frozen storage for 786–852 days. Additionally, frozen storage durations from Trial GLP658 (amendment to study S17-07996) were not reported for isoflucypam-desmethyl-propanol and isoflucypram-propanol. The Meeting calculated the maximum duration of frozen storage of 481 days for green material and straw based on harvest date and date of extraction for analysis.

Residues of isoflucypram, isoflucypram-propanol, or isoflucypram-desmethyl-propanol were generally below the LOQ in control samples, with the following of residues of isoflucypram, isoflucypram-desmethyl-propanol, and isoflucypram-propanol were 0.19, 0.037, and 0.13 mg eq/kg in untreated barley straw from Trial 17-2018-01. The results are in Table 142.

Table 142 Residues of isoflucypram and metabolites (expresses as parent) in barley green material and straw treated once with EC formulation at 50 or 42 g ai/L at BBCH 61

Notes:
dw = dry weight.
[1] DALA = Days after last application.
[2] Application rates are reported as the nominal values if the measured rates were ±5 percent of the planned rates.
[3] Trials 15-2114-01 and 15-2066-01 are not independent.
[4] Trials 15-2114-02, 15-2117-01, and 15-2066-02 are not independent.
[5] Trials 15-2114-03 and 15-2066-03 are not independent.
[6] Trials 15-2114-04 and 15-2066-04 are not independent.
[7] Trials 15-2113-01 and 15-2110-01 are not independent.
[8] Trials 15-2113-02 and 15-2110-02 are not independent.
[9] Trials 15-2113-03 and 15-2110-03 are not independent.
[10] Trials 15-2113-04 and 15-2110-04 are not independent.
[12] Quantifiable residues in control samples. Residues presented are not corrected for residues in controls.
[13] Trials S17-07996-01/GLP658 and S17-07996-02/GLP658 were accidentally overdosed.
[14] Trials S17-07996-03/GLP658-03 and S17-07996-04/GLP658-04 are not independent.
[15] Trials S18-07828-02 and S18-07828-03 are not independent.
[16] Trials S18-07828-04 and S18-07828-05 are not independent.

Wheat

In general, a minimum of 1.00 kg and 0.500 kg of treated sample were collected for green material and straw, respectively.

In general, the maximum storage duration for wheat green material and straw was 544 days which is supported by storage stability data. However, in straw samples from study P672186503 (amendment to studies 16-2053 and 16-2054), residues of isoflucypram-desmethyl-propanol and

isoflucypram-propanol were extracted for analysis after frozen storage for 782–859 days. Additionally, storage durations were not provided for isoflucypram-desmethyl-propanol and isoflucypram-propanol for study GLP655 (amendment to study S17-07939). The Meeting calculated a maximum duration of 483 days based on the harvest date and date of extraction for analysis.

For samples analysed according to Methods 01475 and 46437, version 1, there were no residues in control samples. Therefore, residues in treated samples were not corrected for residues in controls. For samples analysed according to Method 01564, residues of isoflucypram, isoflucypram-propanol, or isoflucypram-desmethyl-propanol were generally below the LOQ in control samples, with the following exceptions: Isoflucypram and isoflucypram-propanol were 0.053 mg/kg and 0.013 mg eq/kg in control wheat straw from Trial 18-2135-03 of 0.053 mg eq/kg (with corresponding field trial residues of 0.35–0.99 mg/kg and 0.12–0.23 mg eq/kg, respectively). Residues in treated samples were not corrected for residues in controls. The results are shown in Table 143.

Table 143 Residue for isoflucypram and metabolites (expressed as parent) in wheat green material and straw treated once with EC formulation at 50 or 42 g ai/L

FATE OF RESIDUES DURING STORAGE AND PROCESSING

Nature of the Residue Upon Processing

The Meeting received studies investigating radiolabelled isoflucypram, isoflucypram-desmethyl-propanol, and isoflucypram-propanol following temperatures and pH conditions simulating typical processing procedures.

Report No. EnSa-16-0135.

The Meeting received a study investigating the degradation of isoflucypram in water with a citrate-based buffer (Heinemann *et al.,* 2017). The radiolabelled test compounds [pyrazole-4-^{14}C] isoflucypram and [phenyl-UL-^{14}C] isoflucypram were used for the hydrolysis investigations.

The experiments were performed with a target concentration of 1 mg/L for the test compound. However, pre-tests showed that the target concentration could not be achieved when the ACN of the stock solution was evaporated before addition of the buffer solution. Therefore, both pyrazole- and phenyl-labelled test compounds were prepared as stock solution dissolved in ACN and aliquots containing the respective amount of test compound for the target concentration were added to a respective amount of buffer solution assuring for final test solutions with ACN content was <1 percent (actual ACN concentration was ≤ 0.9 percent).

Each test was carried out with sterilised, buffered drinking water at three different pH levels and three different temperatures: pH 4/90 °C, pH 5/100 °C and pH 6/120 °C (pH ± 0.1 and temperature ± 5 ˚C) to measure pasteurization, baking/brewing/boiling, and sterilization, respectively. The treatment duration was 20 min, 60 min, and 20 min for the three scenarios, respectively.

The pH value of each buffer and processed sample was measured after every significant step. All pH measurements were conducted at room temperature. An additional control vessel containing buffer solution alone was also prepared for each of the three pH/temperature combinations. The untreated control was used to monitor the temperature.

Before starting the incubation procedures, the pH value of all test solutions was measured and three aliquots of each test solution were subjected to LSC measurement to determine radioactivity. A further aliquot was taken for purity and stability analysis of the test compound by HPLC at test time before hydrolysis.

The tests at 90 °C and 100 °C were carried out using a heating/stirring module. The tests at 120 °C were performed in an autoclave. The temperature was recorded in a separate vial filled with 7 mL buffer. The vials were weighed before and after hydrolysis to correct for possible losses by evaporation of water.

The radioactivity measurement in liquid samples was determined by LSC. Recoveries for HPLC sample preparations determined for all test solutions ranged from 99.0 percent to 103.2 percent confirming that no radioactivity was lost during HPLC sample preparation. Isoflucypram and hydrolysis products were determined by HPLC with radiometric- and UV-detection with MS analysis.

Parent compound was identified in both radiolabeled studies in the tests at 100 °C by LC-MS/MS analysis and by HPLC co-chromatography with the non-radiolabeled reference compound. The assignment and identification of parent compound in the other tests was achieved by comparison of HPLC metabolite profiles.

The material balances for all tests were in the range of 104.2 percent to 110.5 percent and demonstrated that no radioactivity, in form of volatile degradation products, dissipated from the test systems. The amount of ACN in the test solutions accounted for 0.7 percent and 0.9 percent for the pyrazole- and phenyl-labels, respectively.

HPLC profiling of samples before and after processing showed that isoflucypram was predominantly stable under the tested conditions representative for food processing. For all tests, almost complete recovery of the parent compound was observed (≥ 98.0 percent). Identification of parent

compound was accomplished by LC-MS and LC-MS/MS analyses as well as by HPLC co-chromatography with non-radiolabelled reference compound.

Identification rates were in the range of 98.0 to 99.1 percent comprised fully of parent. Degradation products detected under the tested conditions representatively for food processing were very minor (≤ 0.51 percent; ≤ 0.005 mg/L) and were not further investigated (Table 144).

Report No. EnSa-20-0057.

The Meeting received a study investigating the hydrolytic transformation and degradation of isoflucypram-desmethyl-propanol in water in a citrate-based buffer (Lamshoeft *et al.,* 2020). The

radiolabelled test item [propane-1-^{14}C] isoflucypram-desmethyl-propanol was used for the hydrolysis investigations.

The experiments were performed with a target concentration of 1 mg/L of the test item. The test systems were incubated at three representative sets of hydrolysis conditions: 90 °C at pH 4 for 20 min (pasteurisation), 100°C at pH 5 for 60 min (baking/brewing/boiling), and 120 °C at pH 6 for 20 min (sterilisation).

An additional control vessel contacting buffer solution alone also underwent the simulated processing procedures. The untreated control was used to monitor the temperature.

Before starting the incubation procedures, the pH value of all test solution was measured (at room temperature) and three aliquots were subject to LSC to determine radioactivity. The radioactivity content was determined in the samples by LSC before and after undergoing the representative processing conditions.

The pasteurisation and baking/brewing/boiling experiments were carried out using a heating/stirring module. The sterilisation experiment was carried out with an autoclave. The vials were weighed before and after hydrolysis to correct for possible losses by evaporation of water.

Isoflucypram-desmethyl-propanol and hydrolysis products were quantitatively determined using HPLC with radiometric- and UV-detection. Isoflucypram-desmethyl-propanol was identified by LC-MS, LC-MS/MS, and NMR analysis as well as HPLC co-chromatography with non-radiolabelled isoflucypram-desmethyl-propanol. Isoflucypram-desmethyl-propanol-aldehyde was identified by LC-MS and LC-MS/MS analysis.

The stability of isoflucypram-desmethyl-propanol was investigated by HPLC analysis. The chromatogram after structure elucidation exhibited an additional peak which was not detected in the sample before structure elucidation. The additional substance could be identified as the formyl derivative of isoflucypram-desmethyl-propanol (by means of LC-MS/MS). The formation of the artefact can be explained by the addition of formic acid, an ingredient of the HPLC solvents.

The material balances for all tests were in the range of 96.7 percent to 99.7 percent and demonstrated that no radioactivity, in form of volatile degradation products, dissipated from the test systems. Under the tested conditions, the degradation of the test item increased with increasing pH values and temperature. Hydrolysis was very low following conditions representing pasteurisation, slight following conditions representing baking/brewing/boiling, and complete following conditions representing sterilisation.

Approximately 99 percent of the test item was recovered at the end of the pasteurisation experiment and approximately 34 percent following the baking/brewing/boiling experiment. Following the sterilisation experiment, isoflucypram-desmethyl-propanol was not detected. Isoflucypram-desmethyl-propanol-aldehyde was identified as main hydrolysis product following sterilisation conditions.

Identification of test item isoflucypram-desmethyl-propanol and isoflucypram-desmethyl-propanol-aldehyde was accomplished by LC-MS and LC-MS/MS analyses of isolated fractions in the baking/brewing/boiling experiment. Additionally, isoflucypram-desmethyl-propanol was identified by HPLC co-chromatography of the isolated fraction with the non-radiolabelled reference item.

Identification rates ranged between 98 percent and 100 percent with no unknown compound comprising ≥ 1.34 percent of the TRR (Table 145).

Report No. EnSa-19-0734.

The Meeting received a study investigating the hydrolytic transformation and degradation of isoflucypram-propanol in drinking water with a citrate-based buffer (Lamshoeft *et al.,* 2020). The radiolabelled test item [pyrazole-4-^{14}C] isoflucypram-propanol was used for the hydrolysis investigations.

The experiments were performed with a target concentration of approximately 1 mg/L. The test systems were incubated at three representative sets of hydrolysis conditions: 90 °C at pH 4 for 20 min (pasteurisation), 100 °C at pH 5 for 60 min (baking/brewing/boiling), and 120 °C at pH 6 for 20 min (sterilisation).

The pH value of all test solutions was measured in three aliquots of each test solution and were subject to LSC measurements. The pasteurisation and baking/brewing/boiling experiments were carried out with a heating/stirring module and the sterilisation module was carried out with an autoclave. The temperature was recorded in a separate vial filled with 5 mL buffer. The vials were weighed before and after hydrolysis to measure losses due to evaporation.

The pH values of the samples were measured at room temperature. Three aliquots were taken from each test solution for the determination of the radioactivity content by LSC. A further aliquot of all individual test samples was taken for stability analysis of the test item by HPLC at the test time after hydrolysis.

For HPLC profiling of the test solutions at test termination, an aliquot of each test solution was analysed using HPLC. Recoveries from HPLC sample preparations ranged from 95.2 percent to 96.0 percent, confirming that no significant radioactivity was lost during HPLC sample preparation.

[Pyrazole-4-^{14}C] isoflucypram-propanol and possible hydrolysis products were quantitatively determined using HPLC with radiometric- and UV-detection. Identification was achieved by LC-MS and LC-MS/MS, and by HPLC co-chromatography with the non-radiolabelled reference compound. When performing the mass spectrometric analysis, the formic acid used in the HPLC caused the formation of an artifact, which was identified by LC-MS and LC-MS/MS. Reanalysis showed that this artifact is not a metabolite.

The material balances for all tests were in the range of 98.5 percent to 102.0 percent, demonstrating that little to no radioactivity, in form of volatile degradation products, dissipated from the test systems. HPLC profiling of samples before and after processing showed that isoflucypram-propanol was predominantly stable under the tested conditions representative for food processing. For all tests, almost complete recovery of parent compound was observed at approximately 98 percent. No unknown compound was found to comprise more than 0.43 percent TRR (Table 146).

Residues upon processing

The Meeting received two studies investigating the behaviour of isoflucypram in processed wheat and barley commodities.

Barley

Report No. 15-3407

The Meeting received a study investigating residues of isoflucypram in barley grain and processed commodities (Freitag *et al.,* 2017). Two trials were submitted with residues evaluated in/on barley grain and the processed commodities for the processed commodities related to beer (malt sprouts, brewer's malt, brewer's grain, hops draff, brewer's yeast, and beer) and pearl barley (pearl barley rub off and pearl barley). Isoflucypram EC 050, an EC formulation containing 50 g/L, was applied to barley as a spray application at 0.375 kg ai/ha.

No irrigation was applied at either trial location. Barley was harvested 61 (Trial 01) and 58 (Trial 02) days after application. A minimum of 1.34 kg, 1.10 kg, 25.6 kg, and 5.26 kg of barley grain, stored barley grain (raw agricultural commodity [RAC]), barley harvested for processing into beer fractions, and barley harvested for processing into pearled barley, respectively.

Samples of barley stored grain (RAC) and all processed fractions were sent to the facility for cleansing (Gerichshain, Germany) under ambient conditions. At the cleansing facility, grain was separated from soil and contaminants.

Processing procedures simulated commercial practices. Material mass balances were provided in the study report. For processing into beer, samples first were sieved, steeped, allowed to germinate, and

kiln-dried. Brewer's malt and malt sprouts (germ following kiln-drying) were collected for analysis. Samples of brewer's malt was mashed (process of adding ground malt with water at 76 °C) and lautered (process of separating wort from insoluble malt components by filtration). The remaining solids (brewer's grain) were collected for analysis. The wort was boiled for approximately 90 minutes with hop pellets. The flocs (hops draff) were separated in a whirlpool causing the sludge to deposit on the bottom. The hops draff were collected for analysis. Yeast was added and the wort was allowed to ferment at 9 °C for approximately four weeks. During fermentation, the yeast deposits (i.e., brewer's yeast) on the tank bottom were sampled for analysis. The fermented beer was filtered and the mature beer was sampled for analysis.

For processing into pearl barley, the grain was conditioned to a moisture content of 14 percent. Samples were hulled until the stipulation abrasion for pearl barley (30–35 percent) was reached. Pearl barley and pearl barley rub off were sampled. Figure 13 summarises the processing procedures for beer and pearl barley processed commodities.

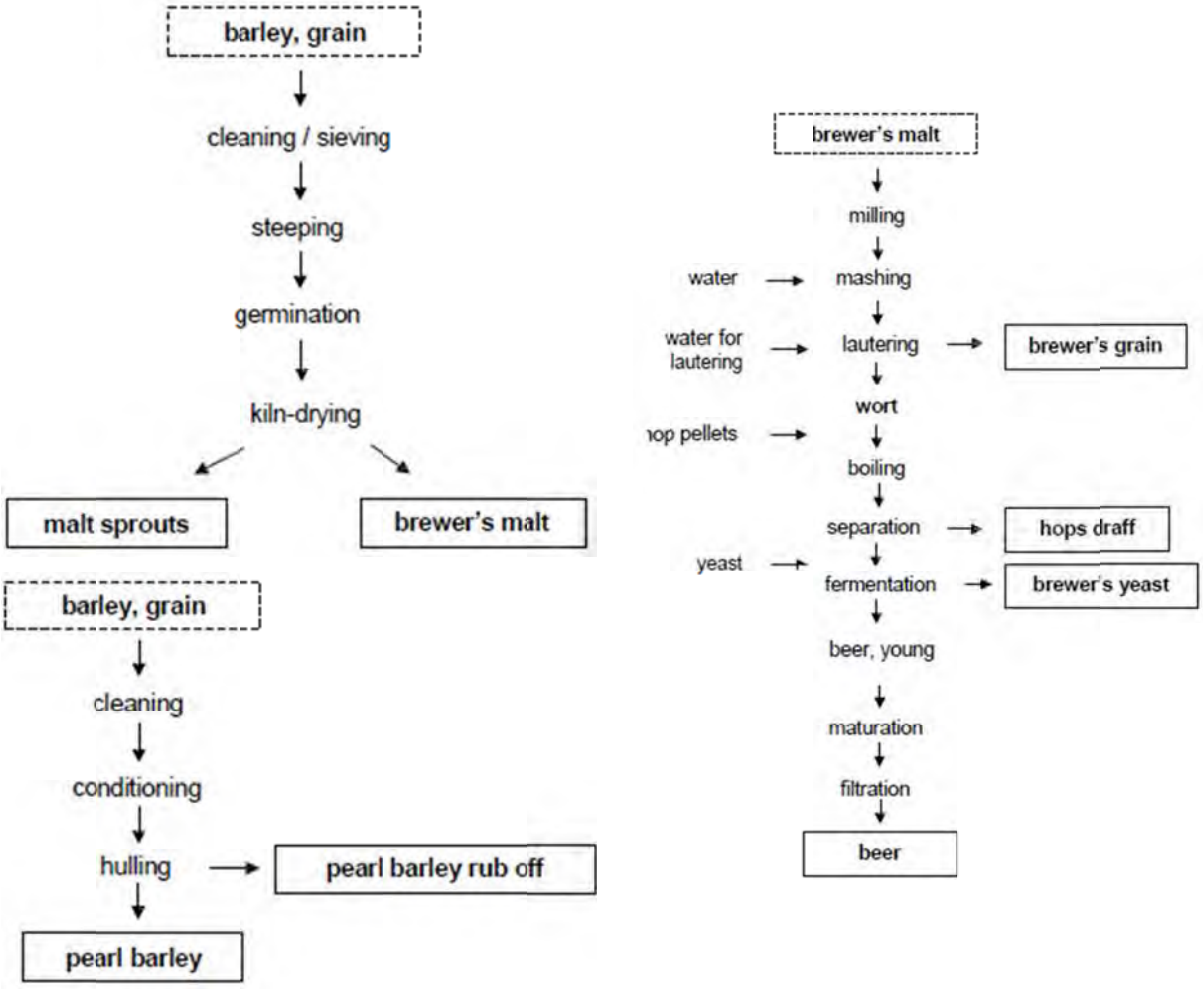

Figure 13 Barley processing procedure

Frozen samples were shipped to the laboratory for preparation (Monheim, Am Rhein) where they were homogenized by shredding with dry ice. Samples were then sent to the laboratory for analysis.

Samples of grain, stored grain (RAC), and processed fractions were maintained under ambient conditions for two days and 71 days for Trial 01 and Trial 02, respectively, prior to processing. After processing, samples were maintained frozen (<-18 °C) for a maximum period of 321 days (Table 147).

Table 147 Sample Weights and Duration of Frozen Stability for Barley RAC and Processed Commodities

Sample	Minimum sample weight (kg)	Maximum storage at ambient temperature (Days)	Maximum storage at -18 °C (Days)
Grain, stored (RAC)	1.07	105	321
Malt sprouts	0.54	239	161
Brewer's malt	0.61	239	161
Brewer's grain	1.10	251	150
Hops draff	0.32	251	160
Brewer's yeast	0.53	259	152
Beer	1.15	286	115
Pearl barley rub off	0.43	109	297
Pearl barley	1.06	109	297

Samples were analysed according to Method 01475. No residues were found in control samples. Therefore, the results were not corrected for concurrent recoveries. The results are shown in Table 148. Average processing factors were <0.67 for barley malt sprouts, brewer's malt, brewer's grain, hops draff, brewer's yeast, beer, and pearl barley. The average processing factor for pearl barley rub off is >1.9.

Table 148 Summary of Residue Data and Processing Factors for Isoflucypram on Barley Grain and Processed Commodities

Trial Number (Country)	Sample	DALA	Isoflucypram (mg/kg)	Processing Factor[1]
15-3407-01 (Netherlands)	Grain, stored (RAC)	61	0.018, 0.012 (0.015)	-
	Malt sprouts		<0.01	<0.67
	Brewer's malt		<0.01	<0.67
	Brewer's grain		<0.01	<0.67
	Hops draff		<0.01	<0.67
	Brewer's yeast		<0.01	<0.67

	Brewer's malt		<0.01	NC
	Brewer's grain		<0.01	NC
	Hops draff		<0.01	NC
	Brewer's yeast		<0.01	NC
	Beer		<0.01	NC
	Grain, stored (RAC)		<0.01, <0.01 (<0.01)	-
	Pearl barley rub off		0.017	>1.7
	Pearl barley		<0.01	NC

Notes:

[1] Processing factor = [residue in processed commodity]/[residue in stored grain (RAC)]. Residues below the LOQ are calculated using the LOQ (0.01 mg/kg). Processing factors were not calculated (NC) when residues are below the LOQ in the RAC and processed commodity.

Wheat

Report No. RALNN137.

The Meeting received a study investigating isoflucypram residues in wheat processed commodities (Harbin, A.; 2017). Two trials were submitted evaluating residues in/on wheat and the processed commodities of bran, white flour, whole meal flour, germ, middlings, shorts, pasta (fresh), pasta (dry), pasta (cooked), pasta (dried and cooked), gluten, starch, aspirated grain fractions (AGF), cooking water, white bread, and whole meal bread. Isoflucypram EC 50, an EC formulation containing 50 g ai/L, was applied at a nominal rate of 0.375 g ai/ha. No adjuvants were added to the spray mixture.

A single composite sample of wheat grain was harvested from the control and treated plots. Samples were harvested at commercial maturity, corresponding to PHIs of 69 and 67 days for Trials C1101 and C1102, respectively. A minimum of 1.31 kg and 306 kg were collected for the RAC and for processed commodities, respectively. Samples for processing were sent under ambient conditions to the laboratory (max = 33 days). Samples of the RAC were frozen within 4 hours of harvest and stored up to 419 days before analysed. Storage duration of processed samples before analysis ranged from 83 to 109 days.

Samples were shipped to the laboratory for analysis at ≤-12 °C for homogenization and analysis. Samples of grain, bran, pasta (fresh, dry, and cooked) white bread, and whole meal bread were homogenized with dry ice. All other processed fractions were considered already homogenized. Samples were analysed according to Method LN-002-P16-01. No residues were found in control samples.

Processing procedure simulateing small-scale industrial procedures are descibed below and ilustrated in Figures 14 and 15.

Generation of Aspirated Grain Fraction.

Samples with a moisture content greater than 13.0 percent were dried in an oven until the moisture content reached 10.0–13.0 percent. Samples were placed in a dust generation room containing a holding bin, two bucket conveyors, and a screw conveyor. As the sample moved through the system, aspiration was used to remove light impurities (grain dust). Each sample was moved for 120 minutes. Material through the 2,360 micron sieve were removed and the ash content was determined

Wheat Milling-Cleaning

Following AGF generation, samples were cleaned by aspiration and screening. Light impurities were removed. After aspiration, samples were screened to separate large and small foreign particles (screenings) from the cleaned grain.

Germ Production

Cleaned wheat was moisture adjusted to 16 percent by adding reverse osmosis water and mixing. After tempering for 1–1.5 hours, the wheat was passed through a disc mill. Ground material was sifted with an 8, 14, and 30 mesh sieve. Material on top of the 30 mesh sieve was aspirated to remove bran from the germ fraction. Germ (with endosperm) was passed through the reduction side of the mill. Germ and reduced endosperm were separated with a sifter equipped with 18, 20, 24, and 28 mesh screens. Germ material was aspirated again to remove additional bran and milled/sieved to remove additional endosperm.

Flour Production

Cleaned wheat was moisture conditioned to 17.5 percent moisture content with a 24hour (+/- 30 minute) resting period before milling. Moisture-adjusted wheat was fed through the spout on a Chopin mill. Breaking of the wheat was accomplished by three break rolls. After passing through the break rolls, the material was fed onto the break sifter screen with sizes of 140 microns 800 microns. Material exiting the break rolls passed over the 800 micron screen first. Material passing through the 800 micron screen is "Break Flour." Material not passing through was conveyed over the 140 micron screen. Material passing through the 140 micron screen is middlings. Material not passing through was conveyed to the end of the sifter. Material exiting the end is bran.

Middlings were poured into the feed hopper of the reduction system. Reduction is achieved through two reduction rolls. After passing through the reduction rolls, the material was fed onto a number 160 micron reduction sifter screen. Material passing through the screen is reduction flour. Material not passing through and conveyed to the end of the sifter is shorts. Representative amounts of break and reduction flours were mixed to produce standard mill run (white flour). Remaining standard mill run flour was used in the production of white bread. Remaining break and reduction flour was used in the production of starch, gluten, and pasta.

Bran exiting the break sieve is placed in the reduction side of the mill but is not reduced with the rollers. The coarse bran is conveyed by beater bars over a number 128 micron screen. Material passing through the screen is "Shorts" and is added to "Shorts" from the reduction mill. Material passing over the screen and exiting the end is "Bran." Requested bran and shorts fractions were collected and placed into frozen storage.

Processing into white bread

Standard mill run flour, sugar, dry milk, salt, margarine, water, and dry yeast were placed in a bread machine. The machine automatically mixed the ingredients, let the dough rise, and baked the bread.

Processing into wholemeal flour and wholemeal bread

Cleaned wheat was ground in a pin mill. Ground material was whole meal flour. Remaining whole meal flour was used to produce "Whole Meal Bread".

Whole meal flour, brown sugar, salt, margarine, water, and dry yeast were placed in a bread machine. The machine automatically mixed the ingredients, let the dough rise and baked the bread.

Wheat Gluten and Starch Production

For vital wheat gluten and starch, break flour was mixed with water. The dough was allowed to rest for two hours. After resting, the dough was kneaded as water washed away the starch, leaving the gluten. This processes continued until the water ran clear, indicating all starch was removed, leaving gluten. Starch was separated from the water using centrifugation and dried in an oven until the moisture content was less than 15 percent. Gluten was dried with a steam heated drum dryer.

Pasta (Noodle) Production

Equal parts of break and reduction flour were mixed with water and salt to form dough. This dough was kneaded and allowed to rest for 20–40 minutes. Dough was fed into a pasta machine to produce a fresh Asian noodle. Requested fresh cooked noodles were produced by placing fresh noodles into boiling water (10:1 ratio water to noodles) for 1–4 minutes. Requested cooking water fractions were also collected.

A portion of the fresh noodles were dried for eight hours at 24–35 °C. Remaining dried noodles were placed into boiling water (10:1 ratio) for 1–4 minutes.

Residues found in RAC and processed commodities with the calculated processing factors are shown in Table 149. The processing factor for wheat flour, middlings, fresh pasta, dry pasta, cooked pasta, dried and cooked pasta, starch, cooking water, white bread, and whole meal bread is <0.63. The processing factor for whole meal flour is 0.67, for shorts is 0.84×, for gluten is 0.94, for germ is 1.13, and for bran is 1.18. The average processing factor for AFG is >119.9.

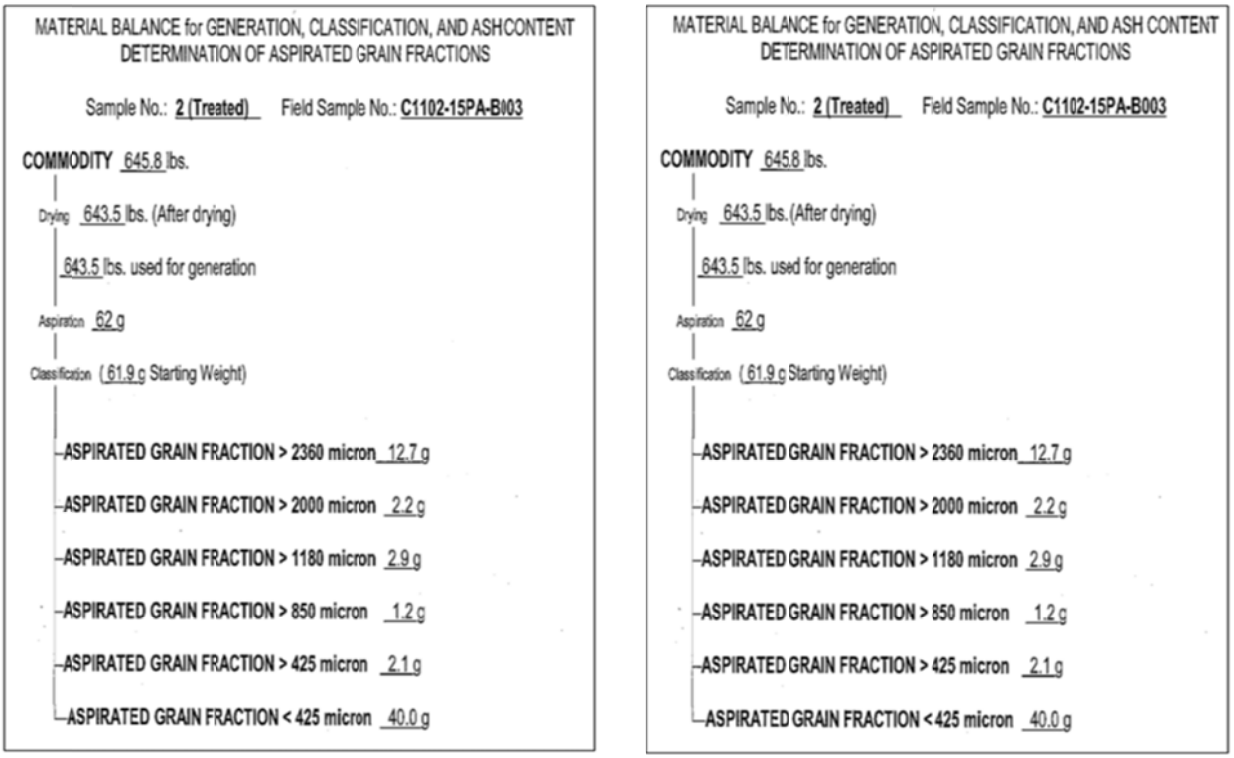

Figure 14 processing procedure and material balance for aspirated grain fractions

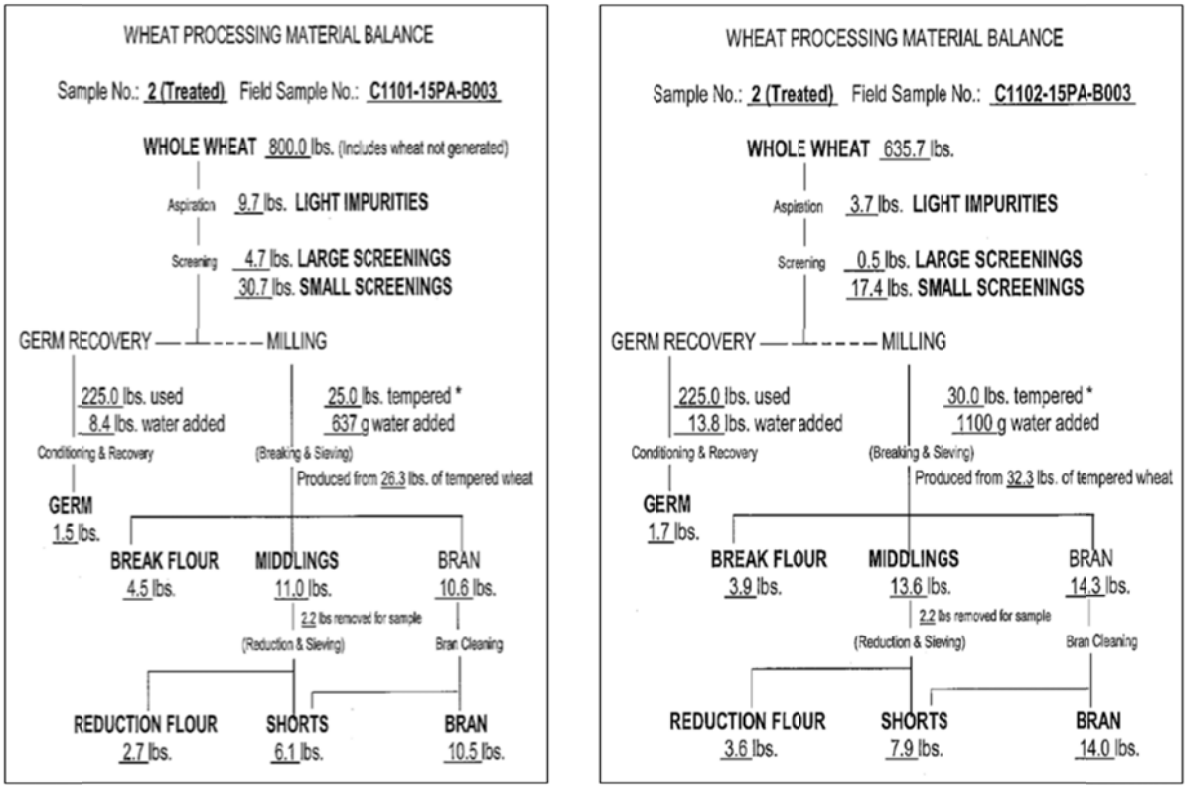

Figure 15 Processing procedure and material balance for wheat processed commodities.

Notes:
[1] Processing factor = [residue in processed commodity]/[residue in stored grain (RAC)]. Residues below the LOQ are calculated using the LOQ (0.01 mg/kg). Processing factors were not calculated (NC) when residues are below the LOQ in the RAC and processed commodity.

RESIDUES IN ANIMAL COMMODITIES

The Meeting received animal feeding studies with lactating cows and laying hens dosed with isoflucypram.

Dairy Cow

Report No. 17-8001.

The Meeting received a study investigating the magnitude of the free isoflucypram, isoflucypram-2-propanol, isoflucypram-carboxylic acid, isoflucypram-propanol, isoflucypram-desmethyl-propanol, and isoflucypram-desmethyl-carboxylic acid in milk, cream, whey, muscle, liver, kidney, and fat of dairy cows orally dosed with isoflucypram for 28 days (Glaubitz *et al.,* 2017). Doses were administered orally via gelatine capsule with a pill gun. Additionally, free plus conjugated isoflucypram-2-propanol and isoflucypram-propanol were analysed in liver and kidney.

Eighteen Holstein Frisian black dairy cows were selected with ages of approximately 2.0–2.7 years and weights ranging from 445–569 kg (determined during the acclimatization phase). Cows were allocated to a control group and 5 treated groups; each group comprised 3 animals. The target dose rates of isoflucypram were 0.05 mg/kg bw/day, 0.15 mg/kg bw/day, 0.5 mg/kg bw/day, 1.5 mg/kg bw/day, and 1.5 mg/kg bw/day for depuration. The amount of feed consumed was monitored daily and ranged from 10.0–21.3 kg/day dry matter. Based on the actual feed intake, the dose rates simulated residue concentrations in feed dry matter of about 1.61 ppm, 4.18 ppm, 15.54 ppm, 48.13 ppm, and 47.13 ppm (for depuration). Stability data were produced for isoflucypram in capsules at ambient room temperature, reflecting the conditions and duration of the study (Table 150).

Table 150 Stability of isoflucypram in capsules

Dose Group	Nominal content of isoflucypram (mg/L)	Storage duration	% remaining	Mean
1.61 ppm	45.69-57.39	0	91, 94, 79	88
4.18 ppm	134.8-168.7	0	101, 97, 101	100
15.54 ppm	467.8-522.1	0	96, 98, 91	95
48.13 ppm	739.7-811.3	0	104, 94, 93, 98, 87, 96	95

Dose Group	Nominal content of isoflucypram (mg/L)	Storage duration	% remaining	Mean
1.61 ppm	45.65-57.20	38	103, 79, 111, 109, 116	104
48.13 ppm	680.4-804.5	34-38	99, 98, 101, 100, 102	100

For the residue analysis, milk samples of from the control, 1.61 ppm, 4.18 ppm, 15.54 ppm, 48.13 ppm, and 47.13 ppm (depuration) groups were taken at various intervals during the acclimation phase, during and dosing phase, and during the depuration phase for the depuration group. Milk was sampled on Day 0-3 (except for the 48.13 ppm group), 4, 7, 9, 11, 14, 16, 18, 21, 23, 28-31, and 32 days (for the 48.13 ppm group only). Additionally, milk was collected from the control group on Day 29, 30, 31, 32, 35, 38, and 45; and from the 47.13 ppm depuration group on Day 32, 35, 38, and 45. Evening milking (prior to dose administration) and morning milk samples were combined for composite analysis. Milk from the control and 47.13 ppm depuration groups were separated into cream and whey by centrifugation on Day 31.

Animals were sacrificed within 24 hours after the final dose except for the 47.13 ppm depuration group, which were sacrificed 4, 7, or 14 days after the last dose. Liver, muscle, kidney, and fat (perirenal, subcutaneous, and mesenteric) were taken for analysis. Samples were either analysed immediately after collection or frozen at -18 °C within 24 hours of collection.

Samples were stored for a maximum of 30 days. Feedstuffs were analysed for isoflucypram according to Method 01475. All residues in feedstuffs were below the LOQ. Milk and tissues were analysed according to Method 01511. There were no residues in pre-dosing or control samples. The results are shown in Tables 151 to 154.

Layer hen

Report No. 17-8002.

The Meeting received a study investigating the magnitude of the free isoflucypram, isoflucypram-2-propanol, isoflucypram-carboxylic acid, isoflucypram-propanol, isoflucypram-desmethyl-propanol, and isoflucypram-desmethyl-carboxylic acid in eggs (whole, white, and yolk), muscle, liver, and fat with skin of laying hens orally dosed with isoflucypram for 28 days. (Glaubitz, J., *et al*., 2017). Doses were administered orally via gelatine capsule. Additionally, free plus conjugated residues of isoflucypram-desmethyl-propanol were analysed in liver.

Forty-two *Gallus domesticus* layer hens were selected with weights ranging from 1.556–2.072 kg (determined during the acclimatization phase). Hens were allocated to a control group and 4 treated groups. Each group was contained two (control only) or three subgroups, each comprised of three animals. The target dose rates of isoflucypram were 0.03 mg/kg bw/day, 0.12 mg/kg bw/day, 0.48 mg/kg bw/day, and 0.48 mg/kg bw/day for depuration. The amount of feed consumed was monitored daily and ranged from 0.010–0.245 kg/day dry matter. Based on the actual feed intake, the dose rates

simulated residue concentrations in feed dry matter of ca. 0.530 ppm, 2.119 ppm, 8.698 ppm, and 8.140 ppm (for depuration).

Stability data were produced for isoflucypram in capsules at ambient room temperature, reflecting the conditions and duration of the study. Samples were analysed directly after preparation for all dose levels with recoveries ranging from 80–109 percent. Five capsules each from 0.530 ppm and 8.698 ppm dose groups were analysed at various days after preparation. Recoveries ranged from 89–90 percent on Day 8, 84–87 percent on Day 11, 83–85 percent on Day 13, and 81–86 percent on Day 17. Further, the stability of isoflucypram in the dosing solution was demonstrated under storage conditions at 2–8 °C for 41 days. At all storage intervals (8, 21, 31, and 41 days), two aliquots from the 0.530 and 8.698 ppm dose solutions were analysed. The recoveries from both dose groups were 97-113 percent on Day 8, 104–132 percent on Day 21, 85–93 percent on Day 31, and 84–111 percent on Day 41.

For the residue analysis, egg samples of the animals of the control, 0.530 ppm, 2.119 ppm, 8.698 ppm, and 8.140 ppm (for depuration) groups were taken at various intervals during the acclimation phase, during and dosing phase, and during the depuration phase for the 8.140 ppm depuration group. For the control, 0.530 ppm, 2.119 ppm, and 8.698 ppm dose groups, eggs were sampled on Day 0-2 (except for the 8.698 ppm group), 3, 4, 8, 9, 11, 14, 16, 21, 23, 28-30, and 31 (8.698 ppm group, only). Additionally, eggs from hens were collected from the control group on day 29, 30, 31, 35, 38, and 45; and from the 8.140 ppm (for depuration) group on Day 21, 23, 31, 35, 38, and 45. Eggs from the control and 8.698 ppm groups were separated into egg white and yolk samples.

Animals were sacrificed within 6 hours after the final dose except for the 8.140 ppm (depuration) group, which were sacrificed 4, 7, or 14 days after the last dose. Liver, muscle, and fat with adhering skin were taken for analysis. Samples were either analysed within 24 hours of collection or frozen at -18 °C within 24 hours of collection.

Feed was analysed for isoflucypram according to Method 01475. All residues in feedstuffs were below the LOQ. Eggs and tissues were analysed according to Method 01511. Samples were stored for a maximum of 6 days. The maximum time from extraction to analysis was 13 days. There were no residues in pre-dosing or control samples. The results are in Tables 155 to 158.

APPRAISAL

Isoflucypram is a novel broad-spectrum fungicide of the chemical class of N-cyclopropyl-N-benzyl-pyrazole-carboxamides. Isoflucypram is a succinate dehydrogenase (SDH) inhibitor.

Isoflucypram was scheduled at the Fifty-first Session of the CCPR for evaluation as a new compound in 2020 and rescheduled to the 2022 JMPR. The 2022 Meeting established an ADI of 0–0.06 mg/kg bw/day and determined that an ARfD was unnecessary. Information on chemical identity,

physical-chemical properties, metabolism and environmental fate, methods of residue analysis, storage stability, intended use patterns, supervised residue trials, fate of residues upon processing, and farm animal feeding studies were submitted for evaluation by the 2022 JMPR.

The chemical structures of isoflucypram and its metabolites/degradates relevant for the appraisal are shown in Talbe 159.

Table 159 Abbreviations used for relevant compounds referred to in the appraisal

Code Name	Chemical Identity (IUPAC)	Structure
Isoflucypram	N-(5-chloro-2-isopropylbenzyl)-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide	M01 Isoflucypram-propanol	N-[5-chloro-2-(1-hydroxypropan-2-yl)benzyl]-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide	M02 Isoflucypram-2-propanol	2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]-carbonyl}amino)-methyl]phenyl}propan-2-yl	M06 Isoflucypram-desmethyl-propanol	N-[5-chloro-2-(1-hydroxypropan-2-yl)benzyl]-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1H-pyrazole-4-carboxamide	
Code Name	Chemical Identity (IUPAC)	Structure
M07 Isoflucypram-desmethyl-1,2-propandiol	N-[5-chloro-2-(1,2-dihydroxypropan-2-yl)benzyl]-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1H-pyrazole-4-carboxamide	M10 Isoflucypram-lactic acid	2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]carbonyl}amino)methyl]phenyl}-2-hydroxypropanoic acid	M11 Isoflucypram-desmethyl-carboxylic acid	2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1H-pyrazol-4-yl]carbonyl}amino)methyl]phenyl}propanoic acid	M12 Isoflucypram-carboxylic acid	2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]-carbonyl}amino)-methyl]phenyl}-propanoic acid	M18 Isoflucypram-propanol-Glyc	N-{5-chloro-2-[1-(hexopyranosyloxy)propan-2-yl]benzyl}-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide	
Code Name	Chemical Identity (IUPAC)	Structure
M19 Isoflucypram-propanol-GlucA (isomer 1 and 2)	2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]-carbonyl}amino)methyl]phenyl}propyl glucopyranosiduronic acid	M20 Isoflucypram-2-propanol-GlucA	2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]carbonyl}amino)methyl]phenyl}propan-2-yl beta-D-glucopyranosiduronic acid	M21 Isoflucypram-propanol-Glyc-MA	2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]-carbonyl}amino)methyl]phenyl}propyl 6-O-(carboxyacetyl)hexopyranoside	M22 Isoflucypram-2-propanol-Glyc-MA	2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]-carbonyl}amino)-methyl]phenyl}propan-2-yl 6-O-(carboxy-acetyl)hexopyranoside	M23 Isoflucypram-hydroxyphenyl-Gluc-MA	2-chloro-4-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]-carbonyl}amino)-methyl]-5-isopropyl-phenyl 6-O-(carboxyacetyl)-beta-D-glucopyranoside	
Code Name	Chemical Identity (IUPAC)	Structure
M23a Isoflucypram-OH-phenyl-Glyc-MA	-	M24 Isoflucypram-hydroxyphenyl-Glyc-MA	2-chloro-4-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]-carbonyl}amino)-methyl]-5-isopropyl-phenyl 6-O-(carboxyacetyl)-hexopyranoside	M25 Isoflucypram-propenol-GlucA	2-{4-chloro-2-[(cycloprop yl{[3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazol-4-yl]carbonyl}amino)methyl]phenyl}prop-2-en-1-yl beta-D-glucopyranosiduronic acid	M36 Isoflucypram-desmethyl-1,2-propandiol-N-GlucA	N-[5-chloro-2-(1,2-dihydroxypropan-2-yl)benzyl]-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-(gluco-pyranuronosyl)-1H-pyrazole-4-carboxamide	M37 Isoflucypram-desmethyl-propanol-N-GlucA	N-[5-chloro-2-(1-hydroxypropan-2-yl)benzyl]-N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-(gluco-pyranuronosyl)-1H-pyrazole-4-carboxamide	M41 Isoflucypram-desmethyl-propanol-Glyc-MA	2-{4-chloro-2-[(cyclopropyl{[3-(difluoromethyl)-5-fluoro-1H-pyrazol-4-yl]carbonyl}amino)methyl]phenyl}propyl 6-O-(carboxyacetyl)hexopyranoside	
Code Name	Chemical Identity (IUPAC)	Structure
M44 Isoflucypram-desfluoro-homoGSH	gamma-glutamyl-S-{4-[(5-chloro-2-isopropylbenzyl)(cyclopropyl)carbamoyl]-3-(difluoromethyl)-1-methyl-1H-pyrazol-5-yl}cysteinyl-beta-alanine	M45 Isoflucypram-desfluoro-Cys-MA	N-(carboxyacetyl)-S-{4-[(5-chloro-2-isopropylbenzyl)(cyclopropyl)carbamoyl]-3-(difluoromethyl)-1-methyl-1H-pyrazol-5-yl}cysteine	M46 Isoflucypram-desfluoro-mercapto-lactic acid-OH	-	M47 Isoflucypram-desfluoro-mercapto-lactic acid-Glyc	3-({4-[(5-chloro-2-isopropylbenzyl)(cyclopropyl)carbamoyl]-3-(difluoromethyl)-1-methyl-1H-pyrazol-5-yl}sulfanyl)-2-(hexopyranosyloxy)propanoic acid	
Code Name	Chemical Identity (IUPAC)	Structure
M48 Isoflucypram-desfluoro-mercapto-lactic acid-propyl-OH-Glyc	-	M49 BCS-CR60082 Isoflucypram-N-methyl-cyclopropyl-pyrazole-carboxamide	N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1-methyl-1H-pyrazole-4-carboxamide	M50 Isoflucypram-N-methyl-pyrazole-carboxylic acid	3-(difluoromethyl)-5-fluoro-1-methyl-pyrazole-4-carboxylic acid	M52 Isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-Cys	-	M54 Isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-GSH	-	
Code Name	Chemical Identity (IUPAC)	Structure
M56 Isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-mercapto-Glyc	-	M57 Isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-mercapto-Glyc-MA	-	M58 Isoflucypram-cyclopropyl-pyrazole-carboxamide	N-cyclopropyl-3-(difluoromethyl)-5-fluoro-1H-pyrazole-4-carboxamide	M62 Isoflucypram-cyclopropyl-pyrazole-carboxamide-Glyc (isomer 1 and 2)	-	
Code Name	Chemical Identity (IUPAC)	Structure
M66 Isoflucypram-cyclopropyl-pyrazole-carboxamide-Ala	3-[4-(cyclopropylcarbamoyl)-3-(difluoromethyl)-5-fluoro-1H-pyrazol-1-yl]alanine	M67 Isoflucypram-desfluoro-cyclopropyl-pyrazole-carboxamide-Ala	3-[4-(cyclopropylcarbamoyl)-3-(difluoromethyl)-1H-pyrazol-1-yl]alanine	M69 Isoflucypram-cyclopropyl-pyrazole-carboxamide-OH-lactic acid (isomer 1 and 2)	-	M77 Isoflucypram-desmethyl-propanol-aldehyde	N-[5-chloro-2-(1-hydroxypropan-2-yl)benzyl]-N-cyclopropyl-5-fluoro-3-formyl-1H-pyrazole-4-carboxamide	
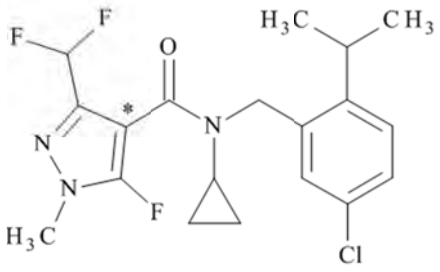
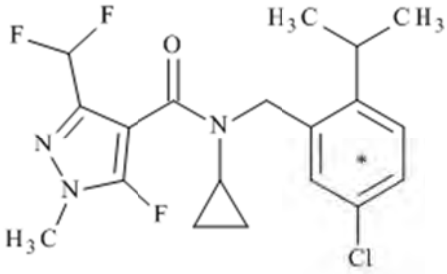
Physical-chemical properties

Isoflucypram is regarded as not volatile, it has a higher solubility in organic solvents compared to its solubility in water, and the partition coefficient (logPow=4.0) indicates potential to sequester into fat.

Plant metabolism

The Meeting received studies describing the metabolism of isoflucypram in tomatoes, wheat, soya bean, and oilseed rape following foliar application, and in potatoes following application to potato seed pieces. The studies were conducted with isoflucypram radiolabelled at either the pyrazole or phenyl position, as shown below. All studies were conducted in a greenhouse and the compound was formulated as emulsifiable concentrate (EC).

[pyrazole-4-^{14}C]isoflucypram	[phenyl-UL-^{14}C]isoflucypram
	




(*): Position of ^{14}C-radiolabel.

Figure 19 Isoflucypram radiolabelled at either the pyrazole or phenyl position

Tomato

Isoflucypram was applied twice to tomatoes at BBCH 14–15 (78–79 g ai/ha) and BBCH 85–87 (78–89 g ai/ha). The interval between applications was 97–99 days. Tomato fruits were harvested 14 days after the last application.

The total radioactive residue (TRR) was 1.8× higher in the pyrazole study (0.17 mg eq/kg) as compared to the phenyl study (0.095 mg eq/kg). The main portion of the radioactivity was recovered in the surface wash, comprising 74–75 percent TRR (0.071–0.13 mg eq/kg). TRR in the acetonitrile (ACN)/water extract was 25–26 percent TRR (0.024–0.045 mg eq/kg), leaving ≤ 0.2 percent TRR (≤ 0.001 mg eq/kg) in the post-extraction solids (PES).

Isoflucypram was the only metabolite observed, comprising 97–98 percent TRR (0.094–0.17 mg/kg). There were no unknown peaks.

Wheat

Isoflucypram was applied twice to wheat, at BBCH 30 at 64–69 g ai/ha and at BBCH 69 at 66–67 g ai/ha. The interval between applications was 28–33 days. Wheat hay was harvested one day prior to the second application (BBCH 69) and allowed to dry for four days. Wheat straw and grain were harvested at maturity (BBCH 89) corresponding to 17–18 days between the final application and harvest.

Total radioactive residues (TRR) in both labels were similar and were highest in straw (16 mg eq/kg), hay (3.0–4.0 mg eq/kg) and grain (0.28–0.39 mg eq/kg). The conventional ACN/water extract released ≥ 94 percent TRR. The conventional extract of pyrazole-labelled wheat straw was subjected to microwave-assisted extraction, releasing an additional 4.7 percent TRR. The conventional extract of wheat hay and straw were hydrolysed with 1 mol/L hydrochloric acid (HCl) at 100 °C for 1 hour.

In wheat hay, parent isoflucypram was the major component representing 50–55 percent TRR (1.7–2.0 mg/kg). Identified metabolites included isoflucypram-propanol-Glyc-MA (7.5-10 percent TRR [0.23–0.41 mg eq/kg]), isoflucypram-desmethyl-propanol-Glyc-MA (2.5–2.7 percent TRR [0.081–0.10 mg eq/kg]), isoflucypram-propanol-Glyc (0.8–2.4 percent TRR [0.023–0.096 mg eq/kg]), and

isoflucypram-propanol (0.7 percent TRR [0.021–0.029 mg eq/kg]). Up to 23 unknown metabolites were characterised in the extracts by their chromatographic behaviour, individually accounting for ≤ 3.1 percent TRR (≤ 0.13 mg eq/kg). PES accounted for ≤ 4.2 percent TRR (≤ 0.17 mg eq/kg).

In hydrolysed extract of wheat hay, parent isoflucypram was the major component representing 44–50 percent TRR (1.5–1.8 mg/kg). Remaining identified metabolites included isoflucypram-propanol (21–22 percent TRR [0.64–0.90 mg eq/kg]), isoflucypram-desmethyl-propanol (6.7–6.9 percent TRR [0.20–0.28 mg eq/kg]), isoflucypram-propanol-Glyc-MA (0.90 percent TRR [0.036 mg eq/kg]), and isoflucypram-propanol-Glyc (0.60–0.80 percent TRR [0.019–0.031 mg eq/kg]).

In wheat straw, parent isoflucypram was the major component representing 62–64 percent TRR (9.9–10 mg/kg). Remaining identified metabolites included isoflucypram-propanol-Glyc-MA (5.0–6.7 percent TRR [0.808–1.042 mg eq/kg]), isoflucypram-propanol-Glyc (2.3–3.7 percent TRR [0.37–0.56 mg eq/kg]), isoflucypram-desmethyl-propanol-Glyc-MA (1.9–2.9 percent TRR [0.306–0.45 mg eq/kg), isoflucypram-propanol (0.9–1.7 percent TRR [0.15–0.27 mg eq/kg]), and isoflucypram-desmethyl-propanol (0.30–1.1 percent TRR [0.052–0.17 mg eq/kg]). Up to 39 unknown metabolites were characterised in the extracts by their chromatographic behaviour, individually accounting for ≤ 2.1 percent TRR (≤ 0.35 mg eq/kg). TRR was successfully extracted as demonstrated by ≤ 4.8 percent TRR (0.77 mg eq/kg) remaining in the PES.

In the hydrolysed extract of wheat straw, parent isoflucypram was the major component representing 61–67 percent TRR (9.8–10 mg/kg). Remaining identified metabolites included isoflucypram-propanol (11–13 percent TRR [1.6–2.0 mg eq/kg]), isoflucypram-desmethyl-propanol (3.6–4.0 percent TRR [0.56–0.64 mg eq/kg]), isoflucypram-desmethyl-propanol-Glyc-MA (0.30 percent TRR [0.054 mg eq/kg]), isoflucypram-propanol-Glyc (0.20–0.30 percent TRR [0.024–0.053 mg eq/kg]), and isoflucypram-propanol-Glyc-MA (0.10–0.30 percent TRR [0.022–0.054 mg eq/kg]).

Wheat grain contained only parent isoflucypram, representing 92–93 percent TRR (0.26–0.35 mg/kg). There were no unknown peaks. TRR was successfully extracted as demonstrated by ≤ 6.5 percent TRR (0.025 mg eq/kg) remaining in the PES.

Soya bean

Isoflucypram was applied three times to soya bean plants, at BBCH 14 (54–59 g ai/ha), BBCH 51 (56–57 g ai/ha) and BBCH 84–85 (65–66 g ai/ha). Application interval was 6–8 days between applications one and two and 62–69 days between applications two and three. Soya bean forage was harvested at BBCH 49, corresponding to 5–6 days after the first application. Soya bean hay was harvested at BBCH 77, corresponding to 38–39 days after the second application, and allowed to dry for four days. Soya bean straw and seed were harvested at BBCH 96, corresponding to 21 days after the final application. TRR in forage was similar for both labels, but was 2.1–3.3× higher in the pyrazole study for remaining soya bean commodities. Radioactivity (phenyl/pyrazole) was highest in straw (8.5/18 mg eq/kg), followed by forage (3.9/4.4 mg eq/kg), hay (1.4/4.7 mg eq/kg) and seed (0.015/0.035 mg eq/kg). For both studies, ≥ 87 percent TRR was extracted in the conventional ACN/water extract, except for phenyl-label seed where 70 percent was extracted, possibly as a result of low overall TRR (0.015 mg eq/kg). Microwave-assisted extraction of soya bean forage, hay, and straw successfully released an additional 2.5–6.9 percent TRR. Soya bean hay extract from microwave-assisted extraction underwent partitioning against ethyl acetate, resulting in complete transfer of the radioactivity to the organic phase.

In soya bean forage, isoflucypram accounted for 19 percent TRR (0.76–0.82 mg/kg). Identified metabolites included isoflucypram-desfluoro-homoGSH (20–23 percent TRR, 0.79–1.0 mg eq/kg), isoflucypram-desfluoro-mercapto-lactic acid-OH (9.5–17 percent TRR, 0.42–0.67 mg eq/kg),

isoflucypram-desfluoro-Cys-MA (8.2–9.2 percent TRR, 0.32–0.40 mg eq/kg), isoflucypram-desfluoro-mercapto-lactic acid-propyl-OH-Glyc (3.4–4.8 percent TRR, 0.15–0.19 mg eq/kg), and isoflucypram-desfluoro-mercapto-lactic acid-Glyc (2.7–3.0 percent TRR, 0.11–0.13 mg eq/kg). Up to 17 unknown peaks were characterised based on chromatographic behaviour, individually accounting for ≤ 3.9 percent TRR (≤ 0.17 mg eq/kg). PES accounted for ≤ 3.4 percent TRR (≤ 0.13 mg eq/kg).

In soya bean hay, isoflucypram accounted for 10 percent TRR (0.14–0.49 mg/kg). Identified metabolites included isoflucypram-desfluoro-Cys-MA (15–21 percent TRR, 0.29–0.72 mg eq/kg), isoflucypram-desfluoro-mercapto-lactic acid-propyl-OH-Glyc (15–18 percent TRR, 0.25–0.71 mg eq/kg), isoflucypram-desfluoro-mercapto-lactic acid-Glyc (11 percent TRR, 0.15–0.52 mg eq/kg), isoflucypram-desfluoro-homoGSH (7.8 percent TRR, 0.11–0.37 mg eq/kg), and isoflucypram-desfluoro-mercapto-lactic acid-OH (2.8–3.2 percent TRR, 0.040–0.15 mg eq/kg). Up to 13 unknown peaks were characterised based on chromatographic behaviour, individually accounting for ≤ 6.1 percent TRR (≤ 0.21 mg eq/kg). PES accounted for ≤ 5.7 percent TRR (≤ 0.27 mg eq/kg).

In soya bean straw, isoflucypram was the major component, representing 65–70 percent TRR (6.0–11 mg/kg). Remaining identified metabolites included isoflucypram-desfluoro-Cys-MA (4.3–4.6 percent TRR, 0.37–0.83 mg eq/kg), isoflucypram-desfluoro-homoGSH (2.8–4.8 percent TRR, 0.24–0.86 mg eq/kg), isoflucypram-desfluoro-mercapto-lactic acid-propyl-OH-Glyc (2.1–3.8 percent TRR, 0.18–0.69 mg eq/kg), isoflucypram-desfluoro-mercapto-lactic acid-Glyc (2.8–3.0 percent TRR, 0.24–0.53 mg eq/kg), and isoflucypram-desfluoro-mercapto-lactic acid-OH (1.9–2.5 percent TRR, 0.22–0.34 mg eq/kg). Up to 20 unknown peaks were characterised based on chromatographic behaviour, individually accounting for ≤ 2.8 percent TRR (≤ 0.33 mg eq/kg). PES accounted for ≤ 4.1 percent TRR (≤ 0.35 mg eq/kg).

In soya bean seed, parent isoflucypram was the only identified component, representing 67–77 percent TRR (0.011–0.027 mg/kg). There were no unknown peaks. Radioactivity remaining in the PES was ≤ 30 percent TRR (≤ 0.005 mg eq/kg).

Oilseed rape

Isoflucypram was applied twice to oilseed rape plants, at BBCH 14 at 63–64 g ai/ha and at BBCH 77 at 62–63 g ai/ha. The interval between applications was 84 days. Oilseed rape was harvested at BBCH 30 for intermediate harvest (whole plant) corresponding to two days after the first application. Oilseed rape forage was harvested at BBCH 55, 40 days after the first application and the plants and seed were harvested at maturity (BBCH 89), 21 days after the final application. TRR was similar between both labels. TRR was highest in intermediate harvest (3.3 and 4.8 mg eq/kg) and plants (3.9 and 4.1 mg eq/kg), followed by seed (0.099 and 0.13 mg eq/kg), and forage (0.008 and 0.012 mg eq/kg). The conventional ACN/water extract released ≥ 71 percent TRR. For seed, an additional 9.8–11 percent TRR was subsequently extracted with microwave-assistance. The purified extract for whole plant intermediate harvest was hydrolysed with 10 mol/L HCl for 1 hour.

In oilseed rape whole plant intermediate harvest, isoflucypram was the major component, representing 82–84 percent TRR (2.8–3.9 mg/kg). Identified metabolites included and isoflucypram-hydroxyphenyl-Glyc-MA (3.1–3.8 percent TRR, 0.13–0.15 mg eq/kg), isoflucypram-hydroxyphenyl-Gluc-MA (2.3 percent TRR, 0.077–0.11 mg eq/kg), isoflucypram-propanol-Glyc-MA (2.2–2.8 percent TRR, 0.071–0.13 mg eq/kg), and isoflucypram-2-propanol-Glyc-MA (1.6–2.2 percent TRR, 0.052–0.11 mg eq/kg). Up to 23 unknown peaks were characterised based on chromatographic behaviour, individually accounting for ≤ 1.5 percent TRR (≤ 0.072 mg eq/kg). Radioactivity remaining in the PES was ≤ 0.50 percent TRR (≤ 0.022 mg eq/kg).

Comparison of metabolic profiles before and after acid hydrolysis of mature plant intermediate harvest indicated cleavage of isoflucypram-hydroxyphenyl-Gluc-MA, isoflucypram-2-propanol-Glyc-MA, isoflucypram-propanol-Glyc-MA, and isoflucypram-hydroxyphenyl-Glyc-MA to less polar compounds.

In oilseed rape forage, no individual peak was observed above the background noise due to low radioactivity. Radioactivity remaining in the PES accounted for ≤ 23 percent TRR (≤ 0.002 mg eq/kg).

In oilseed rape mature plants, isoflucypram was the major component, representing 72–88 percent TRR (2.8–3.6 mg/kg). Identified metabolites included isoflucypram-hydroxyphenyl-Glyc-MA (1.0–3.1 percent TRR, 0.040–0.12 mg eq/kg), isoflucypram-2-propanol-Glyc-MA (0.90–4.6 percent TRR, 0.038–0.18 mg eq/kg), isoflucypram-hydroxyphenyl-Gluc-MA (0.70–2.2 percent TRR, 0.027–0.087 mg eq/kg), and isoflucypram-propanol-Glyc-MA (0.60–2.5 percent TRR, 0.025–0.097 mg eq/kg]. Up to 39 unknown peaks were characterised based on chromatographic behaviour, individually accounting for ≤ 1.3 percent TRR (≤ 0.054 mg eq/kg). Radioactivity remaining in the PES was ≤ 3.8 percent TRR (≤ 0.15 mg eq/kg).

In oilseed rape seeds, parent was the only identified component, representing 71–74 percent TRR (0.070–0.093 mg/kg). There were no unknown peaks. Radioactivity remaining in the PES was ≤ 6.7 percent TRR (≤ 0.008 mg eq/kg).

Potatoes

Isoflucypram was applied to potato seed pieces prior to planting in at 28 g ai/ha (0.55 mg ai/ tuber and 50,000 plants/ha) for a low dose experiment and 274–280 g ai/ha (5.5 mg ai/tuber and 50,000 plants/ha) for a high dose experiment. Potato tubers and leaves were harvested at BBCH 97, corresponding to 119 days after planting.

TRR was higher in the pyrazole study by factors ranging from 1.5–7.5×. TRR was higher in leaves (0.050 and 0.37 mg eq/kg in the low dose experiment; 0.69 and 1.1 mg eq/kg in the high-dose experiment) than in tubers (0.002 and 0.009 mg eq/kg in the low dose experiment; 0.042 and 0.064 mg eq/kg in the high dose experiment). Radioactivity was not extracted in the low dose potato tuber experiments due to low TRRs. For all other matrices, conventional extraction with ACN/water released ≥ 82 percent TRR. Leaf extract from the low dose experiment and potato extract from the high dose experiment were further extracted with microwave assistance to release an additional 7.5 and 12.9 percent TRR, respectively.

In potato leaves, parent isoflucypram was a minor component accounting for 2.0–7.3 percent TRR (0.004–0.007 mg/kg) in the low dose experiment and 2.5–4.0 percent TRR (0.027 mg eq/kg) in the high dose experiment. Remaining identified metabolites included isoflucypram-2-propanol-Glyc-MA (14–29 percent TRR [0.014–0.053 mg eq/kg in the low dose experiment and 0.10–0.15 mg eq/kg in the high dose experiment]); isoflucypram-OH-phenyl-Glyc-MA (6.6–23 percent TRR [0.012–0.025 mg eq/kg in the low dose experiment and 0.10 mg eq/kg in the high dose experiment]); and isoflucypram-cyclopropyl-pyrazole-carboxamide (7.2–10.7 percent TRR [0.040 mg eq/kg in the low dose experiment and 0.077 mg eq/kg in the high dose experiment]). Up to 32 unknown metabolites were characterised based on chromatographic behaviour, individually accounting for ≤ 19.9 percent TRR (≤ 0.064 mg eq/kg). Radioactivity remaining in the PES was ≤ 7.4 percent TRR (≤ 0.073 mg eq/kg).

In potato tubers, parent isoflucypram was the main residue representing 69–86 percent TRR (0.029–0.056 mg/kg). The only remaining identified metabolite was isoflucypram-cyclopropyl-pyrazole-carboxamide (11 percent TRR [0.007 mg eq/kg]). There were no unidentified peaks and no radioactivity remaining in the PES.

Plant metabolism summary and conclusions

The metabolism of isoflucypram was evaluated in tomatoes, wheat, soya bean, and oilseed rape following 2–3 foliar directed applications and in potatoes following seed treatment.

Isoflucypram was the only residue observed in all food commodities (i.e., tomatoes, wheat grain, soya bean seed, oilseed rape seed, and potato tubers) representing 68–98 percent TRR. In oilseed rape intermediate harvest and mature plants, isoflucypram was partially metabolised (72–88 percent TRR) with low levels (up to 4.6 percent TRR) of glucose-malonic acid and glycine-malonic acid conjugates of isoflucypram-propanol, isoflucypram-2-propanol, and isoflucypram-hydroxyphenyl observed. Parent isoflucypram was metabolised to a further extent in wheat hay and straw (50–64 percent TRR) with isoflucypram-propanol and isoflucypram-desmethyl-propanol, as well as their glycine and glycine-malonic acid conjugates, observed up to 10 percent TRR. Hydrolysis data suggest that the conjugated metabolites in oilseed and wheat commodities are hydrolysed to their free forms.

In soya bean forage, hay, and straw, isoflucypram was metabolised to a further extent, representing 10–70 percent TRR. Isoflucypram-desfluoro-Cys-MA, isoflucypram-desfluoro-homoGSH, isoflucypram-desfluoro-mercapto-lactic acid-propyl-OH-Glyc, isoflucypram-desfluoro-mercapto-lactic acid-Glyc, and isoflucypram-desfluoro-mercapto-lactic acid-OH were observed in concentrations up to 23 percent TRR. All identified soya bean metabolites follow a similar pathway resulting in defluorination and conjugation with a sulfur containing moiety. The Meeting noted that hydrolysis data for the soya bean extracts would be informative for concluding whether or not the metabolites observed in soya bean feeds are of interest for animal dietary burden calculations.

When isoflucypram was applied to potato seed pieces prior to planting, near full metabolism of parent was observed (2–7 percent TRR remaining) with the glycine-malonic acid conjugates of isoflucypram-OH-phenyl and isoflucypram-2-propanol observed up to 29 percent TRR. Following application to potato seed pieces prior to planting, parent isoflucypram represented 69–86 percent TRR in mature tubers with isoflucypram-cyclopropyl-pyrazole-carboxamide accounting for up to 11 percent TRR.

Environmental fate

Hydrolytic Degradation

Hydrolytic degradation of pyrazole-labelled isoflucypram was investigated in closed sterile aqueous buffer solutions at pH 4, 7, and 8.9 in the dark at 50.0 °C for 7 days. Isoflucypram was stable at all pH values, and no DT_{50} values were calculated. Hydrolytic degradation is unlikely to contribute to the degradation of isoflucypram under typical environmental conditions.

Photodegradation

In the neutral buffer solution, isoflucypram degraded to 91 and 79 percent of the initial concentration after 150 days of irradiation

Aerobic degradation in soil

The route and rate of degradation of pyrazole (n=8) and phenyl (n=7) labelled isoflucypram were studied in laboratory soil under aerobic conditions in the dark at 20 °C for 120–125 days. The application rate was 75 g ai/ha for most trials, except for two of the pyrazole labelled trials (50 g ai/ha).Trials conducted at 75 g ai/ha were evaluated for degradation rate with the KinGUII software under the FOCUS guideline. Isoflucypram followed single first order (SFO) degradation in all trials, with DT_{50}s ranging from 223 to 875 days (geometric mean = 446 days).

Isoflucypram-carboxylic acid was the only prominent degradate identified, increasing with time to a maximum of 10.9 percent of the applied radioactivity (AR) 120 days after treatment (DAT).

The degradation of isoflucypram-carboxylic acid was investigated in five different laboratory soils under aerobic conditions in the dark at 20°C for 120 days at a nominal rate of 4.12 µg/100 g dry soil. Dissipation kinetics were modelled with the KinGUII software under the FOCUS guideline. Isoflucypram-carboxylic acid dissipated following double first order in parallel (DFOP; n=4) or SFO (n=1) kinetics with DT_{50}s ranging from 17 to 27 days (geometric mean = 22 days).

Terrestrial Field Dissipation

The Meeting received 12 terrestrial field dissipation studies. Isoflucypram was applied to bare soil plots one or two times at rates ranging from 100–500 g ai/ha. Soil samples were collected at various intervals from 749 to 832 days after application to a maximum depth of 60–120 cm. Collected soil was partitioned into 10–15 cm horizons. The rate of isoflucypram degradation was evaluated with the KinGUII software under the FOCUS guideline. The Meeting excluded three DT_{50} values due to low r^2 and/or high chi^2 error values. The remaining acceptable DT_{50} values (first and second applications calculated separately, where applicable) ranged from 9 to 177 days (geometric mean = 46 days). One trial was best fit by SFO, six trials were best fit by DFOP, and four trials were best fit by first order multi-component (FOMC) dissipation.

Isoflucypram-carboxylic acid comprised up to 3.6 percent of the applied dose. Isoflucypram-carboxylic acid was only quantifiable in the top soil segment and peaked in concentration at 30–241 days after the first application.

Confined rotational crop studies

Isoflucypram was applied to bare sandy loam soil as a single spray application at a rate of 198–210 g ai/ha (2.6–2.8× the seasonal cGAP for field crops). Turnips, Swiss chard, and wheat were sown into the treated soil 30, 140, and 287 days after application. Immature samples of Swiss chard (BBCH 45), wheat forage (BBCH 29), and wheat hay (BBCH 75–83) and mature samples of turnip roots, turnip tops, Swiss chard, wheat straw, and wheat grain were harvested and analysed for TRR.

TRR in pyrazole labelled studies was consistently higher than phenyl labelled studies by a factor of 1.1× (immature Swiss chard) to 6.2× (wheat straw). In general, TRR was highest at the second plant-back interval (PBI), followed by the third PBI, and lowest at the first PBI. One notable exception is pyrazole-labelled wheat straw which followed an increasing trend with increasing PBIs. Across both studies, TRR was lowest (0.003–0.011 mg eq/kg) in turnip roots, wheat grain, and phenyl-labelled turnip tops; slightly higher (0.015–0.078 mg eq/kg) in high-water components of crops (pyrazole-labelled turnip tops, Swiss chard, and wheat forage); and highest (0.036–0.34 mg eq/kg) in dry components of crops (wheat hay and straw). The following samples incurred low TRR and were not extracted for residue identification: turnip tops (phenyl label, all PBIs), turnip roots (all samples), wheat grain (phenyl label, all PBIs; pyrazole label, 30-day PBI).

ACN/water extraction released 53–54 percent TRR from wheat grain and 78–98 percent TRR from the other matrices. The PES of wheat hay, wheat straw, and wheat grain were further extracted with microwave assistance with optional dioxane and 5 mol/L HCl, releasing an additional 5.5–32 percent TRR.

In the phenyl study, parent isoflucypram was the only structure identified in extracts prior to hydrolysis, accounting for ≤ 17 percent TRR (≤ 0.004 mg/kg) and decreasing in concentration with increasing PHIs. Up to 17 unknown peaks were characterised based on chromatographic behaviour, individually accounting for ≤ 31 percent TRR (≤ 0.009 mg eq/kg). Up to 11.7 percent TRR (≤ 0.007 mg eq/kg) remained in the PES.

In hydrolysed immature Swiss chard extract at the 30-day PBI, prominent metabolites included isoflucypram-propanol and isoflucypram-carboxylic acid accounting for 11 percent TRR (0.003 mg eq/kg) and 37 percent TRR (0.011 mg eq/kg), respectively. In hydrolysed mature Swiss chard extract at the 30-day PBI, prominent metabolites included isoflucypram, isoflucypram-propanol, and isoflucypram-carboxylic acid accounting for 17 percent TRR (0.003 mg eq/kg), 17 percent TRR (0.004 mg eq/kg), and 41 percent TRR (0.008 mg eq/kg), respectively. In hydrolysed wheat straw extract at the 30-day PBI, the only prominent metabolite was isoflucypram-carboxylic acid (11 percent TRR; 0.006 mg eq/kg).

In the pyrazole study, all identified metabolites contained only the pyrazole ring. Many metabolites shared structural similarities with sugar and/or amino acid conjugates. The Meeting did not receive hydrolysis data for the extracts. The Meeting assigned metabolites to one of the following groups based on structural similarities:

- Compounds containing the isoflucypram-cyclopropyl-pyrazole-carboxamide structure (including isoflucypram-cyclopropyl-pyrazole-carboxamide-Ala and isoflucypram-cyclopropyl-pyrazole-carboxamide-Glyc isomers 1 and 2);
- Compounds containing the isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH structure (including isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-Cys and isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-GSH);
- Compounds containing the isoflucypram-cyclopropyl-pyrazole-carboxamide-OH structure (including isoflucypram-cyclopropyl-pyrazole-carboxamide-OH-lactic acid isomers 1 and 2);
- Compounds containing the isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-mercapto structure (including isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-mercapto-Glyc and isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-mercapto-Glyc-MA).

The following metabolites are not included in the above groups and are summarised individually:

- BCS-CR60082;
- Isoflucypram-desfluoro-cyclopropyl-pyrazole-carboxamide-Ala.

In turnip tops grown in rotation, parent isoflucypram was a minor residue representing 4.8 percent TRR (0.001 mg/kg) at the 30 day PBI and was not detected at other PBIs. Up to 9 unknown peaks were characterised based on chromatographic behaviour, individually accounting for ≤ 9.5 percent TRR (≤ 0.003 mg eq/kg). Radioactivity remaining in the PES was ≤ 7.7 percent TRR (≤ 0.002 mg eq/kg).

In rotational immature and mature Swiss chard, isoflucypram was a minor component representing ≤ 6 percent TRR (≤ 0.002 mg/kg). Compounds containing the isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH structure accounted for 23–57 percent TRR (0.015–0.020 mg eq/kg in immature Swiss chard and 0.013–0.015 mg eq/kg in mature Swiss chard). Up to 22 unknown peaks were characterised based on chromatographic behaviour, individually accounting for ≤ 11 percent TRR (≤ 0.007 mg eq/kg). Radioactivity remaining in the PES was ≤ 7.6 percent TRR (≤ 0.004 mg eq/kg).

In rotational wheat forage, parent isoflucypram was a minor component representing ≤ 7 percent TRR (≤ 0.003 mg/kg). Compounds containing the isoflucypram-cyclopropyl-pyrazole-carboxamide structure accounted for 19–30 percent TRR (0.009–0.023 mg eq/kg) and compounds containing the isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH structure accounted for 8.3–13 percent TRR (0.004–0.010 mg eq/kg). Up to 12 unknown peaks were characterised based on chromatographic behaviour, individually accounting for ≤9.0 percent TRR (≤ 0.007 mg eq/kg).

Radioactivity remaining in the PES was ≤9.0 percent TRR (≤ 0.007 mg eq/kg). In rotational wheat hay, isoflucypram was not detected. Isoflucypram-desfluoro-cyclopropyl-pyrazole-carboxamide-Ala accounted for ND-4.8 percent TRR (ND-0.011 mg eq/kg), compounds containing the isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-mercapto accounted for 5.5–7.1 percent TRR (0.008–0.012 mg eq/kg), compounds containing the isoflucypram-cyclopropyl-pyrazole-carboxamide structure accounted for 15–23 percent TRR (0.023–0.051 mg eq/kg), compounds containing the isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH structure accounted for 5.2–12 percent TRR (0.006-0.026 mg eq/kg), and compounds containing the isoflucypram-cyclopropyl-pyrazole-carboxamide-OH structure accounted for 3.2–12 percent TRR (0.007–0.022 mg eq/kg). Up to 17 unknown peaks were characterised based on chromatographic behaviour, individually accounting for ≤ 4.3 percent TRR (≤ 0.010 mg eq/kg). Radioactivity remaining in the PES was ≤ 4.3 percent TRR (≤ 0.010 mg eq/kg).

In rotational wheat hay, parent isoflucypram was not recovered. Isoflucypram-desfluoro-cyclopropyl-pyrazole-carboxamide-Ala accounted for ND-4.8 percent TRR (ND-0.011 mg eq/kg), compounds containing the isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-mercapto accounted for 5.5–7.1 percent TRR (0.008–0.012 mg eq/kg), compounds containing the isoflucypram-cyclopropyl-pyrazole-carboxamide structure accounted for 15–23 percent TRR (0.023–0.051 mg eq/kg), compounds containing the isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH structure accounted for 5.2–12 percent TRR (0.006–0.026 mg eq/kg), and compounds containing the isoflucypram-cyclopropyl-pyrazole-carboxamide-OH structure accounted for 3.2–12 percent TRR (0.007–0.022 mg eq/kg). Up to 17 unknown peaks were characterised based on chromatographic behaviour, individually accounting for ≤4.3 percent TRR (≤ 0.010 mg eq/kg). Radioactivity remaining in the PES was ≤ 4.3 percent TRR (≤ 0.010 mg eq/kg).

In rotational wheat straw, parent isoflucypram was not detected. BCS-CR60082 accounted for 2.8–7.0 percent TRR (0.007–0.020 mg eq/kg), isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-mercapto accounted for 4.9–9.2 percent TRR (0.012–0.018 mg eq/kg), compounds containing the isoflucypram-cyclopropyl-pyrazole-carboxamide structure accounted for 8.4–16 percent TRR (0.011–0.039 mg eq/kg), compounds containing the isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH structure accounted for 9.2–11 percent TRR (0.012–0.035 mg eq/kg), and compounds containing the isoflucypram-cyclopropyl-pyrazole-carboxamide-OH structure accounted for 5.9–12 percent TRR (0.015–0.037 mg eq/kg). Up to 18 unknown peaks were characterised based on chromatographic behaviour, individually accounting for ≤ 6.4 percent TRR (≤ 0.014 mg eq/kg). Radioactivity remaining in the PES was ≤ 6.4 percent TRR (≤ 0.014 mg eq/kg).

In rotational wheat grain, parent isoflucypram was not detected. Isoflucypram-desfluoro-cyclopropyl-pyrazole-carboxamide-Ala accounted for 13 percent TRR (0.002 mg eq/kg). Three unknown peaks were characterised based on chromatographic behaviour, individually accounting for ≤ 20 percent TRR (≤ 0.002 mg eq/kg). Radioactivity remaining in the PES was ≤ 20 percent TRR (≤ 0.002 mg eq/kg).

Field Rotational Crops

The Meeting received four independent rotational crop field trials following one broadcast application of an EC formulation of isoflucypram at 180 g ai/ha (2.4× the seasonal cGAP for cereal grains). Rotational crops of barley, carrot or turnips, and lettuce were planted in treated plots at PBIs of 21–34 days, 100–201 days, and 299–370 days and analysed for isoflucypram and BCS-CR60082. Soil samples (0–30 cm depth) were taken at from each plot at each PBI and analysed for isoflucypram and isoflucypram-carboxylic acid.

Average residues of isoflucypram were < 0.01 mg/kg in all samples, except carrot tops at one trial at the 106-day PBI (average residue of 0.066 mg/kg). Residues of BCS-CR60082 were < 0.01 mg eq/kg in all samples.

In soil samples, average residues of isoflucypram were between 0.011 and 0.049 mg/kg and average residues of isoflucypram-carboxylic acid were ≤ 0.002 mg eq/kg. Isoflucypram residues generally decreased with increased time between application and soil collection.

Environmental fate and rotational crops summary and conclusions

Isoflucypram is stable to hydrolytic degradation. In aerobic metabolism and terrestrial field dissipation studies, isoflucypram-carboxylic acid was observed at up to 10.9 percent AR or 3.6 percent, respectively. Neither isoflucypram nor isoflucypram-carboxylic acid are persistent in the soil, with geometric mean DT_{50}s of 46 days (field dissipation) and 22 days (aerobic metabolism), respectively.

While isoflucypram-carboxylic acid is a prominent soil metabolite, it is not observed in rotational crops as demonstrated by the confined rotational crops study.

In the confined rotational crops study, only the metabolite group containing the isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH structure was detected at levels higher than 0.01 mg eq/kg in food commodities (up to 0.015 mg eq/kg in mature Swiss chard). The Meeting concluded that, at the cGAP considered by the current Meeting, this group of metabolites may be present at an estimated residue level of 0.0054 mg eq/kg in rotational leafy crops.

The metabolites or groups of metabolites that exceeded 0.01 mg eq/kg in livestock feed items were isoflucypram-desfluoro-cyclopropyl-pyrazole-carboxamide-Ala (up to 0.011 mg eq/kg), compounds containing the isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-mercapto structure (up to 0.018 mg/kg), compounds containing the isoflucypram-cyclopropyl-pyrazole-carboxamide structure (up to 0.051 mg eq/kg), compounds containing the isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH structure (up to 0.035 mg eq/kg), and compounds containing the isoflucypram-cyclopropyl-pyrazole-carboxamide-OH structure (up to 0.037 mg eq/kg). Because the confined rotational crop trials were conducted at approximately 2.7× the cGAP considered by the current Meeting, the Meeting concluded that residues of these metabolites or groups of metabolites would not be expected to contribute significantly to the livestock dietary burdens and are not expected to be detected in animal tissues.

The field rotational crops study analysed residues of isoflucypram and BCS-CR60082. Residues of BCS-CR60082 were < 0.01 mg eq/kg in all crops, except isoflucypram in carrot tops at one trial (0.066 mg/kg). The Meeting noted that the study report attributed this value to spray drift from an application to an adjacent field rather than uptake from the soil. The Meeting concluded that residues of isoflucypram and BCS-CR60082 are not expected in rotational crops.

The Meeting noted that, should a higher cGAP be received in the future, the expectation of residues of the pyrazole metabolites in rotational crops may need to be re-evaluated.

Animal metabolism

The Meeting received studies describing the metabolism of isoflucypram in laboratory rats, lactating goats and laying hens.

Rats

The metabolism of isoflucypram in rats was reviewed in the framework of the toxicological evaluation by the WHO Core Assessment Group of the 2022 JMPR.

Lactating goats

Lactating goats were orally dosed with pyrazole- and phenyl-labelled isoflucypram at 45 ppm or 21 ppm (dry feed) per day in the diet for five consecutive days. Approximately 0.03–0.06 percent of the administered dose (AD) was secreted with milk, correlating to TRRs ranging from 0.008–0.021 mg eq/kg. Per-day pooled milk samples reached a plateau after three days.

Approximately six hours after the final dose, animals were sacrificed and TRRs were determined in liver, kidney, muscle (pooled round and loin), and fat (pooled perirenal and omental). The sum of radioactive residues in edible fractions was 0.27–0.72 percent AD, correlating to TRRs of 0.35–0.72 mg eq/kg in liver, 0.18–0.19 mg eq/kg in kidney, 0.10 mg eq/kg in fat, and 0.011–0.038 mg eq/kg for muscle

Extraction with ACN/water and THF (for pyrazole-labelled milk only) released 89–100 percent TRR. Various matrices were partitioned against n-heptane resulting in low amounts of radioactivity in the organic phase (≤ 1.4 percent; ≤ 0.002 mg eq/kg). Liver and pyrazole-labelled muscle extracts were additionally extracted with microwave assistance and HCl (liver only), together releasing an additional 3.5–4.9 percent TRR.

In plateau-level milk, isoflucypram was the predominant residue, accounting for 33–34 percent TRR (0.004–0.005 mg/kg). The only prominent metabolite was isoflucypram-2-propanol (5.0–20 percent TRR [0.001–0.003 mg eq/kg]). Up to five unknown peaks were characterised based on chromatographic behaviour, individually accounting for ≤ 39 percent TRR (≤ 0.005 mg eq/kg). Radioactivity remaining in the PES was ≤ 1.5 percent TRR (< 0.001 mg eq/kg).

The majority of the radioactivity (approximately 87 percent TRR) in milk remained in the skimmed milk fraction in the pyrazole study, whereas it was evenly distributed between the skimmed milk and cream fractions in the phenyl study.

In muscle, isoflucypram was the predominant residue, accounting for 22 percent TRR (0.002–0.008 mg/kg). Prominent metabolites were isoflucypram-2-propanol (14–18 percent TRR, 0.002–0.006 mg eq/kg) and isoflucypram-propanol (9.0–10 percent TRR, 0.001–0.004 mg eq/kg). Up to 10 unknown peaks were characterised based on chromatographic behaviour between the conventional and exhaustive extract, individually accounting for ≤ 25 percent TRR (≤ 0.003 mg eq/kg). Radioactivity remaining in the PES was ≤ 6.4 percent TRR (≤ 0.002 mg eq/kg).

In fat, only the pyrazole label was studied due to lack of fat on the phenyl labelled goat, although no abnormality on feed consumption, weight, or common behaviour was observed. Isoflucypram was the predominant residue, at 59 percent TRR (0.061 mg/kg). The only prominent metabolite was isoflucypram-2-propanol, accounting for 17 percent TRR (0.017 mg eq/kg). Four unknown peaks were characterised based on chromatographic behaviour, individually accounting for ≤ 7.5 percent TRR (≤ 0.008 mg eq/kg). Radioactivity remaining in the PES was 1.7 percent TRR (0.002 mg eq/kg).

In liver, isoflucypram accounted for 3.5–5.3 percent TRR (0.018–0.025 mg/kg). Prominent metabolites were isoflucypram-2-propanol-GlucA (13–14 percent TRR, 0.045–0.099 mg eq/kg), isoflucypram-propanol-GlucA isomer 1 (8.8–13 percent TRR, 0.031–0.094 mg eq/kg), isoflucypram-propanol-GlucA isomer 2 (5.9–7.7 percent TRR, 0.021–0.055 mg eq/kg), isoflucypram-carboxylic acid (4.2–8.9 percent TRR, 0.015–0.064 mg eq/kg), isoflucypram-propanol (4.9–5.8 percent TRR, 0.017–

0.042 mg eq/kg), isoflucypram-2-propanol (2.6–2.8 percent TRR, 0.010–0.019 mg eq/kg), and isoflucypram-lactic acid (1.3–1.6 percent TRR, 0.005–0.011 mg eq/kg). Up to 32 unknown peaks were characterised based on chromatographic behaviour between the conventional, exhaustive ACN/water and HCl extract, individually accounting for ≤ 6.7 percent TRR (≤ 0.029 mg eq/kg). Radioactivity remaining in the PES was ≤ 8.2 percent TRR (≤ 0.036 mg eq/kg).

Liver extracts were enzymatically cleaved with ß-glucuronidase and arylsulfatase (20 hours at 37 °C) resulting in decreased concentrations of conjugates accompanied by increase concentrations of respective aglycones. Isoflucypram accounted for 4.7–6.1 percent TRR (0.016–0.044 mg/kg). Prominent metabolites were isoflucypram-propanol (18–21 percent TRR, 0.064–0.15 mg eq/kg), isoflucypram-2-propanol (12–13 percent TRR, 0.047–0.085 mg eq/kg), isoflucypram-carboxylic acid (10–12 percent TRR, 0.033–0.084 mg eq/kg), isoflucypram-desmethyl-propanol (4.3–4.6 percent TRR, 0.015–0.033 mg eq/kg), and isoflucypram-desmethyl-carboxylic acid (1.5–2.1 percent TRR, 0.005–0.016 mg eq/kg).

In kidney, isoflucypram was a minor compound accounting for 1.6–2.7 percent TRR (0.003–0.005 mg/kg). Prominent metabolites were isoflucypram-carboxylic acid (6.8–18 percent TRR, 0.012–0.034 mg eq/kg), isoflucypram-propanol-GlucA isomer 2 (7.0–8.6 percent TRR, 0.013–0.016 mg eq/kg), isoflucypram-lactic acid (4.2–6.1 percent TRR, 0.008–0.012 mg eq/kg), isoflucypram-propanol (2.5–5.6 percent TRR, 0.004–0.011 mg eq/kg), isoflucypram-propenol-GlucA (3.6–6.2 percent TRR, 0.007–0.011 mg eq/kg), and isoflucypram-N-methyl-pyrazole-carboxylic acid (5.8 percent TRR, 0.011 mg eq/kg). Up to 21 unknown peaks were characterised based on chromatographic behaviour, individually accounting for ≤ 9.1 percent TRR (≤ 0.017 mg eq/kg). Radioactivity remaining in the PES was ≤ 7.8 percent TRR (≤ 0.015 mg eq/kg).

Kidney extracts were enzymatically cleaved with ß-glucuronidase and arylsulfatase (20 hours at 37 °C) resulting in decreased concentrations of conjugates accompanied by increased concentrations of respective aglycones. Isoflucypram accounted for 1.3–2.6 percent TRR (0.002–0.005 mg/kg). Prominent metabolites were isoflucypram-carboxylic acid (13–23 percent TRR, 0.023–0.044 mg eq/kg), isoflucypram-propanol (11–20 percent TRR, 0.020–0.037 mg eq/kg), isoflucypram-2-propanol (5.5–6.7 percent TRR, 0.010–0.013 mg eq/kg), isoflucypram-desmethyl-carboxylic acid (4.2–6.4 percent TRR, 0.008–0.012 mg eq/kg) and isoflucypram-desmethyl-propanol (4.6–5.0 percent TRR, 0.009 mg eq/kg).

Laying Hen

Laying hens were orally dosed with labelled isoflucypram at 17 ppm and 18 ppm (dry feed) per day for 14 consecutive days. Eggs were collected daily and 0.12–0.14 percent of the AD was recovered corresponding to 0.029–0.066 mg eq/kg TRR. TRR in eggs plateaued on Day 4–6.

Hens were sacrificed approximately six hours after the final dose. Radioactive residues in the tissues were approximately 0.22–0.24 percent AD, corresponding to TRRs of 0.37 mg eq/kg in liver, 0.36–0.39 mg eq/kg in kidney, 0.075–0.11 mg eq/kg in skin, 0.042–0.047 mg eq/kg in subcutaneous fat, 0.029 mg eq/kg in leg muscle, and 0.017–0.018 mg eq/kg in thorax muscle.

Extraction with ACN/water released 84–93 percent TRR. Liver PES underwent extractions with microwave assistance and HCl which together released an additional 15–16 percent TRR. Extracts from various matrices were partitioned with n-heptane resulting in low amounts of radioactivity in the organic phase (≤1.3 percent TRR; 0.001 mg eq/kg).

In eggs, parent isoflucypram was a minor component accounting for 3.7–6.4 percent TRR (0.002–0.003 mg/kg). Prominent metabolites were isoflucypram-propanol (34–35 percent TRR [0.017–0.018 mg eq/kg]) and isoflucypram-desmethyl-propanol (22–23 percent TRR [0.011 mg eq/kg]). Up to five unknown peaks were characterised based on chromatographic behaviour, individually accounting for

≤ 7.7 percent TRR (≤ 0.004 mg eq/kg). Radioactivity remaining in the PES was ≤ 7.2 percent TRR (≤ 0.004 mg eq/kg).

In muscle (thorax and leg analysed separately), parent compound was a minor component accounting for ≤2.9 percent TRR (0.001 mg/kg). Remaining prominent metabolites included isoflucypram-desmethyl-propanol (21–30 percent [0.004–0.009 mg eq/kg]), isoflucypram-desmethyl-1,2-propandiol (14–22 percent TRR [0.003–0.004 mg eq/kg]), isoflucypram-desmethyl-carboxylic acid (12–20 percent TRR [0.002–0.006 mg eq/kg]), and isoflucypram-carboxylic acid (6.6–11 percent TRR [0.001–0.003 mg eq/kg]). Up to four unknown peaks were characterised based on chromatographic behaviour, individually accounting for ≤ 19.5 percent TRR (≤ 0.004 mg eq/kg). Radioactivity was successfully extracted as demonstrated by ≤ 8.2 percent TRR (≤ 0.002 mg eq/kg) remaining in the PES.

In fat, isoflucypram was the predominant component representing 20–24 percent TRR (0.009–0.010 mg/kg). Prominent metabolites included isoflucypram-propanol (6.5–12 percent TRR [0.003–0.005 mg eq/kg]) and isoflucypram-desmethyl-propanol (8.0–10 percent TRR [0.004 mg eq/kg]). Up to seven unknown peaks were characterised based on chromatographic behaviour, individually accounting for ≤ 11.2 percent TRR (≤ 0.005 mg eq/kg). Radioactivity remaining in the PES was ≤ 8.2 percent TRR (≤ 0.004 mg eq/kg).

Parent compound was not detected in the liver. Prominent metabolites were isoflucypram-desmethyl-carboxylic acid (14–22 percent TRR [0.053–0.082 mg eq/kg]), isoflucypram-carboxylic acid (5.8–12 percent TRR [0.022–0.044 mg eq/kg]), isoflucypram-desmethyl-1,2-propandiol-N-GlucA (5.4–9.2 percent TRR [0.020–0.034 mg eq/kg]), isoflucypram-desmethyl-propanol-N-GlucA (6.1–11 percent TRR [0.023–0.040 mg eq/kg]), isoflucypram-desmethyl-1,2-propandiol (5.6–6.9 percent TRR [0.021–0.025 mg eq/kg]), isoflucypram-desmethyl-propanol (2.7–5.3 percent TRR [0.010–0.020 mg eq/kg]), and isoflucypram-desmethyl-2-propanol-N-GlucA (2.5–3.0 percent TRR [0.009–0.011 mg eq/kg]). Up to 27 unknown peaks were identified based on chromatographic behaviour in the conventional extract, exhaustive ACN/water extract, and exhaustive ACN/HCl extract, individually accounting for ≤ 8.4 percent TRR (≤ 0.031 mg eq/kg). Radioactivity remaining in the PES was ≤ 0.1 percent TRR (< 0.001 mg eq/kg).

Liver extracts were enzymatically cleaved with β-glucuronidase and arylsulfatase (96 hours at 37 °C). Parent compound was not identified in the hydrolysed extract. Prominent metabolites included isoflucypram-desmethyl-carboxylic acid (17–26 percent TRR [0.064–0.096 mg eq/kg]), isoflucypram-desmethyl-propanol (14–15 percent TRR [0.053–0.054 mg eq/kg]), isoflucypram-carboxylic acid (9.0–17 percent TRR [0.033–0.062 mg eq/kg]), and isoflucypram-desmethyl-1,2-propandiol (11–12 percent TRR [0.041–0.043 mg eq/kg]),

Animal metabolism summary and conclusions

The distribution and elimination of isoflucypram appeared to be similar in rats, goat and hens. Radioactivity was consistently observed at highest levels in the liver, followed by lower (rat and goat) or similar (hen) levels in kidney, followed by fat. Muscle had the lowest level of radioactivity in the goat and hen.

Isoflucypram was metabolized to a further extent in hens than in goats in all tissues. In fat, muscle, milk, and eggs, low overall radioactivity was observed and metabolites were generally unconjugated. In these matrices, the metabolic pathways differed between the goat and hen species with formation of isoflucypram-propanol and isoflucypram-2-propanol observed in ruminant fat, muscle, and milk (up to 20 percent TRR), and formation of isoflucypram-propanol, isoflucypram-desmethyl-propanol, isoflucypram-carboxylic acid, isoflucypram-desmethyl-carboxlylic acid, and isoflucypram-desmethyl-1,2-propandiol (as well as its N-GlucA conjugate) observed in hen fat, muscle, and egg (up to 35 percent TRR).

Goat liver/kidney and hen liver contained little to no parent isoflucypram and a higher levels of conjugated metabolites. Isoflucypram-carboxylic acid was the only prominent metabolite common to all three matrices. Isoflucypram-propanol (free and/or GlucA conjugates) was prevalent in goat liver/kidney and trace in kidney liver. Isoflucypram-desmethyl-propanol (free and N-GlucA conjugate) and isoflucypram-desmethyl-carboxylic acid were prevalent in hen liver and trace in goat liver/kidney. In goat liver and kidney, common metabolites included isoflucypram-2-propanol (free and GlucA conjugate) and isoflucypram-lactic acid. The metabolites isoflucypram-N-methyl-pyrazole-carboxylic acid and isoflucypram-propenol-GlucA were found only in goat kidney. The metabolites isoflucypram-desmethyl-2-propanol-N-GlucA and isoflucyrapm-1,2-propandiol (free and N-GlucA conjugate) were found only in hen liver.

Methods of analysis

The Meeting received several analytical methods for quantitation of isoflucypram and various metabolites.

Plants

Method 01475 analysed isoflucypram and BCS-CR60082. Successful method validation was performed on tomato fruit, orange fruit, rape seed, wheat grain/straw, and dry bean seed. Samples are extracted twice with ACN/water (dry commodities left to soak in water for 20 minutes before addition of ACN in the first extraction). Internal standards are added and extracts are analysed by LC-MS/MS. The LOQ is 0.01 mg/kg for both analytes in all matrices. The ability of the method to extract incurred residues was successfully demonstrated based on comparison with samples from the primary and confined rotational crop metabolism studies.

Method LN-002-P16-01 uses the same extraction procedure as Method 01475 but only analyses isoflucypram. The method was successfully validated in tomato fruit, orange fruit, wheat grain, soya bean seed, and canola seed. The LOQ is 0.01 mg/kg in all matrices.

Method 01564 analyses isoflucypram, isoflucypram-desmethyl-propanol (free and conjugated), and isoflucypram-propanol (free and conjugated). Successful method validation was performed on wheat green material, grain, and straw. Samples are spiked with isotopic isoflucypram-desmethyl-propanol internal standard, 5 mol/L HCl is added, and samples are heated at 98 °C for 30 minutes followed by two extractions with ACN/water. Isotopic internal standards for isoflucypram and isoflucypram-propanol are added to the combined extracts for LC-MS/MS analysis. The LOQ is 0.01 mg/kg in all matrices. The ability of the method to extract residues and hydrolyse conjugates was successfully demonstrated based on comparison with samples from the wheat hay and straw metabolism studies.

Method 01520 uses the same extraction procedure as Method 01475; however, the only analyte is isoflucypram and the method does not use an internal standard. Successful method validation and Independent Laboratory Validation data were provided on tomato fruit, orange fruit, wheat grain, coffee green bean, oilseed rape seed, and dry bean seed. The LOQ is 0.01 mg/kg in all matrices.

The QuEChERS multi-residue successfully extracted incurred residues of isoflucypram in tomato fruit, soya been seed/straw, and oilseed rape intermediate harvest/seed matrices based on comparison with samples from the crop metabolism studies. Extraction efficiency of the QuEChERS multi-residue method was unsuccessful in wheat hay/straw/grain and soya bean forage/hay matrices.

Animals

Method 01511 analyses parent isoflucypram as well as free isoflucypram-2-propanol, isoflucypram-carboxylic acid, isoflucypram-propanol, isoflucypram-desmethyl-propanol, and isoflucypram-desmethyl-carboxylic acid, in animal matrices. The method also quantitates free and conjugated isoflucypram-propanol and isoflucypram-2-propanol in cow liver and kidney, and free and conjugated isoflucypram-desmethyl-propanol in hen liver.

For free analytes, samples are extracted with ACN/water, isotopic internal standards are added and samples are analysed by LC-MS/MS. Successful method validation was performed in eggs, milk, cow muscle/fat/liver/kidney, and hen liver. For free and conjugated analytes, samples are extracted with ACN/water, allowed to hydrolyse with β-glucoronidase and arylsulfatase at 37 °C, cleaned up by SPE, and analysed by LC-MS/MS. The LOQ is 0.005 mg eq/kg for milk, cream, and whey, and 0.01 mg/kg for all other matrices. The extraction solvent was the same as that used in the animal metabolism studies (≥ 92 percent TRR extracted).

The QuEChERS multi-residue method (Method 01300/M034) was successfully validated for milk, eggs, cattle muscle/fat/liver/kidney, and hen muscle. The LOQ is 0.005 mg eq/kg for milk, cream, and whey, and 0.01 mg/kg for all other matrices. Independent Laboratory Validation data were also submitted. The ability of the method to extract incurred residues was successfully demonstrated based on comparison with aged samples from the goat metabolism study.

In conclusion, methods are available for the analysis of isoflucypram and relevant metabolites in crop and animal matrices. The QuEChERS method is suitable for analysing isoflucypram in high-water and high-oil content crops and animal matrices but not suitable for high-starch content crops, cereal and oilseed animal feeds.

Stability of pesticide residues in stored analytical samples

The Meeting received two storage stability studies for isoflucypram and its metabolites in plants fortified at 0.1 or 0.2 mg/kg. Isoflucypram and BCS-CR60082 are stable during freezer storage (≤-18 °C) for a period of at least 24–25 months in tomato fruit, bean dry seed, wheat grain, rape seed, and orange fruit. Isoflucypram and BCS-CR60082 are also stable following frozen storage for at least 25–26 months at -18 °C followed by six days of storage at -1 ± 2 °C. Isoflucypram-desmethyl-propanol and isoflucypram-propanol are stable in/on wheat grain, green material, and straw under frozen storage conditions (<-18 °C) for at least 30 months. The storage stability data support the storage durations and conditions of the submitted studies. All plant samples in the submitted studies were stored frozen for durations supported by the submitted studies. Storage stability data were not submitted for animal matrices. As dairy cow and laying hen matrices from the farm animal feeding studies were stored frozen for a maximum of 30 days, storage stability data are not needed.

Definition of the residue

Plant commodities

In plant metabolism studies, parent isoflucypram was a major residue in tomato, wheat, soya bean, oilseed rape, and potato tubers grown from treated potato seed pieces (10–98 percent TRR).

A suitable analytical method using LC-MS/MS is available to determine residues of isoflucypram in plant commodities.

The Meeting concluded that isoflucypram was a suitable marker for enforcement purposes.

In deciding which additional compounds should be included in the residue definition for risk assessment, the Meeting considered the likely occurrence of the compounds and the toxicological properties of the candidates. In metabolism studies, no metabolites were identified in the tomato, wheat grain, soya bean seed, oilseed rape seed, or potato tubers. Isoflucypram-propanol (free and conjugated) and isoflucypram-desmethyl-propanol (free and conjugated) were considered based residues in the wheat plants in the metabolism study and quantifiable residues in the wheat grain in supervised residue trials. Additionally, the Meeting considered the group of metabolites containing the isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH structure based on residues > 0.01 mg eq/kg in the confined rotational crop metabolism study.

Based on toxicological properties, isoflucypram-propanol (free and conjugated) is assumed to be covered by the isoflucypram HBGVs. In supervised residue trials matching the cGAP, isoflucypram-propanol (free and conjugated) was observed in cereal grains in three of 39 trials at concentrations of 0.011, 0.014, and 0.019 mg eq/kg with corresponding isoflucypram residues of 0.019, 0.01, and 0.01 mg/kg. Due to low occurrence of quantifiable residues, the Meeting concluded that isoflucypram-propanol should be excluded from in the residue definition for dietary risk assessment.

The Meeting concluded that isoflucypram-desmethyl-propanol (free and conjugated) could be assessed using the threshold of toxicological concern (TTC) approach Cramer Class III (1.5 µg/kg bw/day), results discussed under *animal commodities*).

The Meeting concluded that the metabolites isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-Cys and isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-GSH could be assessed using the TTC approach for genotoxicity (0.0025 µg/kg bw/day). As the metabolites are conjugates of the same structure, the Meeting combined exposures from both metabolites for the TTC assessment.

The Meeting estimated dietary exposures for isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-Cys and isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-GSH of 0.0004–0.0107 µg/kg bw per day, above the TTC for a compound with potential of genotoxicity.

Animal commodities

In the cattle feeding study, isoflucypram was detected in all matrices except kidney. Although isoflucypram was not observed in the hen feeding study, it was observed in the laying hen metabolism study as a major component of fat (20–24 percent TRR) and a minor component of eggs and muscle (2.3–6.4 percent TRR).

A suitable analytical method using LC-MS/MS is available to determine residues of isoflucypram in animal commodities.

The Meeting concluded that isoflucypram was a suitable marker for enforcement purposes.

In deciding which additional compounds should be included in the residue definition for risk assessment, the Meeting considered the likely occurrence of the compounds and the toxicological properties of the candidates. The metabolites isoflucypram-propanol (free and conjugated), isoflucypram-desmethyl-propanol (free and conjugated), isoflucypram-2-propanol (free and conjugated), isoflucypram-carboxylic acid, isoflucypram-desmethyl-carboxylic acid, isoflucypram-lactic acid, isoflucypram-desmethyl-1,2-propandiol, isoflucypram-desmethyl-1,2-propandiol-N-GlucA, isoflucypram-N-methyl-pyrazole-carboxylic acid, isoflucypram-propenol-Gluc-A, and isoflucypram-desmethyl-2-propanol-N-GlucA were > 10 percent TRR and/or > 0.01 mg eq/kg in the lactating goat and laying hen metabolism studies.

Isoflucypram-carboxylic acid, isoflucypram-desmethyl-carboxylic acid, and isoflucypram-propanol (free and conjugated) are considered to be covered by the HBGV for isoflucypram. These metabolites were analysed in the cattle and hen feeding studies and each were quantifiable in at least two matrices, representing a significant portion of the residues covered by the HBGV of isoflucypram. The Meeting concluded that these metabolites should be considered in the residue definition for dietary risk assessment.

Toxicological data are not available for isoflucypram-lactic acid, isoflucypram-desmethyl-1,2-propandiol, isoflucypram-desmethyl-1,2-propandiol-N-GlucA, isoflucypram-N-methyl-pyrazole-carboxylic acid, isoflucypram-propenol-GlucA, and isoflucypram-desmethyl-2-propanol-N-GlucA. These metabolites were not analysed in the feeding studies. Isoflucypram-lactic acid was quantifiable in liver and kidney in the lactating goat metabolism studies (0.011 and 0.012 mg eq/kg, respectively), isoflucypram-desmethyl-1,2-propandiol was quantifiable in all matrices in the laying hen metabolism studies (0.002–0.025 mg eq/kg), isoflucypram-desmethyl-1,2-propandiol-N-GlucA was quantifiable in all matrices in the laying hen metabolism studies (0.001–0.034 mg eq/kg), isoflucypram-N-methyl-pyrazole-carboxylic acid was quantifiable in kidney in the goat metabolism study (0.011 mg eq/kg), isoflucypram-propenol-GlucA goat was quantifiable in kidney in the goat metabolism studies (0.007–0.01 mg eq/kg), and isoflucypram-desmethyl-2-propanol-N-GlucA was quantifiable in liver in the hen metabolism studies (0.009–0.011 mg eq/kg). Because these metabolites are present in low concentrations at the dietary burdens (≤ 0.00029 mg eq/kg), the Meeting concluded that they should be excluded from the residue definition for dietary risk assessment.

Isoflucypram-desmethyl-propanol (free and conjugated) and isoflucypram-2-propanol (free and conjugated) were quantifiable in at least one matrix in the feeding studies. The Meeting determined that these metabolites could be assessed using TTC Cramer Class III (1.5 µg/kg bw/day). The Meeting estimated dietary exposures for isoflucypram-desmethyl-propanol (free and conjugated) of 0.0212–0.1827 µg/kg bw/day and for isoflucypram-2-propanol of 0.0022–0.0194 µg/kg bw/day, below the TTC for Cramer Class III.

Based on the above, the Meeting recommended the following residue definition:

Definition of the residue for compliance with the MRL for plant and animal commodities: *Isoflucypram*.

Because dietary exposure to isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-Cys and isoflucypram-desfluoro-N-methyl-cyclopropyl-pyrazole-carboxamide-OH-GSH were above the TTC for a compound with potential of genotoxicity, the Meeting could not reach a conclusion on a residue definition for dietary risk assessment.

Definition of the residue for dietary risk assessment for plant and animal commodities: A *conclusion could not be reached.*

In deciding whether isoflucypram is fat-soluble, the Meeting noted that the mean residues of isoflucypram at the highest dose tested in the lactating cow feeding study were < 0.01 mg/kg in muscle and 0.081 mg/kg in perirenal fat while residues in cream were 0.11–0.15 mg/kg compared to < 0.005 mg/kg in whey. The Meeting considered the residue to be fat-soluble.

Results of supervised residue trials on crops

The Meeting received supervised field trial data to support isoflucypram uses on wheat and barley.

Cereal Grains

Supervised residue trials are available from a number of European countries and New Zealand.

Barley

The cGAP for barley grain from New Zealand is one application at 75 g ai/ha up to BBCH 61 (56-day pre-harvest interval (PHI)). In independent trials approximating the cGAP, residues of isoflucypram were (n=21): < 0.010(19), 0.013, and 0.10 mg/kg.

The Meeting estimated a maximum residue level of 0.1 mg/kg and a median value of 0.010 mg/kg for barley grain.

Wheat

The cGAP for wheat grain from New Zealand is one application at 75 g ai/ha up to BBCH 69 (42-day PHI). In independent trials approximating the cGAP, residues of isoflucypram were (n=42): < 0.01(39), 0.015, 0.019, and 0.042 mg/kg.

The Meeting estimated a maximum residue level of 0.05 mg/kg and a median value of 0.010 mg/kg for wheat grain.

As the use pattern covers triticale, the Meeting decided to extrapolate the wheat grain maximum residue level and median value to triticale grain.

Residues in animal feeds

The barley and wheat supervised residue trials included residue data on commodities defined as "forage" and "green material."

The Meeting noted that the percent dry matter in these samples collected at the cGAP PHI ranged from 29–91 percent for wheat and from 43–85 percent for barley, well above what the Meeting considers forage. The Meeting therefore considers this crop hay as opposed to forage.

Barley hay and straw

The cGAP for barley hay from New Zealand is one application at 75 g ai/ha up to BBCH 61 (42-day PHI).

Residues in barley hay were adjusted for percent dry matter (dw) in the submitted studies.

In independent trials approximating the cGAP, isoflucypram residues were (n=8): 0.094, 0.11, 0.24, 0.25, 0.32, 0.37, 0.48, and 0.51 and mg/kg (dw).

In independent trials at 116 and 106 g ai/ha (1.5× the cGAP application rate), isoflucypram residues were (n=2): 0.23 and 0.14 mg/kg (dw). By applying a proportionality factor of 0.65 and 0.71, the residues were (n=2): 0.15 and 0.097 mg/kg.

Isoflucypram residues in hay (proportionality factors of 0.65–1.0× applied) were (n=10): 0.094, 0.097, 0.11, 0.15, 0.24, 0.32(2), 0.37, 0.47, and 0.50 mg/kg (dw).

The cGAP for barley straw/stubble from New Zealand is one application at 75 g ai/ha up to BBCH 61 (56-day PHI).

Residues from the trials were corrected with the reported percent dry matter. For trials for which this information was not available, a percent dry matter of 89 percent was assumed for correction.

In independent trials approximating the cGAP, residues of isoflucypram in straw were (n=20): 0.055, 0.088, 0.16, 0.18(3), 0.22, 0.26, 0.27(3), 0.33, 0.36, 0.38, 0.45, 0.46, 0.69, 0.96, 1.1(2) mg/kg (dw).

Based on the straw data, the Meeting estimated a median residue of 0.27 mg/kg and a highest residue of 1.1 mg/kg for isoflucypram in barley hay and straw.

Wheat hay and straw

The cGAP for wheat hay from New Zealand is one application at 75 g ai/ha up to BBCH 69 (28-day PHI).

For 34 of the trials conducted according to cGAP, percent dry matter was reported and residues were corrected accordingly. For the remaining eight trials, a percent dry matter of 54 percent was assumed and corrected by the Meeting, based on the average of the given percent dry matter from the 34 trials above.

In independent trials approximating the cGAP, isoflucypram residues were (n=42): < 0.010, 0.14(2), 0.16, 0.17, 0.19(2), 0.20(2), 0.22, 0.26, 0.29(2), 0.31(2), 0.33(3), 0.36, 0.38, 0.41, 0.44, 0.50, 0.62, 0.86, 0.90, 0.91, 0.95, 1.1(3), 1.2(4), 1.3(2), 1.5(3), 1.7, and 3.3 mg/kg (dw).

The cGAP for wheat straw/stubble from New Zealand is one application at 75 g ai/ha up to BBCH 69 (42-day PHI).

Residues from the trials were corrected with the reported percent dry matter. For trials for which this information was not available, a percent dry matter of 88 percent was assumed for correction.

In independent trials approximating the cGAP, residues of isoflucypram in straw were (n=37): < 0.010, 0.061, 0.081, 0.13, 0.14(3), 0.17, 0.22, 0.25(2), 0.27, 0.32, 0.35, 0.43, 0.44, 0.45, 0.47, 0.55, 0.60, 0.73, 0.93, 1.1, 1.3(2), 1.4, 1.5, 1.6(3), 1.8(2), 1.9, 2.2(2), 2.7, and 3.6 mg/kg (dw).

Based on straw data, the Meeting estimated a median residue of 0.55 mg/kg and a highest residue of 3.6 mg/kg for isoflucypram in wheat hay and straw.

'Barley hay and straw' and 'wheat hay and straw', as commodities moving in trade, may not always be readily distinguishable from each other. The Meeting agreed to use the wheat straw data (dw) for the maximum residue level estimation for both 'barley hay and/or straw (dw)' and 'wheat hay and/or straw (dw)'.

The Meeting estimated a maximum residue level of 5 mg/kg for isoflucypram in/on wheat hay and/or straw (dw), and barley hay and/or straw (dw).

As the use pattern covers triticale, the Meeting decided to extrapolate the estimated maximum residue level, median residue levels, and highest residue levels from wheat hay and straw to triticale hay and straw.

Fate of residues during processing

Nature of the residue in processed commodities

The Meeting received studies investigating radiolabelled isoflucypram, isoflucypram-desmethyl-propanol, and isoflucypram-propanol following temperatures and pH conditions simulating typical processing procedures.

Isoflucypram and isoflucypram-propanol were stable under conditions simulating pasteurisation, baking/brewing/boiling, and sterilisation (test compounds were ≥ 98.0 percent TRR following all simulated processing procedures).

Isoflucypram-desmethyl-propanol was stabile under conditions simulating pasteurisation (approximately 99 percent TRR). Under conditions simulating baking/brewing/boiling, approximately 34 percent TRR was recovered as isoflucypram-desmethyl-propanol and approximately 66 percent TRR was

identified as isoflucypram-desmethyl-propanol-aldehyde. Under conditions simulating sterilisation, isoflucypram-desmethyl-propanol was not recovered and approximately 98 percent TRR was recovered as isoflucypram-desmethyl-propanol-aldehyde.

Residues in processed commodities

The Meeting received studies evaluating the effect of processing on isoflucypram in barley and wheat. Isoflucypram was applied at 5× the cGAP application rate.

Calculated processing factors indicate with a '<' (less-than) sign when the residue in the processed commodity is below the LOQ of the analytical method. The calculation in these cases is based on the LOQ (0.01 mg/kg) of the analytical method and the residue concentration of the RAC. The STMR-P values are calculated by multiplying the PF with the RAC STMR value (Table 160).

Table 160 Processing factors for isoflucypram

Raw Commodity (median)	Processed Commodity	Processing Factors	Median-P = Median $_{RAC}$ X PF (mg/kg)
Barley grain (0.010 mg/kg)	Pearl Barley	< 0.67	0.0067
	Beer	< 0.67	0.0067
	Brewer's Grain	< 0.67	0.0067
Wheat grain (0.010 mg/kg)	Bran, processed	1.2	0.012
	White Flour	< 0.63	0.0063
	Whole Meal Flour	0.67	0.0067
	Germ	1.1	0.011
	Pasta, Dry	< 0.63	0.0063
	Pasta, Cooked	< 0.63	0.0063
	Gluten	0.94	0.0094
	Starch	< 0.63	0.0063
	White Bread	< 0.63	0.0063
	Whole Meal Bread	< 0.63	0.0063
	AGF	148	1.5

Residues in animal commodities

Dairy cow

The Meeting received a study investigating the magnitude of isoflucypram in milk, cream, whey, muscle, liver, kidney, and fat of dairy cows orally dosed with isoflucypram for 28 days. Doses were administered orally via gelatine capsule with a pill gun at 1.6 ppm, 4.2 ppm, 16 ppm, and 48 ppm (dry feed basis).

Animals were sacrificed within 24 hours after the final dose except for the depuration group, which were sacrificed 4, 7, or 14 days after the last dose. Residues of isoflucypram were < 0.005 mg/kg in milk from the 1.6, 4.2, and 16-ppm dosing levels and ranged from 0.006–0.009 mg/kg at the 48-ppm dose level. Isoflucypram partitioned into cream with residues ranging from 0.11–0.15 mg/kg compared to < 0.005 mg/kg in corresponding skim fraction.

Residues of isoflucypram were < 0.01 mg/kg in muscle and kidney at all dose levels. Residues of isoflucypram were < 0.01 mg/kg in fat at the 1.6 and 4.2-ppm dose levels, 0.034 mg/kg at the 16 ppm dose level, and 0.081 mg/kg at the 48 ppm dose level. Residues of isoflucypram were < 0.01 mg/kg in liver

at the 1.6 and 4.2-ppm dose levels, < 0.011 mg/kg at the 16-ppm dose level, and < 0.016 mg/kg at the 48-ppm dose level.

Laying hen

The Meeting received a study investigating the magnitude of isoflucypram in eggs (whole, white, and yolk), muscle, liver, and fat with skin of laying hens orally dosed with isoflucypram for 28 days. Doses were administered orally via gelatine capsule at 0.53 ppm, 2.1 ppm, and 8.7 ppm (dry feed basis).

Animals were sacrificed within six hours after the final dose except for the depuration group, which were sacrificed 4, 7, or 14 days after the last dose. Residues of isoflucypram were < 0.01 mg/kg in all matrices at all dose levels.

Farm animal dietary burdens

Dietary burdens were calculated for beef cattle, dairy cattle, broilers, and laying poultry based on feed items evaluated by the JMPR by the current Meeting. The dietary burdens, estimated using the most recent version of the OECD livestock dietary burden calculator, are presented in Annex 6 and summarised in Table 161.[2]

Table 161 Estimated maximum dietary burdens of farm animals

	Livestock dietary burden, isoflucypram, ppm of dry matter diet							
	Japan		United States-Canada		European Union		Australia	
	Max		Max		Max		Max	
Beef cattle	0.012		0.64		0.84		3.6❶	
Dairy cattle	0.011		0.73		0.84		2.5❷	
Poultry – broiler	0.002		0.012		0.012		0.012	
Poultry – layer	0.004		0.012		0.37❸		0.009	

Notes:

❶ Highest maximum beef cattle dietary burden suitable for MRL estimates for mammalian tissues.

❷ Highest maximum dairy cattle dietary burden suitable for MRL estimates for mammalian milk.

❸Highest maximum poultry dietary burden suitable for MRL estimates for poultry tissues and eggs.

Animal commodity estimations of maximum residue levels and dietary intake

Mammals (other than marine mammals)

The isoflucypram maximum dietary burdens for beef and dairy cattle were 3.6 and 2.5 ppm, respectively. Table 162 shows the anticipated isoflucypram residues in beef and dairy cattle for maximum residue level estimation.

Table 162 Residue of isoflucypram in mammals other than marine mammals for maximum residue level estimation

	Feed level (ppm) for milk residues	Isoflucypram residue (mg/kg) in milk	Feed level (ppm) for tissue residues	Isoflucypram residue (mg/kg) in tissues			
				Muscle	Liver	Kidney	Fat
Maximum residue level estimates for beef and dairy cattle							
Feeding study	4.18	< 0.005	4.18	< 0.01	< 0.01	< 0.01	< 0.01

[2] http://www.fao.org/agriculture/crops/core-themes/theme/pests/pm/jmpr/jmpr-docs/en/

	Feed level (ppm) for milk residues	Isoflucypram residue (mg/kg) in milk	Feed level (ppm) for tissue residues	Isoflucypram residue (mg/kg) in tissues			
				Muscle	Liver	Kidney	Fat
Dietary burden and residue estimate	2.50	< 0.005[a]	3.60	< 0.01	< 0.01	< 0.01	< 0.01

Notes:

[a] Residue of < 0.005 mg/kg at the 15.5 ppm feeding level was used for the determination of the residue in milk fats.

The Meeting estimated the following maximum residue levels: 0.005(*) mg/kg for milks and milk fats and 0.01(*) mg/kg for meat (from mammals other than marine mammals), fat (from mammals other than marine mammals), and edible offal (mammalian).

Poultry

The isoflucypram maximum dietary burden for poultry is 0.37 ppm.

Table 163 shows the anticipated isoflucypram residues in poultry for maximum residue level estimation.

Table 163 Residues of isoflucypram in poultry for maximum residue level estimation

	Feed level (ppm) for egg residues	Isoflucypram residue (mg/kg) in eggs	Feed level (ppm) for tissue residues	Isoflucypram residue (mg/kg) in tissues			
				Muscle	Liver	Kidney	Fat
Maximum residue level estimates for poultry							
Feeding study	0.53	< 0.01	0.53	< 0.01	< 0.01	< 0.01	< 0.01
Dietary burden and residue estimate	0.37	< 0.01	0.37	< 0.01	< 0.01	< 0.01	< 0.01

The Meeting estimated maximum residue levels of 0.01(*) mg/kg for eggs, poultry meat, poultry fat, and poultry edible offal.

RECOMMENDATIONS

Summary of recommendations for isoflucypram

Definition of the residue for compliance with the MRL for plant and animal commodities: *Isoflucypram*.

Definition of the residue for dietary risk assessment for plant and animal commodities: A *conclusion could not be reached.*

The residue is fat-soluble.

DIETARY RISK ASSESSMENT

As the Meeting was unable to recommend residue definitions for dietary risk assessment for plants and animal commodities, chronic and acute dietary risk assessments could not be conducted.

FURTHER WORK OR INFORMATION

Desirable information

- Cereal grain processing data for isoflucypram-desmethyl-propanol.
- Hydrolysis of the extracts from the soya bean metabolism studies.

MANCOZEB (050)

First draft prepared by Dr M Doherty, Environmental Protection Agency, United States of America

EXPLANATION

Mancozeb is an ethylene-bis-dithiocarbamate (EBDC) fungicide that was evaluated for the first time by the JMPR in 1967 and underwent multiple subsequent assessments prior to periodic review in 1993. The 1993 Meeting established an acceptable daily intake (ADI) of 0–0.03 mg/kg bw for the group of EBDCs (mancozeb, maneb, metiram, and zineb; alone or in any combination). In addition, the Meeting has established an ADI of 0–0.004 mg/kg bw for the common EBDC metabolite ethylenethiourea (ETU). To date, no acute reference dose (ARfD) has been established by the Meeting for either the EBDC fungicides or ETU. The dithiocarbamates were last evaluated by the JMPR at its 2014 Meeting.

The definition of the residue for compliance with MRLs in plant and animal commodities is total dithiocarbamates, determined as CS_2, evolved during acid digestion and expressed as mg CS_2/kg. For the estimation of dietary intake in plant and animal commodities, the residue definition is mancozeb plus ethylenethiourea (ETU); in practice, this is done by assessing mancozeb toxicity-equivalent residues. Dithiocarbamate residues are not fat soluble.

The current Meeting received residue data from crop field trials in longan, soya bean, maize, rice, and cotton; processing studies for maize; and supporting information on analytical methods and storage stability.

METHODS OF RESIDUE ANALYSIS

Mancozeb: All analyses for mancozeb used a method similar to VR-036/17 (below), with variations in the temperature and time parameters for the conversion to CS_2. Concurrent recoveries are summarised in Table 2.

VR-036/17 (Magagnato, M. B. B., 2017, VR-036/17)

For this method, residues of mancozeb are extracted from the sample matrix and converted to CS_2 using a solution of stannous chloride/water/conc. HCl (1.5 g/20 mL/33 mL) + isooctane (4+1, v/v) in a sealed flask maintained at 95 °C for 30 minutes. After cooling to room temperature, an aliquot of the isooctane phase was taken for analysis by GC-MS (*m/z* = 76). The validated LOQ for the method is 0.1 mg/kg (0.056 mg/kg as CS_2).

Ethylenethiourea (ETU): Multiple methods were provided for the analysis of ETU and are summarized in Table 1. Concurrent recoveries are summarised in Table 2. Method validation data were not provided.

Table 1 Summary of analytical methods considered by the current Meeting for ETU

STABILITY OF PESTICIDE RESIDUES IN STORED ANALYTICAL SAMPLES

A study depicting the stability of mancozeb and ETU residues in peanut nutmeat was submitted to the Meeting (Viana de Moraes, M. 2017, Report BPL-JM-037-032-16-RF). Control samples of peanut nutmeat were spiked with mancozeb or ETU, each at 1 mg/kg, and placed into frozen storage (≤-20 °C). Samples were analysed after 0 and 160 days in storage. Mancozeb was analysed, as CS_2, using the method described above. For ETU, the method was the same as that described above for soya bean seed and cotton seed. Each method has a limit of quantitation of 0.1 mg/kg. Results are summarised in Table 3.

Data on the stability of mancozeb was generated concurrently with field trials for longan (Table 3). The majority of samples for other commodities evaluated by the 2022 Meeting were stored for *ca*. 30 days or less except maize (≤42 days), cotton (≤40 days), and rice (≤ 425 days).

Table 3 Summary of stability data for residues of mancozeb and ETU residues under frozen conditions

Matrix	Analyte	Storage time, days	Procedural recovery, percent	Fortification level, mg/kg	Residue remaining, mg/kg	Mean percent remaining	Reference
Peanut nutmeat	Mancozeb	0	96	1	0.78, 0.74, 0.78	77	BPL-JM-037-032-16-RF
		160	106	1	0.95, 0.81, 0.80	85	
	ETU	0	80	1	0.86, 0.79, 0.86	82	
		160	72	1	0.79, 0.84, 0.85	83	
Longan	Mancozeb	0	104	1	1.03, 1.01	102	Annex Report Trial 1
		30	98	1	0.89, 0.92	91	
		60	112	1	1.12, 1.13	113	
		180	111	1	1.12, 1.10	111	
		240	95	1	0.91, 0.99	95	
		300	93	1	0.87, 0.99	93	

Data submitted to the current meeting demonstrate stability, under frozen storage conditions, for mancozeb and ETU for at least 160 days in peanut nutmeat and for mancozeb for at least 300 days in longan berries.

USE PATTERN

Registered labels describing the use of mancozeb were submitted to the present Meeting for longan, soya bean, maize, rice, and cotton (Table 4).

Table 4 Registered uses of mancozeb submitted to the 2022 JMPR. All uses are foliar application

Use site	Country	Formulation		Application [a)]					PHI, days

RESULTS OF SUPERVISED RESIDUE TRIALS ON CROPS

The Meeting received data from supervised residue trials conducted on longan, soya bean, maize, rice, and cotton.

The field trial reports included method validation data, as recoveries from spiked samples at levels reflecting those observed in the field trial samples; dates from critical events during the study, including application, harvest, storage, and analysis; as well as information on the field site and treatment parameters. Analytical reports were sufficiently detailed and included example chromatograms and

example calculations. Samples were analysed by the methods described above. All samples were analysed for residues of mancozeb (as CS_2). Some samples were analysed for ETU as indicated in the tables below.

The field trial study designs included control plots. Measured residues from control plots were <LOQ and are not included in the summary tables in this evaluation. All residues for mancozeb are reported as CS_2 in the tables below.

When calculating average residues, values below the LOQ were assumed to be at the LOQ. In the summary tables, residue values leading to maximum residue estimations and used for long-term dietary risk assessment are underlined.

Supervised trials for mancozeb:

Group	Commodity	Table
Tropical/sub-tropical fruit, inedible peel, small	Longan	Table 5
Dry beans	Soya bean	Table 6
Cereals	Maize	Table 7
	Rice	Table 8
Oilseeds	Cotton	Table 9

Longan

Six field trials were conducted in Thailand during the 2015 and 2016 growing seasons (Annex I Reports 1 through 6; full study reports were not provided) using a WP formulation. Treatment consisted of three foliar applications of ca. 0.24 kg ai/hL, on generally a 7-day interval. All trials were residue-decline trials with harvest occurring from 0 up to 42 days after the last application (DALA).

Following harvest, samples (2 kg) were frozen within 1 day of collection and shipped, frozen, to the analytical laboratory. Upon arrival at the facility, samples were put into frozen storage. Prior to analysis, samples were pitted and homogenized in the presence of dry ice and then returned to frozen storage. Samples were stored for a maximum of 300 days prior to analysis.

Samples were analysed for residues of mancozeb and ETU using the methods described above. Concurrent recovery data indicate that the method is suitable, with LOQs of 0.056 mg/kg for CS_2 and 0.01 mg/kg for ETU.

Table 5 Results of mancozeb residue trials in longan

Soya bean

Thirty-two field trials were conducted in Brazil during the 2013, 2014, 2015, 2017, and 2019 growing seasons (see references Table 6). Treatment generally consisted of three foliar applications of mancozeb (SC, WG, and WP formulations) ranging from ca. 1.2 to 2.6 kg ai/ha with a retreatment interval of 7 days. Harvest was targeted for 30 days after last application (DALA), with many trials including residue decline samples ranging from 25 to 40 DALA.

Following harvest, samples (≥ 1 kg) were frozen on the day of collection and transported, frozen, to the laboratory. In preparation for analysis, samples were homogenized in the presence of dry ice and returned to frozen storage. Samples were maintained in frozen storage for a maximum of 30 days prior to analysis.

Samples were analysed for residues of mancozeb (as CS_2) and ETU using the methods described above.

Maize

Fifteen field trials were conducted in Brazil during the 2013, 2014, and 2017 growing seasons (see references Table 7). Treatment consisted of 3 foliar applications at either ca 1.4 or 2.4 kg ai/ha, on a 7- to 10-day interval. Samples were harvested 30 days after the last application.

Following harvest, samples (≥1 kg) were put into put into frozen storage on the day of collection. Samples were shipped frozen to the facility and were immediately placed into frozen storage. Prior to analysis, samples were cryogenically homogenized and returned to frozen storage. Samples were stored for a maximum of 42 days prior to analysis.

Samples were analysed for residues of mancozeb (as CS_2) using the method described above.

Rice

Nineteen field trials were conducted in Brazil during the 2003, 2004, and 2014 to 2018 growing seasons (see references Table 8). Treatment consisted of either 3 foliar applications ranging from ca. 1.19 to 2.16 kg ai/ha, on a 10- to 14-day interval or 2 foliar applications at ca. 2.4 or 4.8 kg ai/ha on a 3- or 8- to 9-day interval. Samples were harvested 18 to 46 DALA, with most harvests occurring around 32 DALA.

Following harvest, samples (≥1 kg) were put into put into frozen storage on the day of collection. Samples were shipped frozen to the facility and were immediately placed into frozen storage. Prior to analysis, samples were cryogenically homogenized and returned to frozen storage. Samples were stored for a maximum of 425 days prior to analysis.

Samples were analysed for residues of mancozeb (as CS_2) using the method described above.

Cotton

Fourteen field trials were conducted in Brazil during the 2013, 2016, or 2017 seasons. Treatment consisted of three foliar applications, each at ca. 2.4 or 1.5 kg ai/ha, on a 7- or 14-day interval. Samples of cotton seeds were harvested 20 to 42 DALA, with most harvests occurring around 30 DALA. Samples of cotton seed were ginned to produce undelinted cotton seed. Samples were shipped frozen to the facility and were immediately placed into frozen storage. Prior to analysis, samples were cryogenically homogenized and returned to frozen storage. Samples were stored for a maximum of 40 days prior to analysis.

Samples were analysed for residues of mancozeb (as CS_2) and ETU using the methods described above.

FATE OF RESIDUES IN STORAGE AND PROCESSING

The Meeting received two studies examining residues of mancozeb and ETU in maize kernels and processed commodities.

In the first study (Schweitzer, M.G., 1989, Report 34-89-21), a single field trial was conducted in the United States. Mancozeb, as a WP formulation was broadcast applied to maize at rates of either 1.35 or 8.1 kg/ha. Six applications were made on a ca. 14-day interval. Maize ears were allowed to dry in the field and then harvested 41 DALA. Harvested ears were shelled and processed into grits, meal, flour refined oil (dry and wet milling), and starch (wet milling) within ca. 1 month of harvest using simulated commercial dry and wet milling practices (Figure 1, Figure 2).

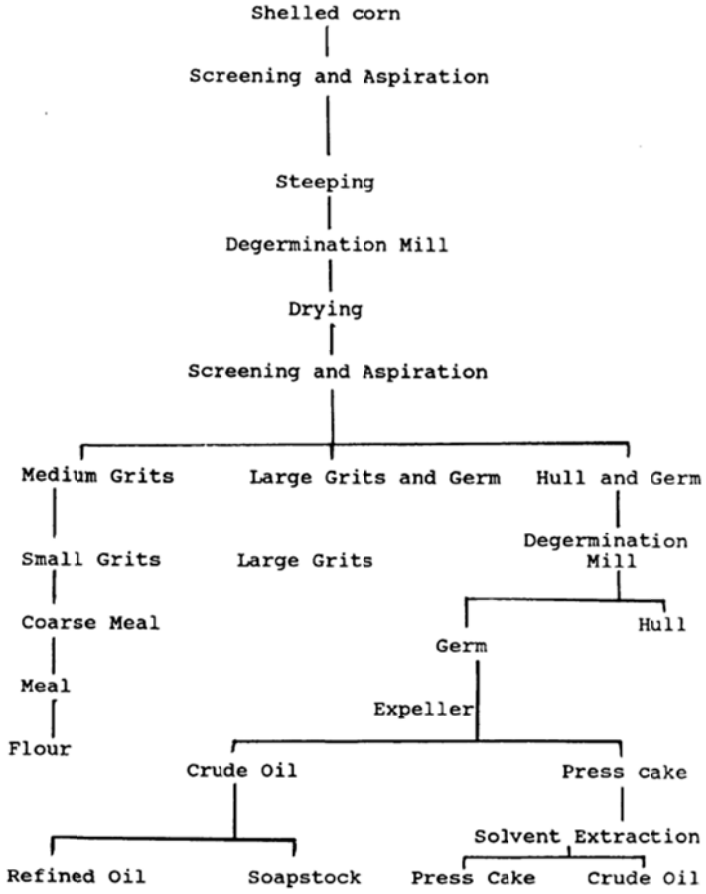

Figure 1 Schematic of maize dry milling processing (Report 34-89-21)

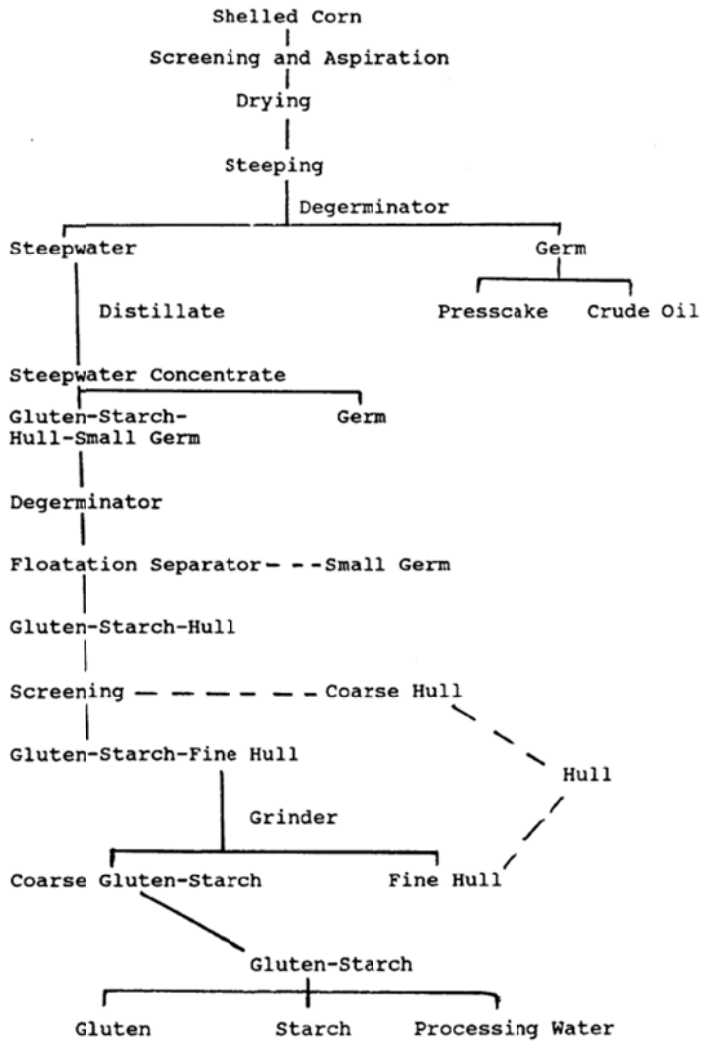

Figure 2 Schematic of maize wet milling processing (Report 34-89-21)

Residues of mancozeb were determined using the method for CS_2 described above, with the exception that a mixture of NaOH/benzene, rather than isooctane, was used to trap CS_2. Procedural recoveries (Table 2) ranged from 87 to 98 percent across all matrices. Residues of ETU were extracted into methanol, followed by clean-up and derivatisation, with analysis by GC-FPD. Procedural recoveries were variable but generally acceptable for all matrices except meal, solvent extracted oil, crude oil, and soapstock.

In the second study (Singer, G.M., 1996, Report AA920302), a single field trial was conducted in the United States. Mancozeb, as a DF formulation was broadcast applied to Pioneer 3489 variety of maize at rates of 6.7 to 6.8 kg/ha. Ten applications were made on a 6- to 13-day interval. Maize ears were harvested 40 DALA. Harvested kernels (ca. 10 kg) were placed into frozen storage within 45 minutes of sampling and shipped frozen to the processing facility. Samples were processed into grits, meal, flour refined oil (dry and wet milling), and starch (wet milling) within ca. 1 month of harvest using simulated commercial dry and wet milling practices (Figure 3, Figure 4).

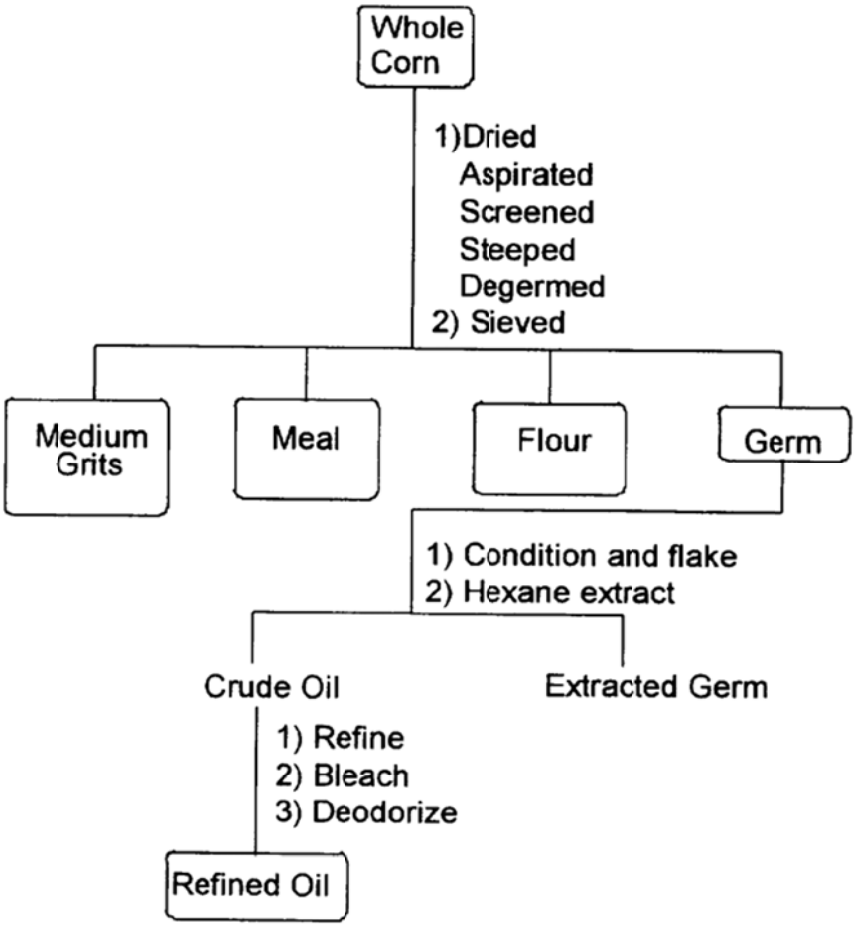

Figure 3 Schematic of maize dry milling processing (Report AA950302)

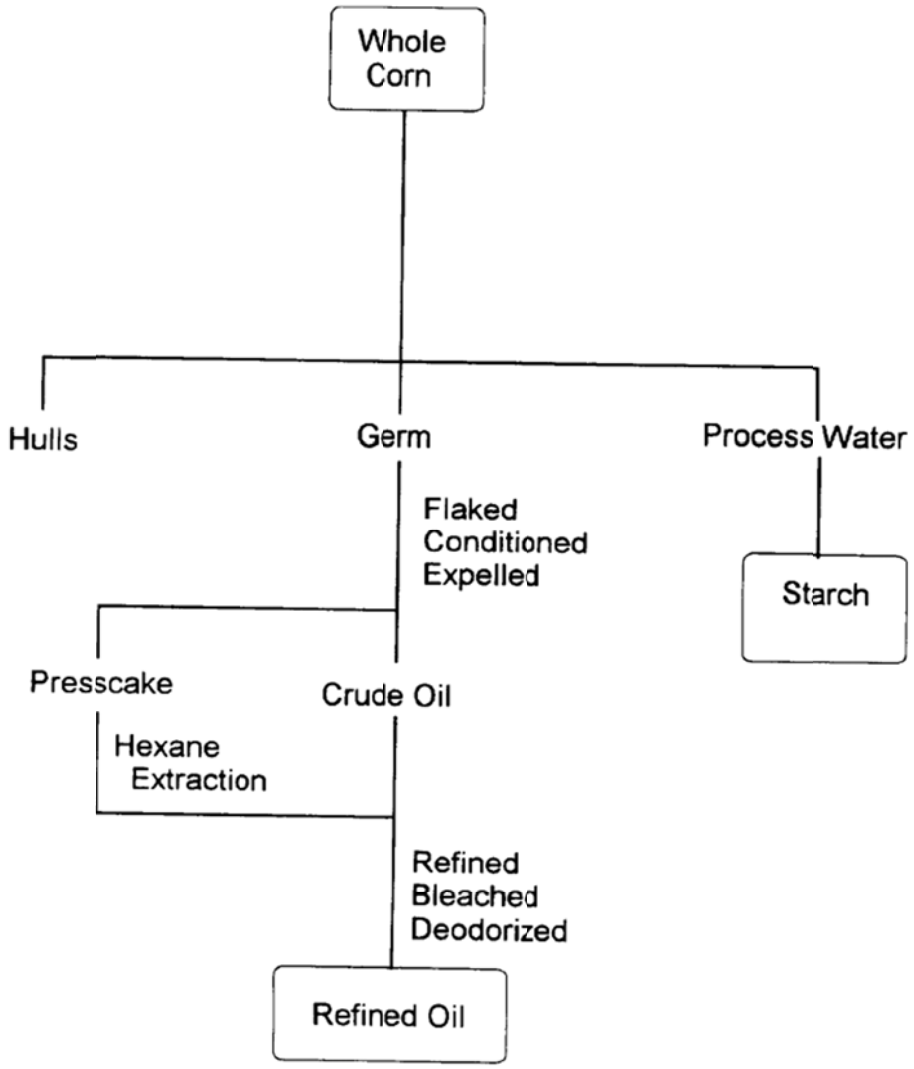

Figure 4 Schematic of maize wet milling processing (Report AA950302)

Residues of mancozeb were determined using the method for CS_2 described above. Procedural recoveries (Table 2) were generally acceptable for all matrices except in flour at the 0.05-mg/kg fortification level and in refined oil (both dry and wet milling, all fortification levels). Residues of ETU were extracted into alkaline solvent and analysed by HPLC-EC. Procedural recoveries were acceptable for all matrices.

Residues of mancozeb and ETU, and their associated processing factors, are summarised below for both studies. For the first study (34-89-21), residues of CS_2 and ETU were below the LOQ in kernels and in most processed commodities; only processed commodities with quantifiable residues at the higher rate are reported here.

Table 10 Residues and processing factors for mancozeb (as CS_2) and ETU in maize commodities

RESIDUE AND ANALYTICAL ASPECTS

Mancozeb was evaluated in 1993 within the CCPR periodic review programme. Mancozeb was last evaluated for new MRLs by the 2014 Meeting.

Mancozeb was scheduled at the Fifty-first Session of the CCPR for the evaluation of additional MRLs by the 2021 Extra JMPR and was re-scheduled to the 2022 JMPR.

The mancozeb residue definition for compliance with MRLs in plants and animals is defined as total dithiocarbamates, determined as CS_2, evolved during acid digestion and expressed as mg CS_2/kg. Dithiocarbamate residues are not fat soluble.

In 1993, the JMPR established a group (alone or in any combination) ADI of 0–0.03 mg/kg bw for ethylene-bis-dithiocarbamates (EBDCs: mancozeb, maneb, metiram and zineb) and an ADI of 0–0.004 mg/kg bw for their metabolite ethylenethiourea (ETU). The parent EBDC and ETU are defined as the residues for evaluating dietary intake in plant and animal commodities. The Meeting is assessing combined residues of mancozeb and ETU using the ratio of the ADIs (7.5) to express residues in terms of mancozeb-toxicity-equivalents (MTE).

At present, there are no ARfDs established by the JMPR for EBDCs or ETU.

The current Meeting received information on analytical methods, storage stability, supervised residue trials, and processing (maize only) to support new MRLs in longan, soya bean, maize, rice, and cottonseed.

Methods of analysis

The Meeting received method validation for analysis of mancozeb (as CS_2) in maize kernels as well as concurrent recovery data for other matrices for which field trials were provided. All methods for analysis of CS_2 use the same basic principles: extraction of mancozeb into an acidified stannous chloride solution with isooctane, *in-situ* conversion of mancozeb to CS_2 which is captured in the isooctane, and analysis of the residue by GC-MS. While validation data for the full method were not provided for all matrix types reviewed by the Meeting, the Meeting agreed that extraction and CS_2 conversion step has been previously validated and that the trapping of CS_2 in organic solvent with analysis by GC has been shown to be a reliable technique[2,3] for the analysis of CS_2. All methods were demonstrated to have adequate performance for recovery of mancozeb (as CS_2), with an LOQ of 0.056 mg/kg in all commodities tested, except for rice (0.028 mg/kg).

The Meeting also received concurrent recovery data for analysis of ETU in longan fruit, soya bean seed, maize, and cotton seed. Neither method validation nor radiovalidation data were provided.

Reported recoveries of ETU in longan fruit ranged from 91 to 104 percent at fortification levels ranging from 0.01 to 0.05 mg/kg, with RSD <7 percent. The description for the method used for the analysis of ETU in longan fruit cites a modified QuEChERS method[4] that uses alkaline acetonitrile as the extraction solvent. The information provided to the Meeting noted that QuEChERS was used for analysis of fruits but did not specif that alkaline acetonitrile was used in the analysis of ETU in longan fruit. Furthermore, there is no information available on the ability of the method to extract incurred residues of ETU. Noting that methods for the analysis of ETU reviewed by prior Meetings and found to be acceptable used non-polar solvents (dichloromethane) or alkaline polar solvents (aqueous ammonia (pH 11–12) + either methanol or ethanol, the Meeting agreed that it could not conclude on the suitability of the method for estimating residues of ETU in longan fruit.

Reported recoveries of ETU in soya bean seed and cotton seed ranged from 69 to 95 percent at fortification levels ranging from 0.1 to 1 mg/kg, with RSD <10 percent. Residues were extracted with methanol with analysis by LC-MS/MS. As noted above, methods previously considered adequate by the JMPR use alkaline methanol for the extraction of ETU. While suitable concurrent recoveries were obtained, there is no information available on the ability of the method to extract incurred residues of ETU. The Meeting agreed that it could not conclude on the suitability of the method for estimating residues of ETU in soya bean seed or cotton seed.

Stability of pesticide residues in stored analytical samples

Concurrent storage stability data were provided for residues of mancozeb in longan fruit. The data demonstrate that residues of mancozeb, analysed as CS_2, are stable in frozen longan fruit for at least 300 days. Samples from the longan trials were stored at ≤ 20 °C for a maximum of 300 days.

For other commodities considered by the present Meeting except rice, samples were kept in frozen storage for up to 42 days. The 1993 Meeting concluded that mancozeb residues are stable during

---

frozen storage for a duration of at least 3 months in commodities similar to those being considered by the current Meeting. Rice samples were stored for up to 425 days. In a storage stability study in wheat reviewed by the 1993 JMPR, residues of mancozeb showed a slow decline beginning at six months and continuing until the end of the study at 24 months. The 1993 JMPR concluded that in wheat grain samples from a storage stability study, mancozeb stability was in the normally acceptable range for up to 2 years. The Current Meeting agreed the storage stability conclusion for wheat supported the storage duration for rice.

Results of supervised residue trials on crops

For estimating maximum residue levels, residues of mancozeb listed below are expressed as CS_2.

For estimating dietary exposure, combined residues of mancozeb and ETU (expressed as mancozeb toxicity-equivalents (MTE)) are calculated based on molecular weights and a potency factor for ETU of 7.5 (derived from the ratio of the ADI for mancozeb to that of ETU). The conversion factor for CS_2 to mancozeb is 1.777 (CS_2=76.1 g/mol; mancozeb = 541.0 g/mol; 4 molecules CS_2 per molecule mancozeb). However, the Meeting noted that in metabolism and field trials evaluated by previous Meetings, residues of ETU are consistently < 0.01 mg/kg and at least an order of magnitude less than residues of mancozeb (expressed as CS_2). Therefore, the Meeting agreed to assume residues of ETU in raw commodities were 0 mg/kg; thus, residues for dietary risk assessment for commodities that are consumed raw were derived directly from residues of mancozeb as 1.777×[CS_2]. Furthermore, the Meeting agreed that for RACs that are heated/cooked prior to consumption (i.e., soya bean, maize, rice, and cottonseed), all residues of mancozeb would be converted to ETU; therefore, STMRs were estimated as 7.5 times the median residue of mancozeb in the RAC (equivalent to 13.33×[CS_2]).

The Meeting received data from supervised residue trials and GAP information on longan, soya beans, maize, rice, and cotton.

Longan

The information provided for residues in longan fruit consisted of summary reports rather than complete study volumes. Nevertheless, sufficient details were provided to be able to evaluate the data for purposes of making recommendations.

The critical GAP for longan is from Thailand. The label allows three applications on a 7-day interval at a maximum spray concentration of 0.24 kg ai/hL and a spray rate of 5 L/tree, with a 14-day PHI.

Residues of CS_2 in the whole fruit (minus the pit) from independent trials matching the critical GAP were (n=5): 2.2, 4.0, 5.5, 6.0, and 7.0 mg/kg.

Based on the reported total sample size and weight (120 fruits, 2 kg) and on the reported weight of longan fruit pits (ca. 1.6 g), the Meeting estimated that the pit constitutes approximately 10 percent of the whole-fruit weight and agreed that an adjustment to the residues to account for weight of the pit is not necessary. The Meeting estimated a maximum residue level of 15 mg/kg for CS_2 in longan fruit.

The median residue of CS_2 was 5.5 mg/kg resulting in an STMR of 9.8 mg MTE/kg.

Soya bean

The critical GAP for soya beans is from Brazil and consists of three applications each at 2.4 kg ai/ha, on a 7-day interval, with a 30-day PHI.

Residues of CS_2 in seed from independent trials matching the critical GAP were (n=12): < 0.056 (8), 0.06, 0.11, 0.16, and 0.22 mg/kg.

The Meeting estimated a maximum residue level of 0.3 mg/kg for CS_2 in soya bean seed.

The median residue of CS_2 was < 0.056 mg/kg resulting in an STMR of 0.75 mg MTE/kg.

Maize

The critical GAP for maize is from Brazil and consists of three applications each at 2.25 kg ai/ha, on a 7-day interval, with a 30-day PHI.

Residues of CS_2 in kernels from independent trials matching the critical GAP were (n=10): < 0.056 (5), 0.069, 0.070, 0.073, 0.089, and 0.11 mg/kg.

The Meeting estimated a maximum residue level of 0.15 mg/kg for CS_2 in maize kernels.

The median residue of CS_2 was 0.0625 mg/kg resulting in an STMR of 0.83 mg MTE/kg.

Rice

The critical GAP for rice is from Brazil and consists of three applications each at 2.8 kg ai/ha, on a 10-day interval, with a 32-day PHI.

Residues of CS_2 in rice grain (paddy rice) from independent trials matching the critical GAP for application and harvest timing but with applications rates ranging from 1.4 to 2.2 kg ai/ha were (n=5): < 0.028 (2), 0.030, 0.22, and 0.32 mg/kg.

After scaling based on application rate (scaling factor range: 1.3–1.99), residues in rice grain from trials with quantifiable residues were (n=3): 0.060, 0.29, and 0.61 mg/kg.

The Meeting agreed that three trials were not sufficient to make a recommendation for rice.

Additional trials were conducted with application rates ranging from 1.2 to 1.5 kg ai/ha at intervals of 14 days and with harvest 34–35 DALA. Quantifiable residues from those trials were (n=5): 0.18, 0.20, 0.25, 0.38, and 0.70 mg/kg.

After scaling based on application rate (scaling factor range: 1.95–2.25), residues in rice grain from trials with quantifiable residues were (n=5): 0.39, 0.42, 0.48, 0.85, and 1.4 mg/kg.

There are too few data points from the first set of trials listed above to complete a statistical comparison of the two data sets. Based on the perceived similarity in the data sets, the Meeting agreed to combine the scaled results from the two sets of trials (n=8): 0.06, 0.29, 0.39, 0.42, 0.48, 0.61, 0.85, and 1.4 mg/kg. The Meeting estimated a maximum residue level of 3 mg/kg for rice grain.

Analysis of husked rice was included for two sites from the second set of trials. Residues in husked rice and rice grain were, respectively, 0.11 mg/kg and 0.38 mg/kg (Trial C94)) and 0.14 mg/kg and 0.18 mg/kg (Trial CDb). The corresponding residue reduction factors were 0.289 and 0.778 (mean = 0.534). Applying the mean factor to the residues listed above for the consideration of the residues in rice grain gives the following residue estimates (n=8): 0.032, 0.15, 0.21, 0.22, 0.26, 0.33, 0.45, and 0.75 mg/kg for CS_2 in husked rice.

The Meeting estimated a maximum residue level of 1.5 mg/kg for CS_2 in husked rice.

The median residue of CS_2 was 0.24 mg/kg resulting in an STMR of 3.2 mg MTE/kg.

A processing study on rice is not available. The Meeting agreed to extrapolate the residue estimates from husked rice to polished rice. The Meeting estimated a maximum residue level of 1.5 mg/kg for CS_2 in polished rice and an STMR of 0.43 mg MTE/kg.

Cotton

The critical GAP for cotton is from Brazil and consists of 3 applications each at 2.25 kg ai/ha, on a 7-day interval, with a 30-day PHI.

Residues of CS_2 in undelinted seed from independent trials matching the critical GAP were (n=8): < 0.056 (4), 0.097, 0.11, 0.13, and 0.24 mg/kg.

The Meeting estimated a maximum residue level of 0.4 mg/kg for CS_2 in cottonseed (undelinted).

The median residue of CS_2 was < 0.056 mg/kg resulting in an STMR of 0.75 mg MTE/kg.

Fate of residues during processing

The 1993 Meeting evaluated the effects of processing on residues in a number of commodities, including maize. Residues in raw and processed commodities were <LOQ for both CS_2 (< 0.03 mg/kg) and ETU (< 0.01 mg/kg), and processing factors could not be calculated.

In the processing study provided to the current meeting, residues of CS_2 were <LOQ in one RAC sample and 0.41 mg/kg in the second RAC sample. Based on that second sample, the Meeting was able to calculate CS_2 processing factors, summarized below, for maize.

Table 1 Processing factors (as CS_2)

Crop	Commodity	Processing factor (CS_2 only)
Maize	Kernels (max. residue level = 0.15 mg/kg; median = 0.11 mg MTE/kg)	--
	Grits	0.205
	Meal	0.873
	Flour	1.07
	Refined oil	< 0.122
	Starch	< 0.122

As no other processing data were available, the Meeting could not conclude on residue levels in processed commodities of soya bean, rice, or cotton.

The Meeting noted that processed commodities of maize, soya bean, rice, and cotton are heated during processing and/or prior to consumption. The Meeting therefore decided not to use empirical processing factors and to assume all residues of mancozeb in processed commodities would be converted to ETU. The Meeting agreed to derive STMRs for processed commodities based on the level of CS_2 in the RAC. The Meeting used the relative potency factor of 7.5 to convert STMRs in the RAC (as MTE) to STMRs in the processed commodities considered by the current Meeting.

The STMRs for processed commodities from RACs considered by the current meeting are:

Soya bean: 0.75 mg MTE/kg

Maize: 0.83 mg MTE/kg

Rice: 3.2 mg MTE/kg

Cotton: 0.75 mg MTE/kg

Residues in animal commodities

The 1993 Meeting recommended maximum residue levels for CS_2 in animal commodities as follows: milks 0.05(*) mg/kg, meat 0.02(*) mg/kg, mammalian edible offal 0.1 mg/kg, eggs 0.05(*) mg/kg, poultry meat 0.1 mg/kg, and poultry edible offal 0.1 mg/kg, noting that those recommendations should accommodate animals (ruminants and poultry) consuming up to 25 ppm CS_2 in their diet. A dietary burden was not provided by the 1993 Meeting. The recommendations from the 1993 Meeting included a large number of animal feed commodities, including cereal grains and fodders, with higher residues than those considered by the current Meeting. Therefore, the Meeting agreed that residues in soya bean, maize kernels, rice grain and cottonseed would not significantly change the dietary burdens for cattle or poultry. The Meeting confirmed is previous recommendations for residues in animal commodities.

RECOMMENDATIONS

On the basis of the data obtained from supervised trials, the Meeting concluded that it could not derive residues suitable for conducting dietary risk assessments. Based on the residue definitions, the residue levels listed in Annex 1 are suitable for establishing maximum residue limits and for IEDI assessment.

Definition of the residue for compliance with MRLs is total dithiocarbamates, determined as CS_2, evolved during acid digestion and expressed as mg CS_2/kg. Dithiocarbamate residues are not fat soluble.

Definition of the residue for dietary risk assessment is the parent EBDC and ETU. The Meeting is assessing combined residues of mancozeb and ETU using the ratio of the ADIs (7.5) to express residues in terms of mancozeb-toxicity-equivalents (MTE).

Dithiocarbamate residues are not fat-soluble

Table 12 Recommendations for residues of mancoaeb from the 2022 JMPR

CCN	Commodity	Recommended Maximum residue level (mg/kg)		STMR or STMR-P mg/kg	HR or HR-P mg/kg
		New	Previous		
SO 0691	Cottonseed	0.3		0.75	
FI 0342	Longan	15		9.8	
GC 0645	Maize	0.15		0.83	
GC 0649	Rice grain	3			
CM 0649	Rice, husked	1.5		3.2	
CM 1205	Rice, polished	1.5		3.2	
VD 0541	Soya bean (dry)	0.3		0.75	
	Soya bean – all processed commodities			0.75	
	Maize – all processed commodities			0.83	
	Rice – all processed commodities			3.2	
	Cottonseed – all processed commodities			0.75	

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The ADI for EBDCs, including mancozeb, is 0–0.03 mg/kg bw. The ADI for ETU is 0–0.004 mg/kg bw (= 7.5 × mancozeb maximum ADI). The International Estimated Daily Intakes (IEDIs) for mancozeb (including ETU) were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the JMPR. The results are shown in Annex 3 of the 2022 JMPR Report.

The IEDIs ranged from 5–50 percent of the maximum ADI. The Meeting concluded that long-term dietary exposure to residues of ethylene-bis-dithiocarbamates from uses considered by the 2014 and current JMPR is unlikely to present a public health concern.

Acute dietary exposure

An ARfD for the EBDCs has not been established. The Meeting noted that the dithiocarbamates were last evaluated in 1993, which was prior to the JMPR establishing ARfDs.

FURTHER WORK OR INFORMATION

Desirable information

- Radiovalidation studies for analysis of ETU by QuEChERS or methods using methanol or ethanol (unaltered) to extract residues.
- Processing studies with soya bean, rice, and cotton, including analysis of ETU

MANDIPROPAMID (231)

First draft prepared by M Irie and S Yoda, Food and Agricultural Materials Inspection Center, Tokyo, Japan

EXPLANATION

Mandipropamid is a fungicide that belongs to the subset mandelamides in the class carboxylic acid amides. It is intended for the control of Oomycete fungal pathogens in a range of crops.

Mandipropamid was first evaluated (toxicology and residues) by the JMPR in 2008. An ADI of 0–0.2 mg/kg bw was established and it was decided that an ARfD was unnecessary. The residue definition for compliance with the MRL and dietary risk assessment for plant and animal commodities is mandipropamid. The residue is not fat-soluble.

The Meeting received information on additional analytical methods, storage stability, high temperature hydrolysis, residues during processing (tomato), GAP information and residue trials for bulb onion, green onion, cucumber, summer squash, melon, tomato, ginseng and basil.

Methods of Analysis

Descriptions of analytical methods together with validation data for residues of mandipropamid in plant and animal matrices were submitted to the Meeting. The methods rely on an initial extraction, usually with acetonitrile/water. After column clean-up, mandipropamid is prepared for LC analysis. Their residues can be measured by mass spectrometric detector (MS/MS), to an LOQ of 0.01 mg/kg. Since the methods use standard extraction solvents and standard detection techniques, they have the potential to be incorporated into existing multi-residue methods.

Detailed descriptions of new analytical methods are presented below.

Plant matrices

High water content, high starch content, high oil content and high acid content category (VV-411985)			
Analyte:	Mandipropamid (m/z 412→328 for quantification, 412→125 for confirmation)	LC-MS/MS	GRM001.07A
LOQ:	0.01 mg/kg		
Description	Samples were extracted by homogenisation with acetonitrile/water (80/20, v/v). Extracts were centrifuged and aliquots (1 mL = 0.1 g) were diluted with water. Clean-up was performed by solid-phase extraction (SPE) using Oasis HLB cartridges. Final determination was by LC-MS/MS.		
High water content, high acid content, high starch content, high protein content, high oil content and dry matrices (VV-414187)			
Analyte:	Mandipropamid (m/z 412→328 for quantification, 412→356 for confirmation)	LC-MS/MS	QuEChERS
LOQ:	0.01 mg/kg		
Description	Residues of mandipropamid were extracted from crop matrices by shaking with acetonitrile, after the addition of a suitable volume of water, if necessary. After the addition of a mixture of magnesium sulphate, sodium chloride, and buffering citrate salts, the extracts were shaken and then centrifuged. In the case of cocoa bean matrices only, the fat was frozen out, and then an aliquot of each extract (for all matrices) was cleaned up using a pre-mixed, commercially available dispersive SPE PSA clean-up tube. For cocoa bean extracts only, a portion of C_{18} was also added prior to shaking with the dispersive SPE clean-up tube. After centrifugation, extracts were diluted to within the calibration range with acetonitrile/water (20/80, v/v, containing 0.1 percent formic acid). Final determination was with LC-MS/MS.		
Fresh ginseng, dried ginseng and red ginseng (JLND2020RS001-A)			
Analyte:	Mandipropamid (m/z 412→328 for quantification, 412→125 for confirmation)	LC-MS/MS	JLND2020RS001-A
LOQ:	0.01 mg/kg		

Description	Residues of mandipropamid were extracted from ginseng samples with acetonitrile and distilled water by homogenizing for 2 minutes, dried ginseng or red ginseng samples with acetonitrile and distilled water by shaking for 1 hour. After filtering under vacuum conditions by Buchner funnel, the filtrate was added with sodium chloride and shaking vigorously. An aliquot of upper layer was transfered to a centrifuge tube containing PSA and anhydrous $MgSO_4$. After dispersive solid-phase extraction, the purified extracts were filtered through a 0.22-μm syringe filter and analysed by LC-MS/MS.

Validation data for methods on plant matrices are summarized in Table 1.

Mean recoveries were within the range of 70–110 percent with RSD values of < 20 percent.

Table 1 Summary of Recovery Data for mandipropamid fortified into plant matrices

Notes:

MV: Method Validation, ILV: Independent Laboratory Validation.

1) Significant (> ±20 percent) suppression of detector response was observed for mandipropamid in the presence of wheat (straw), onions, tomato (sundried) and tomato (dry pomace). Matrix-matched standards were therefore used for quantification of these matrices during the validation study.

Animal matrices

Blood and animal matrices (milk, eggs, meat, liver, kidney and fat) (VV-402660)			
Analyte:	Mandipropamid (m/z 412→328 for quantification, 412→356 for confirmation)	LC-MS/MS	QuEChERS
LOQ:	0.01 mg/kg		
Description	Residues of mandipropamid were extracted from animal matrices by shaking with acetonitrile, after the addition of a suitable volume of water. For fat samples only, water was added and the samples heated in a water bath (40°C) and shaken to reduce clump building of fat; this was done prior to the addition of acetonitrile. After the addition of a mixture of magnesium sulphate, sodium chloride, and buffering citrate salts, the extracts were shaken and then centrifuged. After centrifugation, the acetonitrile phase was decanted and frozen out overnight. Extracts were centrifuged and an aliquot of each extract was cleaned-up using a pre-mixed, commercially available dispersive SPE PSA clean up tube. Extracts were diluted to within the calibration range with acetonitrile/water (1/1, v/v). Final determination was with LC-MS/MS.		

Validation data for methods on animal matrices are summarized in Table 2.

Mean recoveries were within the range of 70–110 percent with RSD values of <20 percent.

Notes:

MV: Method Validation, ILV: Independent Laboratory Validation

[1)] Significant (> ±20 percent) matrix effect was observed in liver. Matrix-matched standards were therefore used for calibration and quantification for liver matrix during the validation study.

STABILITY OF PESTICIDE RESIDUES IN STORED ANALYTICAL SAMPLES

The Meeting received new storage stability data for dried beans, ginseng, basil and potato.

The storage stability of mandipropamid was tested in high protein crop commodity (Khoshab A, 2020: VV-725132). Samples of homogenised dried broad beans (10g) were fortified at 0.10 mg/kg with a known amount of mandipropamid. The solution was left to soak, and the samples were sealed and stored in a freezer at typically ≤-18°C. Duplicate samples were analysed after 1, 3, 6, 12 and 18 months of storage. Mandipropamid was analysed using method GRM001.07A by LC-MS/MS.

Table 3 Recovery of mandipropamid from stored fortified samples of dried broad beans

Storage interval (Actual)	Procedural (percent)	Residues (mg/kg)	Mean of percent remaining
Day 0	94, 97	0.0912, 0.0993, 0.0999	100
1 months (31 days)	104, 107	0.102, 0.103	105
3 months (84 days)	99, 100	0.0925, 0.0978	98
6 months (177 days)	109, 110	0.0857, 0.0875	90
12 months (356 days)	101, 107	0.0967, 0.0987	101
18 months (549 days)	98, 103	0.0150, 0.0155	15
18 months (561 days)	99, 100	0.0162, 0.0170	18

The storage stability of SYN500003 was tested in high starch crop commodity (Khoshab A, 2019: VV-725129). Samples of homogenised potato (10g) were fortified at 0.50 mg/kg with a known amount of SYN500003. The solution was left to soak, and the samples were sealed and stored in a freezer at typically <-18°C. Duplicate samples were analysed after 1, 3, 6 and 12 months of storage. SYN500003 was analysed using method GRM001.01A by LC-MS/MS.

Table 4 Recovery of SYN500003 from stored fortified samples of potato

Storage interval (Actual)	Procedural (percent)	Residues (mg/kg)	Mean of percent remaining
Day 0	106, 108	0.517, 0.514, 0.536	100

1 months (30 days)	95, 98	0.475, 0.473	91
3 months (83 days)	107, 107	0.515, 0.509	98
6 months (180 days)	91, 95	0.440, 0.428	84
12 months (363 days)	103, 100	0.466, 0.461	89

The storage stability of mandipropamid was tested in fresh ginseng and dried/red ginseng (Zhiguang Hou, 2020: JLND2020RS001-S). Homogenised fresh ginseng samples and pulverized dried/red ginseng samples (each 5.0 g) destined for frozen storage were fortified with a known amount of mandipropamid in acetonitrile at a rate of 1.0 mg/kg. The solution was left to soak, and the samples were sealed and stored in a freezer at a nominal temperature of ≤-18°C. Duplicate samples were analysed after 0, 2, 3, 6 and 9 months of storage. Mandipropamid was analysed using method JLND2020RS001-A by LC-MS/MS. The LOQ was 0.01 mg/kg.

Table 5 Recovery of mandipropamid from stored fortified samples of fresh ginseng and dried/red ginseng

6 months (191 days)	107, 105	0.84, 0.82	87
9 months (277 days)	91, 92	0.97, 1.0	104
Dried ginseng			
Day 0	97, 99	0.90, 0.89	100
2 months (76 days)	98, 94	0.98, 0.96	107
3 months (91 days)	95, 98	0.98, 0.98	109
6 months (191 days)	89, 97	0.87, 0.87	97
9 months (277 days)	90, 86	1.1, 1.1	122
Red ginseng			
Day 0	93, 100	0.97, 0.98	100
2 months (76 days)	73, 73	0.81, 0.80	83
3 months (91 days)	94, 95	0.92, 0.93	95
6 months (191 days)	108, 94	0.87, 0.88	90
9 months (277 days)	90, 88	0.99, 0.97	100

The storage stability of mandipropamid and SYN500003 were tested in dried ginseng root (Corley J, 2012: VV-508245). Samples of dried ginseng root (10g) were fortified at 0.10 mg/kg with a known amount of mandipropamid and SYN500003. The storage stability samples were stored under the same storage conditions as field samples at <-20°C for 922 days. Mandipropamid and SYN500003 were analysed using method RAM 415/01 and GRM001.01A by LC-MS/MS.

Table 6 Recovery of mandipropamid and SYN500003 from stored fortified samples of dried ginseng root

Analyte	Storage interval	Procedural (percent)	percent remaining	Mean of percent remaining
Mandipropamid	922 days	99	96, 102, 119	105
SYN500003	922 days	84	90, 105, 105	100

The storage stability of mandipropamid was tested in fresh basil and dried basil (Corley J, 2012: VV-508246). Samples of basil (10g) were fortified at 1.0 mg/kg with a known amount of mandipropamid. The storage stability samples were stored under the same storage conditions as field samples at <-20 °C for 700 days. Mandipropamid was analysed using method RAM 415/01 by LC-MS/MS.

Table 7 Recovery of mandipropamid from stored fortified samples of basil

Commodity	Storage interval	Procedural (percent)	percent remaining	Mean of percent remaining
Basil (fresh)	700 days	105	82, 95, 98	92
Basil (dried)	700 days	85	98, 98, 98	98

USE PATTERN

Mandipropamid belongs to the mandelamide chemical class of funficides and is a synthetic fungicide intended for the control of Oomycete fungal pathogens in a range of crops. The Meeting received labels in China and the United States. The information available to Meeting on registered uses of mandipropamid is summarized in Table below.

Table 8 Registered uses of mandipropamid for crops

Crop	Country	Formulation		Application					PHI, days
		Type	Conc.	Method	Rate kg ai/ha	Water L/ha	No. max	Interval, days	
Bulb Vegetables Dry bulb	United States	SC	250 g/L	Spray	0.15 Max/season 0.59	≥93[1)] ≥47[2)]	-	7-10	7

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received information on mandipropamid supervised field trials for the following crops.

Group	Commodity	Table
Bulb vegetables	Bulb onion	Table 9, 10
	Spring onion	Table 11, 12

Fruiting vegetables, Cucurbits	Cucumber	Table 13, 14
	Summer squash	Table 15
	Melon	Table 16, 17
Fruiting vegetables, other than Cucurbits	Tomato	Table 18, 19
	Peppers	Table 20
Root and tuber vegetables	Ginseng	Table 21
	Dried ginseng	Table 22, 23
Herbs	Basil	Table 24
	Dried basil	Table 25

Mandipropamid formulation was applied for foliar treatment. Each of the field trial sites generally consisted of untreated control plot and treated plot. Application rates and residue concentrations have generally been rounded to two significant figures.

Residue values from the trials, which have been used for the estimation of maximum residue levels, STMRs and HRs, are underlined.

Laboratory reports included method validation with procedural recoveries from spiking at residue levels similar to those occurring in samples from the supervised trials. Date of analyses and duration of residue sample storage were also provided. Although trials included control plots, no control data are recorded in the tables except when residues were found in samples from control plots. Residue data are not corrected for percent recovery.

Conditions of the supervised residue trials were generally well reported in detailed field reports. Most field reports provided data on the applicators used, plot size, field sample size and sampling date.

Bulb vegetables

Bulb Onions, Subgroup of

The Meeting received eight trials on dry bulb onion which were conducted in the United States (Rice F, 2012: VV-507780). All trials received four foliar applications of an SC formulation (250 g ai/L) at a nominal rate of 0.15 kg ai/ha, with an application interval of 5 ± 1 days. All applications were made in tank-mix with an adjuvant, non-ionioc surfactant (NIS) or silicone-based. At each trial, bulbs were taken 7 days after last application (DALA).

Samples were analysed for residues of mandipropamid following analytical method RAM 415/01. The LOQ was 0.01 mg/kg. The overall mean recoveries from concurrent fortifications for mandipropamid in matrix were within 70–120 percent. Onion bulb samples were stored at ca -20 °C for a maximum of 10 months between sampling and analysis.

Green Onions, Subgroup of

The Meeting received three trials on green onion which were conducted in the United States (Rice F, 2012: VV-507780). All trials received three foliar applications of an SC formulation (250 g ai/L) at a nominal rate of 0.15 kg ai/ha, with an application interval of 5 ± 1 days. All applications were made in tank-mix with an adjuvant, NIS or silicone-based. At each trial, green onions were taken 7 DALA.

Samples were analysed for residues of mandipropamid following analytical method RAM 415/01. The LOQ was 0.01 mg/kg. The overall mean recoveries from concurrent fortifications for mandipropamid in matrix were within 70–120 percent. Green onion samples were stored at ca -20 °C for a maximum of 8.9 months between sampling and analysis.

Fruiting vegetables, Cucurbits

Fruiting vegetables, Cucurbits–Cucumbers and Summer squashes, Subfroup of Cucumber

The Meeting received 10 trials on cucumber which were conducted in southern Europe (Spain and Italy) (Anderson L: VV-333902, VV-331995, VV-331994 (2004) and VV333645 (2005), Elliott A: VV333082 and VV333998 (2005), Lakaschus S: VV338985 (2007) and VV394509 (2010)). All trials received four foliar applications of an SC formulation (250 g ai/L) at a nominal rate of 0.15 kg ai/ha, with an application interval of 7 ± 1 days. At each trial, fruits were collected from all treated plots 0, 1, 3, 7 and 14 days after the final application. In some trials, additional fruit samples were taken just before the 2nd application, just before the 3rd application and just before the 4th application.

Samples were analysed for residues of mandipropamid following analytical method RAM 415/01. Additionally, in the 2010 trials, samples were analysed for residues of SYN500003 following analytical method GRM001.01A. The LOQs for both mandipropamid and SYN500003 were 0.01 mg/kg. The overall mean recoveries from concurrent fortifications for mandipropamid and SYN500003 in matrix were within 70–120 percent. Cucumber fruit samples were stored at or below -18 °C for a maximum of 10 months between sampling and analysis.

Fruiting vegetables, Cucurbits–Melons, Pumpkins and Winter squashes Melons, Subgroup of

The Meeting received 8 trials on melon which were conducted in Europe (France, Spain and Italy) (Gill P: VV-332608 and VV332609 (2005), Boxwell C: VV-333097 and VV33098 (2005), Gardinal P & Gill P: VV333790 and VV333791 (2005)). All trials received four foliar applications of an SC formulation (250 g ai/L) at a nominal rate of 0.15 kg ai/ha, with an application interval of 7 ± 1 days. At each trial, fruits were collected from all treated plots immediately before the 2nd application, immediately before the 3rd application, immediately before the last application, then nominally 0, 1, 3, 7 and 14 days after the final application.

Samples were analysed for residues of mandipropamid following analytical method RAM 415/01. The LOQ was 0.01 mg/kg. The overall mean recoveries from concurrent fortifications for mandipropamid in matrix were within 70–120 percent. Melon samples were stored at or below -18 °C for a maximum of 9 months between sampling and analysis.

Fruiting vegetables, other than Cucurbits

Tomatoes, Subgroup of

The Meeting received 14 trials on protected tomato which were conducted in Europe (Richards S: VV-331426, VV-331742, VV331744, VV-331862, VV332991 and VV333934 (2004), Gill JP: VV333205, VV-333389, VV-333398, VV333777, VV333878 and VV-334287 (2005), Simon P: VV333427 (2005)). All trials received four foliar applications of an SC formulation (250 g ai/L) at a nominal rate of 0.15 kg ai/ha, with

an application interval of 7 ± 1 days. At each trial, fruits were collected from all treated plots immediately before the 2nd application, immediately before the 3rd application, immediately before the last application, then nominally 0, 1, 3, 7 and 14 days after the final application. In some trials, additional fruit samples were taken just after the 1st application, just after the 2nd application and just after the 3rd application.

Samples were analysed for residues of mandipropamid following analytical method RAM 415/01. The LOQ was 0.01 mg/kg. The overall mean recoveries from concurrent fortifications for mandipropamid in matrix were within 70–120 percent. Tomato fruit samples were stored at or below -18 °C for a maximum of 12 months between sampling and analysis.

Ginseng

The Meeting received five trials on fresh ginseng which were conducted in China (Zhiguang Hou, 2020: JLND2020RS001). In each of these trials, an SC formulation (23.4 percent) was applied with dosages of 0.21 kg ai/ha for one time using a foliar treatment. At each trial, fresh ginsengs were taken 14, 21 and 28 DALA. In the decline trials additional samples were collected at 7 and 35 DALA.

Samples were analysed for residues of mandipropamid following analytical method JLND2020RS001-A. The LOQ was 0.01 mg/kg. The overall mean recoveries from concurrent fortifications for mandipropamid in matrix were within 70–120 percent. Ginseng samples were stored at -18 °C or below for 18-20 days between sampling and analysis.

Ginseng, dried including red ginseng

The Meeting received five trials on dried ginseng which were conducted in China (Zhiguang Hou, 2020: JLND2020RS001). In each of these trials, an SC formulation (23.4 percent) was applied with dosages of 0.21 kg ai/ha for one time using a foliar treatment. At each trial, fresh ginsengs were taken 14, 21 and 28 DALA. In the decline trials additional samples were collected at 7 and 35 DALA. A portion of fresh ginseng samples were processed into dried ginseng and red ginseng with simulation of industrial practices as closely as possible.

Dried ginseng: fresh samples were baked at 55 °C for 24 h.

Red ginseng: fresh samples were steamed with boiling water for 2.5 ~ 3 hours, and cooled and dried at 70 °C for 6 hours, then were infiltrated with water and dried again at 55 °C for 24 hours.

Samples were analysed for residues of mandipropamid following analytical method JLND2020RS001-A. The LOQ was 0.01 mg/kg for both commodities. The overall mean recoveries from concurrent fortifications for mandipropamid in each matrix were within 70–120 percent. Ginseng samples were stored at -18 °C or below for 18–20 days between sampling and analysis.

Note:

[1)] Mean of replicate field samples is given in parenthesis.

The Meeting received four trials on dried ginseng which were conducted in United States and Canada (Corley J, 2012: VV-508245). All trials received four foliar applications of an SC formulation (250 g ai/L) at a nominal rate of 0.15 kg ai/ha, with an application interval of 6–9 days. All applications were made in tank-mix with an adjuvant, NIS. At each trial, fresh roots were taken 2 DALA. In one trial additional samples were collected at 0, 7, 15 and 21 DALA to provide residue decline data. The roots were rinsed in clean water and dried for 17 or19 days in a commercial dryer at temperatures ranging from 7.2 to 48 °C.

Samples were analysed for residues of mandipropamid and SYN500003 following analytical method RAM 415/01 and GRM001.01A. However modifications were made to improve the performance of the method. Extracts were diluted with ACN:H_2O (20:80, v/v), to produce a solution of ACN:H_2O (1:1, v/v), and analysed for mandipropamid by LC-LC/MS/MS coupled with online cleanup. The LOQ for mandipropamid was 0.022 mg/kg and for SYN500003 was 0.0056 mg/kg. The overall mean recoveries from concurrent fortifications for mandipropamid and SYN500003 in matrix were within 70–120 percent. Dried ginseng root samples were stored at or below -20 °C for a maximum of 31 months between sampling and analysis.

Basil (fresh)

The Meeting received six trials (four in the field and two in the greenhouse) on basil which were conducted in Canada and the United States (Corley J, 2012: VV-508246). All trials received four foliar applications of an SC formulation (250 g ai/L) at a nominal rate of 0.15 kg ai/ha, with an application interval of 6 days. All applications were made in tank-mix with an adjuvant, NIS. At each trial, fresh basil stems and leaves were taken 1 DALA. In one trial additional samples were collected at 3, 7 and 11 DALA to provide residue decline data.

Samples were analysed for residues of mandipropamid following analytical method RAM 415/01. However modifications were made to improve the performance of the method. Extracts were diluted with ACN:H_2O (20:80, v/v), to produce a solution of ACN:H_2O (1:1, v/v), and analysed for mandipropamid by LC-LC/MS/MS coupled with online cleanup.The LOQ for mandipropamid was 0.01 mg/kg. The overall mean recoveries from concurrent fortifications for mandipropamid in matrix were within 70–20 percent. Fresh basil samples were stored at or below -20 °C for a maximum of 24 months between sampling and analysis.

FATE OF RESIDUES IN STORAGE AND PROCESSING

In Processing

The Meeting received information on high temperature hydrolysis of SYN50003 and the fate of mandipropamid residues during the processing of tomato.

High temperature hydrolysis

The hydrolytic stability of [phenyl-U-^{14}C]-SYN500003 was investigated under conditions representative of food processing (Kennedy J, 2019: VV-732906). The conditions used are summarized below.

Temperature, °C	Time, min	pH	Process Represented
90	20	4	Pasteurisation
100	60	5	Baking, Brewing, Boiling
120	20	6	Sterilisation

Test solutions were prepared by adding an aliquot of the radiochemical stock solution to each buffer (0.01 M citrate buffers were prepared at pH 4, 5 and 6) to give a final test concentration of 1.0 mg/L. Test solutions were dispensed into glass vials (which were capable of withstanding the high temperature and pressures expected during incubation) and samples were incubated as per the conditions detailed above. The radioactivity content of incubates sampled prior to and following incubation was determined by LSC analysis. Radioactivity content in incubated samples was compared to control samples.

The total recovery of applied radioactivity ranged from 99.5–101.5 percent for all hydrolysis experiments. Characterisation and identification of the radiolabelled components in treated solutions in this study was carried out by co-chromatography against reference standards using TLC and HPLC. Quantification of the degradates was conducted using the HPLC data.

Table 26 Identification of radioactivity under the conditions for processing simulation

Identified components	Recovery of applied [phenyl-U-^{14}C]-SYN500003 [1.0 mg/L]					
	pH 4, 90 °C, 20min		pH 5, 100 °C, 60 min		pH 6, 120 °C, 20 min	
	% TRR	mg/L	% TRR	mg/L	% TRR	mg/L
SYN500003	98.0, 98.6	1.04, 1.05	98.7, 99.0	1.01, 1.00	98.9, 98.6	1.05, 1.04
Unidentified	2.0, 1.4	0.02, 0.01	1.3, 1.0	<0.01, <0.01	1.1, 1.4	0.01, 0.01
Total	100, 100	1.06, 1.06	100, 100	1.02, 1.01	100, 100	1.06, 1.05

Note:

% TRR: Results are based on the assumption that the chromatographed radioactivity represents 100 percent of the applied radioactivity.

[phenyl-U-^{14}C]-SYN500003 was found to be hydrolytically stable in buffer solutions at pH 4, 5 and 6 at temperatures simulating pasteurisation (90 °C), baking/brewing/boiling (100 °C) and sterilisation (120 °C) respectively.

Tomato

One processing trial on tomato was conducted in Southern France during 2004. Four foliar applications of an SC formulation containing 250 g/L mandipropamid were applied at 0.50 kg ai/ha separated by a 7 day interval. Treated tomato samples were collected at 3 DALA (Gill JP, 2005: WW-333625). Samples were

shipped frozen to the analytical facility for residue analysis and transferred by car directly to the processing facility.

Fresh whole tomatoes were processed into washed fruit, wet and dry pomace, juice, puree and canned tomatoes according to procedures representative of commercial practice. One full balance study and three follow-up studies were carried out for each process.

Washing

Samples were washed with water (500 mL/kg fruit) and strained. Samples of washing water and washed tomatoes were collected and stored for analysis.

Tomato juice processing

Samples of unwashed tomatoes were crushed and sieved to separate juice from the peel and seeds (pomace). The sugar content of the juice was measured and salt (ca. 7 g/kg) and citric acid (to ca. pH 3.5) were added to produce "raw" juice. A sub-sample of raw juice was retained for the canning phase. The remaining juice was pasteurised for 1 minute at 82–85 °C and placed into glass jars. Wet pomace was oven dried at 60 °C for 1–2 days to produce dry pomace.

Tomato puree processing

Samples of unwashed tomatoes were crushed and reduced in a saucepan. Reduction was stopped when the sugar content reached 12 percent. The tomatoes were sieved to remove peel and seeds (pomace), salt (approximately 4 g/kg) and citric acid (to about pH 3.5) were then added to produce "raw" puree. The puree was then sterilised in glass jars for 10 minutes at 115 °C.

Tomato canning

Samples of unwashed tomatoes were blanched and then immediately plunged into cold water to loosen the peel, which was then removed with a knife. The peeled tomatoes were placed into glass jars and the jars filled with "raw" tomato juice at a ratio of two thirds tomatoes to one third juice. The jars were sealed and sterilised for 10 minutes at 115 °C.

Samples of pre-processed whole fruit and processed commodities were analysed for residues of mandipropamid using analytical method RAM 415/01 with an LOQ of 0.01 mg/kg for all commodities. The overall mean recoveries from concurrent fortifications for mandipropamid in each matrix were within 70–120 percent.

Table 27 Residues of mandipropamid in tomato and tomato processed commodities

country, year (variety)	Application		DALA	Commodity	Residues, mg/kg	Processing factor
	kg ai/ha	no.	Days			
France, 2004	0.49	4	3	Fruit	0.38, 0.37, 0.34, 0.35

Notes:

Processing Factor = Mandipropamid residues in processed commodity/ Mandipropamid residues in tomato fruits (prior to processing)

For calculations, 0.01 mg/kg was used for fractions with <LOQ residues.

Processing trial on tomato was conducted in the United States during 2003. Four foliar applications of an SC formulation containing 250 g/L mandipropamid were applied at 0.15 kg ai/ha with a 7 day interval between applications. Applications were also made at 5× rate for processing. Treated tomato samples were collected at 1 DALA (Joseph & Hamilton, 2005: VV-503530).

Samples were analysed for residues of mandipropamid using analytical method RAM 415/01 with an LOQ of 0.01 mg/kg. Samples were fortified between 0.01 and 0.50 mg/kg and recoveries ranged from 73–111 percent.

Table 28 Residues of mandipropamid in tomato and tomato processed commodities

APPRAISAL

Mandipropamid is a fungicide that belongs to the subset mandelamides in the class carboxylic acid amides. It is intended for the control of Oomycete fungal pathogens in a range of crops. It was first evaluated by JMPR in 2008. An ADI of 0–0.2 mg/kg bw was established and decided that an ARfD was unnecessary. The 2018 JMPR further concluded that metabolite SYN500003 should be assessed by TTC as Cramer Class III. The residue definition for compliance with the MRL and dietary risk assessment for plant and animal commodities is mandipropamid. The residue is not fat-soluble. Additional uses were evaluated by the 2013, 2018 and 2021 (extra) JMPR.

Mandipropamid was scheduled at the Fifty-first Session of the CCPR for the evaluation of additional uses in the 2021 JMPR and rescheduled to the 2022 JMPR. The Meeting received information on additional analytical methods, storage stability, high temperature hydrolysis, residues during processing (tomato), GAP information and residue trials for bulb onion, green onion, cucumber, summer squash, melon, tomato, ginseng and basil.

Methods of analysis

The Meeting received descriptive and validation data of analytical methods for residue of mandipropamid in plant and animal commodities.

In the method for determination of mandipropamid in plant, homogenized samples were extracted with acetonitrile: water (80:20 v/v), with clean-up with a solid phase extraction, residues were determined by LC-MS/MS. The method of analysis was validated at various fortification levels with an LOQ of 0.01 mg/kg for mandipropamid.

QuEChERS method was also validated for mandipropamid residue in plant and animal commodities with an LOQ of 0.01 mg/kg.

Stability of residues in stored analytical samples

The Meeting received information on the freezer storage stability of mandipropamid in plant (dried beans, ginseng and basil) and SYN500003 in plant (ginseng and potato). Storage stability results indicated that residues of mandipropamid were stable for up to 12 months in dried broad beans, and for at least 9 months in fresh ginseng, 30 months in dried ginseng and 23 months in basil under freezer conditions at about -18 °C or below.

The Meeting agreed that the demonstrated storage stability for mandipropamid covered the residue sample storage intervals used in the field trials.

Results of supervised residue trials on crops

The Meeting received supervised trial data for the foliar application of mandipropamid on bulb onion, spring onion, cucumber, melon, tomato, ginseng and basil. Residue trial data was made available from Canada, China, France, Germany, Italy, Spain, Switzerland and the United States.

Labels were available from China and the United States describing the registered uses of mandipropamid.

Bulb vegetables

The 2008 JMPR evaluated residue data for mandipropamid on bulb onion and spring onion conducted in the United States. The Meeting received new residue data for bulb onion and spring onion.

Onion, Bulb

Data were available from supervised trials on bulb onion in the United States.

The critical GAP for dry bulb vegetables in the United States (same GAP as that submitted to the 2008 JMPR) allows a maximum seasonal rate of 0.59 kg ai/ha (maximum of 0.15 kg ai/ha per application) with a re-treatment interval (RTI) of 7 days and a PHI of 7 days.

Mandipropamid residues in bulb onion from independent trials (RTI: 6-8 days) conducted in 2004 (submitted to the 2008 JMPR) in the United States matching the US GAP were (n=8): <0.01 (5), 0.01, 0.02 and 0.03 mg/kg.

Mandipropamid residues in bulb onion from independent trials with a RTI of 4-6 days conducted in 2011 in the United States were (n=8): 0.012, 0.032, 0.062, 0.066, 0.068, 0.082, 0.11 and 0.21 mg/kg.

The trials in 2011 were conducted with a shorter RTI than that of the US GAP. The residue populations from trials with a RTI of 5 ± 1 days were significantly different from those from trials with a RTI of 7 ± 1 days according to statistical test (Mann-Whitney U-test).

Based on the residues in bulb onion from trials conducted in 2004 in the United States, the Meeting estimated a maximum residue level of 0.05 mg/kg and an STMR value of 0.01 mg/kg for the subgroup of bulb onions.

The Meeting withdrew the previous recommendation for onion, bulb of 0.1 mg/kg.

Spring Onion

Data were available from supervised trials on spring onion in the United States.

The critical GAP for green onions in the United States (same GAP as that submitted to the 2008 JMPR) allows a maximum seasonal rate of 0.44 kg ai/ha (maximum 0.15 kg ai/ha per application) with a RTI of 7 days and a PHI of 7 days.

Mandipropamid residues in spring onion from independent trials conducted in 2004 (submitted to the 2008 JMPR) in the United States matching the US GAP were (n=3): 0.23, 0.40 and 1.4 mg/kg.

Mandipropamid residues in spring onion from independent trials with a RTI of 5 days conducted in 2011 in the United States were (n=3): 0.73, 1.6 and 3.7 mg/kg.

The trials in 2011 were conducted with a shorter RTI than that of the US GAP. The residue populations from trials with a RTI of 5 ± 1 days were significantly different from those from trials with a RTI of 7 ± 1 days according to statistical test (Mann-Whitney U-test).

The trials for spring onion in the United States were insufficient to estimate a maximum residue level for the commodity, since minimum of five trials need for spring onion. The Meeting could not estimate a maximum residue level for spring onion.

The Meeting withdrew the previous recommendation for spring onion of 7 mg/kg.

Fruiting vegetables, Cucurbits

Fruiting vegetables, Cucurbits–Cucumbers and Summer squashes

The critical GAP for cucurbits in the United States (same GAP as that submitted to the 2008 JMPR) allows a maximum seasonal rate of 0.59 kg ai/ha (maximum of 0.15 kg ai/ha per application) with a RTI of 7 days and a PHI of 0 day.

Cucumber

Data were available from supervised trials on cucumber in Italy, Spain and the United States.

Mandipropamid residues in cucumber from independent trials in Italy, Spain and the United States matching the US GAP were (n=17): 0.011, 0.013(2), 0.014, 0.02, 0.03, 0.033, 0.045, 0.05, 0.06 (2), 0.069, 0.07, 0.08 (3) and 0.14 mg/kg.

Squash, summer

Data were available from supervised trials on summer squash in the United States.

Mandipropamid residues in summer squash from independent trials in the United States matching the US GAP were (n=5): 0.014, 0.023, 0.030, 0.058 and 0.070 mg/kg.

To consider a maximum residue level for a group, residues in individual crops should be similar (e.g. medians should not differ by more than 5×). The Meeting agreed to estimate a maximum residue level for the subgroup of fruiting vegetables, cucurbits–cucumbers and summer squashes. In considering whether to combine data to estimate a maximum residue level, the Meeting recognized that the residue populations from trials on cucumber and summer squash were not different according to statistical test (Mann-Whitney U-test). Therefore, the Meeting decided to combine the data from cucumber and summer squash to estimate a maximum residue level for fruiting vegetables, cucurbits–cucumber and summer squashes.

The combined mandipropamid residues in cucumber and summer squash were in rank order (n=22): 0.011, 0.013(2), 0.014 (2), 0.02, 0.023, 0.03 (2), 0.033, 0.045, 0.05, 0.058, 0.06 (2), 0.069, 0.07 (2), 0.08 (3) and 0.14 mg/kg.

The Meeting estimated a maximum residue level of 0.2 mg/kg and an STMR value of 0.0475 mg/kg for the subgroup of fruiting vegetables, cucurbits–cucumber and summer squashes.

The Meeting withdrew the previous recommendations for cucumber of 0.2 mg/kg and summer squash of 0.2 mg/kg.

Fruiting vegetables, Cucurbits–Melons, Pumpkins and Winter Squashes

Data were available from supervised trials on melons in France, Italy, Spain and the United States.

The critical GAP for cucurbits in the United States (same GAP as that submitted to the 2008 JMPR) allows a maximum seasonal rate of 0.59 kg ai/ha (max 0.15 kg ai/ha per application) with a RTI of 7 days and a PHI of 0 day.

Mandipropamid residues in melons (whole fruit) from independent trials in France, Italy, Spain and the United States matching the US GAP were (n=13): 0.03, 0.045, 0.05, 0.06 (2), 0.07, 0.08, 0.097, 0.11 (2), 0.13, 0.17 and 0.23 mg/kg.

Mandipropamid residues in melons (flesh) from independent trials in France, Italy and Spain matching the US GAP were (n=8): <0.01 (8) mg/kg.

Based on the residues in melon (whole fruit) from trials, the Meeting estimated a maximum residue level of 0.4 mg/kg, and based on the residues in melon (flesh) from trials the Meeting estimated an STMR value of 0.01 mg/kg for the subgroup of fruiting vegetables, cucurbits–melons, pumpkins and winter squashes.

The Meeting withdrew the previous recommendations for melons except watermelon of 0.5 mg/kg.

Fruiting vegetables, other than Cucurbits

The critical GAP for fruiting vegetables in the United States (same GAP as that submitted to the 2008 JMPR) allows a maximum seasonal rate of 0.59 kg ai/ha (max 0.15 kg ai/ha per application) with a RTI of 7 days and a PHI of 1 day.

Peppers

Data were available from supervised trials on peppers in the United States (submitted to the 2008 JMPR).

Mandipropamid residues in bell pepper and non-bell pepper from independent outdoor trials in the United States matching the US GAP were (n=6+3): 0.041, 0.054, 0.062, 0.090, 0.13 and 0.33 mg/kg for bell pepper and 0.083, 0.16 and 0.37 mg/kg for non-bell pepper.

Based on the residues in peppers from trials in the United States, the Meeting estimated a maximum residue level of 0.7 mg/kg and an STMR value of 0.090 mg/kg for the subgroup of peppers (except Martynia, Okra and Roselle) to replace the previous recommendation for peppers of 1 mg/kg.

On the basis of the maximum residue level and the STMR for subgroup of peppers and default dehydration factor of 10, the Meeting estimated a maximum residue level and an STMR value of 7 and 0.9 mg/kg to replace the previous recommendation for peppers, chili, dried.

Tomato

The critical GAP for fruiting vegetables for indoor use tomatoes in the United States (same GAP as that submitted to the 2008 JMPR) allows a maximum seasonal rate of 0.59 kg ai/ha (max 0.15 kg ai/ha per application) with a RTI of 7 days and a PHI of 1 day.

Data were available from supervised trials on tomatoes in France, Germany, Italy, Spain, Switzerland and the United States.

Mandipropamid residues in tomatoes from independent indoor trials in France, Germany, Italy, Spain and Switzerland matching the US GAP were (n=14): 0.08, 0.13 (2), 0.14, 0.17, 0.18, 0.24, 0.28, 0.30, 0.33, 0.34, 0.45, 0.60 and 0.65 mg/kg.

Mandipropamid residues in tomato from independent outdoor trials in the United States matching the US GAP were (n=10): 0.016, 0.032, 0.047, 0.052, 0.056 (2), 0.065, 0.082, 0.10 and 0.18 mg/kg.

The residue populations from trials indoor and outdoor were significantly different according to statistical test (Mann-Whitney U-test).

Based on the residues in tomatoes from indoor trials, the Meeting estimated a maximum residue level of 1 mg/kg and an STMR value of 0.26 mg/kg for the subgroup of tomatoes.

The Meeting withdrew the previous recommendation for tomato of 0.3 mg/kg.

Eggplant

In comparison with the residues in peppers and tomatoes from outdoor trials, the dataset from peppers leads to the highest maximum residue level.

The Meeting agreed that the maximum residue level for the subgroup of peppers could be extrapolated to that of the subgroup of eggplants. The Meeting estimated a maximum residue level of 0.7 mg/kg and an STMR value of 0.090 mg/kg for the subgroup of eggplants.

Root and tuber vegetables

Ginseng and Ginseng, dried including red ginseng

Data were available from supervised trials on ginseng and dried ginseng in China.

The GAP for ginseng in China allows one application of 0.21 kg ai/ha with a PHI of 21 days.

Mandipropamid residues in fresh ginseng from independent trials in China matching Chinese GAP were (n=5): <0.010 (3), 0.013 and 0.077 mg/kg.

Mandipropamid residues in dried and red ginseng from independent trials in China matching Chinese GAP were (n=5): 0.19, 0.23, 0.46, 0.49 and 2.2 mg/kg.

Data were available from supervised trials on dried ginseng in Canada and the United States.

The GAP for ginseng in the United States allows a maximum seasonal rate of 0.59 kg ai/ha (maximum of 0.15 kg ai/ha per application) with a RTI of 7 days and a PHI of 2 days.

Mandipropamid residues in dried ginseng from independent trials in Canada and the United States matching the US GAP were (n=4): 0.033, 0.035, 0.11 and 0.12 mg/kg.

Based on the residues in fresh ginseng from trials in China, the Meeting estimated a maximum residue level of 0.15 mg/kg and an STMR value of 0.010 mg/kg for ginseng.

Based on the residues in dried ginseng from trials in China, the Meeting estimated a maximum residue level of 4 mg/kg and an STMR value of 0.46 mg/kg for ginseng, dried including red ginseng.

Herbs and spices

Basil and Basil leaves, dried

Data were available from supervised trials on basil and dried basil in Canada and the United States.

The critical GAP for basil in the United States allows a maximum seasonal rate of 0.59 kg ai/ha (max 0.15 kg ai/ha per application) with a RTI of 7 days and a PHI of 1 day.

Mandipropamid residues in fresh basil from independent trials in Canada and the United States matching the US GAP were (n=6): 3.6, 6.5, 8.5, 9.0, 9.6 and 19 mg/kg.

Mandipropamid residues in dried basil from independent trials in Canada and the United States matching the US GAP were (n=6): 36, 48, 62, 63, 78 and 91 mg/kg.

Based on the residues in fresh basil from trials in Canada and the United States, the Meeting estimated a maximum residue level of 30 mg/kg and an STMR value of 8.75 mg/kg for basil, leaves.

Based on the residues in dried basil from trials in Canada and the United States, the Meeting estimated a maximum residue level of 200 mg/kg and an STMR value of 62.5 mg/kg for basil leaves, dried.

Fate of residues during processing

High temperature hydrolysis

The hydrolytic stability of [phenyl-U-^{14}C]-SYN500003 was studied under conditions at high temperature in sterile aqueous buffers at pH 4, 5 and 6 for periods of up to 60 minutes so as to simulate common processing practices (pasteurization, baking/brewing/boiling, and sterilization). SYN500003 was detected ranged from 97.5 to 100.4 percent of applied radioactivity at the investigated pH and temperature ranges. SYN500003 is considered stable under hydrolytic conditions at high temperatures.

Residues in processed commodities

The fate of mandipropamid residues has been examined in tomato processing studies. Estimated processing factors and the derived STMR-Ps are summarized in the Table below.

Table 1 Calculated STMR-Ps for processed food and feed commodities

Raw commodity [STMR]	Processed commodity	Processing factors # [Mean or best estimate processing factor]	STMR-P = $STMR_{RAC}$ × PF (mg/kg)
Tomato [0.26 mg/kg]	Wet pomace	1.0	0.26
	Dry pomace	4.4	1.14
	Juice	1.0	0.26
	Puree	0.86, 0.92, 1.1, 1.5, 2.0 [1.1]	0.286
	Canned	0.39	0.101
	Paste	1.9, 2.6, 4.4, 5.9 [3.5]	0.91

Note:

The factor is the ratio of the residue in processed commodity divided by the residue in the RAC.

Residues in animal commodities

The 2022 JMPR evaluated residues of mandipropamid in tomato wet pomace, which is listed in the OECD feeding table. The Meeting noted that the estimation did not result in a change of the dietary burdens of farm animals (20.8 ppm for cattle and 2 ppm for poultry). The previous recommendations of maximum residue level for animal commodities were maintained.

RECOMMENDATIONS

On the basis of the data from supervised trials, the Meeting concluded that the residue levels listed below are suitable for estimating maximum residue limits and for IEDI and IESTI assessment.

Definition of the residue for plant and animal commodities (for compliance with the MRL and for estimation of dietary exposure): *mandipropamid*

The residue is not fat-soluble

Table 2 Residue levels suitable for establishing maximum residue limits and for IEDI assessments

Commodity		Recommended MRL, mg/kg		STMR, mg/kg
CCN	Name	New	Previous	
HH 0722	Basil, leaves	30		8.75
DH 0722	Basil leaves, dried	200		62.5
VA 2031	Bulb Onions, Subgroup of	0.05		0.01
VC 0424	Cucumber	W	0.2	
VO 2046	Eggplants, Subgroup of	0.7		0.090
VC 2039	Fruiting vegetables, Cucurbits–Cucumber and Summer squashes, Subgroup of	0.2		0.0475
VC 2040	Fruiting vegetables, Cucurbits–Melons, Pumpkins and Winter squashes, Subgroup of	0.4		0.01
VR 0604	Ginseng	0.15		0.010
DV 0604	Ginseng, dried including red ginseng	4		0.46
VC 0046	Melon, except watermelon	W	0.5	
VA 0385	Onion, bulb	W	0.1	
VO 0051	Peppers (except Martynia, Okra and Roselle), Subgroup of	0.7	1	0.090
HS 0444	Peppers, Chili, dried	7	10	0.9
VA 0389	Spring onion	W	7	
VC 0431	Squash, summer	W	0.2	
VO 0448	Tomato	W	0.3	
VO 2045	Tomatoes, Subgroup of	1		0.26
	Tomato, canned			0.101
JF 0448	Tomato juice			0.26
	Tomato paste			0.91
DM 0448	Tomato puree			0.286
DM 3525	Tomato pomace			0.26

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The ADI for mandipropamid is 0–0.2 mg/kg bw. The International Estimated Daily Intakes (IEDIs) for mandipropamid were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the JMPR. The results are shown in Annex 3 of the 2022 JMPR Report. The IEDIs ranged from 1–8 percent of the maximum ADI.

The Meeting concluded that long-term dietary exposure to residues of mandipropamid from uses considered by the JMPR is unlikely to present a public health concern.

Acute dietary exposure

The 2008 JMPR decided that an ARfD for mandipropamid was unnecessary. Therefore, the Meeting concluded that the acute dietary exposure to residues of mandipropamid from the uses considered is unlikely to present a public health concern.

Threshold of toxicological concern (TTC) consideration for metabolite SYN500003

At the 2018 JMPR, the Meeting agreed to utilize the TTC approach to assess the metabolite SYN500003 (Cramer Class III). The 2018 JMPR concluded that residues of SYN500003 were only expected in root and tubers vegetables.

In the Canadian and United States trials for dried ginseng, SYN500003 residues were <0.005 mg/kg in all samples. The Meeting agreed that no additional exposure to SYN500003 is expected from ginseng and dried ginseng.

The Meeting concluded that SYN500003 is unlikely to present a public health concern.

MEFENTRIFLUCONAZOLE (320)

First draft prepared by M Thomas and M Le, Pest Management Regulatory Agency, Canada

EXPLANATION

Mefentrifluconazole, (2RS)-2-[4-(4-chlorophenoxy)-2-(trifluoromethyl)phenyl]-1-(1*H*-1,2,4-triazol-1-yl)propan-2-ol, is a triazole fungicide belonging to the group of the sterol biosynthesis inhibitors.

Mefentrifluconazole was scheduled at the Fifty-first Session of the CCPR for Evaluation for Residues and Toxicology by the 2020 JMPR. However, the Toxicology evaluation was conducted by the WHO Core Assessment Group at the 2021 JMPR Meeting, where an ADI of 0–0.04 mg/kg bw and an ARfD of 0.3 mg/kg bw were established. The Residue evaluation was rescheduled to the 2022 JMPR Meeting.

The Meeting received information from the manufacturer on physical and chemical properties, metabolism studies on plants and animals, environmental fate in soil, analytical method and stability in stored analytical samples, use patterns and supervised residue trials, processing studies and livestock feeding studies.

IDENTITY

ISO common Name:	Mefentrifluconazole
IUPAC Name:	(2RS)-2-[4-(4-chlorophenoxy)-2-(trifluoromethyl)phenyl]-1-(1*H*-1,2,4-triazol-1-yl)propan-2-ol
Chemical Abstracts Name:	α-[4-(4-chlorophenoxy)-2-(trifluoromethyl)phenyl]-α-methyl-1*H*-1,2,4-triazole-1-ethanol
CAS No.:	1417782-03-6
CIPAC No.:	Not assigned
Synonyms:	BAS 750F
Molecular Formula:	$C_{18}H_{15}ClF_3N_3O_2$
Structural Formula:	Molecular Weight:	397.78 g/mol

Specifications

Specifications for mefentrifluconazole have not been developed by the FAO.

Physical and chemical properties

Table 1 Physical and chemical properties of the pure active (98 percent purity)

Parameters	Value		Reference
Appearance	White, odourless crystalline powder		Kroehl, 2014
Vapour pressure	Temperature (°C)	Pa	Kroehl, 2014
	20	3.2×10^{-6}	
	25	6.5×10^{-6}	
Melting point	190 °C		Kroehl, 2014
Partition coefficient	pH	Log Kow	Wilbrand, 2013

Parameters	Value		Reference
n-octanol / water (20 °C)	4	3.4	
	7	3.4	
	7 (buffered)	3.3	
	9 (buffered)	3.4	
Solubility in water (22 °C)	Solvent	mg/L	Wilbrand, 2013
	Distilled water	0.81	
	pH 4	0.66	
	pH 7	0.71	
Solubility in organic solvents (20 °C)	Solvent	Solubility (g/L)	Wilbrand, 2013
	n-heptane	0.094	
	xylene	8	
	acetonitrile	50	
	methanol	71	
	acetone	94	
	ethyl acetate	116	
	1,2-dichloroethane	55	
Hydrolysis in water	Stable in water for at least 30 days at 25 °C in sterile aqueous buffer at pH 4, 5, 7, and 9		Hassink, 2015
Photolysis in sterile water	pH	DT_{50} in irradiated sterile buffer	Yan, 2015
	7	2.3 days	
	Irradiation of radiolabelled mefentrifluconazole resulted in the formation of the major photodegradation products M750F005 (≤32 percent applied radioactivity [AR]), M750F006 (≤31 percent AR), M750F007 (≤44 percent AR) and M750F008 (≤7 percent AR)		
Dissociation constant (20 °C)	3.0		Wilbrand, 2013

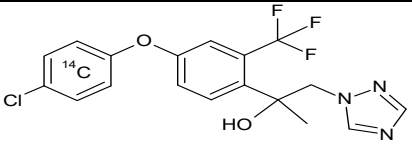
Mefentrifluconazole appears to be slightly soluble in water and moderately soluble in non-polar solvents. It is likely to sequester to fatty matrices based on its octanol/water partition coefficient. It has low potential for volatilization. Hydrolysis and aqueous photolysis are unlikely to be important routes of degradation at environmentally relevant pH levels.

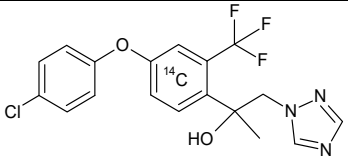
Formulations

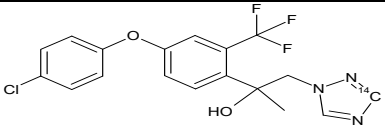
Mefentrifluconazole is available as soluble concentrate or emulsifiable concentrate formulations containing up to 400 g mefentrifluconazole/L.

METABOLISM AND ENVIRONMENTAL FATE

The fate and behaviour of mefentrifluconazole in animals, plants, and the environment was investigated using [^{14}C]-mefentrifluconazole as shown below:

[Chlorophenyl-U-^{14}C]-mefentrifluconazole	[Trifluoromethylphenyl-U-^{14}C]-mefentrifluconazole	[Triazole-3(5)-^{14}C]- mefentrifluconazole
		






Chemical names, structures and code names of metabolites and degradation products of

mefentrifluconazole are summarized in Table 2. Compounds are referred to primarily by the code name.

Table 2 Code names, chemical names and structures of mefentrifluconazole related substances

Plant metabolism

Mefentrifluconazole metabolism data were submitted for grape, soya bean, and wheat.

Grape

Three grapevines (variety *Müller-Thurgau*), grown outdoors under natural climatic conditions, were treated three times foliarly with either a 1:1 mixture of [^{14}C-U-chlorophenyl:^{13}C-U-chlorophenyl]-mefentrifluconazole or a 2:1 mixture of [^{14}C-3(5)-triazole:^{13}C-3(5)-triazole]-mefentrifluconazole at a rate of 150 g ai/ha with re-treatment intervals of 10–11 days (Birk *et al*., 2015, BASF DocID 2015_1073822). Grape leaves and clusters were harvested early, 21 days after the first application (just prior to the third application) and at maturity (BBCH growth stage 89), 12 days following the last application. Grape clusters were manually separated into berries and stalks.

Total radioactive residues (TRR) were analysed following combustion by means of an oxidizer.

For the quantitation of radioactive residues in liquid samples a liquid scintillation counter (LSC) was used. TRRs were also calculated by summing extracted and unextracted residues. TRRs were highest in the leaves, followed by the stalks and berries (Table 3). Similar TRRs were observed between measured and calculated TRRs and for both labels.

Table 3 Total radioactive residues in grape matrices following application of chlorophenyl and triazole radiolabelled mefentrifluconazole (3 × 150 g ai/ha)

Matrix	TRR measured by combustion,mg eq/kg	TRR calculated from extracted and unextracted residues[1] , mg eq/kg
Chlorophenyl label		
Berries (DAT 12)	0.435	0.349 (first extraction)[2] 0.380 (second extraction)[2]
Leaves (DAT 12)	8.860	7.371
Stalks (DAT 12)	0.674	0.648
Triazole label		
Berries (DAT 12)	0.400	0.428 (first extraction)[2] 0.363 (second extraction)[2]
Leaves (DAT 12)	7.245	7.311
Stalks (DAT 12)	1.214	1.135

Notes:

[1] Calculated as the sum of the solvent extracted and unextracted radioactive residues.

[2] Grape berries were extracted twice (for each label) given that the first extraction produced limited amounts of sample material to conduct combustion analysis of the unextracted residues. The first extraction was used for the identification/characterization of the extracted and unextracted residues. The second extraction was used for the determination of the unextracted TRRs by combustion and to investigate storage stability.

Grape berries, leaves, and stalks were extracted three times with methanol and twice with water. After each extraction step, solid material was separated from the extract by centrifugation and filtration. The filtered supernatants (methanol extracts and water extracts) were individually radioassayed. The unextracted residues in each matrix (both labels) were dried, homogenized, and aliquots thereof were radioassayed. Solvent extracted radioactivity ranged between 87–90 percent TRR, 89–91 percent TRR, and 93–94 percent TRR in grape berries, leaves, and stalks, respectively (Table 4).

Table 4 Distribution and extractability of radioactive residues from grape matrices following application of chlorophenyl and triazole radiolabelled mefentrifluconazole (3 × 150 g ai/ha)

Notes:

[1] Not enough sample material for combustion analysis.

The methanol (all matrices) and water (leaves only) extracts for both labels were further purified using an SPE cartridge and analysed by HPLC-MS and/or by comparison of HPLC retention time against standards. For the identification of metabolites, the methanol extracts of the leaves (both labels) were partitioned with isohexane, dichloromethane, and ethyl acetate and the combined phases were fractionated using flash chromatography, and analysed by HPLC-MS and/or by comparison of HPLC retention time against standards.

The unextracted residues were solubilized by sequential treatment with 1 percent ammonia, maceroenzyme, α-amylase:β-amylase:amyloglucosidase (3:2:3), β-glucosidase:hesperidinase (1:2 for berries, 3:4 for leaves, 1:1 for stalks), laccase:tyrosinase (5:6 for berries, 5:8 for leaves, 1:1 for stalks), and protease. The radioactivity remaining after solubilisation were dried, homogenized, and aliquots thereof were radioassayed. As the results from the immature grape samples (treated 21 days after the first treatment) confirmed those from mature sampled grapes, the results from the immature grapes were not reported in the study.

The distribution of radioactivity in grape berries, leaves, and stalks is presented in Tables 5 and 6. Parent mefentrifluconazole (free) was the major identified residue in all matrices accounting for 64–70 percent TRR (0.224–0.301 mg eq/kg) in berries, 60–70 percent TRR (4.431–5.110 mg eq/kg) in leaves, and 86–92 percent TRR (0.556–1.039 mg eq/kg) in stalks. Metabolite M750F019 (free) was identified in berries, leaves, and stalks at 6.1–6.9 percent TRR (0.024–0.026 mg eq/kg), 14.5–21.1 percent TRR (1.058–1.554 mg eq/kg), and 2.3 percent TRR (0.015 mg eq/kg), respectively. Metabolite M750F026 (free) was identified as a minor metabolite in leaves (chlorophenyl-label only) at 1.3 percent TRR (0.097 mg eq/kg).

The application formulation and methanol extracts from grape berries and leaves were further analysed by HPLC to determine the enantiomer ratios of mefentrifluconazole. The relative amounts of the two enantiomers were approximately 1:1 in the application formulations and each matrix (Table 7).

Table 7 Enantiomer ratios from the treatment of grapes with chlorophenyl and triazole radiolabelled mefentrifluconazole

Matrix	Enantiomer 1 (% ROI)	Enantiomer 2 (% ROI)
Chlorophenyl label		
Application Formulation	48.9	51.1
Berries	46.7	53.3
Triazole label		
Application Formulation	47.4	52.6
Leaves	48.1	52.0

Notes:
ROI = region of interest (on the chromatogram).

All samples were extracted 55–57 days after sampling, and were then analysed 14–27 days after extraction. Total time between sampling to analysis was 70–84 days. The stability of the radioactive residues in grape matrices (berries and leaves stored at ≤-18 °C) and extracts (berries and leaves, storage in fridge) was investigated using homogenates and extracts from both labels. Comparison of the chromatographic profiles between matrices extracted 55–57 days after sampling and re-extracted 203–252 days after sampling showed no significant changes to the composition and amounts of radioactivity for each matrix. Similarly, the chromatographic profiles between extracts analysed after 14–27 days of storage and re-analysed after 224–231 days of storage showed no significant changes to the composition and amounts of radioactivity for each extract.

Soya bean

Ten containers of soya bean plants (variety *Sultana*, 13 plants/container), grown in climatic chambers (phytotrons, simulating natural climatic conditions), were treated three times foliarly with either a 1:1 mixture of [^{14}C-U-chlorophenyl:^{13}C-U-chlorophenyl]-mefentrifluconazole or a 2:1 mixture of [^{14}C-3(5)-

triazole:^{13}C-3(5)-triazole]-mefentrifluconazole at a rate of 125 g ai/ha with re-treatment intervals of 17-19 days (Thiaener *et al*., 2015, BASF DocID 2014_1224012). Soya bean forage was harvested 19 days after the first application (just before the second application; BBCH growth stage of 71–72). At harvest, 47–48 days after the final application at BBCH growth stage 89, the leaves were removed from the plants and collected (matrix: rest of plant). The mature pods were removed and manually opened in order to separate seeds from hulls. In addition green pods were also harvested and the remaining stems were cut off and combined with the collected leaves (matrix: rest of plant).

TRRs were analysed following combustion by means of an oxidizer. For the quantitation of radioactive residues in liquid samples a liquid scintillation counter (LSC) was used. TRR were also calculated by summing extracted and unextracted residues. TRR levels found were highest in the rest of plant, followed by the green pods, forage, hull, and seed (Table 8). Similar TRR levels were observed between measured and calculated TRR and for both labels.

Table 8 Total radioactive residues in soya beans matrices following application of chlorophenyl and triazole radiolabelled mefentrifluconazole (3 × 125 g ai/ha)

Matrix	TRR by combustion, mg eq/kg	TRR calculated from extracted and unextracted residues, mg eq/kg
Chlorophenyl label		
Forage (DALA 19[1])	6.516	6.575
Seed (DALA 47)	0.109	0.129
Hull (DALA 47)	3.735	3.838
Rest of Plant (DALA 47)	16.016	16.459
Green Pods (DALA 47)	8.857	8.721
Triazole label		
Forage (DAT 19[1])	4.416	4.609
Seed (DAT 48)	2.592	3.063
Hull (DAT 48)	3.890	4.122
Rest of Plant (DAT 48)	19.934	19.264
Green Pods (DAT 48)	16.005	16.006

Notes:

[1] Days after the first application. Forage was harvested just before the second application.

Forage, hull, and rest of plant samples were extracted three times with methanol and twice with water. After each extraction step, solid material was separated from the extract by centrifugation and filtration. The filtered supernatants (methanol extracts and water extracts) were each pooled; the methanol extracts were purified by SPE fractionation. Soya bean seed and green pod samples were extracted three times with acetonitrile:isohexane (1:1) and twice with water. Solid material was separated from the extract by centrifugation and filtration. The residue after solvent extraction was dried, homogenized, and aliquots thereof were radioassayed. The filtered supernatants (acetonitrile, isohexane, and water extracts) were each pooled.

Solvent extracted radioactivity ranged between 91–93 percent, 69–74 percent, and 87–88 percent in soya bean forage, hull, and rest of plant (Table 9) and between 56–76 percent and 78–83 percent in soya bean seed and green pods (Table 10).

Notes:

[1] Days after the first application. Forage was harvested just before the second application.

Table 10 Distribution of radioactive residues from soya bean seed and green pods following application of chlorophenyl and triazole radiolabelled mefentrifluconazole (3 × 125 g ai/ha)

Matrix	Calculated TRR, mg eq/kg	Acetonitrile Phase	Isohexane Phase	Water Extract	Total Solvent Extracted Residues	Unextracted Residues
		mg eq/kg (% TRR)	mg eq/kg (% TRR)	mg eq/kg (% TRR)	mg eq/kg (% TRR)	mg eq/kg (% TRR)
Chlorophenyl label						
Seed (DALA 47)	0.129	0.005 (3.9)	0.022 (17.1)	0.045 (34.9)	0.072 (55.8)	0.056 (43.4)
Green Pods (DALA 47)	8.721	6.503 (74.6)	0.108 (1.2)	0.660 (7.6)	7.271 (83.4)	1.451 (16.6)
Triazole label						
Seed (DALA 47)	3.063	0.019 (0.6)	0.025 (0.8)	2.272 (74.2)	2.316 (75.6)	0.747 (24.4)
Green Pods (DALA 47)	16.006	10.782 (67.4)	0.141 (0.9)	1.564 (9.8)	12.487 (78.0)	3.518 (22.0)

The forage, hull, and rest of plant unextracted residues were solubilized by sequential treatment with maceroenzyme:cellulase (10:1 for forage and rest of plant, 5:1 for hull), β-glucosidase:hesperidinase (1:1), α-amylase:β-amylase:amyloglucosidase (1:1:1), laccase:tyrosinase (5:16), and protease. The seed unextracted residues were solubilized by sequential treatment with maceroenzyme:cellulase (10:1 or 15:1), β-glucosidase:hesperidinase (1:1), α-amylase:β-amylase:amyloglucosidase (1:1:1), and protease. The maceroenzyme:cellulase hydrosylates for forage, rest of plant, and seed samples were purified using SPE fractionation. The identification and characterization of the components in the extracts was carried out by HPLC-MS, co-chromatography and comparison of retention times.

Sequential enzyme treatment of the unextracted residues released an additional 3.5-33 percent of the TRR in each matrix except for green pods where the post-extraction residues were not further hydrolysed (Tables 11 to 14).

Parent mefentrifluconazole (free and conjugated) was a major residue in forage, hulls, and rest of plant, accounting for 79–80 percent TRR (3.648–5.257 mg eq/kg) in forage, 79–83 percent TRR (3.179–3.257 mg eq/kg) in hulls, and 60–71 percent TRR (9.848–13.698 mg eq/kg) in rest of plant. Mefentrifluconazole (free) was a major residue in green pods 69 percent TRR (5.978 mg eq/kg). Mefentrifluconazole (free) was a minor residue in seed accounting for only 0.4–3.9 percent TRR (0.005–0.013 mg eq/kg). Triazole alanine (free and conjugated) was a major metabolite found only in soya bean

seeds accounting for 48 percent TRR (1.461 mg eq/kg). The minor metabolites, M70F018/M750F020 and M750F012, free and conjugated, were identified in forage, hull, rest of plant, and green pods at levels of 0.03–4.5 percent TRR (0.001–0.748 mg eq/kg) and 0.4–5.9 percent TRR (0.014–0.971 mg eq/kg), respectively. Triazole lactic acid (free) and 1,2,4-triazole (free) were identified as minor metabolites in seed at levels of 1.3 percent TRR (0.04 mg eq/kg) and 0.3 percent TRR (0.008 mg eq/kg), respectively.

Table 11 Characterisation and identification of C-Label residues in soya bean forage, hull, and rest of plant

The application formulation and methanol extracts from soya bean forage, hull, and rest of plant were further analysed by HPLC to determine the enantiomer ratios of mefentrifluconazole. Chiral analysis was not conducted for seeds due to the low amounts of mefentrifluconazole found. The relative amounts of the two enantiomers were approximately 1:1 in the application formulations and in each matrix tested (Table 15).

Table 15 Enantiomer ratios from the treatment of soya beans with chlorophenyl and triazole radiolabelled mefentrifluconazole

Matrix	Enantiomer 1 (% ROI)	Enantiomer 2 (% ROI)
Chlorophenyl label		
Application Formulation	50.5	49.5
Forage	45.5	54.5
Hull	45.6	54.4
Rest of Plant	46.6	53.4
Triazole label		
Forage	51.3	48.7
Hull	48.1	51.9
Rest of Plant	42.7	57.3

Notes:

ROI = region of interest (on the chromatogram).

All samples were extracted 21–86 days after sampling, and were then analysed 17–85 days after extraction. Total time between sampling to analysis was 49–114 days. The stability of the radioactive residues in soya bean matrices (forage and rest of plant stored at ≤-18 °C) and extracts (soya bean forage, rest of plant, and seed, storage in fridge) was investigated using homogenates and extracts from both

labels. Comparison of the chromatographic profiles between matrices extracted 21–86 days after sampling and re-extracted 350–374 days after sampling showed no significant changes to the composition and amounts of radioactivity for each matrix. Similarly, the chromatographic profiles between extracts analysed after 17–85 days of storage and re-analysed after 294–330 days of storage showed no significant changes to the composition and amounts of radioactivity for each extract.

Wheat

Twenty containers of spring wheat (variety *Thassos*, 10 containers per label), grown in phytotrons simulating natural climatic conditions, were treated twice foliarly with either a 1:1 mixture of [^{14}C-U-chlorophenyl:^{13}C-U-chlorophenyl]-mefentrifluconazole or a 2:1 mixture of [^{14}C-3(5)-triazole:^{13}C-3(5)-triazole]-mefentrifluconazole at a rate of 150 g ai/ha with a re-treatment interval of 21 days(Thiaener *et al.*, 2015, BASF DocID 2015_1001872). Wheat forage was harvested 15 days after the first application (just before the second application; BBCH growth stage 61). Straw and grain were harvested 35 days after the final application at BBCH 89.

Total radioactive residues (TRR) were analysed following combustion by means of an oxidizer. For the quantitation of radioactive residues in liquid samples a liquid scintillation counter (LSC) was used. TRR were also calculated by summing extracted and unextracted residues.

TRR levels found were highest in straw, followed by forage and grain (Table 16). Similar TRR levels were observed between measured and calculated TRR and for both labels.

Table 16 Total radioactive residues in wheat matrices following application of chlorophenyl and triazole radiolabelled mefentrifluconazole (2 × 150 g ai/ha)

Matrix	TRR by combustion in mg eq/kg	TRR calculated from extracted and unextracted residues[1], mg eq/kg
Chlorophenyl label		
Forage (DALA 15[2])	2.472	2.378
Grain (DALA 35)	0.065	0.062
Straw (DAT 35)	24.305	24.380
Triazole label		
Forage (DALA 15[2])	2.634	2.310
Grain (DALA 35)	0.619	0.620
Straw (DALA 35)	14.339	13.984

Notes:

[1] Calculated as the sum of the solvent extracted and unextracted radioactive residues.

[2.] Days after the first application. Forage was harvested just before the second application.

Forage and straw samples were extracted three times with methanol and twice with water. After each extraction step, solid material was separated from the extract by centrifugation and filtration. The filtered supernatants (methanol extracts and water extracts) were each pooled.

Wheat grain was extracted three times with acetonitrile:isohexane (1:1) and two times with water. Solid material was separated from the extract by centrifugation and filtration. The filtered supernatants (acetonitrile, isohexane, and water extracts) were each pooled. The residue after solvent extraction was dried, homogenized, and aliquots thereof were radioassayed.

Solvent extracted radioactivity ranged between 95–96 percent, 44–78 percent, and 83–86 percent in wheat forage, grain, and straw, respectively (Table 17).

Table 17 Distribution and extractability of radioactive residues from wheat forage and straw following

application of chlorophenyl and triazole radiolabelled mefentrifluconazole (2 × 150 g ai/ha)

Matrix	Calculated TRR, mg eq/kg	Methanol Extract	Water Extract	Total Solvent Extracted Residues	Unextracted Residues

Straw (DALA 35)	13.984	10.869 (77.7)	1.213 (8.7)	12.082 (86.4)	1.901 (13.6)

Notes:

[1] Days after the first application. Forage was harvested just before the second application.

Table 18 Distribution and extractability of radioactive residues from wheat grain following application of chlorophenyl and triazole radiolabelled mefentrifluconazole (2 × 150 g ai/ha)

Matrix	Calculated TRR, mg eq/kg	Acetonitrile Phase	Isohexane Phase	Water Extract	Total Solvent Extracted Residues	Unextracted Residues
		mg eq/kg (% TRR)	mg eq/kg (% TRR)	mg eq/kg (% TRR)	mg eq/kg (% TRR)	mg eq/kg (% TRR)
Chlorophenyl label						
Grain (DALA 35)	0.062	0.011 (17.7)	0.001 (1.6)	0.015 (24.2)	0.027 (43.5)	0.035 (56.5)
Triazole label						
Grain (DALA 35)	0.620	0.022 (3.5)	0.001 (0.2)	0.460 (74.2)	0.483 (77.9)	0.137 (22.1)

The water extract of the grain samples was adjusted to pH 4 with formic acid and precipitated with acetone. The acetone precipitate was sequentially treated with protease, α-amylase:β-amylase:amyloglucosidase (2:1:1), 1 percent ammonia, and again with α-amylase:β-amylase:amyloglucosidase (2:1:1).

The forage and straw unextracted residues were solubilized by sequential treatment with 1 percent ammonia, maceroenzyme, α-amylase:β-amylase:amyloglucosidase (1:1:1), β-glucosidase:hesperidinase (1:2), and tyrosinase:laccase (5:1).

The identification and characterization of the components in the extracts and hydrolysates was carried out by HPLC-MS, co-chromatography and comparison of retention times.

The distribution of radioactivity in wheat forage, grain, and straw is presented in Tables 19 and Table 20. Parent mefentrifluconazole was a major identified residue in forage and straw accounting for 84–89 percent TRR (2.007–2.063 mg eq/kg, free) in forage and 59–69 percent TRR (9.574–14.298 mg eq/kg, free and conjugated) in straw. Mefentrifluconazole was not found in grain. Triazole alanine (free and conjugated) and triazole acetic acid (free and conjugated) were major metabolites found only in wheat grain accounting for 46 percent TRR (0.282 mg eq/kg) and 22 percent (0.133 mg eq/kg), respectively. As minor metabolites, M750F009, M750F012, M750F019, and M750F018/M750F020 were identified in both forage (all metabolites were in free form) and straw (free and conjugated metabolites) at levels of 1.1–1.3 percent TRR (0.025–0.178 mg eq/kg), 0.1–2.1 percent TRR (0.008–0.158 mg eq/kg), 0.1–5.8 percent TRR (0.003–1.406 mg eq/kg), and 0.1–6.9 percent TRR (0.037–1.682 mg eq/kg), respectively. Minor metabolites M750F010 (free), M750F018 (free and conjugated), and M750F012/M750F021 (free and conjugated) were identified in only straw at levels of 1.3 percent TRR (0.178 mg eq/kg), 2.9–5.5 percent TRR (0.717–0.766 mg eq/kg), and 3.4–4.9 percent TRR (0.47–

1.184 mg eq/kg), respectively. 1,2,4–Triazole (free) was identified as minor metabolite in grain at level of 1.0 percent TRR (0.006 mg eq/kg). Sequential enzyme treatment released an additional 1.9–42 percent of the TRR in each matrix

The application formulation and methanol extracts from wheat forage and straw were further analysed by HPLC to determine the enantiomer ratios of mefentrifluconazole. Chiral analysis was not conducted for wheat grain as mefentrifluconazole was not found in this matrix. The relative amounts of the two enantiomers were approximately 1:1 in the application formulations and in each matrix (Table 21).

Table 21 Enantiomer ratios from the treatment of wheat with chlorophenyl and triazole radiolabelled mefentrifluconazole.

Matrix	Enantiomer 1 (% ROI)	Enantiomer 2 (% ROI)
Chlorophenyl label		
Application Formulation	53.56	46.44
Forage	47.49	52.51
Straw	48.16	51.84
Triazole label		
Application Formulation	48.53	51.47
Forage	49.01	50.99
Straw	47.82	52.18

Notes:

ROI = region of interest (on the chromatogram).

All samples were extracted 42–182 days after sampling, and were then analysed 13–197 days after extraction. Total time between sampling to analysis was 196–281 days. The stability of the radioactive residues in wheat forage (stored at ≤-18 °C) and extracts of wheat forage (storage in fridge) was investigated using homogenates and extracts from both labels. Comparison of the chromatographic profiles between wheat forage extracted 84–85 days after sampling and re-extracted 623–624 days after sampling showed no significant changes to the composition and amounts of radioactivity in forage. Similarly, the chromatographic profiles between extracts analysed after 12–195 days of storage and re-analysed after 540–595 days of storage showed no significant changes to the composition and amounts of radioactivity in wheat forage extracts. Although storage stability was not assessed in wheat grain and straw matrices and extracts, all samples were extracted within 6 months of sampling. The extracts from wheat grain and straw were refrigerated for up to 197 days prior to analysis which is adequately covered by the storage period demonstrated in extracts from wheat forage. Furthermore extracts from grape leaves and soya bean seeds were also stable for up to 231 days and 374 days, respectively.

In summary, the metabolism of mefentrifluconazole is adequately understood in grapes, soya beans, and wheat, representing a fruit, a pulse crop, and a cereal crop. Unchanged parent was the predominant residue in grapes (berries, leaves, and stalks), wheat (forage and straw), and soya bean

(green pods, forage, and hulls). The parent was further conjugated by sugars resulting in numerous minor metabolites found in low levels compared to the parent. In contrast, in wheat grain and soya bean seed, the predominant component of the residue was triazole alanine formed by cleavage of the parent at the triazole-bridge. In wheat grain, triazole lactic acid was also a major component of the residue. Unchanged parent was absent in wheat grain and present in very low amounts in soya bean seed. Metabolites formed by conjugation with sugars were present in minor amounts (< 6 percent TRR and low relative to the parent).

Figure 1 shows a proposed metabolic pathway of mefentrifluconazole in crops.

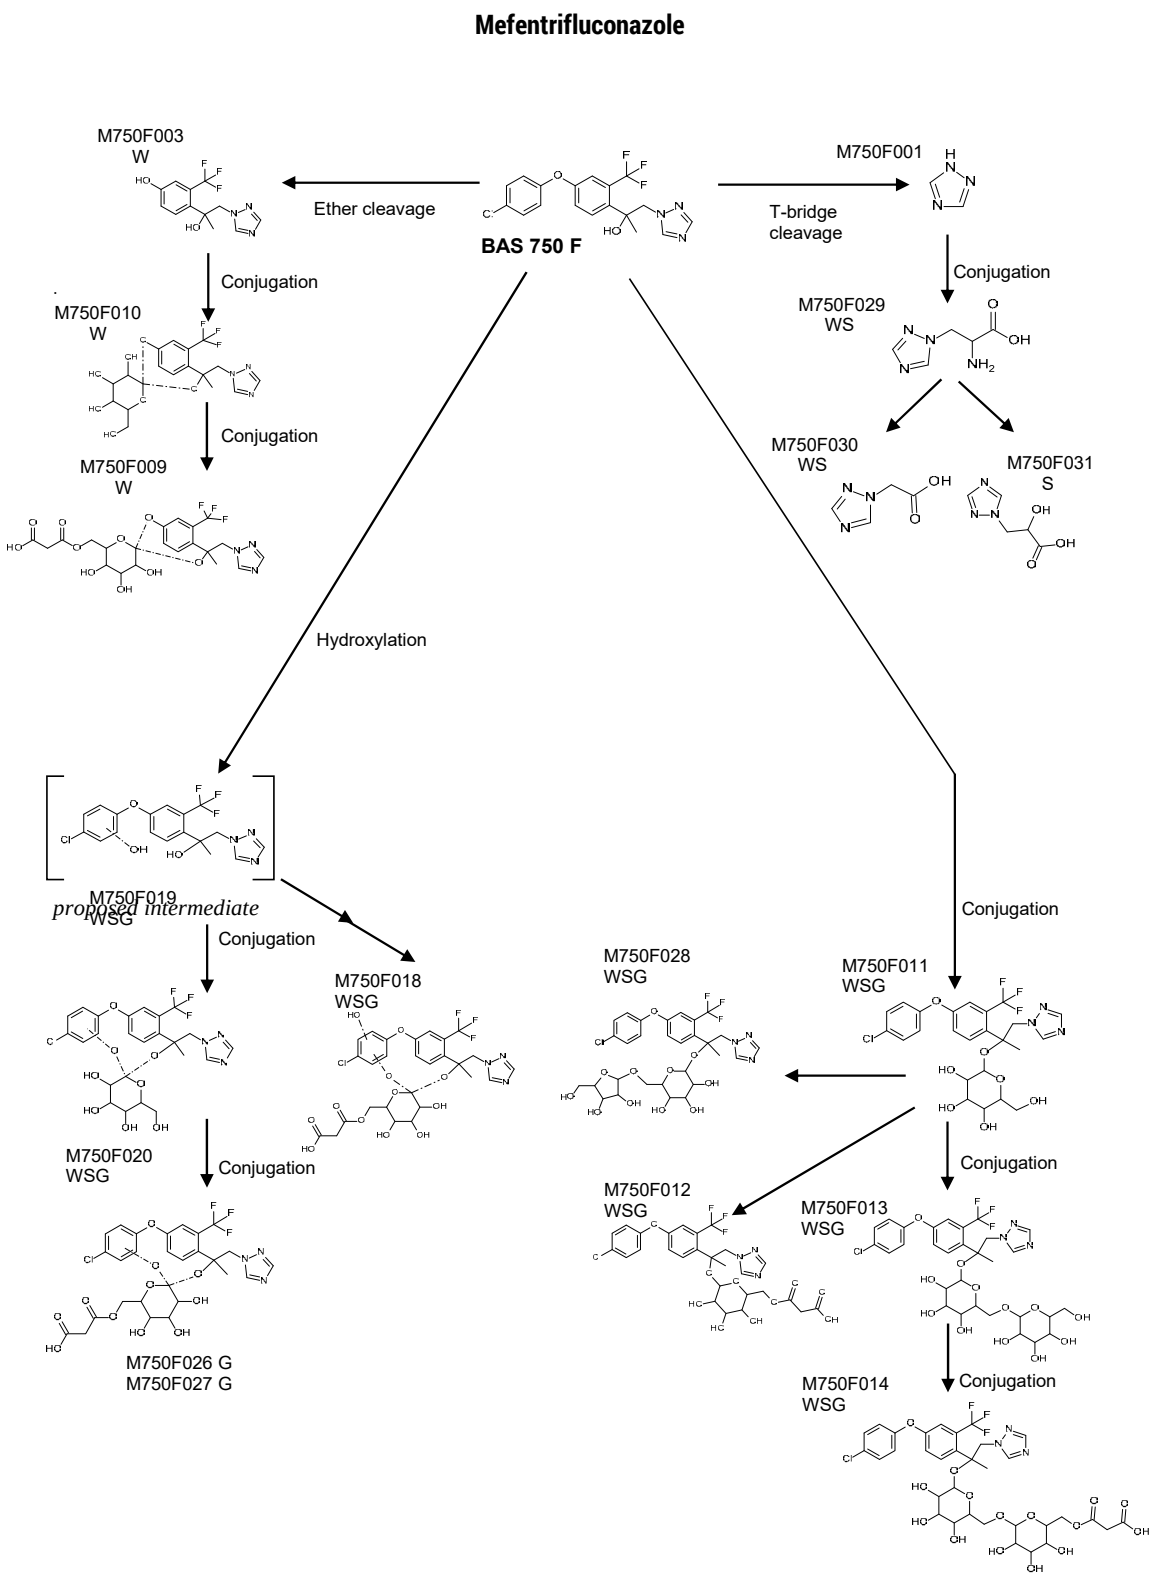

Figure 1 Proposed metabolic pathway of mefentrifluconazole in primary crops

Animal metabolism

Laboratory animal studies

Metabolism of mefentrifluconazole in rats was evaluated by the WHO Core Assessment Group of the 2020 JMPR.

Lactating goats

The metabolism of chlorophenyl-U-^{14}C-labelled (C-Label), triazole-3-(5)- ^{14}C-labelled (T-Label) or trifluoromethylphenyl-ring-U-^{14}C-labelled (TFMP-Label) mefentrifluconazole was investigated in lactating goats (British Saanen, 66–74 kg bw) (Thiaener et al., 2015, BASF DocID 2015_1078841). For the C and T labels, two goats each, and for the TFMP-label one goat, were dosed orally once daily for 14 consecutive days (C- and T-Label) or for 12 consecutive days (TFMP-Label). Feed consumption during the dosing period ranged from 0.72–1.78 kg/day, with animals offered 1 kg concentrate and 1 kg hay per day. The nominal daily doses were equivalent to 12 ppm in the diet (0.34 mg/kg bw). Milk production averaged 2.2 kg/day for the four goats. During the dosing period, urine and faeces were sampled once daily, while milk was collected twice daily, in the afternoon and in the morning and combined per 24 hour period. Following analysis of the individual whole milk samples the remaining bulk from the 6–7, 7–8, 8–9, 9–10, 10–11 and 11–12 day samples were combined and analysed. This whole milk pool was then divided into two equal portions, one was retained as whole milk and the second was centrifuged to separate the cream from the skimmed milk. Tissues, organs (liver, kidney, muscle and fat samples) and bile were collected after animal sacrifice, approximately 23 hours after administration of the last dose.

TRRs in liquid samples were determined by Liquid Scintillation Counting (LSC) while those in solid samples were determined by combustion analysis. Plateau levels of radioactive residues in milk were reached within 5–6 days after administration of the first dose (Table 22).

Table 22 TRRs in milk after administration of ^{14}C-Mefentrifluconazole to goats

Most of the radioactivity was recovered in the excreta with urine containing 25.9–40.2 percent of the administered dose (AD) and faeces containing 34.5–49.6 percent of the AD. The radioactivity recovered in milk and tissues was low, each accounting for ≤ 2.2 percent of the AD.

Table 23 Material balance after administration of ^{14}C- Mefentrifluconazole to goats

The calculated total radioactive residues (TRRs) in the pooled milk samples (144–288 h) of the C- and T-labels and the TFMP-label was 0.029 mg eq/kg, 0.273 mg eq/kg, and 0.062 mg eq/kg for whole milk and 0.016 mg eq/kg, 0.270 mg eq/kg and 0.036 mg eq/kg for skimmed milk, respectively. The TRRs in cream were 0.207 mg eq/kg, 0.289 mg eq/kg and 0.521 mg eq/kg for the C-label, the T-label and the TFMP-label, respectively. For tissues, TRRs were highest in liver (0.650–1.332 mg eq/kg), followed by kidney (0.352–0.422 mg eq/kg), composite fat sample (0.213–0.532 mg eq/kg) and composite muscle sample (0.047–0.223 mg eq/kg). In general, levels of radioactivity were lowest in milk and muscle (Table 24).

Table 24 TRRs in milk and tissues

Matrix	C-Label		T-Label		TFMP-Label	
	TRR measured (mg eq/kg)	TRR calculated (mg eq/kg)	TRR measured (mg eq/kg)	TRR calculated (mg eq/kg)	TRR measured (mg eq/kg)	TRR calculated (mg eq/kg)

Cream	0.204	0.207	0.266	0.289	0.491	0.521

Subsamples of liver, kidney and muscle (all labels) were sequentially extracted with methanol (3×) and water (2×). Subsamples of fat (all labels) were sequentially extracted with acetonitrile (2×) and isohexane (3×). After each extraction step, the samples were centrifuged and concentrated. The respective methanol and water extracts (liver, kidney, muscle) or acetonitrile and isohexane extracts (fat) were combined and analysed. The methanol extracts of kidney (C-label) and liver (C- and T-labels) were incubated with β-glucuronidase/arylsulfatase to investigate the presence of glucuronic acid conjugates M750F064 and M750F068.The unextracted residues were dried, homogenised and combusted for determination of the radioactive residues. In the case of liver, unextracted residues were subjected to protease hydrolysis.

Subsamples of the pooled whole milk and skimmed milk were extracted using acetonitrile and isohexane and centrifuged. Since after centrifugation, three phases were obtained, water was added to the supernatants to enable phase separation and the samples (whole milk and skimmed milk) were

centrifuged again. For skimmed milk, the centrifuged supernatant was filtered into a separating funnel. The acetonitrile phase and the isohexane phase of whole milk and skimmed milk were collected. For the C-label, the unextracted residue of whole milk and skimmed milk was subjected to additional extractions using methanol (3×) and water (2×; only for skimmed milk). The extracts were separated from the unextracted residues by centrifugation and filtered. The methanol and water extracts were combined while the unextracted residues were dried prior to analysis. Subsamples of the pooled cream were extracted once with acetonitrile and isohexane (2× for C-label). The acetonitrile and isohexane phases were collected and combined while the dried residues were homogenized prior to analysis.

Extraction of whole milk with acetonitrile released the majority of the radioactivity (86–96 percent TRR), with ≤5 percent TRR extracted using isohexane. Unextracted residues represented 2.0–7.5 percent TRR (0.001–0.020 mg eq/kg). In the acetonitrile extracts of whole milk, from the C- and TFMP-label, the parent compound was the major residue, accounting for 44.5–47.5 percent TRR (0.014–0.028 mg/kg) as was the metabolite M750F043, representing 14.2–25 percent TRR (0.004–0.016 mg eq/kg). Three additional minor metabolites were identified M750F022 (1.2–2.2 percent TRR; 0.001mg eq/kg), M750F041 (6.0–7.2 percent TRR; 0.002–0.004 mg eq/kg) and M750F072 (5.8–11.2 percent TRR; 0.002–0.004 mg eq/kg). In the acetonitrile extracts of whole milk, from the T-label, 1,2,4-triazole was the predominant metabolite detected, accounting for 78.4 percent TRR (0.214 mg eq/kg) with the parent compound representing 3 percent TRR (0.008 mg eq/kg). A similar metabolic profile was observed in skimmed milk and cream.

Although subjected to the same extraction procedure as milk, the distribution of radioactivity in fat was different. Moreover, isohexane extraction of the composite fat samples released the majority of the radioactivity (>91 percent TRR; >0.19 mg eq/kg) for all three labels. Acetonitrile-extracted and unextracted residues accounted for 1–5 percent TRR (0.003–0.011 mg eq/kg) and ≤4 percent TRR (0.008 mg eq/kg), respectively. In the isohexane extracts, parent compound was the main residue for all three labels (85–88 percent TRR; 0.18–0.47 mg/kg). Metabolite M750F022 was the only other metabolite detected in fat of the C- and TFMP-label studies (up to 5.8 percent TRR; 0.031 mg eq/kg) while 1,2,4-triazole was the only metabolite observed in the T-label study at 4.7 percent TRR (0.01 mg eq/kg).

Extraction of composite muscle samples with methanol released greater than 92 percent TRR, with ≤0.7 percent TRR extracted using water and <1.5 percent TRR remaining unextracted. In the methanol extract of muscle of the C- and TFMP-label, the parent compound was the main residue, accounting for 88–96 percent TRR (0.04–0.09 mg/kg). In the methanol extract of muscle of the T-label, the metabolite 1,2,4-triazole was the main residue (87 percent TRR; 0.19 mg eq/kg) with mefentrifluconazole accounting for 12 percent TRR (0.027 mg/kg). Metabolite M750F022 was only observed in muscle of the C-label and represented 6.7 percent TRR (0.003 mg eq/kg).

Similar to muscle, extraction of liver with methanol released greater than 88 percent TRR, with ≤2 percent TRR extracted using water. The remaining unextracted radioactivity (up to 9 percent TRR) was subjected to protease hydrolysis which released an additional 2–3 percent TRR (0.01–0.04 mg eq/kg), with 4–6 percent TRR (0.04–0.09 mg eq/kg) remaining as bound residues. In the methanol extracts, the parent compound represented one of the main residues for all three labels (26–50 percent TRR; 0.17–0.62 mg/kg) together with the metabolite M750F016 (10–15 percent TRR; 0.065–0.20 mg eq/kg). Metabolite M750F068, resulting from glucuronidation of the parent compound, was also observed in liver of all three labels but at lower levels (3–4 percent TRR; 0.03–0.06 mg eq/kg). In addition, the minor metabolite M750F022 and its glucuronide derivative M750F038, were found in the methanol extracts of the C- and TFMP-label (5–11 percent TRR; 0.05–0.15 mg eq/kg). For the T-label, 1,2,4-triazole and a likely conjugate of 1,2,4-triazole, which was converted entirely into 1,2,4-triazole after addition of hydrochloric acid, accounted together for 32 percent TRR (0.21 mg eq/kg).

Methanol extraction of kidney released greater than 96 percent TRR with ≤1 percent TRR being extracted with water and ≤3 percent TRR remaining unextracted. In the methanol extract of kidney, the parent compound was one of the main components for C-label (28 percent TRR; 0.100 mg/kg) and TFMP-label (46 percent TRR; 0.20 mg/kg). Conversely, for the T-label, triazole was the main component (68 percent TRR; 0.27 mg eq/kg) while the parent compound was only present at 10 percent TRR (0.04 mg/kg). In the C-label, the major metabolites M750F038 (14.8 percent TRR; 0.052 mg eq/kg) and M750F064 (11.8 percent TRR; 0.042 mg eq/kg) and M750F068 (18 percent TRR; 0.06 mg eq/kg) were identified. In addition, M750F022 was identified (6 percent TRR; 0.02 mg eq/kg). Incubation of the methanol extract with β-glucuronidase/arylsulfatase led to cleavage of glucuronic acid from M750F064, resulting in the formation of metabolite M750F022 and of M750F068 generating the parent compound. In the methanol extract of the TFMP-label, the metabolites M750F022 and M750F038 were also predominant, accounting for 14 percent TRR (0.06 mg eq/kg) and 11 percent TRR (0.05 mg eq/kg), respectively. The metabolites M750F003, M750F015, M750F016 and M750F072 were also observed but none represented greater than 4 percent TRR (0.02 mg eq/kg).

The results are shown in Tables 25 to 27. Urine, faeces and bile were also subjected to characterization/identification, where several other metabolites, in addition to those in milk and tissues, were observed.

Table 25 Characterisation and identification of C-Label residues in solvent extracts from goat milk, fat, muscle, liver and kidney

Fraction	Whole milk TRR = 0.029 mg eq/kg		Fat TRR = 0.307 mg eq/kg		Fraction	Muscle TRR = 0.044mg eq/kg		Liver TRR = 1.122 mg eq/kg		Kidney TRR = 0.353 mg eq/kg

Notes:

[A] The metabolite 1,2,4-triazole derivative was detected in a ratio of about 2:1 following HPLC analysis. The 1,2,4-triazole derivative was entirely converted to 1,2,4-triazole after addition of hydrochloric acid, evidence that the derivative was a conjugate of 1,2,4-triazole.

In order to analyse if one enantiomer of mefentrifluconazole was preferably metabolised in goat, enantiomer-specific analysis of the parent compound, isolated from selected matrices of the T-label and TFMP-label, was performed. While the ratio of both isomers was found to be approximately 50:50 in the doses administered to the animals and in the extracts of faeces, the relative amount of the (S)-isomer was lower compared to the (R)-isomer in the other investigated matrices (cream, liver and fat (T-label study) and kidney and muscle (TFMP-label study)). The relative amounts of (S)-isomer: (R)-isomer ranged from 20 percent:80 percent to 30 percent:70 percent. These findings demonstrated that matrix-specific differences were observed.

To demonstrate storage stability, analyses of stored extracts were performed for the samples of whole milk, skimmed milk (TFMP- and T- labels only), cream, liver, kidney, muscle and fat of all labels. Extracts were stored for up to 156 days prior to the first analysis with re-analysis occurring up to 428 days thereafter, for a minimum storage duration of 435 days. No significant changes were observed following comparison of the metabolic HPLC profiles of the various extracts.

The metabolic pathway of mefentrifluconazole in lactating goats appears to proceed via two main transformation reactions. The first is hydroxylation at the chlorophenyl-ring leading to M750F015, M750F016, M750F017, further glucuronidation generating M750F063 and M750F068. M750F041 and M750F091 are intermediates of the C-ring oxygenation reaction leading to C-ring hydroxyl metabolites (notably M750F016). Cleavage of the parent compound at the T-bridge generates 1,2,4-triazole as well as the two-ring metabolite M750F022, which itself is subject to oxidation (M750F038), followed by demethylation (M750F040), as well as to hydroxylation (M750F078), to sulfatation (M750F043), and to glucuronidation (M750F064).

The second transformation reaction, observed only to a minor extent, is cleavage of the parent molecule at the ether bridge, generating the two-ring metabolite M750F003. Notably, metabolites consisting of either the C-ring or the TFMP-ring were not observed in any of the samples of the C-label or the TFMP-label. Also seen only to a minor extent is hydroxylation at the methyl of the triazole bridge (M750F039, which is further sulfated to M750F072 or oxidized to M750F042).

The metabolic pathway of mefentrifluconazole in goats is ilusttrated in Figure 2.

Laying hen

The metabolism of chlorophenyl-U-^{14}C-labelled (C-Label), triazole-3-(5)- ^{14}C-labelled (T-Label) or trifluoromethylphenyl-ring-U-^{14}C-labelled (TFMP-Label) mefentrifluconazole was investigated in laying hens (Lohmann Brown, 1.5–2.0 kg) following repeated oral administration (Wenzel *et al*., 2015, BASF DocID 2015_1001001). The test item was administered once daily by gavage to laying hen (ten animals per label) for 14 consecutive days at a nominal dose of 12 ppm feed. The mean actual concentrations were 16.7 ppm feed (C-label), 15.9 ppm feed (TFMP-label) and 15.0 ppm feed (T-label), corresponding to daily means of 1.09, 1.07 and 1.08 mg/kg body weight, respectively. Feed consumption during the dosing period ranged from 96–142 g/day with birds offered 200 g of pellets/day. During the dosing period, excreta were collected once daily, while eggs were collected twice daily after which they were separated into egg whites and egg yolks. Tissues, organs (liver, kidney, muscle and fat samples) and bile were collected after animal sacrifice, 3–6 hours after administration of the last dose.

TRRs in liquid samples were determined by Liquid Scintillation Counting (LSC) while those in solid samples were determined by combustion analysis.

^{14}C-residues in egg yolk reached a plateau concentration within 7 days of dosing at 0.5 mg/kg, 0.6 mg/kg, and 0.3 mg/kg (C-, TFMP-, T-labels, respectively). In egg white, ^{14}C-residues reached a plateau within 3 days at 0.013 mg/kg for the C-label, within 5 days at 0.013 mg/kg for the TFMP-label and within 7 days at 0.39 mg/kg for the T-label (Table 28).

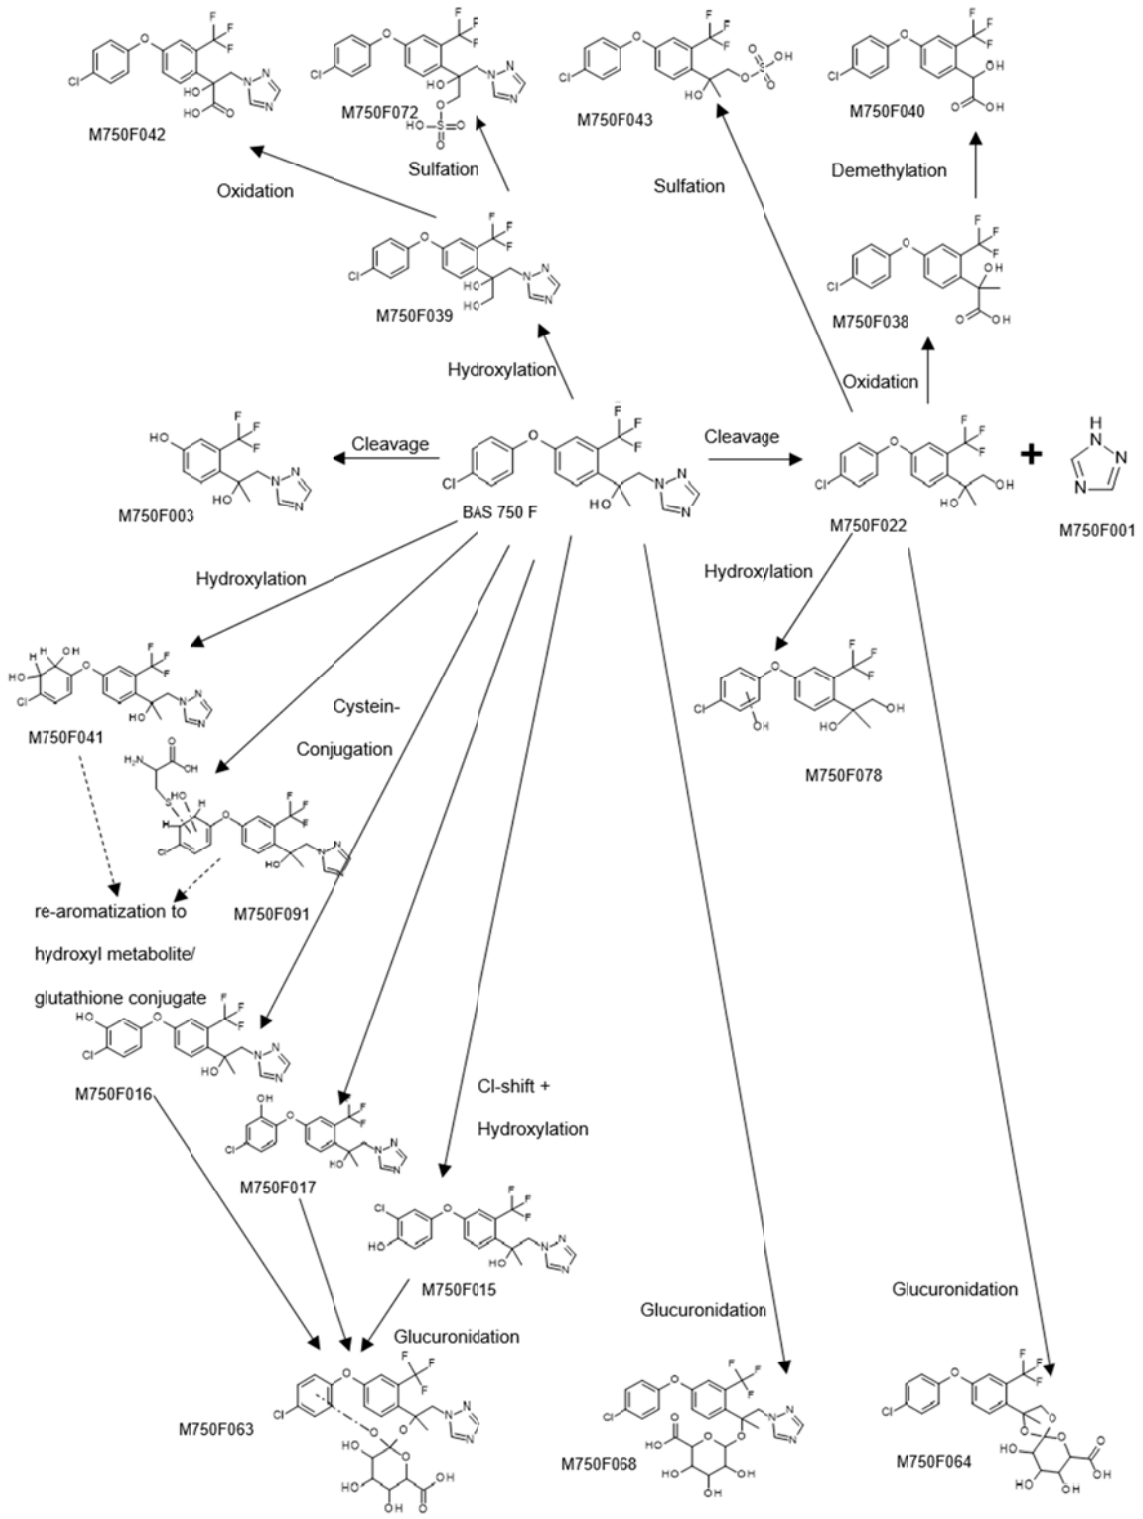

Figure 2 Proposed metabolic pathway of mefentrifluconazole in lactating goats

The radioactive residues in excreta amounted to 75–89 percent of the total administered dose (AD). For all labels, only low portions of the administered dose (≤ 0.3 percent) were retained in edible tissues or in egg (<1 percent of dose). The results are shown in Tables 29 and 30.

Table 29 Material balance after administration of ^{14}C-Mefentrifluconazole to hen

Matrix	C-label Mean % AD	TFMP-label Mean % AD	T-label Mean % AD
Egg white	0.01	0.02	0.55

Blood	<0.00	<0.00	<0.00
Cage wash	2.53	2.61	2.37
Total recovery	79.52	92.36	93.99

For the C- and TFMP-labels, ^{14}C-residues were highest in composite fat samples (0.72–1.1 mg eq/kg), followed by kidney (0.42–0.64 mg eq/kg), liver (0.31–0.58 mg eq/kg) and composite muscle samples (0.053–0.078 mg eq/kg). Following administration of the T-label, the trend was slightly different where TRRs were highest in kidney (0.57 mg eq/kg), followed by liver (0.50 mg eq/kg), muscle (0.36 mg eq/kg) and fat (0.21 mg eq/kg).

Table 30 TRRs in eggs and tissues

Matrix	C-label		TFMP-label		T-label	
	TRR measured (mg eq/kg)	TRR calculated (mg eq/kg)	TRR measured (mg eq/kg)	TRR calculated (mg eq/kg)	TRR measured (mg eq/kg)	TRR calculated (mg eq/kg)

Matrix	C-label		TFMP-label		T-label	
	TRR measured (mg eq/kg)	TRR calculated (mg eq/kg)	TRR measured (mg eq/kg)	TRR calculated (mg eq/kg)	TRR measured (mg eq/kg)	TRR calculated (mg eq/kg)
Liver	0.320	0.311	0.582	0.580	0.480	0.498
Kidney	0.427	0.419	0.610	0.642	0.565	0.577
Fat (omental/subcutaneous/renal)	0.702	0.717	0.893	1.102	0.190	0.209

The homogenised samples of muscle, egg white (T-label), egg yolk, liver and kidney (TFMP- and T-labels) were extracted with methanol (3×) or methanol (3×) followed with water (2×). Kidney (C-label) was extracted sequentially 3× with methanol, 2× with dichloromethane and 1× with isohexane. Fat (C- and TFMP-labels) was extracted up to 3× with a mixture of acetonitrile/ isohexane (1/1, v/v) while fat from the T-label was extracted 3× with a mixture of methanol/isohexane (1/1, v/v). For all tested matrices, the solvent extracts were individually combined and the residue was dried.

After solvent extraction, the combined isohexane extract of fat (C-label) was partitioned 3× against acetonitrile. The methanol extract of muscle (T-label) was concentrated and partitioned with acetonitrile / isohexane (1/1, v/v) and water. The pooled methanol extracts of egg white (T-label) and egg yolk (T-label) were concentrated and partitioned up to 3× with acetonitrile / isohexane (1/1, v/v). The methanol extract of liver (C-label) was concentrated, supplemented with acetonitrile and partitioned against isohexane.

The post-extraction solids of egg yolk (C- and TFMP-labels), muscle (C-label), liver (all labels) and kidney (all labels) were subjected to protease treatment (suspension in 0.1 mol/L Tris (pH 7), incubation for 24–72 hours at 37 °C). The fatty acid conjugates in fat (TFMP-Lable) were cleaved enzymatically (suspension in 10 mL water (pH 7.7), incubation with 10 mg lipase over night under constant shaking at 37 °C) or via alkaline hydrolysis (incubated with 4 mL 2 mol/L NaOH for 1 hour in the rotary evaporator at room temperature).

Only egg whites from the T-label study contained sufficient radioactivity to be subjected to further analysis, where methanol and water extraction released almost all of the radioactivity (98.2 percent TRR; 0.350 mg eq/kg). M750F001 was the only identified metabolite in this matrix accounting for all of the radioactivity in the acetonitrile extract (83.2 percent TRR; 0.297 mg eq/kg). A loss of radioactive residues (13.4 percent TRR) was observed during the concentration and partition steps of the pooled methanol extract. However, a parallel workup of the extract revealed that approximately 7.0 percent TRR of this loss may be attributable to the metabolite 1,2,4-triazole.

Following sequential extractions of egg yolks with methanol and water, greater than 89 percent TRR was released, with 2.6 percent TRR remaining unextracted (T-label only). For the C- and TFMP-label studies where the PES accounted for 5–6 percent TRR, these were subjected to enzymatic hydrolysis which released up to 2.5 percent TRR (up to 0.015 mg eq/kg). For the C- and TFMP-label studies, M750F022 represented the major metabolite (39–47 percent TRR; 0.186–288 mg eq/kg). The parent compound and the fatty acid conjugates of the metabolite M750F022 (sum of M750F023, M750F024 and/or M750F025) were present in amounts of 6–12 percent TRR (0.031–0.071 mg eq/kg) and 14–15 percent TRR (0.066–0.091 mg/kg), respectively. In egg yolk of the T-label, 1,2,4-triazole and the parent were detected at similar levels (each accounting for approximately 42 percent TRR (0.12 mg eq/kg)).

Methanol and/or methanol/water extraction of muscle samples released greater than 85 percent TRR (>0.043 mg eq/kg) with 1.4–2.8 percent TRR remaining unextracted from the muscle samples collected from the TFMP- and T-label studies. The enzymatic hydrolysis of the muscle post-extraction solids (PES), from the C-label study, released 7.2 percent TRR (0.004 mg eq/kg) with 8.2 percent TRR

(0.004 mg eq/kg) remaining unextracted. A similar metabolic profile was observed for the C- and TFMP-labels with M750F022 representing the main component (50–77 percent TRR; 0.025–0.051 mg eq/kg). The parent, mefentrifluconazole and the fatty acid conjugates of M750F022 (sum of M750F023, M750F024 and/or M750F025) were present in low amounts of 5.6–7.4 percent TRR (0.003–0.005 mg eq/kg) and 9.8–19.5 percent TRR (0.007–0.010 mg eq/kg), respectively. In muscle from the T-label study, only 1,2,4-triazole was detected (91.4 percent TRR; 0.322 mg eq/kg).

For the C-, TFMP- and T-label studies, sequential extraction of liver with methanol/water released 83–100 percent TRR, with 3–14 percent TRR remaining bound. Enzyme hydrolysis of the unextracted radioactivity released an additional 2–7 percent TRR. Similar observations were made for the C-label and TFMP-labels regarding the metabolic profile, where M750F022 represented the major metabolite (29.3–36.7 percent TRR; 0.118–0.171 mg eq/kg). The parent mefentrifluconazole and the fatty acid conjugates of M750F022 (sum of M750F023, M750F024 and/or M750F025) were present in low amounts 5.8–7.2 percent TRR (0.03 mg/kg) and 6.9–11.6 percent TRR (0.021–0.068 mg/kg), respectively. Additionally, M750F034, a glutathione conjugate, was present at low levels in liver of the C-label (4.3 percent TRR; 0.014 mg eq/kg) and at considerably higher amounts in liver of the TFMP-label (20.1 percent TRR; 0.117 mg eq/kg). In liver of the T-label, 1,2,4-triazole was the main metabolite (85.2 percent TRR; 0.409 mg eq/kg) and the parent and M750F034 were detected at comparably low levels (≤6.7 percent TRR; 0.032 mg eq/kg).

Extraction of kidney with methanol/isohexane (C- and TFMP-label) and methanol/water (T-label) released 83.7–100 percent TRR (0.357–0.603 mg eq/kg) with ≤17 percent TRR remaining unextracted. Following enzymatic hydrolysis of the PES from the C- and TFMP-label studies, 4–10 percent TRR were solubilised. Similar to egg yolk and other tissues, comparable metabolic profiles were observed for the C-label and TFMP-label, with M750F022 representing the major fraction (20.1 percent TRR; 0.086–0.123 mg eq/kg). By contrast, the parent and the fatty acid conjugates of M750F022 (sum of M750F023, M750F024 and/or M750F025) were present in low amounts in kidney of the C-label, 4.0 percent TRR (0.017 mg/kg) and 3.9 percent TRR (0.017 mg eq/kg), respectively, while only mefentrifluconazole (3.7 percent TRR; 0.022 mg eq/kg) was detected in kidney of the TFMP-label. In kidney of the T-label study, only 1,2,4-triazole was identified (65.6 percent TRR; 0.371 mg eq/kg).

Extraction of fat with acetonitrile/isohexane (C- and TFMP- labels) and methanol/water (T-label) released >100 percent TRR with <1.4 percent TRR remaining in the PES. Similar metabolic profiles were observed between the C-label and TFMP-label where the fatty acid conjugates of M750F022 (sum of M750F023, M750F024 and M750F025) accounted for the main portion of radioactive residues (~42 percent TRR; 0.287–0.380 mg eq/kg) followed by metabolite M750F022 (25.4–41.1 percent TRR; 0.178–0.367 mg eq/kg). The parent was present at lower levels in fat of the C-label (5.4 percent TRR; 0.04 mg/kg) in comparison to the fat of the TFMP-label (11.7 percent TRR; 0.10 mg/kg). In fat of the T-label, 1,2,4-triazole was detected as the main metabolite (73.1 percent TRR; 0.139 mg eq/kg) with the parent present in lower amounts (20.1 percent TRR; 0.038 mg/kg).

The incubation of the pooled methanol extract of fat (TFMP-label) with lipase led to a cleavage of the fatty acid conjugates resulting in the metabolite M750F022. A second aliquot of the same extract) was subjected to alkaline treatment, where a complete cleavage of fatty acid conjugates was noted by HPLC analysis. Additionally, the pooled extract of fat after alkaline hydrolysis was partitioned against tetrahydrofuran (THF). The THF phase was analysed by HPLC, where only M750F022 was detected. Therefore, hydrolysis of the fatty acid conjugates appears to result in the formation of the metabolite M750F022 (Table 31).

Chiral analysis of mefentrifluconazole residue in representative egg yolk and fat samples demonstrated that the ratio of enantiomers in both matrices was 43:57, comparable to the ratio in the administered dose which was determined to be 50:50

The stability of the radioactive residues in various frozen matrices (≤-18 °C) and extracts (storage in fridge) was investigated using homogenates and extracts from the C-label and T-label studies, representing all edible matrices. Comparison of the chromatographic profiles between sampling and the first analysis showed no significant changes to the composition and amounts of radioactivity for each matrix and extract for a storage duration of up to 274 days and 77 days, respectively. Similarly, between the first analysis and re-analysis, no significant changes to the composition and amounts of radioactivity for each matrix and extract were observed over the storage durations of up to 378 days and 354 days, respectively. No stability investigations were conducted for samples collected from the TFMP-label study, however, the stability demonstrated in the C-label and T-label studies can be extended to the samples from the TFMP-label study.

Overall, the results of the laying hen metabolism study show that the metabolic pathway appears to proceed via the cleavage of mefentrifluconazole at the azo-bridge of the propyl-triazole moiety resulting in the metabolites 1,2,4-triazole and M750F022. Metabolite M750F022 is further conjugated with fatty acids forming M750F023, M750F024 (both conjugated with an unsaturated fatty acid) and M750F025 (conjugated with a saturated fatty acid). Hydroxylation of mefentrifluconazole followed by epoxidation and conjugation with glutathione leads to the formation of the liver-specific metabolite M750F034. The incubation of the fat extracts (TFMP-Label) with lipase or sodium hydroxide led to a cleavage of the fatty acids conjugates yielding the metabolite M750F022.

Figure 3 shows a metabolic pathway of mefentrifluconazole in laying hen

In summary, the metabolism of mefentrifluconazole is comparable in both lactating goats and laying hens, although more extensive in laying hens. In addition to the parent, mefentrifluconazole, the major components identified in the tested goat matrices included the metabolites M750F043 (milk only), M750F016 and M750F038 (liver and kidney), M750F022 (kidney) as well as the T-label specific metabolite 1,2,4-triazole in milk and all tissues. In the hen matrices tested, the parent compound was present albeit

at low levels. The predominant metabolites observed in eggs and all tissues was M750F022 while the metabolites M750F023, M750F024 and/or M750F025, fatty acid conjugates of M750F022, were predominant in fat only. Similar to goats, the major T-label specific metabolite 1,2,4-triazole was present in significant levels in eggs and tissues.

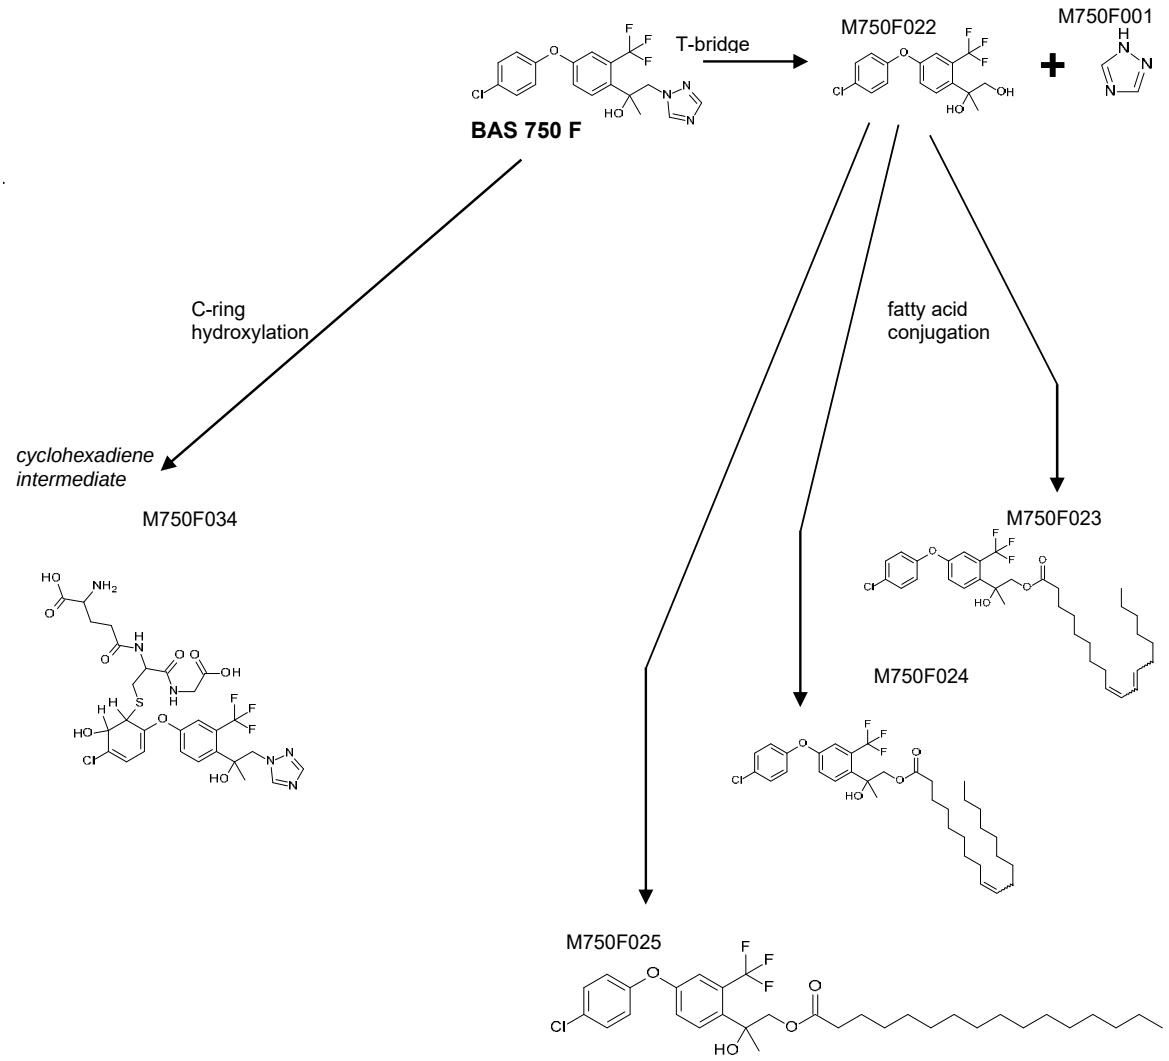

Figure 3 Proposed metabolic pathway of mefentrifluconazole in laying hen

ENVIRONMENTAL FATE

The Meeting received information on soil aerobic metabolism, hydrolysis and photolysis properties of mefentrifluconazole Studies were also received on the behaviour of [^{14}C]-mefentrifluconazole in confined rotational crops.

Route of degradation in soil

Aerobic soil metabolism

The aerobic soil metabolism of mefentrifluconazole was investigated in five agricultural soils

(Staudenmaier, 2015, BASF DocID 2014_1275177, 2014_1275178 and 2015_1003306), two from Europe (Germany; soil LUFA 5M and soil L10) and three from the United States (New Jersey and Indiana). Soil characteristics are summarized in Table 35, as per United States Department of Agriculture (USDA) soil texture classifications.

Table 35 Soil characteristics

Soil designation	Germany		United States		
	LUFA 5M	L10	New Jersey	New Jersey	Indiana
Textural class (USDA scheme)	Loamy sand	Loamy sand	Loam	Loam	Loam
Soil texture (%)					
Sand 0.050-2 mm	82.8	84.0	29	33	35
Silt 0.002-0.050	11.1	11.0	49	46	46
Clay <0.002 mm	6.1	5.0	22	21	19
Organic matter (%)	3.50	1.60	2.3	2.2	2.0
pH (H_2O)	7.9	6.6	6.9	6.8	6.3
pH ($CaCl_2$)	7.2	6.1	Not determined	6.4	5.8
Cation exchange capacity (cmol/kg)	11.4	3.7	9.1	8.5	10.3
Max water holding capacity (g/100 g dry soil)	25.2	26.9	37.0	33.3	33.3

The soils were treated separately with [chlorophenyl-U-^{14}C]mefentrifluconazole (C-label), [triazole-3(5)-^{14}C]mefentrifluconazole (T-label) or [trifluoromethylphenyl-ring-U-^{14}C] mefentrifuconazole (TFMP-label). The test materials were applied at a nominal rate of 150 g ai/ha. Soil was weighed into test vessels and placed into an incubation cabinet. The incubations were carried out in the dark in the laboratory under aerobic conditions at a soil moisture of 40 percent of the maximum water holding capacity and a temperature of 20 °C. A closed incubation system with continuous aeration (moistened air) was used with an attached trapping system for the determination of volatile compounds. During and at the end of the incubation, the microbial biomass was determined by the substrate induced respiration method, verifying that the soil was viable throughout the incubation period.

Samples from the C-, T-label and/or TFMP-label experiments were taken at 0, 3, 7, 14, 30, 58/62, 90/91 and 120/121 days after application (DAA). At each sampling time, two replicate soil samples were extracted twice with acetonitrile, twice with acetonitrile :water (80:20, v/v), and twice with acetonitrile :water (50:50, v/v). The individual extracts were analysed by liquid scintillation counting (LSC). The individual combined extracts were concentrated and analysed by radio-HPLC. The remaining soil after extraction was combusted in order to determine the amount of unextracted soil bound residues. These were further characterized by NaOH extraction and subsequent fractionation into fulvic acids, humic acids, and humins. A full material balance was provided for each sampling interval.

In the German soil samples treated with mefentrifluconazole radiolabelled in either the C-ring (LUFA 5M) or T-ring (LUFA 5M and L10), the amount of extracted radioactivity slightly decreased from an average of 99.0 percent and 99.1–99.5 percent TAR at day 0 to 82.4 percent and 81.9–86.0 percent TAR after 120/121 days of incubation for the respective labels. The material balance ranged from 98.8–100.5 percent TAR for both labels. The most prominent peak present in the extracts of the German soils consisted of the parent compound. During the course of the study, the amounts of parent compound in the total extracts slightly decreased from an average of 98.2 percent (C-label) and 98.9 percent (T-labels) TAR at day 0 to 80.8 percent and 81.2–83.5 percent TAR after 120/121 days of incubation. A number of metabolites were detected in low amounts, none of them exceeding 0.9 percent and 0.8 percent TAR at any sampling time for the C- and the T-labeled test materials, respectively. The metabolites 1,2,4-triazole and M750F003 were detected when the T-labeled test materials were applied, reaching maximum

amounts of about 0.5 percent TAR (121 DAAT; LUFA 5M soil) and 1.5 percent TAR (90 DAA; L10 soil) and 0.6 percent TAR (14 DAA; LUFA 5M soil) and 1.8 percent TAR (30 DAA; L10 soil).

In soil samples treated with the C-labeled material, unextracted soil residues increased from an average of 1.0 percent TAR on day 0 to a maximum of 12.7 percent TAR. In soil samples treated with the T-labeled material, unextracted soil residues increased from about 0.5–0.9 percent TAR at day 0 to about 12.6–17.9 percent TAR by the end of the study. About half of the unextracted residues could be attributed to the humin fraction. Mineralization was low and amounted to 4.7 percent (C-label) and 0.2–0.5 percent TAR (T-labels) at the end of the studies.

In the United States soil samples treated with mefentrifuconazole radiolabelled as either the C-label (New jersey), T-label (New Jersey and Indiana) or TFMP-label (New Jersey), the amount of extracted radioactivity decreased from an average of approximately 99 percent TAR at day 0 to 66–90 percent TAR at the end of the study, after 120/121 days of incubation. The material balance ranged from 95–103 percent TAR for all labels. The most prominent peak observed in the soil extracts was the parent compound, mefentrifluconazole declining from 98–99 percent TAR (day 0) to 63–87 percent TAR after 120/121 days. In soil extracts of samples treated with the T-labeled test material, the metabolite 1,2,4-(1H) triazole was detected at 0.2–0.8 percent TAR on day 0 and increased to a maximum of 5 percent TAR for the New Jersey soil and 1.2 percent TAR for the Indiana soil. Metabolite M750F003 was detected at a maximum level of 1.4 percent TAR (14 DAAT; New Jersey) and 0.6 percent TAR (58 DAT; Indiana). A number of other metabolites were also detected in very low amounts, none of them exceeding 1.4 percent (C-label) and 0.8–0.9 percent TAR (T-labels) at any sampling. For the TFMP-label, a number of metabolites were detected in low amounts, none of them exceeding 1.7 percent TAR at any sampling time. The metabolite M750F003 was the only metabolite identified reaching a maximum of 1.6 percent TAR at 30 DAA. The sum of metabolites in this soil sample never exceeded 2 percent TAR.

Compared to the German soil, unextracted residues in United States soil samples were formed in slightly higher amounts, increasing from an average of 0.8 percent (C-label) and 0.5 percent TAR (T-label and TFMP-label) on day 0 to a maximum of 19.5 percent TAR (C-label), 12.7–26.7 percent TAR (T-label) and 24 percent TAR (TFMP-label). About half of the unextracted residues could be attributed to the humin fraction. Mineralization was low to moderate and amounted to 9.7 percent (C-label), 0.3–0.5 percent TAR (T-labels) and 5.3 percent TAR (TFMP-label) at the end of the study.

Throughout the incubation period, R- and S-enantiomers of mefentrifluconazole (both labels) were almost equally present in the pooled acetonitrile as well as acetonitrile:water extracts of the German LUFA 5M and Indiana soils. In pooled extracts of New Jersey soil (both labels) and L10 soil (T-label), the ratio changed from an equal distribution of both enantiomers to a slightly higher ratio of the S-enantiomer of mefentrifluconazole at the end of the study (about 45:55 (R:S). 48:52 (R:S) and 46:54 (R:S)). Kinetic analysis and calculation of DT_{50} and DT_{90} values for mefentrifluconazole showed mefentrifluconazole to be persistent in soil (Table 36).

Table 36 DT_{50} and DT_{90} values in various soils in the United States

Soil	Label	Best-fit kinetic model	DT_{50}[A] (days)	DT_{90}[A] (days)
LUFA 5M	Chlorophenyl	DFOP	329	>1000
	Triazole	DFOP	356	>1000
L10	Triazole	DFOP	994	>1000
New Jersey	Chlorophenyl	DFOP	167	761
	Triazole	DFOP	>1000	>1000
	Trifluoromethylphenyl	DFOP	156	>1000
Indiana	Triazole	SFO	367	>1000

Notes:

DFOP: Double first-order in parallel.

SFO: Single first order.

[A] The predicted values were extrapolated well beyond the study duration and should be viewed with extreme caution.

A proposed degradation pathway of mefentrifluconazole in soil is shown in Figure 4.

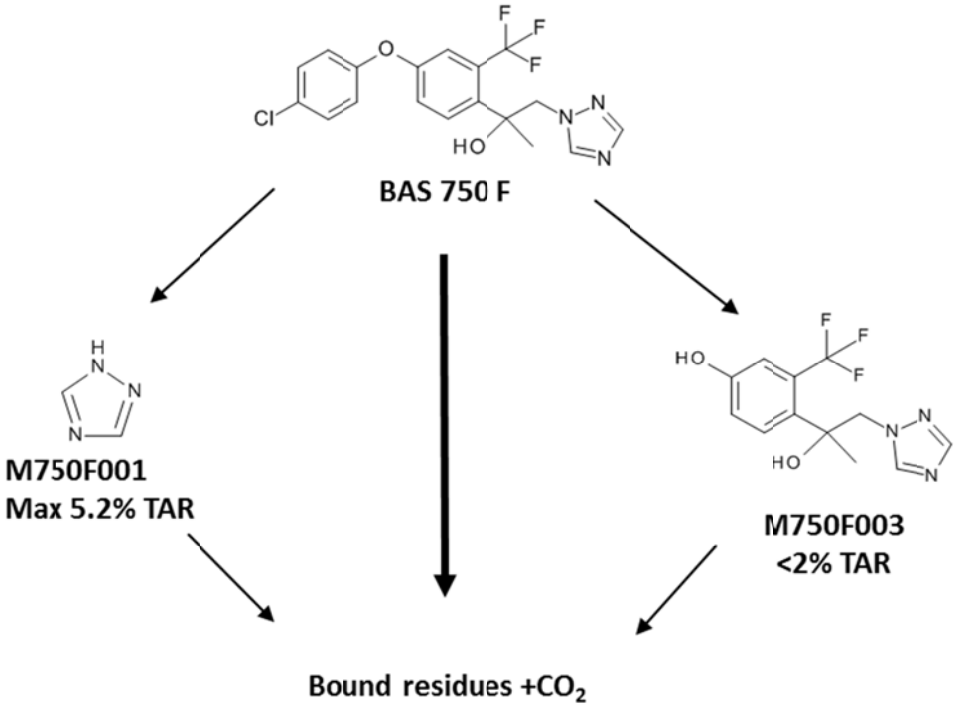

Figure 4 Degradation pathway of mefentrifluconazole in soil

Terrestrial field dissipation studies

United States

Terrestrial field dissipation studies were conducted in the United States at six different sites (Jacobson, 2016, BASFDocID 2015_7006396; Mitchell, 2017, BASF DocID 2016_7006418). Mefentrifluconazole formulated as an emulsifiable concentrate (EC) formulation (containing 100 g ai/L) was applied at the Illinois, North Dakota and Oklahoma sites, while at the New York, Washington, and California sites, the soluble concentrate (SC) formulation (containing 400 g ai/L) was applied. The target application rates, selected to represent a variety of proposed uses, were: 3 × 150 g ai/ha at 7-day intervals for the New York, North Dakota, Washington, and California sites; 3 × 200 g ai/ha at 14-day intervals for the Oklahoma site; and 2 × 150 g ai/ha at 7-day intervals at the Illinois site. Total application rates ranged from 300 g ai/ha for the Illinois site to 600 g ai/ha at the Oklahoma site while the rate at all other sites was 450 g ai/ha.

At each test site there were two test plots: one treated bare soil plot and one control bare soil plot. The treated plot at each test site was divided into three replicate subplots. The plots were kept in a bare soil condition throughout the study. The soil characteristics are shown in Table 37.

Rainfall was supplemented with irrigation at all six of the test sites. At each sampling event, five cores to a depth of 120 cm were taken from one sampling block in each replicate area (subplot). This results in 15 cores being collected during a sampling event (except on days of application when a duplicate set of 0–8 cm cores were taken). Soil cores were sampled prior to and immediately after each test substance application and 2/3, 7, 15/18, 30/32, 58–61, 82–90, 162–183 (209 for Illinois site), 266–

294, 346–391, 579–592, 602–693 DALA. Soil cores were sectioned into segments of 0–15, 15–30, 30–45, 45–60, 60–75, 75–90, 90–105 and 105–120 cm.

The samples were analysed for mefentrifluconazole and the metabolites M750F003 and 1,2,4-triazole (not further discussed herein) using the LC-MS/MS method L0214/01. The validated LOQ and LOD were 0.002 mg/kg and 0.0004 mg/kg, respectively. Soil samples were stored for up to 132 days (4.3 months) prior to analysis. A freezer storage stability study using soil from each site to support the storage conditions of incurred samples is in progress. The results are shown in Table 38.

Notes:

DAFA = days after first application.

DALA = days after last application.

– Means not applicable.

[A] The mass per area values were calculated by multiplying the equivalent dry weight mass of soil in one hectare for each core segment by the analytical dry weight concentration of the analyte.

The total mass of mefentrifluconazole in the entire sampled soil profile (0–120 cm) as well as the total mass in the upper soil profile only (0–45 cm) were assessed. All kinetic analyses were conducted from the day of the last application onward. When assessing dissipation of the total mass of mefentrifluconazole in the entire 0–120 cm sample profile, the mefentrifluconazole DT_{50} values ranged from 33 to 315 days. DT_{50} values could not be determined at the New York test site due to high variability. Dissipation of the total mass of mefentrifluconazole in the upper 0–45 cm of the soil profile, which was proposed to better represent the actual dissipation behaviour of mefentrifluconazole, gave DT_{50} values of 81–386 days (Table 39). Given the low levels of M750F003 formed, kinetic assessment for the metabolite was not attempted.

Table 39 DT_{50}s of Mefentrifluconazole from field dissipation studies conducted in the United States

Field trial	Soil type (USDA)	Best-fit kinetic model	DT_{50} (days)
New York, bare plot	Data from the last 3 sampling events did not fit a data trend, therefore, it was not possible to obtain a reliable DT_{50} from this trial site.		
North Dakota, bare plot	Clay	SFO	386
Washington, bare plot	Loamy sand	SFO	317
California, bare plot	Loamy sand	SFO	230
Oklahoma, bare plot	Sandy loam	SFO	318
Illinois, bare plot	Silty clay loam	FOMC	81

In a separate study, mefentrifluconazole, formulated as a suspension concentrate (containing 400 g ai/L) was applied three times to bare-ground and turf-cropped plots at test sites located in California and Georgia (White, 2017, BASF DocID 2016_7006417). Mefentrifluconazole was applied at a target rate of 1 kg ai/ha for a total of 3 kg ai/ha. Re-treatment intervals varied between 14–18 days.

The study design consisted of a treated bare-soil plot, a treated turf-cropped plot, and an

untreated bare-soil control plot at each test site. The treated plots at each test site were divided into three replicate areas for soil sampling purposes. The soil characteristics are shown in Table 40.

At each site overhead sprinkler irrigation was used to supplement natural precipitation. Soil core samples were taken from the soil surface to a depth of 120 cm at various times prior to and after each application from each replicate subplot and 0, 3, 7, 14/15, 30/32, 59, 83/87, 111, 180/182, 268/272, 386/392, 511/512, 632/634 and 667/678 days after the last application (DALA). Collected soil cores were sectioned into segments of 0–15, 15–30, 30–45, 45–60, 60–75, 75–90, 90–105 and 105–120 cm.

The samples were analysed for mefentrifluconazole and the metabolites M750F003 and 1,2,4-triazole (not further discussed herein) using the LC-MS/MS method D1503/01. The validated LOQ and LOD were 0.002 mg/kg and 0.0004 mg/kg, respectively.

Soil samples were stored for up to 24 months prior to analysis. Results from a soil storage stability study using fortified control soils from the California and Georgia test sites indicate that mefentriflconazole and M750F003 are stable for at least 21 months (Table 41).

DALA = days after last application.

– Means not applicable.

[A] The mass per area values were calculated by multiplying the equivalent dry weight mass of soil in one hectare for each core segment by the analytical dry weight concentration of the analyte in that.

The total mass of mefentrifluconazole in the entire sampled soil profile (0–120 cm) at each sampling event was used in the initial kinetic assessment. However, the distribution of mefentrifluconazole residue with depth and time did not appear to follow a typical pattern. Specifically, the residue concentration decreased quickly with depth, but then increased again in the lower half of the core, with highest subsoil concentrations typically observed in the deepest segment, 105–120 cm. Cross-contamination during processing of the 0–120 cm samples was likely the cause. Therefore, only the upper 0–45 cm of the soil profile was used to derive the kinetic dissipation kinetics for mefentrifluconazole.

Kinetic models were not fit to the metabolite M750F003 data due to the low and/or variable levels observed (Table 42).

Europe

Six field dissipation studies were conducted in representative growing regions of Northern and Southern Europe including Germany (2), Denmark, Northern France, Italy and Spain (Schaufele, 2015, BASF DocID 2015_1046920; Schaufele, 2015, BASF DocID 2015_1242234; Studenroth, 2015, BASF DocID 2015_1249176). An emulsifiable concentrate formulation containing 100 g/L of mefentrifluconazole was applied to bare soil at rates ranging from 152–166 g ai/ha. Immediately after application, plots were covered by a layer of sand of approximately 5 cm in thickness to protect the applied product from surface processes such as volatilization or photolysis, and to exclude any potential impact on the degradation of the test material caused by any of these processes.

Soil specimens were taken at intervals of up to 720 days after application and to a depth of 50 cm. Soil cores were cut into 10 cm sections.

Rainfall was supplemented with irrigation, when necessary. Soil samples were stored for up to 20 months prior to analysis. Results from a soil storage stability study using fortified control soils indicate that mefentriflconazole and M750F003 are stable for at least 22 months.

Soil specimens were analysed for residues of mefentrifluconazole, M750F003 and 1,2,4-triazole (not further discussed herein) according to the LC-MS/MS method L0214/01. The results are shown in Table 44. The method involved extraction of the soil using acetonitrile:water (70:30). Field soil specimens from the treated plot were analysed to a depth until at least one soil layer was free of detectable residues (<LOD of 0.0004 mg/kg).

Notes:

[1] Residue values of mefentrifluconazole in mg/kg dry soil were converted to residue rates in g/ha taking into account the actual dry soil density of the individual field samples. These were summed up for all depths between 0 and 50 cm. Residue values <LOQ or <LOD were reported and treated as zero

DAA Days after application

* No sample taken

** Sample not analysed

Residues of mefentrifluconazole degraded at all six European field sites from 108–133 g ai/ha at day 0 to 8–74 g ai/ha within 2 years. Considering the distribution of mefentrifluconazole residues in the soil profiles, residues remained predominantly and exclusively in the top 0–10 cm layer of soils. No residues above the LOQ were detected below 20 cm. Residues of the metabolite M750F003 were not detected. The calculated DT_{50}s are shown in Table 45.

Table 45 DT_{50} of mefentrifluconazole from field dissipation studies conducted in Europe

Field trial	Soil type (USDA)	Best-fit kinetic model	DT_{50} (days)	Kinetic model	Normalized[A] DT_{50} (days)

Poggio Renatico, Italy	Silty clay loam	SFO	847[B]	SFO	611
Utrera, Spain	Loamy sand	DFOP	200[C]	SFO	313

Notes:

[A] Normalised for soil moisture and soil temperature. The predicted DT_{50} value was extrapolated well beyond the study duration and should be viewed with extreme caution. Endpoint was derived with the initial concentration fixed to the mean of the measured values.

China

Terrestrial field dissipation studies were conducted at three sites in China representative of Northern, Central and Southern China (Chenchao, 2019, BASF DocID 2019_2047604; Shbaita, 2019, BASF DocID 2019_8000062). Mefentrifluconazole formulated as a suspension concentrate (SC) formulation (containing 400 g ai/L) was applied once to bare soil at rates of 414–484 g ai/ha.

At each test site there were two test plots: one treated bare soil plot and one control bare soil plot. The treated plot at each test site was divided into two subplots. The plots were kept in a bare soil condition throughout the study. Soil specimens were taken at intervals up to 185 days after application ad to maximum depth of 30 cm. Soil cores were cut into 10 cm sections.

Summary of soil dissipation studies

The dissipation of mefentrifluconazole under field conditions has been studied in the field in eight studies in the United States (bare soil only), six studies in Europe and three studies in China. In summary, quantifiable residues of mefentrifluconazole were detected only in the first 20 cm of the soils. No residues above the LOQ were detected below 20 cm in any sample at any site. The summary is shown in Table 49. The overall geometric mean (non-normalised) DT_{50} was estimated to be 149 days.

Table 49 Summary of DT_{50} values for mefentrifluconazole

Hydrolysis

The hydrolytic stability of [triazole-3(5)-^{14}C]-labelled mefentrifluconazole in buffered solutions at pH 4, 5, 7 and 9 for a study period of 30 days at 25 ºC was investigated (Hassink, 2015, BASF DocID 2015_1046919). No hydrolysis of the parent was observed as 98–101 percentTAR was still present in the test systems after the duration of incubation. No degradation products at greater than 2 percent TAR were identified, nor was there any evidence of a change in the isomer ratio of the test material. As mefentrifluconazole is stable in aqueous solutions at environmentally relevant pHs, half-lives could not be estimated.

Soil Photolysis

German soil (LUFA 5M; the same as the aerobic soil degradation study) was treated with [chlorophenyl-U-^{14}C] (C-label) and [triazole-3(5)-^{14}C]-labelled mefentrifluconazole (T-label) at an application rate of 150 g/ha (Hassink, 2014, BASF DocID 2014_1181666). Soil samples were placed under continuous irradiation. The incubation temperature was kept at 22 °C and the soil moisture was adjusted daily to approximately 60 percent of the maximum water holding capacity corresponding to pF 2.0–2.5. The samples for the dark control were kept in an incubation cabinet and treated in a similar manner.

Soil samples were collected at 0, 1, 3, 6/7, 10 and 15 days after application (DAA). The samples were extracted three times with acetonitrile and twice with acetonitrile/water (1:1, v/v). The extracts were analysed for total radioactivity and if the TAR was greater than 5 percent, the extracts were subjected to HPLC analysis. The soil remaining after extraction was extracted three times with NaOH and if the TAR was greater than 5 percent, the amount of alkali-soluble components was determined. The dried soil was then combusted, to determine the amount of unextracted residues.

The overall values for the material balance in the photolysis and the dark control were in the range of 98–105 percent TAR. Carbon dioxide was the only trapped volatile degradation product found in the trapping solutions. After 15 days of treatment the following amounts were detected: for the C-label, 1.1 percent TAR in the irradiated samples and 0.4 percent TAR in the dark control; T-label, 0.3 percent

TAR in the irradiated samples and 0.1 percent TAR in the dark control. The amount of extracted radioactive residues in the study with the C-label test material decreased from 99 percent TAR on day 0 to 92 percent TAR on day 15 in the photolysis test, and from ~100 percent TAR on day 1 to 96 percent TAR on day 15 in the dark control. Similarly, in the study with the T-label test material, extracted residues decreased from 99 percent TAR on day 0 to 97 percent TAR on day 15 in the photolysis test, and from 102 percent TAR to 99 percent TAR in the dark control.

At the end of the study about 5 percent TAR for the C-label and 7 percent TAR for the T-label remained unextracted in the irradiated soil samples. About 5 percent TAR was unextracted at the end of incubation of the dark control samples, for both radiolabels. The alkali-soluble radioactivity in the irradiated samples amounted to 2.3 percent TAR and 4.2 percent TAR, for the C-label and the T-label respectively, representing the fulvic acids and the humic acids. Similar values (2.0 percent TAR and 2.3 percent TAR, respectively) were obtained for the dark control samples.

Analysis of the organic extracts by radio-HPLC demonstrated that, after 15 days, the amount of mefentrifluconazole decreased to 87 percent TAR in the photolysis experiment and to 93 percent TAR in the dark control samples for the C-label. Similarly, for the T-label, the amount of mefentrifluconazole decreased within the same time (15 days) to 94 percent TAR in the photolysis experiment and to 96 percent TAR in the dark control samples. For both labels, several degradation products were detected in the extracts, but none of them appeared in amounts higher than 2 percent TAR.

Kinetic analysis and calculations of DT_{50} and DT_{90} values for mefentrifluconazole in soil were conducted by non-linear regression methods and demonstrated that, there was limited degradation of the parent compound observed for either label in both irradiated and dark control samples, hence photolysis was not an important route of dissipation. However, as the predicted DT_{50} values were extrapolated well beyond the study duration, the values listed in Table 50 should be viewed with caution.

Table 50 DT_{50}s of Mefentrifluconazole from soil photolysis studies

Label	Test system	DT_{50}	DT_{90}	Kinetic model
Chlorophenyl	Irradiated	93	310	SFO
	Dark control	173	574	
Triazole	Irradiated	170	565	
	Dark control	225	747	

Confined Rotational Crop Study

[Chlorophenyl-U-^{14}C] (C-label) and [triazole-3(5)-^{14}C]-labelled mefentrifluconazole (T-label), formulated as EC formulations, were applied to bare sandy loam soil, in plastic containers maintained in either a glass roofed vegetation hall, phytotron of in a glass house, at an application rate of 300 g ai/ha (Rabe, *et al*., 2015, BASF DocID, 2015_1001871). Spinach (variety *Corvette)*, white radish (variety *April Cross)* and spring wheat (*Thasos*) were sown 30/31, 120/122 and 364/365 days after the soil treatment. All crops were harvested at maturity and additional immature spinach samples as well as spring wheat forge samples (in part dried to hay) were collected 25–33 days and 49–55 days after planting (DAP), respectively. Homogenised plant samples were subjected to oxidative combustion to determine TRRs ("TRR combusted").

Notes:

[A] DAT=days after soil treatment (soil aging interval), DAP=days after planting/sowing (cultivation interval),

[B] TRR=sum methanol and water extracts and the unextracted residues remaining after solvent extraction

[C] No extraction performed,

[D] Straw samples including chaff fraction

For samples which underwent extraction, comparable values were obtained for the "TRR calculated" (sum of extracted and unextracted). Significant uptake and translocation of radioactive residues from soil into the secondary crops was observed, particularly in the case of the T-label over all plant-back intervals (PBI) and matrices (particularly spring wheat grain) which is due to the uptake and translocation of high amounts of triazole-specific metabolites and/ or triazole. The highest levels of radioactive residues were found in spring wheat straw (30-day PBI) and hay (120-day PBI) in the case of the C-label and in the dry matrices spring wheat grain, hay and straw after the 122-day PBI in the case of the T-label. The TRRs in spinach and white radish matrices were generally lower compared to those in wheat matrices. Overall, residues remained similar or decreased at longer PBIs, except for wheat grain from the C-label study where residues peaked at the 120-day PBI followed by a slight decrease by the 365-day PBI, yet still higher than the TRRs at the 30-day PBI.

The homogenised plant samples were consecutively extracted with methanol (3×) and water (2×). Spinach and white radish extracts after the 365-day PBI (C-label) contained only low amounts of TRRs

(based on combustion analysis) and were therefore not subjected to any further analysis. Subsamples of the purified and/ or concentrated methanol extracts of representative crop matrices (C-label: mature spinach, 120-day PBI, white radish root, 30-day PBI, spring wheat forage, 365-day PBI and spring wheat hay, 365-day PBI; T-label: immature spinach, 31-day PBI) were fractionated using HPLC where the parent fraction was collected and concentrated, and the concentrated parent fraction was subjected to chiral analysis.

In the case of the C-label, the extractability of radioactive residues in all tested matrices, except wheat grain, ranged from 34-83 percent TRR, while those in wheat grain were significantly lower, ranging from 8–21 percent TRR. Extracted residues in the wheat matrices were lower at the longest PBI compared to the 30–day PBIs. In the case of the T-label, the extractability of TRRs was much higher than that of the C-label, ranging from 95–99 percent TRR for all spinach and white radish matrices and from 82–96 percent TRR for the spring wheat matrices. The main portions of the TRRs were generally extracted with methanol, except for spring wheat grain where comparable portions of the radioactive residues were extracted with methanol and with water (Table 52).

The nature of the residue in extracts of all matrices, except spinach and white radish (365-day PBI; C-label) was investigated using two different HPLC methods (radiodetection). Assignment of chromatographic peaks and identification of metabolites was based on co-chromatography with ^{14}C-labelled reference compounds as well as by comparison of retention times and elution pattern (metabolic profile). Characterization of the PES was performed by sequential hydrolysis using aqueous ammonia, amylases/amyloglucosidase, macerozyme/cellulase, and tyrosinase/laccase.

Mefentrifluconazole was the main component detected in all tested samples from the C-label study (85.2 percent TRR and 91.2 percent TRR [0.008 and 0.012 mg/kg]) in immature and mature spinach respectively at 30-day PBI, 42.5–70.4 percent TRR [0.006–0.101 mg/kg] in the other tested matrices at 30-day PBI, 35.7–60.8 percent TRR [0.006–0.055 mg/kg] in spinach and wheat at 120-day PBI and 17.7–41.0 percent TRR [0.002–0.018 mg/kg] in wheat samples at 365-day PBI. No parent or metabolites were detected in radish roots or tops beyond the 30-day PBI. In spinach and wheat, minor metabolites accounting for 2.2–79.7 percent TRR (0.0003–0.018 mg eq/kg), 5.0–83.3 percent TRR (0.0004–0.032 mg eq/kg) and 21.5–65.4 percent TRR (0.004–0.022 mg eq/kg) at 30-, 120- and 365-day PBIs, respectively, were characterised by their chromatographic properties.

In the case of the T-label study, mefentrifluconazole was detected at the 31-day PBI in immature and mature spinach at 25.2 percent (0.013 mg/kg) and 13.9 percent TRR (0.08 mg/kg), in white radish top at 5.6 percent TRR (0.010 mg /kg) and in all wheat samples except grain at 4.1–5.0 percent TRR (0.015–0.043 mg/kg). At longer PBIs, the parent was only detected in wheat hay (122-day PBI: 1.3 percent TRR [0.030 mg/kg]) and straw (122-day PBI; 1.3 percent TRR [0.014 mg/kg] and 365-day PBI; 0.8 percent TRR [0.008 mg/kg]). In most cases, the main constituent in the crop matrices was triazole alanine (13.2–93.5 percent TRR; 0.022–0.982 mg eq/kg), followed by triazole lactic acid 8.8–38.6 percent TRR (0.005–0.807 mg eq/kg). The only exceptions were spring wheat hay (122 DAT) and spring wheat straw (all PBIs),

where, triazole lactic acid was the most abundant component among all the analytes identified. In spring wheat grain, triazole alanine (42.5–72.6 percent TRR; 0.98–2.36 mg eq/kg) was the main component followed by triazole acetic acid (20.0–24.3 percent TRR; 0.46–0.69 mg eq/kg). The sum of the triazole derivative metabolites and 1,2,4-triazole in all secondary crops ranged from 64.6–101.4 percent TRR (Tables 54 and 55).

Notes:

TA: Triazole alanine; TAA: Triazole acetic acid; TLA: Triazole lactic acid.

The PES (post extracted solids) following methanol and water extraction of mature spinach, white radish top and root (all C-label, 30-day PBI) as well as all the wheat matrices were characterised by sequential solubilisation procedures applying treatment with aqueous ammonia solution and one or two incubations with enzyme mixtures. The ammonia residues of spring wheat grain were subsequently incubated with amylases and amyloglucosidase. The amylase/ amyloglucosidase residues of spring wheat grain as well as the ammonia residues of the other investigated matrices were incubated with macerozyme and cellulase. In the cases of spring wheat forage and hay (third plant back interval) and spring wheat straw, the PES were further incubated with tyrosinase and laccase. The supernatants resulting from the aqueous ammonia treatment and after incubation with enzymes were analysed by HPLC. The results are shown in Tables 56 to 58. Samples from the Plant-back Interval (PBI) of 365 days from the C-label study were not analysed.

Notes:

[A] AM, ammonia, A/G amylase/amyloglucosidase, M/C macerozyme/cellulase, T/L tyrosinase/laccase.

[B] combined ammonia hydrolysate from two solubilisation steps in the cases of spring wheat hay, straw and grain; only one solubilisation step was performed in the case of spring wheat forage.

N/A: not analysed.

Hydrolysis of the PES of selected matrices demonstrated that both the parent mefentrifluconazole and the triazole derivative metabolites were associated with plant constituents, namely starch and cell wall polymers, neither of which was further characterised. The presence of radioactivity in the final unextracted residues, following the extensive hydrolysis steps, was evidence of incorporation into non-hydrolysable cell constituents.

Enantiomer-specific analysis of mefentrifluconazole in all representative crops and both labels showed that both S-enantiomer and R-enantiomer are present as a racemic mixture confirming that the

1:1 ratio of the test substance applied to bare soil remains unchanged. The unchanged enantiomer ratio indicates absence of preferential metabolism and /or translocation of one of the two enantiomers in rotational crops.

Directly after harvesting, samples were transferred in a freezer and stored at ≤ -20 °C until extraction. Extracts were stored in a refrigerator. Storage stability of the methanol extracts of the various matrices demonstrated that the metabolite profiles after 270–469 days of storage was comparable to the metabolite profiles obtained in the initial analysis of the extracts (14–127 days), thus confirming stability of the radioactive residues in extracts for at least 284 days.

In rotational crops cultivated on mefentrifluconazole-treated soil, the residues include mainly two components, the parent and triazole derivative metabolites, the latter being generated by cleavage of the parent molecule at the triazole bridge (Figure 5).

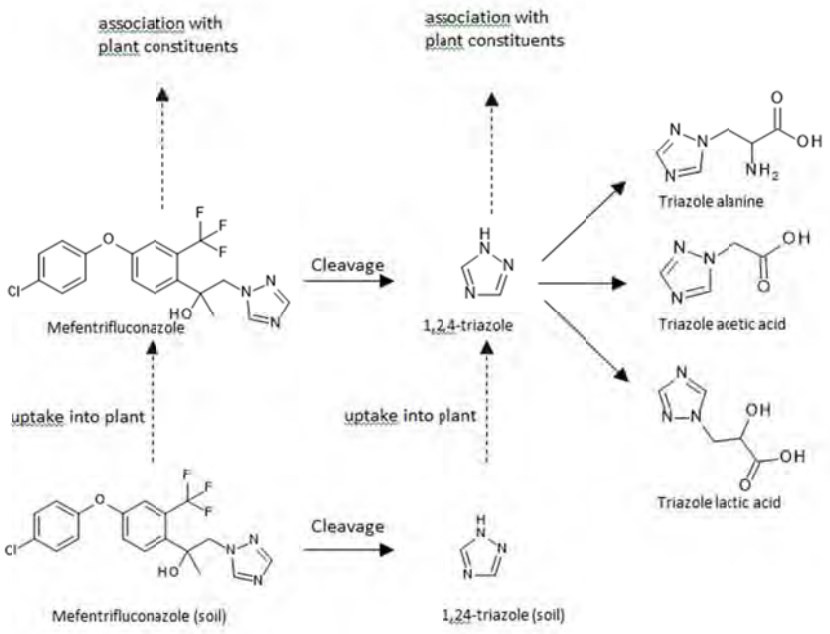

Figure 5 Proposed metabolic pathway of ^{14}C-Mefentrifluconazole in rotational crops

Field rotational crop study

United States

Field rotational crop studies were conducted in the American states of Georgia and Texas during the 2014 growing season (Schreier, 2016, BASF DocID, 2016_7006244). Treated plots received three broadcast soil directed spray applications, of an emulsifiable concentrate (EC) formulation, at rates of 0.196 to 0.207 kg ai/ha/application, with a 7-day retreatment interval, for a total rate of 0.595 to 0.614 kg ai/ha/season. The applications were made using 200 to 224 L/ha spray volumes with ground boom equipment. An adjuvant was added to the spray mixture for all applications at all trials. At intervals of 1, 3, 4 and 12 months following the last application to the bare soil, wheat (AGS 03108E-10E26, TAM 112 and Glenn), lettuce (romaine), and radish (Crunchy Royale and D'Avignon) were planted.

The residues of mefentrifluconazole in/on rotational crop RAC samples were quantitated using the LC-MS/MS Method D1511/01. The LOQ was 0.01 mg/kg. Procedural recoveries from control samples fortified with mefentrifluconazole at 0.01 to 10.0 mg/kg were 78 to 121 percent. Average procedural recoveries for individual crop matrices ranged from 88 percent to 106 percent. Samples were stored

frozen for up to 553 days (approximately 18 months) prior to extraction and analysis. Adequate storage stability data are available to support the storage conditions and durations for the samples in the present study. The results are shown in Table 59.

With the exception of wheat matrices, mefentrifluconazole residues in lettuce and radish (roots and tops) collected from trials conducted in Georgia were equivalent to or higher than those from trials conducted in Texas. For wheat, residues of mefentrifluconazole were magnitudes greater in trials conducted in Texas compared to those in wheat matrices collected from trials conducted in Georgia, where mefentrifluconazole residues in almost all wheat RACs were <0.01 mg/kg.

Among the two locations, maximum individual mefentrifluconazole residues were 2.38, 0.69, 1.13, and 1.57 mg/kg in/on wheat forage samples collected following the 1, 3, 4 and 11 month PBIs, respectively, and were 0.53, 0.87, 2.65 and 1.97 mg/kg in/on wheat hay samples collected from the 1, 3, 4 and 12 month PBIs, respectively. Maximum individual mefentrifluconazole residues in/on wheat straw samples collected from the 1, 3, 4 and 12 month PBIs were 0.06, <0.01, 0.02 and 0.01 mg/kg, respectively. Residues of mefentrifluconazole in/on wheat grain and lettuce were <0.01 mg/kg (<LOQ) at all PBIs. Maximum mefentrifluconazole residues were 0.07, 0.04, 0.02 and <0.01 mg/kg in/on radish tops (leaves) collected from the 1, 3, 4 and 12 month PBIs, respectively, and were 0.03, 0.02, 0.02 and <0.01 mg/kg in/on radish root samples collected from the 1, 3, 4 and 12 month PBIs, respectively. Based on the findings of the study, limited uptake of mefentrifluconazole residues from the soil into the plants was observed and residues declined with longer PBIs.

Europe

During the 2014–2015 growing seasons, a total of four field trials were conducted using four rotational crops (wheat, carrot/radish, cauliflower/broccoli and lettuce/spinach) planted at 1, 4 and 12 months after the application to bare soil in different representative growing regions of Germany, Netherlands, Italy and Spain. Each field trial consisted of three treated plots.

An emulsifiable concentrate (EC) formulation was applied once to all plots at a rate equivalent to 271-327 g ai/ha. The spray volume used was 200 L/ha.

The residues of mefentrifluconazole in/on rotational crop RAC samples were quantitated using the LC-MS/MS method No. L0076/09 (535/1). The LOQ was 0.01 mg/kg. Average procedural recoveries from control samples fortified with mefentrifluconazole at 0.01, 0.1 and 1.0 ppm ranged from 77 to 92 percent.

Samples were stored frozen for up to 305 days (~10 months) prior to extraction and analysis. Adequate storage stability data are available to support the storage conditions and durations for the samples in the present study. The results are shown in Table 60

Residues of mefentrifluconazole in all tested crops, including a cereal grain (wheat), root crop (carrot and radish), leafy (lettuce and spinach) and Brassica (broccoli and cauliflower) vegetables were consistently below the LOQ of 0.01 mg/kg at all plant-back intervals of 1, 4 and 12 months in field rotational studies conducted in Germany, Netherlands, Italy and Spain.

In summary, the environmental fate data demonstrated that mefentrifluconazole is persistent in soil yet does not dissipate significantly, being almost exclusively detected in the top 15–20 cm. Notwithstanding its presence in the upper soil layer, the uptake of mefentrifluconazole residues was observed predominantly at the 30-day PBI before dissipating rapidly as a result of the cleavage of the triazole ring to generate the triazole derivative metabolites. Mefentrifluconazole is stable in aqueous solutions at environmentally relevant pHs and photolysis of mefentrifluconazole on the soil surface is not anticipated to be an important dissipation process.

The metabolism in rotational crops was assessed and determined to be similar to that in primary crops with no rotational crop specific metabolites. The magnitude of both mefentrifluconazole and triazole derivative metabolites was investigated under field conditions. Based on the results obtained in the field accumulation study, uptake of mefentrifluconazole residues is not expected

METHODS OF RESIDUE ANALYSIS

The Meeting received descriptions and validation data for several analytical methods for residues of mefentrifluconazole in diverse plant and animal matrices. Only the methods capable of analysing mefentrifluconazole will be reported herein.

Plants

Method L0076/09

Analytical method L0076/09 (de Paula José, 2015, BASF DocID 2015_3001681) involves extraction of soya bean (seed), dry beans (seed), tomato (whole fruit), citrus (whole fruit), wheat (grain), coffee (grain), and wheat (straw) with methanol:water: 2 mol/L HCl (70:25:5:v). For wheat straw, the extraction was conducted twice. The extract was transferred to a tube containing 0.2 mol/L NaOH solution and then partitioned with cyclohexane. The resulting organic phase was evaporated to dryness and reconstituted in methanol:water (50:50) prior to filtration and analysis.

The final extracts were quantified for residues of mefentrifluconazole using HPLC- and UPLC-MS/MS, comprising a C18 column that incorporated 0.1 percent formic acid in water and 0.1 percent formic acid in methanol mobile phases. Quantitation was by multiple reaction monitoring (MRM) in

positive mode with a mass transition of *m/z* 398 → 182 and m/z 398→ 133. The LOQ was 0.01 mg/kg for citrus fruit, coffee grains, dry bean seeds, soya bean seeds, tomato fruit, wheat grain and wheat straw.

Recovery and repeatability data for the determination of mefentrifluconazole residues in plant matrices are presented in Table 61. Average recovery values ranged from 73–100 percent for the three fortification levels tested while the percent RSD ranged from 1.1–14 percent. Additionally, two replicates of unfortified control samples were examined. All results from the control samples were below 0.002 mg/kg. (0.2× LOQ). No interfering peaks were detected in the samples analysed. The linearity of the detector response (r^2 > 0.9900), using non-matrix matched standards, over a concentration range of 0.04 to 2 ng/mL (n=6). For this study the matrix-matched standard solutions was not used for quantification because the sensitivity of the analyte was not influenced by matrix.

Analytical method L0076/09 (Ford, 2017, BASF DocID 2017_1192681) was independently validated for the determination of mefentrifluconazole residues in seven different plant matrices (orange fruit, coffee grains, dry bean seeds, soya bean grain, tomato fruit, wheat straw and grain) fortified at the LOQ of 0.01 mg/kg and 0.1 mg/kg. Average recoveries ranged from 76–100 percent with percentRSD ranging from 0.5–8.9 percent.

This method was also subjected to radiovalidation, where wheat (straw and forage), soya bean (green pod), and grape (berries) from the metabolism studies (Birk *et al*., 2015, BASF DocID 2014_1261057) were analysed using method L0076/09. When comparing the results from the residue analysis procedure against those of the metabolism extraction procedures, extraction efficiencies for mefentrifluconazole from wheat forage, wheat straw, soya bean green pods, and grape berries were 98 percent, 111 percent, 102 percent, and 93 percent, respectively, demonstrating the efficiency of the analytical method to extract incurred residues of mefentrifluconazole (Table 61). The analytical method L0076/09 was demonstrated to be suitable for the analysis of mefentrifluconazole in plant matrices.

Method L0295/01

Analytical method L0295/01 (Klimmek *et al*., 2015, BASF DocID 2015_1106708) is a multiresidue method (QuEChERs) that involves extraction of tomato (fruit), orange (whole fruit), dry bean seeds, wheat grain, and soya bean seeds with acetonitrile (water was added prior to extraction if needed). The extract was partitioned by adding a salt solution containing magnesium sulphate, sodium chloride, and sodium citrate followed by centrifugation. The acetonitrile phase was purified by freezing out at ≤ -18 °C (except for tomato fruit) and/or by dispersive SPE with primary/secondary amine (PSA) and Octadecyl silica (ODS) sorbent (QuEChERS modules C1 and C4, respectively). The extract was reconstituted into acetonitrile and water.

The final extracts were quantified for residues of mefentrifluconazole using LC-MS/MS, comprising a C18 column that incorporated 0.1 percent formic acid in acetonitrile and 0.1 percent formic acid in water mobile phases. MS/MS quantitation was by electrospray ionisation in positive mode with a mass transition of *m/z* 398 → 70, while confirmation analysis was conducted with a mass transition of

m/z 398→ 182. The LOQ was 0.01 mg/kg for tomato (fruit), orange (whole fruit), dry beans (seeds), wheat (grain) and dry soya beans (seeds).

Recovery and repeatability data for the determination of mefentrifluconazole residues in plant matrices are presented in Table 62. Average recovery values ranged from 70–97 percent for the two fortification levels tested while the percentRSD ranged from 1.1–20 percent. Additionally, two replicates of unfortified samples were examined and results were all below 0.3× LOQ. No interfering peaks were detected in the samples analysed. The linearity of the detector response (r^2 > 0.99), using solvent standards (tomato fruit, dry bean seeds, and dry soya bean seeds) and matrix-matched standards (wheat grain), over a concentration range of 0.15 to 7.5 ng/mL (n=7).

Analytical method L0295/01 (Richter *et al*., 2015, BASF DocID 2015_1240004) was independently validated for the determination of mefentrifluconazole residues in five different plant matrices (tomato fruit, wheat grain, dried broad beans, dried soya beans and whole orange) fortified at the LOQ of 0.01 mg/kg and 0.1 mg/kg. Average recoveries ranged from 85–110 percent with percentRSD ranging from 1.1–10 percent.

This method was also subjected to radiovalidation, where wheat (straw and forage), soya bean (green pod), and grape (berries) from the metabolism studies (Birk *et al*., 2015, BASF DocID 2014_1261057) were analysed using the QuEChERS multiresidue method. When comparing the results from the residue analysis procedure against those of the metabolism extraction procedures, extraction efficiencies for mefentrifluconazole from wheat forage, wheat straw, soya bean green pods, and grape berries were 80 percent, 59 percent, 99 percent, and 98 percent, respectively, which demonstrated the efficiency of the analytical method to extract incurred residues of mefentrifluconazole from most matrices. In the metabolism study, wheat straw samples were extracted three times with methanol and twice with water. However analytical method L0295/01 only extracted samples once with acetonitrile which may explain the low extraction efficiency for this method in wheat straw. The method L0295/01 was demonstrated to be suitable for the analysis of mefentrifluconazole in plant matrices (Table 62).

Notes:

[1] Statistical outlier according to Dixons Q test (95 percent confidence interval) and was discarded for the calculation of the mean recovery and RSD.

Method 1511/01

Analytical method 1511/01 (Downs, 2016, BASF DocID 2015_7005822) was validated and considered acceptable as a method for data collection when analysing for residues of mefentrifluconazole in grape fruit, apple fruit, wheat grain, dried bean seed, and canola seed with an LOQ of 0.01 mg/kg in each matrix.

The method employed extraction by shaking with methanol:water (80:20, v/v). The extract is subsequently centrifuged, diluted with methanol:water (50:50, v/v), and filtered. The extracts were quantified for residues of mefentrifluconazole using LC-MS/MS, comprising a reversed phase column that incorporated 0.1 percent formic acid in water and 0.1 percent formic acid in acetonitrile mobile phases. MS/MS quantitation for mefentrifluconazole was by electrospray ionisation in positive mode with a mass transition of m/z 398 → 70, while confirmation analysis was conducted with a mass transition of m/z 400 → 70.

Recovery and repeatability data for the determination of mefentrifluconazole residues in plant matrices are presented in Table 63. Average recovery values ranged from 72–122 percent for the two fortification levels tested while the percentRSD ranged from 2–18 percent. Additionally, two replicates of unfortified samples were examined and results were all below 0.002 mg/kg (0.2× LOQ). No interfering peaks were detected in the samples analysed. The linearity of the detector response (r^2 > 0.9938), using solvent-based calibration standards, over a concentration range of 0.004 to 0.4 ng/mL (n=5).

This method was also subjected to radiovalidation, where wheat (straw and forage), soya bean (green pod), and grape (berries) from the metabolism studies (Rabe *et al*., 2017, BASF DocID 2016_1126366) were analysed using method 1511/11. When comparing the results from the residue

analysis procedure against those of the metabolism extraction procedures, extraction efficiencies for mefentrifluconazole from wheat forage, wheat straw, soya bean green pods, and grape berries were 98 percent, 100 percent, 114 percent, and 96 percent, respectively, which demonstrates the efficiency of the analytical method to extract incurred residues of mefentrifluconazole. The method 1511/01 was demonstrated to be suitable for the analysis of mefentrifluconazole in plant matrices (Table 63).

Animal matrices

Method L0272/01

Analytical method L0272/01 has been developed for the analysis of mefentrifluconazole in animal matrices, including bovine meat, milk, cream, fat, liver, kidney and hen eggs (Devine, 2015, BASF DocID 2015_1106707).

For matrices containing fat (milk, cream, fat), mefentrifluconazole is extracted using a mixture of acetonitrile and iso-hexane. An aliquot of the extract is centrifuged and partitioned twice using iso-hexane. For matrices containing proteins (muscle, kidney, liver and egg), mefentrifluconazole is extracted using a mixture of methanol/water/2N HCl (70/25/5, v/v/v). An aliquot of the extract is centrifuged and partitioned twice using cyclohexane. Final analysis is performed by LC-MS/MS and monitoring for two mass ion transitions (398 → 182 m/z for quantification and 398 → 133 m/z). The LOQ was 0.01 mg/kg.

Recovery and repeatability data for the determination of mefentrifluconazole residues in animal matrices are presented in Table 64. Average recovery values ranged from 73–110 percent for the two fortification levels tested while the percent RSD ranged from 0.4–11 percent. No interfering peaks were detected in the samples analysed. The linearity of the detector response (r^2 > 0.9997), using matrix matched and non-matrix matched standards, depending on the animal commodity, covered a range of concentrations of 0.04 to 10 ng/mL (n=8).

The LC-MS/MS method L0272/01 was successfully validated by an independent laboratory (Richter et al., 2015, BASF DocID 2015_1240005) for the determination of mefentrifluconazole residues in seven different animal matrices (milk, cream, fat, egg, meat, kidney and liver) fortified at the LOQ of 0.01 mg/kg and 0.10 mg/kg. Average recoveries ranged from 77–101 percent with percent RSD ranging from 2.2–19 percent. The method L0272/01 was demonstrated to be suitable for the analysis of mefentrifluconazole in all animal matrices based (Table 64)

Method D1704/01

Residues of mefentrifluconazole in livestock commodities are extracted with acidified acetonitrile by mechanical shaking; for "dry" matrices (liver, kidney, muscle, fat), the homogenized samples are soaked (hydrated) first by the addition of water (Downs, 2017, BASF DocID 2017_7008027). The residues in the extracts are cleaned-up and partitioned by shaking in the presence of a mixture of salts (magnesium sulfate and sodium acetate) into the organic layer, and centrifuged. The residues in an aliquot of the acetontrile layer are then further purified with the addition of a second salt mixture (containing $MgSO_4$ to remove residual water and primary secondary amine (PSA) sorbent to remove other interferences) and centrifuged. The residues in an aliquot of the resulting extract are diluted to final volume with 5 mM formic acid in acetonitrile:water (25:75, v/v). Final determination by LC-MS/MS was conducted by monitoring two MS/MS ion mass transitions (398→70 m/z for quantification and 400→70 m/z for confirmation). The LOQ was 0.01 mg/kg.

Matrix effects on the detection of mefentrifluconazole in extracts of bovine liver, kidney, muscle, fat, milk and poultry egg were found to be insignificant (< 20 percent). Therefore, solvent standards were used for quantification. All mean recoveries obtained at each fortification level were within the range of 78–100 percent with a RSD of 4–19 percent. Quantitation of residues in all samples was achieved using calibration curves calculated by linear regression (1/x weighting) of instrument responses. Linearity was demonstrated over a range of eight concentrations from 0.004 to 0.4 ng/mL (r=0.9981).

The LC-MS/MS method D1704/01 was successfully validated by an independent laboratory (Ivanov, 2017, BASF DocID 2017_1198105) for the determination of mefentrifluconazole residues in six different animal matrices (bovine liver, kidney, muscle, fat and hen eggs) fortified at the LOQ of 0.01 and 1.0 mg/kg. Average recoveries ranged from 86–110 percent with percent RSD of ≤ 15 percent,

demonstrating the reproducibility of the method. The results demonstrated the ability of the method to reliably determine residues of mefentrifluconazole in all animal matrices (Table 65).

Table 65 Recoveries of mefentrifluconazole in animal matrices by LC-MS/MS (Method D1704/01)

Method L0309/01 – Metabolite M750F022

The analytical method L0309/01 was developed for the determination of the metabolite M750F022 in animal matrices including bovine meat, milk, fat, liver, kidney and hen eggs (Heger, 2015, BASF DocID 2015_1106706).

For fat containing matrices (milk and fat), samples are extracted twice with acetonitrile and iso-hexane. The resulting acetonitrile phase is partitioned twice against iso-hexane after which the acetonitrile phase is dried, dissolved in MeOH/H_2O (50/50) cleaned up on an SPE column prior to GC-MS analysis. For protein containing matrices (egg, muscle, liver and kidney) samples are extracted by macerating with MeOH/H_2O/2N HCl (70/25/5). The extract is partitioned twice against 0.2N NaOH and cyclohexane (muscle and liver) or dichloromethane (egg and kidney). An aliquot of the cyclohexane or dichloromethane phase is dried and dissolved in MeOH/H_20 (50/50) prior to clean up on an SPE column and analysis using GC-MS, monitoring one characteristic fragment ion for quantification (295 m/z) and two characteristic fragment ions for confirmation (297 m/z, 317 m/z). The LOQ was 0.01 mg/kg.

Recovery and repeatability data for the determination of residues of the metabolite M750F022 in animal matrices are presented in Table 66. Except for bovine fat, average recovery values ranged from 71–104 percent for the two fortification levels tested while the percent RSD ranged from 3.4–9.6 percent. In fat, average recoveries ranged from 108–124 percent with percentRSD ≤9.7 percent. No interfering peaks were detected in the samples analysed. The linearity of the detector response (r^2 > 0.9929), using matrix matched standards, covered a range of concentrations of 2.5 to 100 ng/mL (n=8).

During the validation of method L0309/01, the results demonstrated that the matrix-load in bovine fat and milk had a significant influence on the detection of the analyte. However, the validation was carried out using solvent standards. Therefore, the method was revalidated using matrix-matched standards in order to show the applicability of the method in these matrices (Heger, 2015, BASF DocID 2017/1002385). The mean recoveries resulting from these revalidation experiments were between 79 percent and 96 percent within the same fortification levels and fragment ions. The relative standard deviations for all fortification levels were ≤ 10 percent.

The GC-MS method L0309/01 was successfully validated by an independent laboratory (Bendig et al., 2015, BASF DocID 2015_1240006) for the determination of metabolite M750F022 residues in six

different animal matrices (milk, fat, egg, meat, kidney and liver) fortified at the LOQ of 0.01 mg/kg and 0.10 mg/kg. Average recoveries ranged from 72–101 percent with percentRSD ranging from 3.1–18 percent. Despite the minor modifications made during the ILV, none had an important impact on the analyte determination in animal matrices. Furthermore, based on acceptable recoveries and retention time, sensitivity and selectivity being comparable to those during method development, the method was shown to be reproducible.

The overall procedural validation of the GC-MS analytical method L0309/01 demonstrated the ability of the method to reliably determine residues of M750F022 in all animal matrices (Table 66).

Table 66 Recoveries of metabolite M750F022 in animal matrices by GC-MS

Matrix	Fortification level (mg/kg)	Range (%)	Mean (%)	RSD (%)	Range (%)	Mean (%)	RSD (%)	Range (%)	Mean (%)	RSD (%)
		Fragment 295 m/z (quantification)			Fragment 297 m/z			Fragment 317 m/z

Method L0309/02– M750F022 and Fatty Acid Conjugate M750F025 in poultry matrices

This method was developed to allow the determination of M750F022 and its fatty acid conjugates in hen matrices using GC-MS *(*Guedez Orozco, 2016, BASF DocID 2016_1001326). In order to determine the magnitude of residues of the fatty acid conjugates, the amount of M750F022 was determined in each sample twice, with and without hydrolysis. The fatty acid conjugates of M750F022 are hydrolysed to M750F022 using NaOH (10 M). In order to verify the functionality of the method, fortifications were done using the conjugate M750F025 as being representative of all the fatty acid conjugates, which are measured as M750F022. The fatty acid conjugates of M750F022 are extracted from fat containing matrices (fat, skin) with iso-hexane followed by two liquid-liquid partitions with acetonitrile. NaOH (10 M) together with tetrahydrofuran were added to the acetonitrile phase to initiate hydrolysis. The hydrolysate was dissolved in MeOH/water (50/50) and cleaned up using an SPE column. For protein containing matrices (muscle, liver and egg), the same procedure is followed, with the exception of the initial extraction where MeOH is used. Analysis is conducted using GC-MS monitoring one characteristic fragment ion for quantification (295 m/z) and two characteristic fragment ions for confirmation (297 m/z,

317 m/z). The LOQ was 0.01 mg/kg in each matrix for M750F022. Good linearity of the detector response was observed in the range of 2.5 to 100 ng/mL.

The analytical method L0309/02 is equivalent to the analytical method L0309/01 for the determination of M750F022 in animal matrices except for the extraction solvent used, which was changed to acetonitrile:iso-hexane (for fat containing matrices) or methanol (for protein containing matrices). This modification to the method was made because it was observed during method development that the use of HCl in the extraction solvent led to lower recoveries for the fatty acid conjugates. This does not have any impact on the extractability of M750F022, because the extraction solvent was the same as that used in the metabolism study.

The mean recovery values of the validation experiments were between 71 and 97 percent at both fortification levels of 0.01 and 0.10 mg/kg, respectively, except for hen liver and fat fortified at 0.10 mg/kg where recoveries were 62 percent (fragment 317 m/z) and 62–65 percent (all fragment ions), respectively (Table 67). The relative standard deviations for all fortification levels were ≤16 percent, demonstrating overall good repeatability.

Due to the consistently lower recoveries of the fatty acid conjugate M720F025 (reported as M750F022) in hen fat, method L0309/02 was revalidated (Heger, 2017, BASF DocID 2016_1002385). Following the revalidation, recoveries of M750F022 ranged from 79.1–82.1 (percent RSD ≤ 12.7), 73.0–84.1 percent (percent RSD≤14.9) and 78.2–85.9 percent (percent RSD≤14.3) when hen fat was fortified with the fatty acid conjugate at 0.01, 0.10 and 1.0 mg/kg, respectively.

The overall procedural validation of the GC-MS analytical method L0309/02 demonstrated the ability of the method to reliably determine residues of M750F025 as M750F022 in all hen matrices (Table 67)

Table 67 Recoveries (n=5) of M750F025 in hen matrices measured as M750F022 using GC-MS

The efficiency of the analytical methods L0272/01 and L0309/01 to adequately extract bio-incurred residues of mefentrifluconazole and M750F022 from samples collected from the lactating goat and laying hen metabolism studies was investigated (Thiaener *et al*., 2016, BASF DocID 2015_1161960). Cream, whole milk and kidney from lactating goats as well as fat, liver, muscle and egg yolk from laying hens were selected as edible matrices containing the target compounds and total residue concentrations above 0.010 mg/kg. The results of each extraction procedure were compared to the extraction performed within the respective metabolism studies.

For mefentrifluconazole, extraction efficiencies were 80 percent or higher for most matrices (milk, cream, muscle, kidney, fat, egg yolk), and lower for liver (46 percent) using method L0272/01. The extractability of mefentrifluconazole using the multi-residue method DFG S 19 was similar to the

extraction within the respective metabolism studies (95.1 to 112.1 percent) for the goat matrices and hen muscle and hen egg yolk, whereas the amounts of mefentrifluconazole extracted from hen fat (62.5 percent) and hen liver (74.3 percent) were lower. The extraction efficiency of the QuEChERS method was comparable to the metabolism study (80.1 to 99.1 percent) for most matrices; however, for hen egg yolk and fat, it was lower (73.0 and 6.0 percent, respectively) (Table 68).

For M750F022, extraction efficiencies were 90 percent or higher for most matrices (milk, cream, kidney, fat) and lower for egg yolk (66 percent), muscle (61 percent) and liver (46-50 percent) using method L0309/01. The concentrations of metabolite M750F022 extracted using method DFG S 19 were higher for egg yolk and cream (123.8 and 144.3 percent, respectively) or comparable for the other matrices (79.7 to 105.6 percent). The extractability of M750F022 using the QuEChERS method was similar to the extractability within the respective metabolism study for cream, kidney, liver and muscle (from 80.5 to 95.1 percent). Lower amounts of M750F022 were extracted from egg yolk (67.8 percent) and hen fat (19.0 percent) using QuEChERS (Table 69).

Notes:

[A]. extraction efficiency = amounts extracted using analytical method compared to amount extracted in metabolism study (normalizedto 100 percent). For cream (goat) extraction efficiency was calculated as the percent TRR in metabolism study divided by percent TRR extracted with analytical method.

[B]. In the case of cream (goat) and liver (hen), two different subsamples were extracted for confirmation.

Notes:

[A] extraction efficiency = amounts extracted using analytical method compared to amount extracted in metabolism study (normalized to 100 percent). For cream (goat) extraction efficiency was calculated as the percent TRR in metabolism study divided by percent TRR extracted using analytical method.

[B] As confirmation of the results obtained, for cream (goat) two different subsamples were extracted for confirmation. For liver (hen) three different subsamples were extracted. For egg yolk (hen), two different subsamples were extracted.

[C] The value calculated for milk appears to be an overestimation resulting from low analyte concentration.

[D] The value calculated for yolk is an underestimation since an additional 0.011 mg/kg (2.4 percent TRR) was recovered after concentration of the extract prior to HPLC analysis.

In summary, all analytical methods provided to the Meeting were determined to be acceptable for the analysis of mefentrifluconazole and Metabolite M750F022 in milk, eggs and bovine and poultry tissues and M750F025 (measured as M750F022) in hen matrices, based on average recoveries that were in the range of 70–120 percent and relative standard deviations of ≤20 percent. The detector responses were linear within the ranges tested. Radiovalidation information demonstrated the ability of the methods L0272/01 and L0309/01 to extract bioincurred residues of mefentrifluconazole and M750F022.

STABILITY OF PESTICIDE RESIDUES IN STORED ANALYTICAL SAMPLES

Plant matrices

The stability of mefentrifluconazole was investigated in wheat (whole plant, straw, grain), soya bean seed, rape seed, potato tuber, apple fruit, lemon fruit, dried bean seed, grape fruit, tomato fruit, and dried pea seed (Orozco *et al*., 2016, BASF DocID 2016_1112644). Samples were fortified at a concentration level of 0.10 mg/kg, stored frozen, and analysed after approximately 0, 30, 90, 180, 365, 545, and 730 days. Analytical method L0076/09 (de Paula José, 2015, BASF DocID 2015_3001681) was used to determine residues of mefentrifluconazole. The LOQ was 0.01 mg/kg in all matrices. The recoveries of mefentrifluconazole after frozen storage are summarized in Table 70.

Notes:

[A] Normalised to Day 0 stored sample residues, not corrected for procedural recoveries.

[B] Samples were injected twice.

[C] Reserve samples (prepared in case of failing analyses, repetitions or additional samplings).

Residues of mefentrifluconazole were determined to be stable at ≤-18 ºC for up to 24 months in high water content commodities (tomato, apple, wheat whole plant), high oil content commodities (rape, seed), high protein content commodities (dried bean seed, dried pea seed, soya bean seed), high starch content commodities (potato tuber), high acid content commodities (grape, lemon), and wheat straw.

Animal matrices

In two freezer storage stability studies, samples of bovine liver, kidney, muscle, fat, milk and cream and hen eggs were fortified with the parent compound mefentrifluconazole (Heger, 2015, BASF DocID 2015_1106711) or metabolite M750F022 (Heger, 2015, BASF DocID 2015_1106710) at concentrations of 0.10 mg/kg/analyte (Tables 71 and 72). Samples were stored at ≤-18 ºC for a period of up to 180 days (6 months), which covered the sample storage interval in the feeding studies. Samples were analysed for the parent compound using the LC-MS/MS analytical method L0272/01 and for the metabolite using the GC-MS method L0309/01. The LOQ reported for each method was 0.010 mg/kg.

Residues of mefentrifluconazole and M750F022 were determined to be stable at ≤-18 ºC for up to 6 months in milk, cream, eggs and bovine and poultry tissues (Tables 71 and 72).

USE PATTERNS

Mefentrifluconazole is used as SC or EC formulation for foliar, in-furrow or seed treatment. Table 73 summarizes the use pattern and Table 74 shows the crop rotation restrictions on United States labels for foliar-applied fungicides

Table 73 Registered uses of mefentrifluconazole for the crops for which residue trials were submitted

Notes:

* United States spray volumes: 94 L/ha (ground) and 19 L/ha (aerial), unless otherwise specified.

NS: Not specified; NA: Not applicable.

PHI: Pre-harvest interval; on the United States labels, the PHI is the same as the grazing/feeding interval, unless otherwise specified.

[A] Citrus (subgroups 10-10a, 10-10b and 10-10c): inluding calamondin; citron; citrus hybrids; grapefruit (grapefruit, Japanese summer); kumquat; lemon; lime (lime, Australian desert, Australian finger, Australian round, Brown River finger, Mount White, New Guinea wild, Russell River, sweet, Tahiti); mandarin (Mediterranean, satsuma); orange (sour, sweet, tachibana, trifoliate); pummelo; tangelo; tangerine (mandarin); tangor; uniq fruit; cultivars, varieties, and/or hybrids of these.

[B] Pome fruits (crop group 11-10): including apple; azarole, crabapple; loquat; mayhaw; pear; Asian pear; quince; Chinese quince, Japanese quince, tejocote; cultivars, varieties, and/or hybrids of these.

[C] Stone fruits (crop group 12-12): including apricot; Japanese apricot; capulin; black cherry, Nanking cherry; sweet cherry, tart cherry; Chinese Jujube; nectarine; peach; plum; American plum, beach plum, Canada plum, cherry plum, Chickasaw plum, Damson plum, Japanese plum, Klamath plum, prune plum; plumcot; sloe; cultivars, varieties, and/or hybrids of these.

[D] Caneberries (crop subgroup 13-07A): including caneberry (blackberry; loganberry; raspberry, black and red; wild raspberry; cultivars, varieties, and/or hybrids of these).

[E] Bushberries (crop subgroup 13-07B): including aronia berry; blueberry, highbush; blueberry, lowbush; buffalo currant; Chilean guava; cranberry, highbush; currant, black; currant, red; elderberry; European barberry; gooseberry; honeysuckle, edible; huckleberry; jostaberry; juneberry (Saskatoon berry); lingonberry; native currant; salal; sea buckthorn; cultivars, varieties, and/or hybrids of these).

[F] Low growing berries (crop group 13-07G): including bearberry; bilberry; blueberry, lowbush; cloudberry; cranberry; lingonberry; muntries; partridgeberry; strawberry; cultivars, varieties, and/or hybrids of these.

[G] Bulb vegetables (crop group 3-07): including chive, fresh leaves; chive, Chinese, fresh leaves; daylily, bulb; elegans hosta; fritillaria, bulb; fritillaria, leaves; garlic, bulb; garlic, great-headed, bulb; garlic, serpent, bulb; kurrat; lady's leek; leek; leek, wild; lily, bulb; onion, Beltsville bunching; onion, bulb; onion, Chinese, bulb; onion, fresh; onion, green; onion, macrostem; onion, pearl; onion, potato, bulb; onion, tree, tops; onion, Welsh, tops; shallot, bulb; shallot, fresh leaves; cultivars, varieties, and/or

hybrids of these.

[H] Cucurbit vegetables (crop group 9): including chayote (fruit); Chinese waxgourd (Chinese preserving melon); citron melon; cucumber; gherkin; gourd, edible (includes hyotan, cucuzza, hechima, Chinese okra); Momordica spp (includes balsam apple, balsam pear, bittermelon, Chinese cucumber); muskmelon (includes true canteloupe, cantaloupe, casaba, crenshaw melon, golden pershaw melon, honeydew melon, honey balls, mango melon, Persian melon, pineapple melon, Santa Claus melon, and snake melon); pumpkin; squash, summer (includes crookneck squash, scallop squash, straightneck squash, vegetable marrow, zucchini); squash, winter (includes butternut squash, calabaza, hubbard squash, acorn squash, spaghetti squash); watermelon.

[I] Fruiting vegetables (crop group 8-10): including African eggplant; bush tomato; bell pepper; cocona; currant tomato; eggplant; garden huckleberry; goji berry; groundcherry; martynia; naranjilla; okra; pea eggplant; pepino; non-bell pepper; roselle; scarlet eggplant; sunberry; tomatillo; tomato; tree tomato; cultivars, varieties, and/or hybrids of these.

[J] Leafy vegetables (crop group 4-16): including amaranth, Chinese; amaranth, leafy; arugula; aster, Indian; blackjack; broccoli, Chinese; broccoli raab; cabbage, abyssinian; cabbage, Chinese, bok choy; cabbage, seakale; cat's whiskers; chamchwi; cham-na-mul; chervil, fresh leaves; chipilin; chrysanthemum, garland; cilantro, fresh leaves; collards; corn salad; cosmos; cress, garden; cress, upland; dandelion, leaves; dang-gwi, leaves; dillweed; dock; dol-nam-mul; ebolo; endive; escarole; fameflower; feather cockscomb; Good King Henry; hanover salad; huauzontle; jute, leaves; kale; lettuce, bitter; lettuce, head; lettuce, leaf; maca, leaves; mizuna; mustard greens; orach; parsley, fresh leaves; plantain, buckhorn; primrose, English; purslane, garden; purslane, winter; radicchio; radish, leaves; rape greens; rocket, wild; shepherd's purse; spinach; spinach, Malabar; spinach, New Zealand; spinach, tanier; Swiss chard; turnip greens; violet, Chinese, leaves; watercress; cultivars, varieties, and hybrids of these commodities.

[K] Legume Vegetables (crop group 6, except soybean and edamame); including broad bean (fava bean), chickpea (garbanzo bean), guar, jackbean, lablab bean, lentil, pigeon pea, sword bean. - Lupinus spp.: grain lupin, sweet lupin, white lupin, white sweet lupin. - Phaseolus spp.: field bean, kidney bean, lima bean, navy bean, pinto bean, runner bean, snap bean, tepary bean, wax bean. - Vigna spp.: adzuki bean, asparagus bean, blackeyed pea, catjang, Chinese longbean, cowpea, Crowder pea, moth bean, mung bean, rice bean, southern pea, urd bean, yardlong bean. - Pisum spp.: dwarf pea, edible-pod pea, English pea, field pea, garden pea, green pea, snow pea, sugar snap pea.

[L] Non-grass Forages (crop group 18): including alfalfa; bean, velvet; clover (Trifolium spp., Melilotus spp.); kudzu; lespedeza; lupin; sainfoin; trefoil; vetch; vetch, crown; vetch, milk.

[M] Root vegetables (crop subgroup 1B): including Detailed Crop (Subgroup 1B) List - beet, garden; burdock, edible; carrot; celeriac; chervil, turnip-rooted; chicory; ginseng; horseradish; parsley, turnip-rooted; parsnip; radish; radish, oriental (daikon); rutabaga; salsify; salsify, black; salsify, Spanish; skirret; turnip.

[N] Tuberous and Corm Vegetables (crop subgroup 1C): arracacha; arrowroot; artichoke, Chinese; artichoke, Jerusalem; canna, edible; cassava, bitter and sweet; chayote (root); chufa; dasheen (taro); ginger; leren; potato; sweet potato; tanier; turmeric; yam bean; yam, true.

[O] Tree nuts (crop group 14-12): including African nut-tree; almond; beechnut; Brazil nut; Brazilian pine; bunya; bur oak; butternut; cajou nut; candlenut; cashew; chestnut; chinquapin; coconut; coquito nut; dika nut; ginkgo; Guiana chestnut; hazelnut (filbert); heartnut; hickory nut; Japanese horse-chestnut; macadamia nut; mongongo nut; monkeypot; monkey puzzle nut; okari nut; pachira nut; peach palm nut; pecan; pequi; pili nut; pine nut; pistachio; sapucaia nut; tropical almond; walnut (black, English); yellowhorn; cultivars, varieties, and/or hybrids of these.

[P] Rapeseed (crop subgroup 20A): including borage; crambe; cuphea; echium; flax seed; gold of pleasure; hare's ear mustard; lesquerella; lunaria; meadowfoam; milkweed; mustard seed; oil radish; poppy seed; rapeseed; sesame; sweet rocket; cultivars, varieties, and/or hybrids of these.

[Q] Sunflower seed (crop subgroup 20B): including calendula; castor oil plant; Chinese tallowtree; euphorbia; evening primrose; jojoba; niger seed; rose hip; safflower; stokes aster; sunflower; tallowwood; tea oil plant; vernonia; cultivars, varieties, and/or hybrids of these.

Table 74 Crop rotation restrictions on United States labels for foliar-applied fungicides

Rotational Crops	Planting Time From Last Applicaiton
Root and tuber vegetables (crop groups 1 and 2) Bulb vegetables (crop group 3-07) Leafy vegetabltes (crop group 4-16) Fresh herbs Brassicas (crop group 5-16) Legume vegetables, including soybeans (crop group 6) Foliage of legume vegetables (crop group 7)	0 days

Fruiting vegetables (crop group 8-10) Cucurbit vegetables (rop group 9) Fruit, small vine climbing, except fuzzy kiwi (subgroup 13-07F) Low-growing berries (crop group 13-07G) Cereals (crop groups 15 and 16) Grass and non-grass animal feeds (crop groups 17 and 18) Oilseeds (crop group 20) Peanut Stalk, stem and leaf petiole vegetables (crop group 22) Sugarcane Any other crop labeled for direct application of a product containing mefentrifluconazole	
Other food and feed crops, not listed above	May not be planted in rotation

RESULTS OF SUPERVISED RESIDUE TRIALS ON CROPS

The Meeting received information on supervised field trials for mefentrifluconazole on the following crops or crop groups:

Crops/Crop Groups	Table No.
Food commodities	
Citrus fruits	75
Pome fruits	76
Stone fruits	77
Caneberries	78
Blueberries	79
Grapes	80
Strawberry	81
Bananas	82
Avocado	83
Papaya	84
Mango	85
Bulb vegetables	86
Fruiting vegetables, cucurbits	87
Fruiting vegetables, other than cucurbits	88
Legume vegetables	89
Beans with pods	90
Peas with pods	91
Succulent beans without pods	92
Pulses	93
Dry beans	94
Dry peas	95
Soya beans	96
Lentils	97
Root vegetables	98
Potato	99
Wheat – North America	100

Mefentrifluconazole

Crops/Crop Groups	Table No.
Wheat - Europe	101
Barley – North America	102
Barley – Europe	103
Rice – United States	104
Rice – China	105
Rice – Brazil	106
Sorghum	107
Maize	108
Sweet corn	109
Sugar cane	110
Tree nuts	111
Rape seed	112
Sunflower seed – North America	113
Sunflower seed – Europe	114
Cottonseed	115
Peanuts	116
Coffee	117
Animal feeds	
Dry pea vines	118
Cowpea forage	119
Soya bean forage	120
Alfalfa forage	121
Clover forage	122
Dry pea hay	123
Cowpea hay	124
Soya bean hay	125
Alfalfa hay	126
Clover hay	127
Sugar beet tops	128
Wheat forage	129
Wheat whole plant, ears and rest of plant - Europe	130
Barley whole plant, ears and rest of plant - Europe	131
Sorghum forage	132
Maize forage	133
Sweet corn forage	134
Grass forage	135
Sorghum stover	136
Maize stover	137
Sweet corn stover	138
Wheat hay	139

Crops/Crop Groups	Table No.
Barley hay	140
Grass hay	141
Wheat straw - North America	142
Wheat straw - Europe	143
Barley straw - North America	144
Barley straw - Europe	145
Rice straw – United States	146
Rice husks and straw - China	147
Almond hulls	148
Peanut hay	149

Trials were generally well documented with laboratory and field reports. Laboratory reports included method validation with procedural recoveries from spiking at residue levels like those occurring in samples from the supervised trials. Dates of analyses or duration of residue sample storage were also provided. Although trials included control plots, no control data are recorded in the tables except where residues in control samples exceeded the LOQ. Unless stated otherwise, residue data are recorded unadjusted for recovery.

Residue values from the trials conducted in accordance with the critical GAP have been used for the estimation of maximum residue levels. Those results included in the evaluation are underlined.

Conditions of the supervised residue trials were generally well reported in detailed field reports. Trial designs used non-replicated plots. Field reports provided data on the sprayers used, plot size, field sample size and sampling date.

Where duplicate field samples from an un-replicated plot were taken at each sampling time and were analysed separately, the mean of the two analytical results was taken as the best estimate of the residues in the plot and only the means are recorded in the tables. Similarly, where samples were collected from replicate plots the mean result is reported.

Citrus fruits

Table 75 Residues of mefentrifluconazole in whole citrus fruits from trials conducted in the United States following applications of an EC formulation using dilute and concentrated spray volumes (Bledsoe, 2017, BASF DocID 2017_7008898; Lucas, 2019; BASF DocID 2019_3000581)
