LIST OF PARTICIPANTS

2022 Joint FAO/WHO Meeting on Pesticide Residues
13–22 September 2022 (FAO pre-meeting 8–12 Sep.)
Rome, Italy

Dr C Anagnostopoulos, Benaki Phytopathological Institute, Athens, Greece

Dr J Cudmore, Health and Safety Executive, York, the United Kingdom

Dr M Doherty, United States Environmental Protection Agency, Arlington, VA, the United States of America (*Chair*)

Mr J Giordano, Environmental Protection Agency, Washington, DC, the United States of America

Dr J Heidler, Federal Institute for Risk Assessment, Berlin, Germany

Mr M Irie, Food and Agricultural Materials Inspection Centre, Tokyo, Japan

Dr H Kobayashi, Ministry of Agriculture, Forestry and Fisheries Tokyo, Japan

Ms M Le, Pest Management Regulatory Agency, Health Canada, Ottawa, Ontario, Canada

Mr D Lunn, Ministry for Primary Industries, Wellington, New Zealand (*FAO Rapporteur*)

Dr D MacLachlan, Australian Government Department of Agriculture, Fisheries and Forestry, Canberra, ACT, Australia

Ms K Mahieu, Department of Food Safety, Bilthoven, the Netherlands

Mr D Poflotski, Australian Pesticides and Veterinary Medicines Authority, Armidale, NSW, Australia

Dr C Sieke, Federal Institute for Risk Assessment, Berlin, Germany

Ms M Thomas, Pest Management Regulatory Agency, Health Canada, Ottawa, Ontario, Canada

Ms T van der Velde-Koerts, Department of Food Safety, Bilthoven, the Netherlands

Dr Y Yamada, National Institute of Health Sciences; Tokyo, Japan

JMPR Joint Secretariat

Mr K Bodnaruk, West Pymble, NSW, Australia (*FAO Editor*)

Professor Eloisa Dutra Caldas, University of Brasilia, Ribeiro, Brazil (*FAO Editor*)

Dr Guibiao Ye, Ministry of Agriculture and Rural Affairs, P. R. China, Beijing, China (*CCPR Chair*)

Ms YongZhen, Food and Agriculture Organization of the United Nations Rome, Italy (*FAO JMPR Secretariat*)

Use of JMPR reports and evaluations by registration authorities

Most of the summaries and evaluations contained in this report are based on unpublished proprietary data provided for use by JMPR in making its assessments. A registration authority should not grant a registration on the basis of an evaluation unless it has first received authorisation for such use from the owner of the data provided for the JMPR review or has received the data on which the summaries are based, either from the owner of the data or from a second party that has obtained permission from the owner of the data for this purpose.

1. Introduction

A Joint Meeting of the Food and Agriculture Organization of the United Nations (FAO) Panel of Experts on Pesticide Residues in Food and the Environment and the World Health Organization (WHO) Core Assessment Group on Pesticide Residues (JMPR) was held at FAO Head-quarters, Rome (Italy), from 13 to 22 September 2022. The FAO Panel Members met in preparatory sessions from 8–12 September.

The Meeting was opened by Dr Jingyuan Xia, Director, Plant Production and Protection Division (NSP), FAO. On behalf of FAO and WHO, Dr Xia welcomed and thanked the participants for providing their expertise and for devoting significant time and effort to the work of the JMPR, noting that this was the first physical JMPR meeting since 2019 due to the impact of the COVID-19 pandemic, with 45 participants from 15 countries.

Dr Xia highlighted food safety is fundamental to healthy and sustainable food systems. The establishment of pesticide residue standards is a key and critical element in the global effort to improve food safety and agricultural development in the world. The unique role of the JMPRs work in establishing internationally acceptable MRLs for pesticide residues in food and feed which acted as global benchmarks in trade facilitation, as well as providing authoritative assessments, important in consumer protection. Dr Xia then outlined how the JMPRs efforts aligned with the Divisions strategic objectives of ensuring food security and nutrition; enhancing food quality and safety; supporting farmers' livelihoods; protecting the environment and biodiversity; and facilitating safe trade and economic growth. As the establishment of global standards were a key and critical element in the global efforts to improve food safety and agricultural development in the world.

Dr Xia also took the opportunity to express his and called on the meeting participants toexpress their appreciation to Madam YongZhen Yang, retiring FAO JMPR Secretariat, for her dedicated commitment and outstanding contribution in fulfilling the secretariat role over the past 16 years.

Dr Soren Madsen, WHO JMPR Secretariat, took the opportunity to thank the FAO for giving priority to JMPR to alow the meeting to occur at the FAO.

During the meeting, the FAO Panel of Experts was responsible for reviewing residue and analytical aspects of the pesticides under consideration, including data on their metabolism, fate in the environment and use patterns, and for estimating the maximum levels of residues that might occur as a result of use of the pesticides according to good agricultural practice (GAP). Maximum residue levels and supervised trials median residue (STMR) values were estimated for commodities of animal origin. The WHO Core Assessment Group was responsible for reviewing toxicological and related data in order to establish acceptable daily intakes (ADIs) and acute reference doses (ARfDs), where necessary.

The Meeting evaluated 34 pesticides, including seven new compounds and four compounds that were re-evaluated within the periodic review programme of the CCPR, for toxicity or residues, or both.

The Meeting established ADIs and ARfDs, estimated maximum residue levels and recommended them for use by CCPR, and estimated STMR and highest residue (HR) levels as a basis for estimating dietary intake.

The Meeting also estimated the dietary exposures (both short-term and long-term) of the pesticides reviewed and, on this basis, performed a dietary risk assessment in relation to the relevant ADI and where necessary ARfD. Cases in which ADIs or ARfDs may be exceeded were clearly indicated in order to facilitate the decision-making process by CCPR.

The Meeting considered a number of current issues related to the risk assessment of chemicals, the evaluation of pesticide residues and the procedures used to recommend maximum residue levels.

AFIDOPYROPEN (312)

First draft prepared by Mr C Sieke, Federal Institute for Risk Assessment, Berlin, Germany

EXPLANATION

Afidopyropen is an insecticide developed for control of piercing and sucking insects. Afidopyropen disrupts the gating of TRPV (Transient Receptor Potential Vanilloid) channel complexes in chordotonal stretch receptor organs of insects. This disrupts feeding and other behaviour in target insects leading to death by starvation.

Afidopyropen was first evaluated by the 2019 JMPR when an ADI of 0–0.08 mg/kg bw was established. The Meeting also established an ARfD of 0.2 mg/kg bw for women in childbearing age and an ARfD of 0.3 mg/kg for the general population. In addition, it was concluded that the metabolites M440I007 and CPCA are likely to be of similar toxicity to its parent. The 2021 JMPR reconsidered the wording of the residue definition. The residue definitions are:

Definition of the residue for compliance with the MRL for plant and animal commodities: *afidopyropen*

Definition of the residue for dietary risk assessment for plant commodities: sum of afidopyropen + dimer of [(3R,6R,6aR,12S,12bR)-3-[(cyclopropanecarbonyl)oxy]-6,12-dihydroxy-4,6a,12b-trimethyl-11-oxo-9-(pyridin-3-yl)-1,3,4,4a,5,6,6a,12,12a,12b-decahydro-2H,11H-naphtho[2,1-b]pyrano[3,4-e]pyran-4-yl]methyl rac-cyclopropanecarboxylate (M007)

Definition of the residue for dietary risk assessment for animal commodities, except liver: afidopyropen + M001 + CPCA and its carnitine conjugate, expressed as afidopyropen

Definition of the residue fir dietary risk assessment for liver: afidopyropen + M001 + M017 + CPCA and its carnitine conjugate, expressed as afidopyropen

The residue is not fat-soluble.

At the Fifty-first Session of the CCPR (2019), afidopyropen was scheduled for toxicology and residue evaluation by the 2022 JMPR.

The Meeting received information from the manufacturer on aerobic soil metabolism, use patterns and residues resulting from supervised trials on strawberries, sorghum and alfalfa/clover.

ENVIRONMENTAL FATE IN SOIL

The Meeting received information on environmental fate in soil.

Aerobic metabolism and degradation in soil with afidopyropen

In an aerobic soil metabolism study (Nejad, H., 2020, 2018/7007218), a silt loam from New Jersey (NJ), a loamy sand from California (CA), loamy sand (LUFA 2.2 or L2) and sandy loam (LUFA 5M or L5) soils from Germany were dosed with pyranone-6-^{14}C-afidopyropen at approximately 0.2 mg/kg (~10.3 µg/vessel). This concentration was selected to represent an application rate of 50 g/ha considering uniform distribution to 2.5 cm depth and a soil bulk density of 1.0 g/cm^3. Following dosing, the soil sample vessels were incubated aerobically in the dark at approximately 50 percent of maximum water holding capacity moisture and 20±2 °C over 120 days. Additional samples of each soil were dosed with solvent blank acetonitrile and incubated similarly for determination of biomass. High dosed samples were prepared at

10 times rate with mixture of ^{12}C and ^{14}C-afidopyropen (approximately 50:50 ratio) at approximately 0.102 mg/vessel.

Table 1 Soil characteristics (pyranone label)

Soil name	LUFA 2.2 (L2)	LUFA 5M (L5)	California (CA)	New Jersey (NJ)

Moisture holding capacity at 1/3 bar (percent moisture)	10.7	14.5	5.8	27.4
Moisture holding capacity at 15 bar (percent)	7.3	8.2	3.4	9.3
Microbial biomass (mg microbial carbon/100 g dry soil)	171.6 (0 DAT) 179.0 (120 DAT)	112.2 (0 DAT) 133.0 (120 DAT)	38.6 (0 DAT) 20.9 (120 DAT)	115.7 (0 DAT) 126.2 (120 DAT)

Notes:

MWHC = Maximum Water Holding Capacity.

Duplicate samples for each label were removed at 0, 5, 12, 29, 62, and 120 days after treatment (DAT). The soil moisture of each vessel was adjusted periodically to maintain approximately 50 percent MWHC.

Immediately after removal from the incubator system, the soil samples were extracted with solvents (as outlined below) by shaking for approximately 30 minutes at 300 rpm followed by centrifugation at 4000 rpm for another 15 minutes. The supernatant was decanted into a graduated cylinder, the volume adjusted, and an aliquot assay by LSC.

Sample concentration:

For 0–5 DAT, equal aliquots from each extract were pooled together. For 12 DAT and on, equal aliquots of each extract were pooled together, concentrated by rotary evaporator at 30 °C to small volume then, the rotavap flask was rinsed with ACN, followed by water. The combined concentrate was further concentrated to smaller volume and adjusted to final volume, vortexed and centrifuged prior to liquid scintillation counting (LSC) and high-pressure liquid chromatography (HPLC) analysis.

Volatiles Analysis:

The aqueous sodium hydroxide traps were assayed at all sampling times (except for 0 DAT) by directly adding aliquots of the trapping solution into liquid scintillation cocktail and counting by LSC. The traps were replaced with fresh aqueous sodium hydroxide (1N), at each sampling time.

Bound Residues Analysis:

Non-extractable radioactive residues (NER) were characterized by destructive NaOH treatment with 0.5 M NaOH. The radioactivity was determined by LSC analysis.

The remaining soil was allowed to dry at room temperature. Triplicate aliquots of samples were combusted and the resulting $^{14}CO_2$ was trapped and measured by LSC in order to determine the ^{14}C residues in the humin fraction.

To fractionate the fulvic acids and the humic acids, the fractions were adjusted to pH 1–2 by adding concentrated HCI and storing in the refrigerator. After precipitation, the suspension was centrifuged. The supernatant containing the fulvic acids was decanted and analysed by LSC. The radioactivity found in the humic acid was calculated based on the following equation: Humic Acid = [Sum(NaOH Ext 1-3 and water wash)-Fulvic Acid]. The fulvic acid fraction was further analysed by partitioning two times with ethyl acetate. Each ethyl acetate phase and the aqueous phase were measured by LSC. The ethyl acetate extracts were combined and reduced to dryness using a rotary evaporator, the remainder was taken up using an appropriate solvent and measured by LSC. An aliquot was subjected to HPLC analysis.

Notes:

n.a. = Not analysed; ERR: extracted radioactive residue; NER = non-extracted residue;–= not detected (<0.1 percent TAR).

*Others reflects a combined value of two or more peaks. No individual peak in "Others" exceeded 2 percent TAR.

Characterization of post extraction solids (PES) was performed with selected samples from both soils and both label treatments by NaOH extraction and subsequent fractionation into fulvic acids, humic acids and humins.

Table 4 Characterisation of none-extracted residues in soils treated with 0.2 g ai/kg (50 g ai/ha) [4-PYR-^{14}C]- labelled afidopyropen or [6-PYRA-^{14}C/2,6-PYRI-^{14}C]-labelled afidopyropen in German and US soils (values are means of replicate analyses)

USE PATTERN

For the purpose of estimating new MRLs, use pattern information for afidopyropen from the United States were submitted.

Table 6 List of uses of afidopyropen considered by the current Meeting

Crop or crop group	Country	Rate	Number of treatments (minimum interval)	Pre-harvest interval (PHI)
Strawberries	United States	0.05 kg ai/ha (max. 0.1 kg ai/ha and crop and max. 0.3 kg ai/ha per year)	7 days	0 days
Sorghum	United States	0.02 kg ai/ha (max. 0.044 kg ai/ha and year)	14 days	7 days (forage) 14 days (grain and stover)
Grass forage, fodder and hay group	United States	0.036 kg ai/ha (max. 0.058 kg ai/ha and year)	7 days	0 days
Non-grass animal feed group (forage, fodder, hay, seed and straw) [a]	United States	0.036 kg ai/ha (max. 0.058 kg ai/ha and year)	7 days	0 days

Notes:

[a] alfalfa, bean velvet, clover, kudzu, lasperdeza, lupin, sainfoin, trefoil, vetch, vetch crown, vetch milk.

RESULTS OF SUPERVISED RESIDUE TRIALS ON CROPS

The Meeting received information on supervised residue trials for strawberries, sorghum, alfalfa and clover.

Crop	Commodity	Treatment	Table no.
Strawberries	Fruits	Foliar	Table 7
Alfalfa	Seeds	Foliar	Table 8
Sorghum	Grain	Foliar	Table 9
Alfalfa	Forage	Foliar	Table 10
Clover	Forage	Foliar	Table 11
Grass	Forage	Foliar	Table 12
Sorghum	Forage	Foliar	Table 13
Alfalfa	Hay	Foliar	Table 14
Clover	Hay	Foliar	Table 15
Grass	Hay	Foliar	Table 16
Alfalfa	Straw	Foliar	Table 17
Sorghum	Straw	Foliar	Table 18

All trials have been conducted with a Dispersible Concentrate (DC) formulation. Application rates, spray concentrations and residues have been rounded to two figures. Residue data are recorded un-adjusted for percentage recoveries or for residue values in control samples unless otherwise stated. Soil characteristics were not included in the tables as all applications are foliar applications.

The limit of quantification (LOQ) for the method is 0.01 mg/kg for parent afidopyropen and plant metabolite M007. Non-quantifiable residues are listed as <0.01 mg/kg. For calculation of total residues, residues below LOQ are considered as <0.01 mg/kg.

Residues are expressed in their respective analytes. The totals are summed and expressed in parent equivalents, without correction.

Where multiple analyses were conducted on a single sample, the average value is reported. Where multiple samples were taken from a single plot, the individual and average values are reported. Results are therefore sometimes presented as single values or as duplicate/triplicate single values with the (mean) value between brackets. Where results from separate plots with distinguishing characteristics such as different formulations, crop varieties or treatment schedules were reported, results are listed separately for each plot.

Residues from the trials conducted according to the critical GAP, which have been used for the estimation of maximum residue levels (mean values), STMR and HR (based on the individual samples) values are underlined.

Strawberries

A total of five greenhouse trials were conducted on strawberries during the 2016 and 2017 growing seasons in the United States.

Each trial consisted of one untreated plot (Treatment 01) and one treated plot (Treatment 02). At each trial, four foliar applications of afidopyropen (100.0 g ai/L DC formulation) were made to the treated plots targeting 0.010 kg ai/ha/application for the first and second application and 0.050 kg ai/ha/application for the third and forth application with 7-day retreatment intervals each, totaling 0.120 kg ai/ha per season. The applications were made with 315–567 L/ha of spray volume with an adjuvant added to the spray mixture for all applications. All applications were made using appropriate spray equipment, and the spray volume was sufficient to provide adequate dispersal of the test substance.

At all the greenhouse trials, fresh strawberries were harvested on the day of the last application (0-day PHI). In decline trial, 11680.16-FL127, samples were collected at 0, 1, 3, 7 and 14 days after the last application.

A minimum sample size of 60 fruits respective of >1kg of fruit/sample were harvested for all trials. Frozen samples were delivered from the field sites via freezer truck to IR-4 North Central Research Center in Lansing, Michigan. Fruit samples were stored frozen until processed. Raw agricultural commodity (RAC) samples were ground using a Robot Coupe RSI 10B blender with dry ice. The entire sample was chopped and homogenized. Sample analysis for residues of afidopyropen was conducted by the IR-4 North Central Research Center, Lansing, MI, United States.

All samples were analysed for residues of afidopyropen and metabolite M440I007 using BASF Method D1103/01, which quantifies residues by LC-MS/MS and was already reviewed by the 2019 JMPR. Additional concurrent recoveries of afidopyropen and M440I007 in strawberry samples ranged from 78 to 114 percent and 70 to 115 percent for M440I007 with RSDs of 1–16 percent. The limit of quantification (LOQ) was 0.01 mg/kg.

The maximum freezer storage interval between sampling and analysis was 289 days for all analytes. Extracts were analysed within 24 hours.

Notes:

RTI = retreatment interval (days).

[a] Residues are expressed in their respective analytes. The totals expressed the sum of both analytes, without molar correction.

Sorghum (grain)

A set of twelve supervised field trials was conducted in the United States, each field trial included three plots, an application-free control plot and two treated plots. The first treated plot was for the collection of sorghum forage and the second treated plot was the collection of sorghum grain and stover. The test item (100.0 g ai/L DC formulation) was applied as two broadcast foliar applications at the maximum label nominal rate of 0.019–0.021 kg ai/ha with a 13–15 day retreatment interval, resulting in a total rate of 0.039–0.041 kg ai/ha. Applications were made to the first treated plot at target 21- and 7-days before normal commercial harvest. Applications were made to the second treated plot at target 28- and 14-days before normal commercial harvest. The applications were made using a spray volume of 193–278 L/ha. A commercially available adjuvant was added to the spray mixture.

Samples of forage, grain and stover were collected 0 to 21 days after the last application. A simulated aspirated grain fraction (AGF) was collected by sieving the frozen sorghum grain stored prior to homogenization. One composite simulated AGF sample was generated by combining the grain from

multiple trials. Forage samples were frozen within 4 hours of collection and weighed at least 1 kg. Grain and stover samples were frozen within 4 hours of collection and weighed at least 1 kg or 0.5 kg, respectively.

All RAC samples were maintained frozen at the field facilities and were kept on dry until homogenization and analysis. The residues of afidopyropen and M440I007 in sorghum samples were quantitated by LC-MS/MS using BASF Method No. D1103/01, which was already reviewed by the 2019 JMPR. Additional concurrent recoveries of afidopyropen and M440I007 in sorghum forage, grain and stover ranged from 72.0 to 108 percent (RSDs 9–11 percent), based on 4-5 replicate samples each at fortification levels of 0.01 and 1.0 mg/kg. For aspirated grain fractions, single concurrent recovery samples at 0.01 and 5 mg/kg showed recoveries of 76 to 95 percent. The maximum storage period for sorghum-based based samples in this study was 306 days (~10 months). Extracts were stored for a maximum of three days under refrigerator conditions, accompanied by concurrent standards.

Notes:

RTI = retreatment interval (days).

[a] Residues are expressed in their respective analytes. The totals expressed the sum of both analytes, without molar correction.

Alfalfa (forage)

A total of 21 field trials were conducted during the 2017 and 2018 growing seasons, twelve on alfalfa and nine on clover. Each field trial included two plots, an application-free control plot and one treated plot. In the treated plot, DC test formulations were applied as two broadcast foliar applications. The first application was applied at a target rate of 0.022 kg ai/ha. The second application was applied with a 6 to 8 day retreatment interval (RTI) at a target rate of 0.034 kg ai/ha. The spray volume ranged from 131 to 187 L/ha. A commercially available adjuvant was added to the spray mixture.

The plots were harvested for either forage and hay (alfalfa and clover trials) or seed and straw (select alfalfa trials) at 0 and 7 DALA, targeting crop maturity. For the alfalfa trials, additional samples were taken at the second and third cuttings. For the two alfalfa decline trials, samples were harvested, targeting maturity, at 0, 3, 7, 14, and 21 days after last application. A sample size for alfalfa of 0.4–1.3 kg (hay), 1.0–2.9 kg (forage), 1.0–2.7 kg (seed) and 1.0–1.4 kg (straw) and for clover of 1.1–1.9 kg (forage) and 0.5–1.3 kg (hay) 1 to 2 kg was collected for all trials. All RAC samples were shipped frozen to the laboratory where samples were homogenized to a consistency appropriate for analysis using commercial equipment and stored in freezers. The frozen pre-homogenized samples were shipped from BASF to EAG Laboratories (Columbia, MO) for analysis.

The residues of afidypyropen and M440I007 in alfalfa forage, hay, seed, and straw, as well as clover forage and hay samples were quantitated by LC-MS/MS using BASF Method No. D1103/01. The concurrent recoveries for afidypyropen were 87 to 107 percent (95±6.5, n=12) in alfalfa forage, 83 to 110 percent (97±8.4, n=12) in alfalfa hay, 88 to 104 percent (94±7.8, n=4) in alfalfa seed, 98 to 111 percent (104±6.4, n=4) in alfalfa straw, 85 to 104 percent (97±7.3, n=9) in clover forage and 83 to 95 percent (90±4.9, n=9) in clover hay. M440I007 recoveries were 78 to 103 percent (90±9.2, n=12) in alfalfa forage, 83 to 121 percent (101±9.6, n=12) in alfalfa hay, 73 to 100 percent (88±14.7, n=4) in alfalfa seed, 84 to 105 percent (95±9.2, n=4) in alfalfa straw, 89 to 104 percent (98±5.7, n=9) in clover forage and 92 to 106 percent (97±4.6, n=9) in clover hay.

The non-grass animal feed RAC samples were stored frozen, from collection to extraction, for a maximum of 420 days, and were analysed within 9 days of extraction.

Notes:

RTI = retreatment interval (days).

[a] Residues are expressed in their respective analytes. The totals expressed the sum of both analytes, without molar correction.

Grasses (forage)

A total of twelve field trials were conducted during the 2017 growing season, four each on Bermuda grass and bluegrass and two each on fescue and brome grass, respectively across the United States.

Each field trial included two plots, an application-free control plot and one treated plot. In the treated plot, ta DC formulation was applied as two broadcast foliar applications. The first application was applied at a rate of 0.0196 to 0.0204 kg ai/ha. The second application was applied with a 6 to 7-day retreatment interval (RTI) at a rate of 0.0346 to 0.0359 kg ai/ha. The spray volume ranged from 140 to 187 L/ha using ground equipment, with a commercially available adjuvant added to the spray mixture for all applications.

For each trial, a forage sample were collected at normal crop maturity (~BBCH 38-60) 0 and 7 days after the last application (DALA). For the decline trials (R170029 for Bermuda grass and R170035 for fescue), forage samples were collected 3, 14, and 21 days after the last application. Forage samples weighed at least 1 kg each.

In addition, hay samples were collected at normal crop maturity (~BBCH 38-60) 0 and 7 days after the last application (DALA). The samples were allowed to dry for 1 to 10 days to a typical moisture level (10–20 percent) for hay. Hay samples weighed at least 0.4 kg each.

Frozen samples were shipped to the laboratory, homogenized using commercial processing equipment (vertical cutter and mill with dry ice) and stored in freezers. The frozen subsamples were then shipped for analysis. Samples were stored for a maximum of 396 days and analysed within 36 days of extraction. Stored extract were confirmed to be stable by concurrent recovery samples extracted and stored in parallel.

The residues of afidopyropen and M440I007 in grass forage and hay samples were quantitated by LC-MS/MS using BASF Method No. D1103/01. Concurrent recoveries of afidopyropen for forage matrices (bermuda grass, bluegrass, bromegrass, and fescue) ranged from 86 to 96 percent (mean=92 ± 2.9 percent, n=11, RSD=3.2). Concurrent recoveries of M440I007 for forage samples ranged from 83 to 107 percent (mean=96 ± 7.5 percent, n=11, RSD=7.8). Concurrent recoveries of afidopyropen for hay samples ranged from 84 to 100 percent (mean=93 ± 4.0 percent, n=12, RSD=4.3). Concurrent recoveries of M440I007 for hay samples ranged from 88 to 117 percent (mean=101 ± 8.8 percent, n=12, RSD=8.7).

All residues were observed to decline between the day 0 PHI and day 7 PHI. This was also observed in the decline trials for bermuda grass (forage and hay) and fescue (forage and hay) were residues decreaed with increasing pre-harvest intervals.

Notes:

RTI = Retreatment interval (days).

[a] Residues are expressed in their respective analytes. The totals expressed the sum of both analytes, without molar correction.

APPRAISAL

Afidopyropen is an insecticide developed for control of piercing and sucking insects. Afidopyropen disrupts the gating of TRPV (Transient Receptor Potential Vanilloid) channel complexes in chordotonal stretch receptor organs of insects. This disrupts feeding and other behaviour in target insects leading to death by starvation.

Afidopyropen was first evaluated by the 2019 JMPR when an ADI of 0–0.08 mg/kg bw was established. The Meeting also established an ARfD of 0.2 mg/kg bw for women in childbearing age and an ARfD of 0.3 mg/kg for the general population. In addition, it was concluded that the metabolites M440I007 and CPCA are likely to be of similar toxicity to its parent. The 2021 JMPR reconsidered the wording of the residue definition. The residue definitions are:

Definition of the residue for compliance with the MRL for plant and animal commodities: *afidopyropen*

Definition of the residue for dietary risk assessment for plant commodities: *sum of afidopyropen + dimer of [(3R,6R,6aR,12S,12bR)-3-[(cyclopropanecarbonyl)oxy]-6,12-dihydroxy-4,6a,12b-trimethyl-11-oxo-9-(pyridin-3-yl)-1,3,4,4a,5,6,6a,12,12a,12b-decahydro-2H,11H-naphtho[2,1-b]pyrano[3,4-e]pyran-4-yl]methyl rac-cyclopropanecarboxylate (M007).*

Definition of the residue for dietary risk assessment for animal commodities, except liver: *afidopyropen + M001 + CPCA and its carnitine conjugate, expressed as afidopyropen.*

Definition of the residue fir dietary risk assessment for liver: *afidopyropen + M001 + M017 + CPCA and its carnitine conjugate, expressed as afidopyropen.*

The residue is not fat-soluble.

At the Fifty-first Session of the CCPR (2019), afidopyropen was scheduled for toxicology and residue evaluation by the 2022 JMPR.

The Meeting received information from the manufacturer on aerobic soil metabolism, use patterns and residues resulting from supervised trials on strawberries, sorghum and alfalfa/clover.

Environmental fate in soil

The Meeting received information on environmental fate in soil.

Aerobic soil metabolism

The aerobic metabolism and degradation in soil was tested on four soil types from the United States, including silt loam, loamy sand and sandy loam soils. Pyranone-6-^{14}C-afidopyropen was applied at approximately 0.2 mg/kg and soil samples were incubated for up to 120 days at 20 °C with 50 percent maximum water holding capacity. Major degradation products exceeding 10 percent of the applied radioactivity were M057 (max. 25.7 percent AR after 29 days) and M003 (max. 11.8 percent after 5 days). Modelled DT_{50} and DT_{90} values for parent afidopyropen were 9.5–14 days and 82–268 days, respectively, following Gustafson-Holden model kinetics (FOMC). The major metabolites followed single 1st order kinetics with estimated DT_{50}/DT_{90} values of 17.5–23.8/58–79 days for M003 and 7.7-39/26–132 days for M057.

The current Meeting noted that both the metabolic pattern following aerobic soil degradation observed in the newly provided study and the estimated half-life times are similar to the conclusion drawn by the 2019 Meeting. The Meeting confirms its previous conclusion, that afidopyropen and its soil metabolites are not persistent in soil.

Methods of analysis

The current Meeting did not receive additional analytical methods for afidopyropen. All supervised field trials were analysed with analytical methods already evaluated and described by the 2019 Meeting.

Stability of pesticide residues in stored analytical samples

The current Meeting did not receive additional information on the storage stability of afidopyropen and its metabolite M007.

The 2019 Meeting evaluated the storage stability of these analytes and concluded that they are stable for at least 24 months in all plant commodity categories. Field trial samples were analysed within this interval.

Results of supervised residue trials on crops

The Meeting received information on use patterns and supervised residue trials for strawberries, sorghum, alfalfa and clover from the United States.

Strawberries

Afidopyropen is registered in the United States for the use on strawberries with a maximum GAP involving two foliar spraying of 0.05 kg ai/ha each (7 day retreatment interval (RTI)) and a PHI of 0 days. The maximum rate is 0.1 kg ai/ha per crop and a maximum of 0.3 kg ai/ha and year.

Supervised field trials conducted in Canada and the United States on strawberries were provided approximating the cGAP both with two additional initial treatments at ~ 0.01 kg ai/ha at 7 day RTI (treatment regime: 0.01 kg ai/ha + 0.01 kg ai/ha + 0.05 kg ai/ha + 0.05 kg ai/ha, total crop rate:

0.12 kg ai/ha). The Meeting concluded that the two first treatments in addition to the cGAP do not affect residue concentrations at harvest.

Residues of afidopyropen in strawberries were (n=5): 0.0326, 0.0356, 0.0439, 0.0475, 0.06 mg/kg.

Residues of afidopyropen plus M007 in strawberries were (n=5): 0.0426, 0.0456, 0.0539, 0.0575, 0.07 mg/kg. Highest residues in a single sample were 0.0778 mg/kg.

The Meeting estimated a maximum residue level of 0.15 mg/kg for afidopyropen and STMR and HR values of 0.0539 mg/kg and 0.0778 mg/kg, respectively, for afidopyropen plus M007 in strawberries.

Sorghum

Afidopyropen is registered in the United States for the use on sorghum with a maximum GAP involving two foliar spraying of 0.02 kg ai/ha each (14 day RTI) and a PHI of 14 days for grain. The maximum rate is 0.044 kg ai/ha per year.

Supervised field trials conducted in the United States on sorghum were provided approximating the cGAP.

Residues of afidopyropen in sorghum grain were (n=12): < 0.01(3), 0.01, 0.016, 0.019, 0.034, 0.041, 0.042, 0.067, 0.071, 0.104 mg/kg.

Residues of afidopyropen plus M007 in sorghum grain were (n=12): < 0.02(3), 0.02, 0.026, 0.029, 0.044, 0.051, 0.052, 0.077, 0.081, 0.114 mg/kg.

The Meeting estimated a maximum residue level of 0.2 mg/kg for afidopyropen and an STMR value of 0.0365 mg/kg for afidopyropen plus M007 in sorghum grain.

Alfalfa forage

Afidopyropen is registered in the United States for the use on non-grass animal feed crops with a maximum GAP involving two foliar spraying of 0.022 kg ai/ha followed by 0.036 kg ai/ha (7 day RTI) and a PHI of 0 days for forage. The maximum rate is 0.058 kg ai/ha per year.

Supervised field trials conducted in the United States on alfalfa were provided approximating the cGAP.

Residues of afidopyropen plus M007 in alfalfa forage were (n=9): 0.783, 0.999, 1.08, 1.13, 1.19, 1.24, 2.07, 2.31, 2.45 mg/kg (as received).

The Meeting estimated a median residue level of 1.19 mg/kg and highest residue level of 2.45 mg/kg for afidopyropen plus M007 in alfalfa forage (as received).

Clover forage

Afidopyropen is registered in the United States for the use on non-grass animal feed crops with a maximum GAP involving two foliar spraying of 0.022 kg ai/ha followed by 0.036 kg ai/ha (7 day RTI) and a PHI of 0 days for forage. The maximum rate is 0.058 kg ai/ha per year.

Supervised field trials conducted in the United States on clover were provided approximating the cGAP.

Residues of afidopyropen plus M007 in clover forage were (n=9): 0.601, 0.662, 0.926, 1.01, 1.39, 1.68, 2.09, 2.22, 2.59 mg/kg (as received).

The Meeting estimated a median residue level of 1.39 mg/kg and highest residue level of 2.59 mg/kg for afidopyropen plus M007 in clover forage (as received).

Grass forage

Afidopyropen is registered in the United States for the use on grass animal feed crops with a maximum GAP involving two foliar spraying of 0.022 kg ai/ha followed by 0.036 kg ai/ha (7 day RTI) and a PHI of 0 days for forage. The maximum rate is 0.058 kg ai/ha per year.

Supervised field trials conducted in the United States on grass were provided approximating the cGAP.

Residues of afidopyropen plus M007 in grass forage were (n=12): 0.805, 1.09, 1.36, 1.36, 1.48, 1.92, 2.04, 2.1, 2.19, 2.82, 3.2 and 4.12 mg/kg (as received).

The Meeting estimated a median residue level of 1.98 mg/kg and highest residue level of 4.12 mg/kg for afidopyropen plus M007 in grass forage (as received).

Sorghum forage

Afidopyropen is registered in the United States for the use on sorghum with a maximum GAP involving two foliar spraying of 0.02 kg ai/ha each (14 day RTI) and a PHI of 7 days for forage. The maximum rate is 0.044 kg ai/ha per year.

Supervised field trials conducted in the United States on sorghum were provided approximating the cGAP.

Residues of afidopyropen plus M007 in sorghum forage were (n=12): 0.0225, 0.0275, 0.037, 0.0375, 0.039, 0.0485, 0.0515, 0.06, 0.063, 0.103, 0.25 and 0.255 mg/kg (as received).

The Meeting estimated a median residue level of 0.05 mg/kg and highest residue level of 0.255 mg/kg for afidopyropen plus M007 in sorghum forage (as received).

Alfalfa fodder

Afidopyropen is registered in the United States for the use on non-grass animal feed crops with a maximum GAP involving two foliar spraying of 0.022 kg ai/ha followed by 0.036 kg ai/ha (7 day RTI) and a PHI of 0 days for cutting. The maximum rate is 0.058 kg ai/ha per year.

Supervised field trials conducted in the United States on alfalfa were provided approximating the cGAP. Alfalfa was cut according to GAP treatment and left in the field to dry until commercial dryness.

Residues of afidopyropen in alfalfa hay were (n=9): 0.362, 1.32, 1.35, 1.83, 2.71, 2.8, 2.91, 3.12 and 4.19 mg/kg (fresh).

Residues of afidopyropen plus M007 in alfalfa hay were (n=9): 0.382, 1.81, 1.81, 3.10, 4.13, 4.76, 5.13, 5.29 and 5.46 mg/kg (as received).

The Meeting estimated a maximum residue level of 8 mg/kg (dry matter, based on 89 percent dry-weight) for afidopyropen and a median and highest residue for afidopyropen plus M007 in alfalfa fodder (as received) of 4.13 mg/kg and 5.46 mg/kg, respectively.

Clover fodder

Afidopyropen is registered in the United States for the use on non-grass animal feed crops with a maximum GAP involving two foliar spraying of 0.022 kg ai/ha followed by 0.036 kg ai/ha (7 day RTI) and a PHI of 0 days for cutting. The maximum rate is 0.058 kg ai/ha per year.

Supervised field trials conducted in the United States on clover were provided approximating the cGAP. Clover was cut according to GAP treatment and left in the field to dry until commercial dryness.

Residues of afidopyropen in clover hay were (n=9): 1.24, 1.47, 1.59, 2.43, 2.5, 2.64, 3.95, 4.28 and 5.93 mg/kg (fresh).

Residues of afidopyropen plus M007 in clover hay were (n=9): 1.92. 2.23, 2.26, 3.23, 3.50, 3.58, 4.37, 4.42 and 8.55 mg/kg (as received).

The Meeting estimated a maximum residue level of 10 mg/kg (dry matter, based on 89 percent dry-weight) for afidopyropen and a median and highest residue for afidopyropen plus M007 in clover fodder (as received) of 3.5 mg/kg and 8.55 mg/kg, respectively.

Grass hay

Afidopyropen is registered in the United States for the use on grass animal feed crops with a maximum GAP involving two foliar spraying of 0.022 kg ai/ha followed by 0.036 kg ai/ha (7 day RTI) and a PHI of 0 days for cutting. The maximum rate is 0.058 kg ai/ha per year.

Supervised field trials conducted in the United States on grass were provided approximating the cGAP. Grass was cut according to GAP treatment and left in the field to dry until commercial dryness.

Residues of afidopyropen in grass hay were (n=12): 2.39, 2.59, 2.77, 3.15, 3.27, 3.48, 4.12, 4.46, 4.64, 4.82, 5.76 and 8.38 mg/kg (DM based).

Residues of afidopyropen plus M007 in grass hay were (n=12): 3.36, 3.69, 3.83, 4.53, 5.24, 5.85, 6.79, 7.06, 7.13, 8.9, 14.0 and 14.9 mg/kg (DM based).

The Meeting estimated a maximum residue level of 15 mg/kg (dry-matter, trial specific dry-weight basis) for afidopyropen and a median and highest residue for afidopyropen plus M007 in grass hay (dry-matter) of 6.32 mg/kg and 14.9 mg/kg, respectively.

Sorghum stover

Afidopyropen is registered in the United States for the use on sorghum with a maximum GAP involving two foliar spraying of 0.02 kg ai/ha each (14 day RTI) and a PHI of 14 days for stover. The maximum rate is 0.044 kg ai/ha per year.

Supervised field trials conducted in the United States on sorghum were provided approximating the cGAP.

Residues of afidopyropen in sorghum stover were (n=12): 0.0105, 0.011, 0.0155, 0.0155, 0.0205, 0.0305, 0.048, 0.0505, 0.081, 0.085, 0.119, 0.14 mg/kg (fresh).

Residues of afidopyropen plus M007 in sorghum stover were (n=12): 0.0205, 0.021, 0.0255, 0.0255, 0.0305, 0.0405, 0.0605, 0.0635, 0.091, 0.098, 0.134 and 0.155 mg/kg (as received).

The Meeting estimated a maximum residue level of 0.3 mg/kg (dry matter, based on 88 percent dry-weight) for afidopyropen and a median and highest residue for afidopyropen plus M007 in sorghum stover (as received) of 0.0505 mg/kg and 0.155 mg/kg, respectively.

Residues in animal commodities

Farm animal feeding studies

The 2019 Meeting evaluated farm animal feeding studies with afidopyropen on lactating cows and laying hens.

In the following tables, residues in bovine tissues and milk and in poultry tissues and eggs according to the residue definitions for MRL setting (afidopyropen) and for exposure estimation

(*afidopyropen + M001 + CPCA and its carnitine conjugate, expressed as afidopyropen* for animal commodities except liver and *afidopyropen + M001 + M017 + CPCA and its carnitine conjugate, expressed as afidopyropen* for liver) are summarised:

Table 19 Overview of mean and highest residue levels observed in the dietary feeding study with lactating cows (based on 2019 JMPR Report)

	1.54 ppm		4.61 ppm		15.3 ppm	
	parent	Total [a]	parent	Total [a]	parent	Total [a]
Liver	0.017 (0.019)	0.15 (0.15)	0.046 (0.056)	0.18 (0.19)	0.19 (0.20)	0.36 (0.37)
Kidney	< 0.01 (< 0.01)	< 0.13 (< 0.13)	< 0.01 (< 0.01)	< 0.13 (< 0.13)	< 0.01 (< 0.01)	< 0.13 (< 0.13)
Muscle	< 0.01 (< 0.01)	< 0.13 (< 0.13)	< 0.01 (< 0.01)	0.15 (0.17)	< 0.01 (< 0.01)	0.29 (0.29)
Fat	< 0.01 (< 0.01)	< 0.13 (< 0.13)	< 0.01 (< 0.01)	< 0.13 (< 0.13)	< 0.01 (< 0.01)	< 0.13 (< 0.13)
Milk	< 0.001 (< 0.001	< 0.013 (< 0.013)	< 0.001 (< 0.001	0.016 (0.020)	< 0.001 (< 0.001	0.035 (0.044)

Notes:

[a] Total residues include parent+M001+CPCA-carnitine, corrected for their respective molecular weights in g/mol (parent = 593.67, M001 = 457.52, CPCA-carnitine =265.74). In liver residue levels of parent were corrected for M017 using a correction factor of 1.2.

Table 20 Overview of mean (and highest) residue levels observed in the dietary feeding study with laying hens (based on 2019 JMPR Report)

	0.20 ppm		0.62 ppm		2.0 ppm	
	parent	Total [a]	parent	Total [a]	parent	Total [a]
Liver	0.010 (0.011)	0.14 (0.15)	0.025 (0.027)	0.16 (0.17)	0.085 (0.095)	0.24 (0.28)
Muscle	< 0.01 (< 0.01)	< 0.13 (< 0.13)	< 0.01 (< 0.01)	< 0.13 (< 0.13)	0.011 (0.012)	0.14 (0.13)
Fat	< 0.01 (< 0.01)	< 0.13 (< 0.13)	0.011 (0.012)	0.14 (0.14)	0.036 (0.042)	0.16 (0.17)
Eggs	< 0.01 (< 0.01)	< 0.13 (< 0.13)	0.011 (0.018) [b]	0.14 (0.14)	0.026 (0.036)	0.15 (0.16)

Notes:

[a] Total residues include parent+ M001+CPCA-carnitine (+ M017 in liver) corrected for molecular weight differences in g/mol (parent = 593.67, M001 = 457.52, M017 = 609.7; CPCA-carnitine =265.74).

[b] Results from day 28 and 32 only.

Farm animal dietary burden

Dietary burdens were calculated for beef cattle, dairy cattle, broilers and laying poultry based on feed items evaluated by the JMPR in 2019 and the current recommendations. The dietary burdens, estimated using the most recent version of the OECD livestock dietary burden calculator diets are presented in Annex 6 and summarised below. As Australia does not allow the importation of fodders due to biosecurity concerns, forage and fodder commodities were excluded from the dietary burden calculation for Australia.

Table 21 Estimated maximum and mean dietary burdens of farm animals (sum of afidopyropen and M007)

	Animal dietary burden: sum of afidopyropen and M007, ppm of dry matter diet							
	United States-Canada		European Union		Australia /[a]		Japan	
	max	mean	max	mean	max	mean	max	mean
Beef cattle	3.8	1.7	17.5	8.7	0.09	0.09	6.67	3.1
Dairy cattle	9.4	4.53	18.2 ❶	9.0 ❷	0.082	0.082	12.2	5.8
Broilers	0.04	0.04	0.036	0.036	0.035	0.035	0.035	0.035
Layers	0.037	0.037	1.2 ❸	0.54 ❹	0.035	0.035	0.03	0.03

Notes:

[a/] Excluding forage/fodder due to import restrictions.

❶ Highest maximum beef or dairy cattle dietary burden suitable for HR estimates for mammalian tissues and milk.

❷ Highest mean beef or dairy cattle dietary burden suitable for STMR estimates for mammalian tissues and milk.

❸ Highest maximum poultry dietary burden suitable for HR estimates for poultry tissues and eggs.

❹ Highest mean poultry dietary burden suitable for STMR estimates for poultry tissues and eggs.

Animal commodity maximum residue levels

Cattle

The calculations used to estimate maximum residue levels, STMR and HR values for cattle matrices are shown below. For cattle, the maximum dietary burden of 18.2 ppm represents 119 percent of the highest dose administered in the provided feeding study, which is at the upper end of acceptable under dosing for the estimation of residues in animal commodities.

Table 22 Anticipated residues of afidopyropen in cattle commodities

	Feed Level (ppm) for milk residues	Total residues (mg eq/kg) in milk	Feed Level (ppm) for tissue residues	Total residues (mg eq/kg)			
				Muscle	Liver	Kidney	Fat
HR Determination (beef or dairy cattle)–Parent + M001+ CPCA-carnitine + M017 (liver only)							
Feeding Study	15.3	0.035	15.3	0.29	0.38	< 0.13	< 0.13
Dietary burden and estimate of highest residue	18.2	0.042	18.2	0.34	0.45	< 0.15	< 0.15
STMR Determination (beef or dairy cattle)–Parent + M001 + CPCA-carnitine + M017 (liver only)							
Feeding Study	4.61 15.3	0.016 0.035	4.61 15.3	0.15 0.29	0.18 0.36	< 0.13 < 0.13	< 0.13 < 0.13
Dietary burden and estimate of median residue	9.0	0.024	9.0	0.21	0.25	< 0.13	< 0.13
MRL Determination (beef or dairy cattle)–Parent							
Feeding Study	15.3	< 0.001	15.3	< 0.01	0.20	< 0.01	< 0.01
Dietary burden and estimate of highest residue	18.2	< 0.001	18.2	< 0.01	0.24	< 0.01	< 0.01

The Meeting confirms its previous recommendation on maximum residue levels of 0.001(*) mg/kg in milk, 0.3 mg/kg in edible offal (based on liver), 0.01(*) mg/kg in meat (mammalian except marine mammals) and 0.01(*) mg/kg in mammalian fats.

For estimating dietary exposure, calculated HR values are: 0.45 mg/kg for edible offal (based on liver), 0.34 mg/kg for muscle, and 0.15 mg/kg for kidney and fat and 0.042 mg/kg in milk. Calculated STMRs are: 0.25 mg/kg edible offal (based on liver), 0.21 mg/kg for muscle, 0.13 mg/kg for kidney and fat, and 0.024 mg/kg for milk.

Poultry

The calculations used to estimate maximum residue levels, STMR and HR values for poultry matrices are shown below.

Table 23 Anticipated residues of afidopyropen in poultry commodities

	Feed Level (ppm) for egg residues	Total residues (mg eq/kg) in egg	Feed Level (ppm) for tissue residues	Total residues (mg eq/kg)		
				Muscle	Liver	Fat
HR Determination (poultry broiler or layer)–Parent + M001+ CPCA-carnitine + M017 (liver only)						
Feeding Study	0.62	0.14	0.62	< 0.13	0.17	0.14
	2.0	0.16	2.0	0.14	0.28	0.17
Dietary burden and estimate of highest residue	1.2	0.149	1:2	0.134	0.22	0.16
STMR Determination (poultry broiler or layer) – Parent + M001+ CPCA-carnitine + M017 (liver only)						
Feeding Study	0.20	< 0.13	0.20	< 0.13	0.14	< 0.13
	0.62	0.14	0.62	< 0.13	0.16	0.14
Dietary burden and estimate of median residue	0.54	0.138	0.54	< 0.13	0.156	0.138
MRL Estimation (poultry broiler of layer) – Parent only						
Feeding Study	0.62	0.018	0.62	< 0.01	0.011	< 0.01
	2.0	0.036	2.0	< 0.01	0.027	0.012
Dietary burden and estimate of highest residue	1.2	0.027	1.2	< 0.01	0.019	0.011

The Meeting confirms its previous recommendation on a maximum residue level of 0.01(*) mg/kg in poultry meat (muscle).

The Meeting estimated maximum residue levels of 0.015 mg/kg in poultry fat, 0.02 mg/kg in poultry edible offal and 0.03 mg/kg in eggs to replace its previous recommendation.

For estimating dietary exposure calculated HR values are: 0.22 mg/kg for poultry edible offal (based on liver), 0.134 mg/kg for muscle, 0.16 mg/kg for fat and 0.149 mg/kg for eggs. Calculated STMRs are: 0.156 mg/kg for liver and poultry edible offal (based on liver), 0.13 mg/kg for muscle, 0.138 mg/kg for fat and 0.138 mg/kg for eggs.

RECOMMENDATIONS

On the basis of the data from supervised trials, the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessment.

Definition of the residue for compliance with the MRL for plant and animal commodities: *afidopyropen*

Definition of the residue for dietary risk assessment for plant commodities: *sum of afidopyropen + dimer of [(3R,6R,6aR,12S,12bR)-3-[(cyclopropanecarbonyl)oxy]-6,12-dihydroxy-4,6a,12b-trimethyl-11-oxo-9-(pyridin-3-yl)-1,3,4,4a,5,6,6a,12,12a,12b-decahydro-2H,11H-naphtho[2,1-b]pyrano[3,4-e]pyran-4-yl]methyl rac-cyclopropanecarboxylate (M007).*

Definition of the residue for dietary risk assessment for animal commodities, except liver: *afidopyropen + M001 + CPCA and its carnitine conjugate, expressed as afidopyropen.*

Definition of the residue fir dietary risk assessment for liver: *afidopyropen + M001 + M017 + CPCA and its carnitine conjugate, expressed as afidopyropen.*

The residue is not fat-soluble.

Table 24 Recommendations for residues of afidopyropen from the 2022 JMPR

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The ADI for afidopyropen is 0–0.08 mg/kg bw. The International Estimated Daily Intakes (IEDIs) for afidopyropen were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the JMPR. The results are shown in Annex 3 of the 2022 JMPR Report.

The IEDIs ranged from 0–4 percentof the maximum ADI. The Meeting concluded that long-term dietary exposure to residues of afidopyropen from uses considered by the JMPR is unlikely to present a public health concern.

Acute dietary exposure

The ARfD for afidopyropen is 0.2 mg/kg bw for women of child bearing age and 0.3 mg/kg bw for adults and children. The International Estimate of Short Term Intakes (IESTIs) for afidopyropen were calculated for the food commodities and their processed commodities for which HRs/HR-Ps or STMRs/STMR-Ps were estimated by the present Meeting and for which consumption data were available. The results are shown in Annex 4 of the 2022 JMPR Report.

The IESTIs were 0–1 percent of the ARfD for women of childbearing age and 0–2 percent of the ARfD for children and 0–1 percent of the ARfD for adults. The Meeting concluded that acute dietary exposure to residues of afidopyropen from uses considered by the present Meeting is unlikely to present a public health concern.

AZOXYSTROBIN (229)

First draft prepared by Dr A Leahigh, Environmental Protection Agency, Washington, United States of America

EXPLANATION

Azoxystrobin was first evaluated for toxicology and residues by JMPR in 2008. It was evaluated for residues by the JMPR in 2011, 2012, 2013, 2017, and 2019. An ADI of 0–0.2 mg/kg bw was established and an ARfD was unnecessary.

The residue definition for compliance with MRL and for dietary intake for plant and animal commodities is parent azoxystrobin. The residue is fat soluble.

Azoxystrobin was scheduled at the Fifty-first Session of the CCPR for the evaluation of additional MRLs in 2021 and rescheduled to the 2022 JMPR. The current Meeting received additional analytical methods, storage stability data, GAP information, and residue trial data from uses on mango, papaya, sugar beet, and sugar beet processed commodities.

METHODS OF RESIDUE ANALYSIS

Residue analytical method RAM 305/03 was used for the analysis of azoxystrobin and R230310 residues in the supervised residue trials on mango, papaya, sugar beet, and processing studies on sugar beet. The method RAM 305, was previously validated as version RAM 305/01 in a wide range of crops and crop types by the 2008 JMPR. These data were considered sufficient. The version RAM 305/03 used in the residue studies in this submission is procedurally the same as the version RAM 305/01 and validation data evaluated for RAM 305/01 are applicable to RAM 305/03.

Briefly, residues of azoxystrobin and R230310 were extracted by homogenizing samples with a mixture of acetonitrile and water (90/10, v/v). Final determination was achieved by high performance liquid chromatography using triple quadrupole mass spectrometric detection (LC-MS/MS), monitoring for the primary transition (m/z 404 → 372) and the confirmatory transitions (m/z 404 → 344 and m/z 404 → 329).

RAM 305/03 was validated for the determination of residues of azoxystrobin in mango pulp and peel, papaya pulp and peel, sugar beet, and processed sugar beet commodities (juice, sugar, molasses, pulp, and press water). Method validation recoveries were all within the acceptable range and with acceptable relative standard deviations.

The limit of quantification for azoxystrobin and R230310 residues was established at 0.01 mg/kg for mango and papaya peel and pulp, and sugar beet roots and its processed products.

The Meeting concluded that Residue analytical method RAM 305/03 has been successfully validated for the analysis of azoxystrobin and R230310 residues in mango peel and pulp, papaya peel and pulp, and sugar beet and its processed commodities at an LOQ of 0.01 mg/kg.

Table 1 Method validation data relevant to mango, papaya, sugar beet, and processed commodities of sugar beet.

USE PATTERN

The registered use patterns for azoxystrobin on mango, papaya, and sugar beet are summarised in Table 2. For mango and papaya, both pre-harvest foliar applications and post-harvest dip or spray applications may be made.

Table 2 Registered uses of azoxystrobin using dip and/or foliar application

Crop	Country	Formulation Content[1]	Formulation Type	Application Method	Application Rate	Conc. (g ai/hL)	No. of Apps	Timing/ PHI	Remarks
Mango	Brazil	239 g ai/L	SC	Dip or spray	NA	60-120	1	Post-harvest	Contact time of 2 minutes for dip application
Mango	Brazil	200 g ai/L	SC	Foliar spray	60-120 g ai/ha	6-20[2]	4	After pre-flowering/ 7 days	RTI = 14 days; spray volume = 600-1000 L/ha
Papaya	Brazil	239 g ai/L	SC	Dip or spray	NA	60-120	1	Post-harvest	Contact time of 2 minutes for dip application

Crop	Country	Formulation Content[1]	Formulation Type	Application Method	Application Rate	Conc. (g ai/hL)	No. of Apps	Timing/ PHI	Remarks
Papaya	Brazil	200 g ai/L	SC	Foliar spray	60-100 g ai/ha	6-17[2]	4	Fruit development / 3 days	RTI = 14 days; spray volume = 600-1000 L/ha
Sugar beet	United States	238 g ai/L	SC	Spray	4.7 g ai/t roots[3]	NA	1	Post-harvest	Roots must be tumbling

Notes:

NA: Not applicable.

RTI: Re-treatment interval.

[1] Content of azoxystrobin only.

[2] Calculated based on the GAP spray volume range of 600-1000 L/ha.

[3] Metric conversion from 0.0093 lb ai/2000 lb roots.

[4] Metric conversion from 0.5 gallons water/tonne.

RESULTS OF SUPERVISED RESIDUE TRIALS ON CROPS

The field trial reports included method validation data, as recoveries from spiked samples at levels reflecting those observed in the field trial samples; dates from critical events during the study, including application, harvest, storage, and analysis; as well as detailed information on the field site and treatment parameters. Analytical reports were sufficiently detailed and included example chromatograms and example calculations.

Mango

Four supervised trials with azoxystrobin on mango were conducted in 2020. Trials were conducted in Brazil using a suspension concentrate formulation nominally containing 200 g azoxystrobin/L and 125 g difenoconazole/L which was applied four times as a broadcast foliar spray at 120 g ai/ha with a 14 day treatment interval.

For some trials, foliar applications were followed by one post-harvest immersion or spray application of a suspension concentrate formulation nominally containing 239 g azoxystrobin/L and 239 g fludioxonil/L, which was applied 7 days after the last foliar application. Fruits were washed before being immersed for approximately 2 minutes in the treatment solution in a stainless steel tank, or sprayed with the formulation at a nominal concentration of 120 g ai/hL. Following the post-harvest treatment, fruits were left to dry before being sprayed with carnauba storage wax (diluted with water 1/4, v/v) before being left to dry and placed in storage.

Samples of treated and untreated whole fruits (at least 12 per sample) were collected at 7 days after the last foliar application, and at 0, 21, and 42 days after the post-harvest treatment. The whole samples were separated into peel and flesh fractions, and the stones were also removed. Peel and flesh samples were frozen (nominally -20 °C) and maintained in frozen storage for periods of up to 2.7 months prior to analysis, or placed in storage under conditions that simulate commercial practice: 1 day at 18–20 °C, 5 weeks at 11 °C, and 1 week at 18–20 °C.

Residues of azoxystrobin in mango were determined using the analytical method RAM 305/03. This method is validated for use on mango flesh and peel with an LOQ of 0.01 mg/kg.

The results of the trials are summarised Table 3, where residues relevant to the setting of an MRL for mango are underlined. Residues in control samples were <LOQ.

Table 3 Residues of azoxystrobin on mango in Brazil.[1]

Notes:

[1] Reference: LBS19053

[2]The amount of residues in whole fruit was calculated as follows: [(weight of the pulp sample x residue found in the pulp sample) + (weight of peel sample x residue found in the peel sample)] / weight of the whole fruit sample. The weight of the whole fruit sample was calculated as follows: weight of the pulp sample + weight of peel sample + weight of seeds.

Papaya

Four supervised trials with azoxystrobin on papaya were conducted in 2020 in Brazil. Trials were conducted using a suspension concentrate formulation nominally containing 200 g azoxystrobin/L and 125 g difenoconazole/L which was applied four times as a broadcast foliar spray at rates of 100 g ai/ha with a 14 day RTI.

For some trials, foliar applications were followed by one post-harvest immersion or spray application of a suspension concentrate formulation nominally containing 239 g azoxystrobin/L and 239 g fludioxonil/L, which was applied 3 days after the last foliar application. Fruits were washed before being immersed for approximately 2 minutes in the treatment solution in a stainless steel tank, or sprayed with the formulation at a nominal concentration of 120 g ai/hL. Following the post-harvest treatment, fruits

were left to dry before being sprayed with carnauba storage wax (diluted with water 1:4, v/v) before being left to dry and placed in storage.

Samples of treated and untreated whole fruits (at least 12 per sample) were collected 3 days after the last foliar application, and at 0, 6, and 13 days after the post-harvest treatment. The whole samples were separated into peel and flesh fractions, and the seeds removed.

Peel and flesh samples were frozen (nominally -20 °C) and maintained in frozen storage for periods of up to 2.9 months prior to analysis, or placed in storage under conditions that simulate commercial practice: 1 day at 20 °C, 5 days at 10 °C, and 7 days at 18–20 °C.

Residues of azoxystrobin in papaya were determined using the analytical method RAM 305/03. This method is validated for use on papaya flesh and peel in with an LOQ of 0.01 mg/kg.

The results of the trials are summarised in Table 4, where residues relevant to the setting of an MRL for papaya are underlined. Residues in control samples were generally <LOQ, with the exception of three peel samples where residues >LOQ were observed (corresponding to whole fruit control residues of 0.02 mg/kg, 0.09 mg/kg, and 0.12 mg/kg). When compared to the whole fruit residue values used for MRL calculation, the values in the corresponding control samples are considered negligible and to have no impact on the study or the derived MRL and STMR values.

Notes:

[1] Reference: LBS19052.

[2] The amount of residues in whole fruit was calculated as follows: [(weight of the pulp sample x residue found in the pulp sample) + (weight of peel sample x residue found in the peel sample)] / weight of the whole fruit sample. The weight of the whole fruit sample was calculated as follows: weight of the pulp sample + weight of peel sample + weight of seeds.

[3] Control sample contained a residue of 0.08 mg/kg.

[4] Control sample contained a residue of 0.42 mg/kg.

[5] Control sample contained a residue of 0.43 mg/kg.

Sugar Beet

Six supervised trials with azoxystrobin on sugar beet were conducted in the United States in 2015/2016. Trials were conducted using a flowable suspension concentrate formulation containing 239.4 g azoxystrobin/L and 239.4 g fludioxonil/L which was applied once to mature sugar beet roots post-harvest at 4.7 g ai/tonne.

Samples of sugar beets (at least 12 per sample) were collected at maturity and the tops removed. The application was made as a direct spray to the roots, which were tumbled during application to ensure uniform application and to simulate commercial practice. Following the application, the roots were allowed to dry for approximately 2-3 hours (with the exception of trial 04) prior to storage. In trial 04, additional samples of sugar beet roots were taken for processing.

All samples of roots were and maintained in frozen storage (-20 °C) for periods of up to 265 days prior to analysis.

Residues of azoxystrobin and R230310 in sugar beet were determined using the analytical method RAM 305/03 with an LOQ of 0.01 mg/kg per analyte.

The results of the trials are summarised in Table 5. Residues in all control samples and residues of R230310 in treated samples were <LOQ.

FATE OF RESIDUES DURING PROCESSING

One processing trial on sugar beet was conducted in Minnesota, United States in 2015/2016 as part of the magnitude of residues study on sugar beet roots (Trial TK0044248-04). The field trial contained one untreated plot and two treated plots. In the treated plots, one post-harvest application of a SC formulation containing a nominal concentration of 239.4 g/L azoxystrobin and 235.9 g/L fludioxonil was made at a rate equivalent to 4.8 g ai/t.

Sugar beet roots were collected immediately after treatment and stored frozen prior to shipment to the processing facility. The roots were cleaned and sliced, and the following processed fractions were produced: raw juice, wet pulp, pressed pulp, press water, dried pulp, thick juice, raw sugar, refined sugar, and molasses.

Raw juice and wet pulp fractions were prepared by placing sliced sugar beet roots (cossettes) in water baths set at 88–92 °C for 30 to 45 seconds, followed by 68–74 °C for at least 9 minutes. Following diffusion, the raw juice was sieved, and the raw juice and wet pulp fractions were collected and placed into frozen storage.

Pressed pulp fractions were prepared from the diffused cossettes using a hydraulic press. Dried beet pulp was produced by drying the pressed pulp at 54–71 °C until the final moisture content was ≤ 15 percent. Pressed and dried pulp samples, in addition to the press water, were collected and placed in freezer storage.

Raw juice was mixed at high temperature (80–85 °C) at pH 10.5 until precipitation. Centrifugation was used to separate the mud and juice. The juice was then mixed again at high temperature (80–85 °C) at pH 9.1–9.3. The juice was centrifuged and filtered to obtain a clear juice (i.e., thin juice). This was again mixed at 80–85 °C, and the pH was reduced to 8.8–9.0 with sodium bisulfite. Evaporation under vacuum at 29 °C was performed until a thick juice (50–60 percent solids) was obtained. Following filtration, thick juice fractions were collected and placed into frozen storage.

Further evaporation of this juice was performed until 70–80 percent solids juice (syrup) was achieved. Following seeding with white sugar, the solution was allowed to cool, and the raw sugar fractions were collected and placed into frozen storage. Sugar and molasses were separated by centrifugation and placed into frozen storage.

In order to obtain ensiled beet pulp, pressed pulp was vacuum sealed in bags and exposed to elevated temperatures (*ca.* 40–46 °C) for 2 days. Following this, after 12 days storage at ambient temperature, the ensiled pulp was collected and placed into frozen storage until arrival at the analytical laboratory.

All samples of sugar beet processed commodities were and maintained in frozen storage (-20 °C) for periods of up to 265 days prior to analysis.

Processed fractions were analysed for residues of azoxystrobin by method RAM 305/03, validated for determination of azoxystrobin in sugar beet roots and processed fractions to an LOQ of 0.01 mg/kg.

Residues of azoxystrobin in sugar beet roots (RAC) were 2.0 mg/kg. Residues were diluted in all the processed fractions of treated sugar beet, with processing factors ranging from 0.017 (refined sugar) to 0.47 (dried pulp).

Table 6 Azoxystrobin residues in sugar beet and processed commodities[1]

Trial Number	Crop (Variety)	Country (Region)	Application Rate[2,3] (g ai/t)	Water volume[3] (L/t)	Crop Part Azoxystrobin residue, mg/kg	(mean)[2,3]	Processing Factors[4]
TK0044248-04 2015/2016	Sugar beet (SX1521N)	United States (St. Cloud, MN)	4.8	2.1	Root	1.9, 2.1 (2.0)	-
					Raw juice	0.56	0.29
					Thick juice	0.21	0.11
					Raw sugar	0.32	0.16
					Refined sugar	0.033	0.017
					Molasses	0.38	0.20
					Wet pulp	0.034	0.018
					Ensiled pulp	0.24	0.12
					Dried pulp	0.93	0.47
					Pressed pulp	0.33	0.17
					Press water	0.54	0.27

APPRAISAL

Azoxystrobin was first evaluated for toxicology and residues by the JMPR in 2008. It was evaluated for residues by the JMPR in 2011, 2012, 2013, 2017 and 2019. An ADI of 0–0.02 mg/kg bw was established and an ARfD was considered unnecessary.

The residue definition for compliance with the MRL and for dietary risk assessment for plant and animal commodities is parent azoxystrobin. The residue is fat soluble.

Azoxystrobin was scheduled at the Fifty-first Session of the CCPR for the evaluation of additional MRLs in 2021 and rescheduled to the 2022 JMPR. The current Meeting received additional analytical methods, storage stability data, GAP information and residue trial data from uses on mango, papaya, sugar beet, and sugar beet processed commodities.

Methods of analysis

Residue analytical method RAM 305/03 was used for the analysis of azoxystrobin in the supervised residue trials on mango, papaya, sugar beet, and the processing study on sugar beet. Method RAM 305 was previously validated as version RAM 305/01 in a wide range of crops and crop types by the 2008 JMPR. Method RAM 305/03 is procedurally the same as the version RAM 01 and validation data evaluated for RAM 305/01 are applicable to RAM 305/03.

Recoveries and percentRSDs for RAM 305/03 were within the acceptable range (70–120 percent). The LOQ is 0.01 mg/kg for all versions of the method and all plant commodities tested.

The Meeting concluded that RAM 305/03 was sufficiently validated and is suitable to measure azoxystrobin in mango peel and flesh, papaya peel and flesh, and sugar beet and its processed commodities.

Stability of pesticides residues in stored analytical samples

In 2008, the JMPR evaluated data on the stability of azoxystrobin in plant and animal commodities stored frozen at ≤-18 °C. The 2008 Meeting concluded that residues of azoxystrobin were stable for at least 24 months in high water and high starch commodities.

The Meeting concluded that the storage stability data are adequate to support the storage durations in studies provided to the current Meeting.

Results of supervised residue trials on crops

Mango

The cGAP for azoxystrobin on mango from Brazil is four foliar-directed applications at 120 g ai/ha with a 7-day PHI and 14-day re-treatment interval (RTI), followed by a post-harvest dip or spray application at 120 g ai/hL.

In independent trials matching the cGAP for foliar + post-harvest dip applications, residues of azoxystrobin in whole fruit were (n=4): 1.67, 1.93, 2.11, and 2.67 mg/kg.

In independent trials matching the cGAP for foliar + post-harvest spray applications, residues of azoxystrobin in whole fruit were (n=4): 1.66, 2.16, 2.31, and 2.54 mg/kg.

The Meeting considered the foliar + post-harvest dip and foliar + post-harvest spray applications independent and agreed to combine the data sets to estimate a maximum residue level.

Residues of azoxystrobin in mangos (whole fruit) from trials approximating the cGAP were (n=8): 1.66, 1.67, 1.93, 2.11, 2.16, 2.31, 2.54, and 2.67 mg/kg.

The Meeting estimated a maximum residue level (based on the mean + 4 SD) of 4 mg/kg (Po) for azoxystrobin in mangoes and withdrew its previous recommendation.

Residues in mango flesh from trials approximating cGAP were (n=8): 0.02 (4), 0.05, 0.06 (2), and 0.07 mg/kg.

The Meeting estimated an STMR of 0.035 mg/kg for mango flesh.

Papaya

The cGAP for azoxystrobin on papaya from Brazil is four foliar-directed applications at 100 g ai/ha with a 3 day PHI and 14 day re-treatment interval (RTI), followed by a post-harvest dip or spray application at 120 g ai/hL.

In independent trials matching the cGAP for foliar + post-harvest dip applications, residues of azoxystrobin were (n=4): 1.12, 1.13, 1.22, and 2.40 mg/kg.

In independent trials matching the cGAP for foliar + post-harvest spray applications, residues of azoxystrobin were (n=4): 0.93, 1.31, 1.33, and 1.50 mg/kg.

The Meeting considered the foliar + post-harvest dip and foliar + post-harvest spray applications independent and agreed to combine the data sets to estimate a maximum residue level.

Residues of azoxystrobin in mangos (whole fruit) from trials approximating the cGAP were (n=8): 0.93, 1.12, 1.13, 1.22, 1.31, 1.33, 1.50, and 2.40 mg/kg.

The Meeting estimated a maximum residue level (based on mean + 4 SD) of 4 mg/kg (Po) for azoxystrobin in papaya to replace its previous recommendation.

Residues in papaya flesh from trials approximating the cGAP were (n=8): 0.01, 0.05 (2), 0.10 (2), 0.12, 0.13, and 0.17 mg/kg.

The Meeting estimated an STMR of 0.10 mg/kg for papaya flesh.

Sugar beet

The critical GAP in the United States consists of one post-harvest application at a rate of 4.7 g ai/tonne roots.

In independent trials matching the cGAP, residues of azoxystrobin in sugar beet roots were (n=6): 0.73, 1.1, 1.3, 1.4, 2.0, 2.4 mg/kg.

The Meeting estimated a maximum residue level (based on mean + 4 SD) of 4 mg/kg (Po) and an STMR of 1.35 mg/kg for azoxystrobin in sugar beets. Furthermore, the Meeting withdrew its previous recommendation of 1 mg/kg for azoxystrobin in root and tuber vegetables except potato and recommended a new maximum residue level of 1 mg/kg for azoxystrobin in root and tuber vegetables except potato and sugar beet.

Fate of residues during processing

Processing factors and residue estimates for sugar beet processed commodities are summarised below.

Table 7 Processing factors and residue estimates for azoxystrobin

Raw commodity	STMR	Processed commodity	Processing Factors	STMR-P/ Median-P
Sugar beet root	1.35	Molasses	0.20	0.27
		Refined sugar	0.017	0.023
		Dried pulp	0.47	0.635
		Ensiled pulp	0.12	0.162

The Meeting estimated the STMR-Ps/median-Ps listed in Table 1 for use in dietary risk assessment and estimation of animal dietary burdens.

Residues in animal commodities

Dietary burdens were calculated for beef cattle, dairy cattle, broilers and laying poultry based on feed items evaluated by the JMPR. The dietary burdens, estimated using the 2018 OECD Feed diets listed in Appendix XIV Electronic attachments to the 2016 Edition of the FAO manual, are presented in Annex 6.

Of the commodities evaluated by the current Meeting, only sugar beet molasses, dried pulp, and ensiled pulp need consideration with respect to livestock diets.

Table 8 shows the dietary burdens calculated by the 2013 JMPR and the current Meeting.

Table 8 Estimated maximum and mean dietary burdens of farm animals

	Livestock dietary burden, azoxystrobin, ppm of dry matter diet (2013/2022)							
	Japan		**United States-Canada**		**European Union**		**Australia**	
	Max	Mean	Max	Mean	Max	Mean	Max	Mean
Beef cattle	0.96/6.9	0.96/1.8	17/25	12/16	61/63	25/26	72/83❶	51/51❸
Dairy cattle	16/19	3.0/3.5	30/45	12/14	74/81❷	29/31❹	46/51	20/22
Poultry – broiler	1.4/1.4	1.4/1.4	1.7/1.7	1.7/1.7	2.2/5.7	1.9/5.0	1.7/1.7	1.7/1.7
Poultry – layer	1.4/1.4	1.4/1.4	1.7/1.7	1.7/1.7	21/25❺	9.5/12❻	1.7/1.7	1.7/1.7

Notes:

❶ Highest maximum beef or dairy cattle burden suitable for MRL estimates for mammalian tissues.

❶ Highest maximum dairy cattle burden suitable for MRL estimates for milk

❸ Highest mean beef or dairy cattle burden suitable for STMR estimates for mammalian tissues

❹ Highest mean dairy cattle burden suitable for STMR estimates for milk.

❺ Highest maximum poultry broiler or layer burden suitable for MRL estimates for poultry eggs and tissues.

❻ Highest mean poultry broiler or layer burden suitable for STMR estimates for poultry eggs and tissues.

The Meeting noted that the new estimations did not result in a signification change of the dietary burdens of farm animals. Based on the minor change in livestock dietary burden, the Meeting did not recalculate residues in animal commodities or revise its recommendations for maximum residue levels.

RECOMMENDATIONS

On the basis of the data from supervised trials, the Meeting concluded that the residue levels listed in Annex 1 are suitable for establishing maximum residue limits and for IEDI and IESTI assessment.

Definition of the residue for compliance with the MRL and for dietary risk assessment for plant and animal commodities: *azoxystrobin*.

The residue is fat-soluble.

Table 9 Recommendations for residues of azoxystrobin from the 2022 JMPR

CCN	Crop/Commodity	MRL, mg/kg		STMR or STMR-P, mg/kg	HR or HR-P, mg/kg
		New	Previous		
FI 0345	Mango	4 (Po)	0.7	0.035	--
FI 0350	Papaya	4 (Po)	0.3	0.1	--
VR 0596	Sugar beet	4 (Po)	--	1.35	--

VR 0075	Group of root and tuber vegetables except potato and sugar beet	1	--	0.23	--
For dietary risk assessment and/or animal dietary burden calculation					
DM 0596	Sugar beet molasses	--	--	0.27	--
DM 3523	Sugar beet refined sugar	--	--	0.023	--
AM 3599	Sugar beet dried pulp	--	--	Median: 0.635	--
	Sugar beet ensiled pulp	--	--	Median: 0.162	--

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The ADI for azoxystrobin is 0–0.2 mg/kg bw. The International Estimated Daily Intakes (IEDIs) for azoxystrobin were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the previous and present JMPR. The results are shown in Annex 3 of the 2022 JMPR Report. The IEDIs ranged 3–20 percent of the maximum ADI.

The Meeting concluded that the long-term intake of residues of azoxystrobin from uses considered by the JMPR is unlikely to present a public health concern.

Acute dietary exposure

The 2008 Meeting determined that the establishment of an acute reference dose is unnecessary for azoxystrobin. The Meeting concluded that the acute dietary exposure to residues of azoxystrobin, from uses considered by the present Meeting, is unlikely to present a public health concern.

BENZOVINDIFLUPYR (261)

First draft prepared by T. van der Velde-Koerts, Centre for Nutrition, Prevention and Health Services (VPZ), National Institute for Public Health and the Environment (RIVM), The Netherlands

EXPLANATION

Benzovindiflupyr is a broad-spectrum fungicide first evaluated by JMPR in 2013 for Toxicology and in 2014 for Residues. The compound was re-evaluated in 2016, 2018 and 2019 for additional uses.

An ADI of 0–0.05 mg/kg bw and an ARfD of 0.1 mg/kg bw were established by the 2013 JMPR. The 2014 JMPR Meeting recommended the residue definition for plant and animal commodities (for compliance with MRLs and for estimation of dietary intake) as: benzovindiflupyr. The residue is fat soluble.

Benzovindiflupyr was scheduled at the Fifty-first Session of the CCPR for evaluation of additional uses by the 2021 JMPR and rescheduled for evaluation by the 2022 JMPR. The Meeting received additional information from the manufacturer on the toxicity of metabolites, method of residue analysis, use patterns, supervised residue trials (blueberries, dried ginseng, sugar beets and maize) and processing studies on sugar beets.

RESIDUE ANALYSIS

Analytical methods used in supervised residue trials

HPLC-MS/MS Method GRM042.03A

The Meeting received additional reduced validation data for blueberries, dried ginseng roots, sugar beet commodities and maize commodities for HPLC-MS/MS Method GRM042.03A (dated 4 August 2011). This method was summarized and evaluated by the JMPR 2014 and was considered valid for the determination of parent and metabolite SYN 546039 (free and conjugated) in the range 0.01–0.1 mg/kg for apples, grapes, wheat (forage, grain, hay, straw, flour), spinach, lettuce, peanuts, coffee beans, carrot (roots and leaves), turnip (roots and leaves), radish (roots and leaves), orange juice and sugarcane. The valid range was extended to 0.5 mg/kg for wheat forage and wheat hay.

Blueberries

Blueberries were analysed for benzovindiflupyr using a modification of method GRM042.03A. The modification was described in [Byeongseok, 2019, VV-619742 and Clark, 2016, 2017] and was dated 8 December 2016 (equivalent to 23 January 2017). The modifications involved direct determination of the parent compound without clean-up and a change in HPLC-MS/MS conditions. The metabolite SYN 546039 was not determined.

Blueberries (10 g) were extracted by homogenization in 80/20 (v/v) acetonitrile/water followed by centrifugation. The supernatants were diluted with acetonitrile/water (50:50, v:v) and analysed for benzovindiflupyr by UPLC-MS/MS using negative ion – turbo ion spray ionization – Q-trap triple quadrupole mass spectrometry with multiple reaction monitoring (MRM). Benzovindiflupyr was monitored at m/z 395.9 (Q1) and 90.9 (Q3) for quantification and at m/z 395.9 (Q1) and 368 (Q3) or 324 (Q3) for confirmation.

Dried ginseng roots

Dried ginseng roots were analysed for benzovindiflupyr and the metabolite SYN 546039 including its conjugates using a modification of method GRM042.03A. The modification (WO 9.222 v1) was described in [Lennon, 2019, VV-547840] and was dated 18 October 2017. The modification included a change in acid hydrolysis concentration to release the SYN 546039 aglycon, change in clean-up procedures, the use of matrix matched standards for SYN 546039 and a change in HPLC-MS/MS instrumentation and conditions.

Homogenised dried ginseng roots (5 g) were pre-soaked with water for 30 min. The samples were extracted by homogenization with 80/20 (v/v) acetonitrile/water, followed by centrifugation. An aliquot of the supernatant was removed, the acetonitrile was evaporated off and 1 M HCl added. The acidified aliquot was partitioned four times with iso-hexane to separate parent off.

The combined iso-hexane fractions containing the parent compound were evaporated to dryness, dissolved in acetonitrile/water (50:50, v/v) and analysed for benzovindiflupyr by UPLC-MS/MS using negative ion – electrospray ionization (ESI-) – Q-trap triple quadrupole mass spectrometric detection with multiple reaction monitoring (MRM). Benzovindiflupyr was monitored at m/z 396 (Q1) and 91 (Q3) for quantification and at m/z 396 (Q1) and 368 (Q3) for confirmation.

The acidic aqueous fraction containing the metabolite SYN 546039 and its conjugates was heated in a water bath at 100°C and agitated for 6 hours to hydrolyse conjugates of SYN 546039. The samples were cooled and cleaned up on an Agilent Bond Elut Phenyl Modified (PH) SPE column, followed by clean-up with aminopropyl functionated silica gel (PSA). The eluant was diluted with acetonitrile/water (50:50, v/v) and analysed for SYN 546039 by UPLC-MS/MS using negative ion – electrospray ionization (ESI-) – Q-trap triple quadrupole mass spectrometric detection with multiple reaction monitoring (MRM). SYN 546039 was monitored at m/z 412 (Q1) and 91 (Q3) for quantification and at m/z 412 (Q1) and 340 (Q3) for confirmation using matrix matched standards.

Sugar beet tops, sugar beet roots, dried pulp

Sugar beet commodities were analysed for benzovindiflupyr and the metabolite SYN 546039 including its conjugates using a modification of method GRM042.03A. The modification was described in [Dorsey, 2019, VV-547512; Shepard, 2019, VV-547573 and Rodgers, 2015a] and was dated 23 October 2015 (sugar cane). Modifications included a change in acid hydrolysis concentration to release the SYN 546039 aglycon, change in clean-up and HPLC-MS/MS instrumentation and conditions.

Sugar beet tops, roots, and dried pulp samples were extracted with acetonitrile:water (80:20, v:v) using a homogenizer followed by centrifugation. Aliquots of the extract were diluted with acetonitrile:water (50:50, v:v) and analysed for benzovindiflupyr by HPLC-MS/MS using positive ion – turbo ion spray (TIS) – triple quadrupole mass spectrometric detection with multiple reaction monitoring (MRM). Benzovindiflupyr was monitored at m/z 398 (Q1) and 342 (Q3) for quantification and at m/z 398 (Q1) and 322 (Q3) or 286 (Q3) for confirmation.

For the analysis of the metabolite SYN 546039 (including its conjugates), additional aliquots of the acetonitrile:water extracts were evaporated in a heated water bath to remove the acetonitrile. Aqueous 1 M HCl was added, followed by three partitions with iso-hexane. The acidic, aqueous fraction was collected and heated at 100 °C for six hours in a heating block with regular, manual agitation to hydrolyse conjugates of SYN 546039. The samples were cooled and taken through a Waters Oasis HLB SPE cartridge. SYN 546039 was eluted from the cartridge with acetonitrile:water (50:50, v/v). Samples were diluted with acetonitrile:water (50:50, v/v) and analysed for SYN 546039 by HPLC-MS/MS using positive ion–turbo ion spray (TIS)–triple quadrupole mass spectrometric detection with multiple reaction

monitoring (MRM). SYN 546039 was monitored at m/z 414 (Q1) and 159 (Q3) for quantification and at m/z 414 (Q1) and 238 (Q3) for confirmation.

Sugar beet refined sugar and sugar beet molasses

Sugar beet commodities were analysed for benzovindiflupyr and the metabolite SYN 546039 including its conjugates using modifications of method GRM042.03A [Dorsey, 2019, VV-547512; Shepard, 2019, VV-547573 and Rodgers, 2015b, Rodgers, 2015c] dated 30 November 2015 (molasses) and 17 December 2015 (refined sugar). The modification included a change in extraction solvent, change in acid hydrolysis concentration to release the SYN 546039 aglycon, change in clean-up and HPLC-MS/MS instrumentation and conditions.

Refined sugar samples were dissolved in water and molasses samples were dissolved in acetonitrile:water (50:50, v:v). Aliquots of the molasses samples were evaporated in a heated water bath to remove the acetonitrile. Aliquots of the sugar and molasses samples were acidified with aqueous 1 M HCl. The acidified aliquot was partitioned with iso-hexane to separate parent compound off. The iso-hexane fraction was diluted with acetonitrile/water (50:50, v/v) and analysed for benzovindiflupyr by HPLC-MS/MS using positive ion – turbo ion spray (TIS) – triple quadrupole mass spectrometric detection with multiple reaction monitoring (MRM). Benzovindiflupyr was monitored at m/z 398 (Q1) and 342 (Q3) for quantification and at m/z 398 (Q1) and 322 (Q3) or 286 (Q3) for confirmation

The acidic, aqueous fraction containing SYN 546039 and its conjugates was heated at 100 °C for six hours in a heating block to hydrolyse conjugates of SYN 546039. The samples were cooled and taken through a Waters Oasis HLB SPE cartridge. SYN 546039 was eluted from the cartridge with acetonitrile:water (50:50, v:v). Samples were diluted with acetonitrile:water (50:50, v:v) then analysed for SYN 546039 by HPLC-MS/MS using positive ion – turbo ion spray – triple quadrupole mass spectrometric detection with multiple reaction monitoring (MRM). SYN 546039 was monitored at m/z 414 (Q1) and 159 (Q3) for quantification and at m/z 414 (Q1) and 238 (Q3) for confirmation.

Maize forage, fodder and grains

Maize commodities were analysed for benzovindiflupyr and the metabolite SYN 546039 including its conjugates using a modification of method GRM042.03A. The modification is described in [Banman, 2020, VV-872218]. The modification involved direct determination of the parent compound without clean-up, a change in acid hydrolysis concentration to release the SYN 546039 aglycon and a change in HPLC-MS/MS conditions.

Maize forage (10 g) was extracted by homogenization in 80/20 (v/v) acetonitrile/ water, followed by centrifugation. Maize stover and maize grains, 5 g sub samples were pre-soaked with water prior to homogenization with 80/20 (v/v) acetonitrile/ water. An aliquot of the supernatant was diluted with acetonitrile/water (50:50, v:v) and analysed for benzovindiflupyr by HPLC-MS/MS with negative ion – electrospray ionization (ESI) – tandem mass spectrometry with multiple reaction monitoring (MRM). Benzovindiflupyr was monitored at m/z 396.1 (Q1) and 91 (Q3) for quantification and at m/z 398 (Q1) and 368 (Q3) for confirmation.

For the analysis of the metabolite SYN 546039 (including its conjugates), additional aliquots of the acetonitrile:water extracts were evaporated in a heated water bath to remove the acetonitrile. Aqueous 1 M HCl was added, followed by three partitions with iso-hexane. The acidic, aqueous fraction was collected and heated at 100 °C for six hours in a heating block with regular, manual agitation to hydrolyse conjugates of SYN 546039. The samples were cooled and taken through a Waters Oasis HLB SPE cartridge. SYN 546039 was eluted from the cartridge with acetonitrile:water (50:50, v:v). Samples

were diluted with acetonitrile:water (50:50, v/v) and analysed for SYN 546039 by HPLC-MS/MS with negative-ion – electrospray ionization (ESI) – triple quadrupole mass spectrometry with multiple reaction monitoring (MRM). SYN 546039 was monitored at m/z 395.5 (Q1) and 90.9 (Q3) for quantification and at m/z 395.5 (Q1) and 368 (Q3) for confirmation.

The analytical method was validated by spiking macerated samples with benzovindiflupyr just before extraction and by spiking the hydrolysates with SYN 546039 (just after hydrolysis at 100 °C and subsequent cooling). Validation results for blueberries, dried ginseng roots, sugar beet commodities and maize commodities are shown in Table 1 (benzovindiflupyr) and Table 2 (metabolite SYN 546039).

Remark by the reviewer:

- Samples were fortified with the free form of SYN536039 just after the acid hydrolysis procedure and thus validation only covers the clean-up part. The JMPR 2014 report indicates that acceptable reduced validation data were available, where SYN 546039 was added before extraction. In addition, the JMPR 2014 report indicates that acceptable validation data are available for the hydrolysis of SYN546039 conjugates using 0.5 M HCl in a radio-validation study. The acid concentration has changed from 0.5 M HCl in the original method to 1 M HCl in the current method. As the hydrolysis efficiency is acceptable at the 0.5 M HCl treatment, it can be assumed that the hydrolysis efficiency is also acceptable at 1 M HCl.
- HPLC-MS/MS method GRM042.03A modifications are considered reduced validated for the determination of benzovindiflupyr in the range 0.01–3.0 mg/kg in maize stover, 0.01–2.0 mg/kg in blueberries and 0.01–1.0 mg/kg in dried ginseng roots, sugar beet commodities (roots, tops, dried pulp, molasses, refined sugar) and 0.01–0.1 mg/kg in other maize commodities (grain, forage).
- HPLC-MS/MS method GRM042.03A modifications are considered reduced validated for the determination of SYN546039 (including its conjugates) in the range 0.01–1.0 mg/kg in sugar beet commodities (roots, tops, dried pulp, molasses, refined sugar) and 0.01–0.1 mg/kg in dried ginseng roots and maize commodities (grain, forage, stover).

Notes:

[a] SYN 546039 was spiked after hydrolysis.

USE PATTERN

The Meeting received new authorised labels from the United States for lowbush blueberries, ginseng, sugar beet and maize. These are summarised in Table 3.

The label indicates a plant back interval of 6 months (180 days), except for crops mentioned in the United States label (i.e. lowbush blueberries, bulb vegetables, rape seed (canola), wheat, barley, triticale, rye, oat, maize (field corn, popcorn), sweet corn, cotton, cucurbit vegetables, fruiting vegetables, ginseng, grasses grown for seed (bluegrass, bromegrass, fescue, orchard grass, ryegrass), pulses (dry legumes), peanuts, potatoes, soya beans, sugar beets, sugar cane, tomatoes, tuberous and corm vegetables).

Table 3 Registered outdoor pre-harvest uses of benzovindiflupyr

Crop	Country	Form (g ai/L)	Application				PHI, days
			Method	Rate kg ai/ha	Water L/ha	Number (RTI in days)	
Blueberries lowbush	United States	EC 100	foliar spray [d]	0.076 max seasonal rate 0.15	[c]	2 (10-14)	1
Ginseng	United States	EC 100	foliar spray [d]	0.076 max seasonal rate 0.31	[c]	4 (14)	15
Sugar beet	United States	EC 100 [a]	in furrow or banded soil application followed by a foliar spray [d]	0.075 [b] maximum seasonal rate 0.15	[c]	1 soil + 1 foliar	soil at 2-8 leaf stage; foliar up to BBCH 31
	United States	EC 100 [a]	foliar spray [d]	0.075 [b] max seasonal rate 0.15	[c]	2 (5-14)	up to BBCH 31
Maize (field corn; popcorn)	United States	EC 100 [a]	foliar spray [d]	0.029-0.051 max seasonal rate 0.10	[c]	2 (14)	7
Maize [e]	Canada	EC 100	foliar spray (aerial or field sprayers)	0.030-0.075 max seasonal rate 0.15	[f]	2 (7)	7 [g h]

Notes:

[a] For foliar sprays, the addition of a spreading/penetrating type adjuvant such as organo-silicon blends with either non-ionic surfactants (NIS) or vegetable based crop oils (COC); or vegetable based COC (not mineral); or NIS with at least 90 percent concentration is recommended. Sugar beet soil applications: tank mixtures with crop oil concentrates (COC) or methylated spray oil (MSO) may result in sugar beet crop injury.

[b] Dose rates for in-furrow or banded soil applications are based on planted row spacing and row width.

[c] For foliar sprays, thorough coverage is necessary to provide good disease control. Ground equipment: apply in a minimum of 93 L/ha (10 GPA) for sugar beet (soil and foliar applications) and maize, 187 L/ha (20 GPA) for lowbush blueberries, 467 L/ha (50 GPA) for ginseng. Aerial equipment: apply in a minimum of 19 L/ha (2 GPA) for lowbush blueberries, ginseng, maize and sugar beet foliar applications. Do not apply through any ultra-low volume sprays.

[d] Foliar sprays may be applied by all types of spray equipment commonly used for making ground and aerial applications. Ginseng, sugar beets and maize may also be treated by chemigation (i.e. irrigation equipment).

[e] Maize includes field corn, sweet corn, popcorn and specialty including all cultivars and/or hybrids of these, including seed production.

[f] For foliar sprays, thorough coverage is necessary to provide good disease control. Ground equipment: apply in a minimum of 200 L/ha for maize. Aerial equipment: apply in a minimum of 45 L/ha. Do not apply through any ultra-low volume sprays.

[g] PHI of 7 days for forage, sweet corn and maize grain

[h] Rotational crop restriction of 180 days. No rotational crop restrictions for tuberous and corm vegetables (including potatoes), pulses (including soya beans); fruiting vegetables (including cucurbits), cereals, maize and rapeseed.

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received supervised trials to support additional MRLs for benzovindiflupyr- (Table 4).

In many trials duplicate field samples were taken and analysed separately; in the residue trials summary tables, the individual residue results for duplicate field samples were presented together with their mean (in parenthesis). When residues were not quantifiable they were shown as below the LOQ (e.g. < 0.01 mg/kg). Residues, application rates and spray concentrations were rounded to two significant figures; unrounded figures were used to calculate mean residues. Results were not corrected for concurrent method recoveries. Data used in estimation of MRL, HR and STMR values were underlined in the residue trials summary tables. Where higher residue values occurred at longer PHIs than the cGAP, these higher values were underlined and used in the estimation.

Subgroup of Bush berries (004B)

Blueberries

The Meeting received nine supervised residue trial data on highbush and lowbush blueberries conducted outdoors in Canada in 2016 [Byeongseok, 2019, VV-619742]. Highbush and lowbush blueberries were sprayed two times with an EC formulation in the range between 0.074–0.079 kg ai/ha for each application, using 246–287 L/ha water. Two trials were conducted at exaggerated rates. Non-ionic surfactants were added to the tank mix. The application was by tractor mounted CO_2 sprayer or hand-held CO_2 sprayer. No rain occurred within 24 hours after the first or second application, except for trial 154.

Sampling: For lowbush blueberries, mature fruits were harvested with a hand rake in a diagonal swath across the plot avoiding at least 0.5 m from plot ends. Individual plots were at least 60 m^2. Samples were collected from 12–14 areas within the plot and from high and low areas of the plant, which contained sheltered and exposed fruits. Collected berries were placed on a clean screen and a fan was used to remove leaves and stems. Two replicate samples were collected from each plot. Each sample weighed between 0.5–0.9 kg.

For highbush blueberries (and lowbush trial 288), mature fruits were handpicked from two sides of the row, avoiding the bush at the row ends. Individual plots consisted of at least 6 plants. Samples were collected from at least 12 areas in the plot, from inside and outside, top and bottom, exposed and sheltered areas of bushes. Stems and leaves were removed while harvesting. Two replicate samples were collected from each plot. Each sample weighed between 0.5–0.9 kg.

Storage: Blueberries were frozen within 7 hrs after harvest and were stored for 155–227 days (7.5 months) at -10 °C or lower. Actual storage temperatures reached -5.9 °C for trial 160.

Analysis: Benzovindiflupyr was determined in the homogenised berries using a modification of HPLC-MS/MS method GRM042.03A with an LOQ of 0.01 mg/kg. Individual concurrent recoveries ranged from 98–108 percent at 0.01–2.0 mg/kg. Residues in the control samples were <LOQ (n=10). Table 5

The results for replicate field samples and their average are shown in Table 5. Average benzovindiflupyr concentrations ranged between 0.22–0.87 mg/kg. Highest benzovindiflupyr concentration in an individual sample was 1.1 mg/kg benzovindiflupyr (trial 159).

Remarks by the reviewer:

- The United States label refers to lowbush blueberries only.
- Sample sizes of blueberries in study VV-619742 (0.5–0.9 kg) are lower than recommended in the FAO manual (at least 1 kg) for representative samples.
- The demonstrated storage stability of 24 months at -18 °C in high acid commodity groups (oranges) by JMPR 2014 covers the storage period of 227 days for blueberries in study VV-619742. However, as the samples in study VV-19742 were stored frozen at a higher temperature, i.e., -10 °C (one trial at -5.9 °C), it is not clear whether degradation of residues occurred.
- The modification of HPLC-MS/MS method GRM042.03A is reduced validated for the determination of benzovindiflupyr in blueberries in the range 0.01–2.0 mg/kg. The benzovindiflupyr concentrations reported in study VV-619742 are covered by the validation of this analytical method.
- SYN 546039 was not analysed for in the blueberry samples.

Notes:

[a] 0.2 percent v/v Agral 90 non-ionic surfactant (NIS) was added to the tank mix.

[b] First rain started within 3 hrs after the second application (0.2 mm rain) in trial 154.

Subgroup of Root Vegetables (016A)

Ginseng – dried ginseng

The Meeting received four supervised residue trial data on ginseng conducted outdoors in the United States in 2016 [Lennon, 2019, VV-547840]. Three to five year old ginseng plants under a shade structure were sprayed four times with an EC or SC formulation in the range between 0.073–0.080 kg ai/ha for each application, using 626–682 L/ha water. Non-ionic surfactants were added to the tank mix. The applications were by CO_2 backpack sprayer. No rain occurred within 24 hours after each of the applications, except for trial MI182.

Ginseng plants were grown in different soil types to allow production of different shapes of ginseng roots: long thin roots are expected from sandy soils and shorter roots with more branching are expected from heavier soils.

Sampling: Fresh ginseng roots were collected from 12 impartially selected areas of each plot and avoiding 15 cm inches from bed sides and 1.8 m from bed ends. Roots were collected by using potato forks to loosen the soil around the roots after which they were handpicked. Two replicate samples were collected from each plot. Each sample weighed 4.1–4.5 kg (9–10 lbs).

Roots were hand washed by softly agitating the roots until the majority of the dirt was removed. Roots were spread onto drying racks in a commercial dryer. Fresh ginseng roots were dried for 6–8 days to an estimated 70 percent to 90 percent dry matter content using a commercial protocol. Dried ginseng root samples weighed at least 0.91 kg (2 lbs), except for trials MI214 and MI215, where samples weighed 0.77–0.87 kg (1.71–1.93 lbs).

The commercial protocol consisted of forced air-drying in a commercial tray dryer at 38 °C (32–38 °C) at a relative humidity of 45 percent (30–45 percent) and an air-flow rate of 0.7 ft/s [Answers to Questions, July 2021] Typical drying times under these conditions are 8–14 days depending on the root diameter and tray loading rate. Actual dry matter content of the individual ginseng root samples was not measured nor recorded [Answers to Questions, July 2021].

Storage: Dried ginseng roots were frozen within 1 hr after the drying was complete and were stored for 399–460 days (15 months) at -18 °C or lower.

Analysis: Benzovindiflupyr and metabolite SYN 546039 (including its conjugates) were determined in the dried ginseng roots using a modification of HPLC-MS/MS method GRM042.03A with an LOQ of 0.01 mg/kg for each analyte. Mean concurrent recoveries in dried ginseng roots ranged from 71–71 percent at 0.01–1.0 mg/kg for benzovindiflupyr and 69–112 percent at 0.01–0.1 mg/kg for SYN 546039. Residues in the control samples were < LOQ (n=4) for each analyte.

The results for replicate field samples and their average are shown in Table 6. Average benzovindiflupyr concentrations in dried ginseng roots ranged between 0.030–0.14 mg/kg. Highest residue in an individual sample was 0.16 mg/kg benzovindiflupyr (trial 16-MI215). SYN 546039 (including conjugates) residues were < 0.01 mg/kg in each individual sample.

Remarks by the reviewer:

- Sample sizes of fresh ginseng roots in study VV-547840 (12 roots; 4.1–4.5 kg) are compliant with the recommendations in the FAO manual (12 roots; at least 2 kg) for representative samples.
- The demonstrated storage stability of 24 months at -18 °C in high starch commodity groups (wheat grain, potato) and dried commodities (wheat straw, dried fruits) by JMPR 2014 covers the storage period of 399–460 days (15 months) for dried ginseng roots in study VV-547840.
- The modification of HPLC-MS/MS method GRM042.03A is reduced validated for the determination of benzovindiflupyr in dried ginseng roots in the range 0.01–1.0 mg/kg and SYN546039 including conjugates in the range 0.01–0.1 mg/kg. The benzovindiflupyr and SYN546039 (including conjugates) concentrations in study VV-547840 are covered by the validation of this analytical method.
- According to the Codex Classification, ginseng should comply with Codex Standard 295R-2009. This regional standard has been replaced by Codex Standard 321-2015. Codex Standard 321-2015 stipulates that dried ginseng roots should contain no more moisture than 14.0 percent (i.e. have a dry matter content of at least 86.0 percent). The actual dry matter content of the

individual dried ginseng root samples from the supervised field trials were not reported, but were estimated at 70–90 percent in the study report.

Notes:

DAT + DT = harvest at indicated days after treatment followed by drying time (in days) after which dried ginseng roots were stored frozen.

[a] Scanner non-ionic surfactants (NIS) was added to the tank mix at an unstated concentration.

[b] First rain started 1 hr after the second application (0.13 inches of rain) for trial MI182.

Sugar beet roots

The Meeting received 24 supervised residue trial data on sugar beets conducted outdoors in the United States in 2017 and 2018 and in Canada in 2017 [Dorsey, 2019, VV-547512; Shepard, 2019, VV-547573]. Sugar beet plants were treated with two applications of a WG or EC formulation in the range between 0.072–0.083 kg ai/ha for each application, using 93–410 L/ha water. The first application was performed as an in-furrow or banded soil application at sowing/planting (BBCH 00). The second application was

performed at BBCH 30–32 as a banded foliar application, except United States trials TK0296310 -03 and -05 where a broadcast foliar application was performed and Canadian trials TK03034334-03 and -04 where the second application was at BBCH 19–32 and BBCH 12–32, respectively. The foliar application was made in conjunction with either a non-ionic surfactant (NIS) or crop oil concentrate (COC) tank mix adjuvant. Two United States trials (TK0296310 -01 and -02) included an additional plot treated at an exaggerated rate to obtain samples for processing. The applications were made by handheld, backpack, tractor- or ATV-mounted sprayers (ATV = all-terrain vehicle). Information on rain within 24 hrs after each application was not stated in the report.

Sampling: From the United States trials at least 12 sugar beet plants were collected at normal commercial harvest (BBCH 47–50, i.e. when beets have reached 70–100 percent of their normal size). Sugar beet plants in trial TK0296310-07 were harvested at BBCH 39 (when leaves cover 90 percent of the soil, and roots are small). Sugar beet plants were separated into tops and roots. Two replicate samples were collected from each plot. Sample weights were not stated in the report.

The sample weights for the 12 roots from the immature sugar beet plants from trial TK0296310-07 were 5.6 kg (13.0 lbs) for each of the replicate samples [Answers to questions, July 2021].

Sugar beet plants from the Canadian trials were collected at maturity (BBCH 49); sugar beet plants in trial TK03043334-03 (at DAT 69) were harvested at BBCH 39–49, which is a broad range of beets having reached 0 to 100 percent of their normal size). Two replicate samples were collected from each plot. The sample weights and number of sampled sugar beet plants were not stated in the report.

In the Canadian trials 12 sugar beet plants were harvested for each replicate sample. The small roots from the immature sugar beet plants from trial TK03043334-03 weighted 5.6–9.4 kg for each of the replicate samples at each pre-harvest interval [Answers to questions, July 2021].

Storage: Samples were frozen and stored for 2.0–14.2 months at -10 °C or lower.

Analysis: Benzovindiflupyr and metabolite SYN 546039 (including its conjugates) were determined in the sugar beet roots using a modification of HPLC-MS/MS method GRM042.03A with an LOQ of 0.01 mg/kg for each analyte. Individual concurrent recoveries in sugar beets roots ranged from 79–109 percent at 0.01–1.0 mg/kg for benzovindiflupyr and 76–116 percent at 0.01–0.1 mg/kg for SYN 546039. Residues in the control samples were < LOQ (n=22) for each analyte.

The results for replicate field samples and their average are shown in Table 7. Average benzovindiflupyr concentrations in sugar beet roots ranged between <0.01–0.073 mg/kg. Highest residue in an individual sample was 0.076 mg/kg benzovindiflupyr (trial TK0296310–05). SYN 546039 (including conjugates) residues were < 0.01 mg/kg in each individual sugar beet root sample.

Remarks by the reviewer:

- Two of the Canadian trials, TK-0304334-04 and -06 took place at the same location. As the planting and application differed by 30 days, these trials are considered to be independent.
- Sample sizes in the United States study VV-547512 and the Canadian study VV-547573 are compliant with the recommended sample size in the FAO manual (at least 12 plants).
- In trial TK0296310-07, the sugar beet plants were harvested at BBCH 39 and in trial TK03043334-03, the sugar beet plants were harvested at BBCH 39–49. Although BBCH 39 reflects immature plants, sample weights for these 12 roots were at least 5.6 kg (460 g/root) and can thus be considered representative for MRL derivation.

- The demonstrated storage stability of 24 months at -18 °C in high starch commodity groups (wheat grain, potato) by JMPR 2014 covers the storage period of 2.0–14.2 months for sugar beet roots in study VV-547512.
- The modification of HPLC-MS/MS method GRM042.03A is reduced validated for the determination of benzovindiflupyr and SYN 546039 (including its conjugates) in sugar beet roots in the range 0.01–1.0 mg/kg. The benzovindiflupyr and SYN 546039 (including conjugates) concentrations in studies VV-547512 and VV-547573 are covered by the validation of this analytical method.

Notes:

[a] For the foliar applications crop oil concentrates (COC) or non-ionic surfactants (NIS) were added to the tank mix. **COC**: Superb HC 0.5 percent-1.0 percent v/v (United States trial 01, 06, 08); Prime oil 0.5-1.0 percent v/v (United States trial 03, 05, 13, 14), Chem Spray 1 percent v/v (United States trial 04), Herbimax 0.6 percent v/v (United States trial 09), **NIS**: Preference 0.25 percent v/v (United States, trial 02, 12), Induce 0.12 percent v/v (United States trial 07, Kinetic 0.3 percent v/v (United States trial 10), R-11 0.13 percent v/v (United States trial 11), Agral 90 0.2 percent v/v (Canada trial 01, 02, 03, 04, 05, 06, 07, 08).

[b] Samples used in the sugar beet root processing study.

Subgroup of Maize Cereals (020E)

Maize

Data from supervised residue trials on maize in the United States were summarized and evaluated by the JMPR 2016. The Meeting received an additional eight supervised residue trial data on maize conducted outdoors in the United States in 2019 [Banman, 2020, VV-872218]. Plots with maize plants were treated with two broadcast foliar sprays with an EC formulation in the range between 0.050–0.053 kg ai/ha for each application using 121–224 L/ha water. Non-ionic surfactants or crop oil concentrates were added to the tank mix. The application was by backpack or tractor-mounted sprayer. Information on rain within 24 hrs after each application was not stated in the report.

Sampling: Whole maize plants were harvested at BBCH 89 and separated into maize grains and remaining plants. Maize grains were collected from at least 12 areas of the plot. Two replicate samples were collected from each plot. Each sample weighed at least 1 kg.

Storage: Samples were frozen and stored for 212–344 days (9.4–11.3 months) at -10 °C or lower.

Analysis: Benzovindiflupyr and metabolite SYN 546039 (including its conjugates) were determined in the maize grains using HPLC-MS/MS method GRM042.03A with an LOQ of 0.01 mg/kg for each analyte. Individual concurrent recoveries in maize grains ranged from 89–120 percent at 0.01–0.1 mg/kg for benzovindiflupyr and 82–98 percent at 0.01–0.1 mg/kg for SYN 546039. Residues in the control samples were < LOQ (n=10) for each analyte.

The results for replicate field samples and their average are shown in Table 8. The average benzovindiflupyr concentrations in maize grains ranged between <0.01–0.016 mg/kg. Highest residue in an individual sample was 0.019 mg/kg benzovindiflupyr (TK0462705-03 – P3). SYN 546039 (including conjugates) residues were < 0.01 mg/kg in each individual maize grain sample.

Remarks by the reviewer:

- Sample sizes of maize grains in study VV-872218 (1 kg) are compliant with the recommendation in the FAO manual (at least 1 kg) for representative samples.
- The demonstrated storage stability of 24 months at -18 °C in high starch commodity groups (wheat grain, potato) by JMPR 2014 covers the storage period of 212–344 days (9.4–11.3 months) for maize grains in study VV-872218.
- The modification of HPLC-MS/MS method GRM042.03A is reduced validated for the determination of benzovindiflupyr and SYN546039 (including conjugates) in maize grains in the range 0.01–0.1 mg/kg. The benzovindiflupyr and SYN 546039 (including conjugates) concentrations in study VV-872218 are covered by the validation of this analytical method.

Cereal grains and grasses feed products – subgroup of products with high water content (050B)

Maize forage

Data from supervised residue trials on sweet corn forage and maize forage from the United States were summarized and evaluated by the JMPR 2016. The Meeting received an additional eight supervised residue trial data on maize forage conducted outdoors in the United States in 2019 [Banman, 2020, VV-872218]. As the whole plants were harvested at BBCH 85–89, they are considered not representative for green forage plants, as the plants already lost moisture and thus may have concentrated their residues. The trials were listed together with maize stover.

Cereal grains and grasses feed products – subgroup of products with low water content (051B)

Maize stover

Data from supervised residue trials on sweet corn stover and maize stover in the United States were summarized and evaluated by the JMPR 2016. The Meeting received an additional eight supervised residue trial data on maize whole plants and maize stover conducted outdoors in the United States in 2019 [Banman, 2020, VV-872218]. Plots with maize plants were treated with two broadcast foliar sprays with an EC formulation in the range between 0.050–0.053 kg ai/ha for each application using 121–224 L/ha water. Non-ionic surfactants or crop oil concentrates were added to the tank mix. The application was by backpack or tractor-mounted sprayer. Information on rain within 24 hours after each application was not stated in the report.

Sampling: Plot P2 at each location (trials submitted as maize forage whole plants but considered stover) was treated at growth stage BBCH 75–85 and whole maize plants were harvested at BBCH 85–87. Plot P3 at each location (trials submitted as maize stover) was treated at growth stage BBCH 87–89 and whole maize plants were harvested at BBCH 89 and separated into maize grains and remaining plants (stover). Maize whole plants and maize stover were collected from at least 12 plants and from 12 areas of the plot. Two replicate samples were collected from each plot. Each sample weighed at least 1 kg.

Storage: Samples were frozen and stored for 212–344 days (9.4–11.3 months) at -10 °C or lower.

Analysis: Benzovindiflupyr and metabolite SYN 546039 (including its conjugates) were determined in the maize whole plants and maize stover using HPLC-MS/MS method GRM042.03A with an LOQ of 0.01 mg/kg for each analyte. Mean concurrent recoveries in maize whole plants and maize stover ranged from 94–103 percent at 0.01–3.0 mg/kg for benzovindiflupyr and 74–82 percent at 0.01–0.1 mg/kg for SYN 546039. Residues in the control samples were < LOQ (n=10) for each analyte.

The results for replicate field samples and their average are shown in Table 9. The average benzovindiflupyr concentrations in maize whole plants and maize stover ranged between 0.10–2.9 mg/kg. Highest residue in an individual sample was 2.9 mg/kg benzovindiflupyr. SYN 546039 (including conjugates) residues were < 0.01 mg/kg in each individual maize whole plant and maize stover sample.

Remarks by the reviewer:

- Trials submitted as maize forage (Plot P2 at each location) were treated at growth stage BBCH 75–85 and whole maize plants were harvested at BBCH 85–87. As the whole plants were harvested at BBCH 85–89, they are considered not representative for green forage plants, as the plants already lost moisture and thus may have concentrated their residues. The trials were listed together with maize stover.
- Sample sizes of whole maize plants and maize stover in study VV-872218 (12 plants) are compliant with the recommendation in the FAO manual (at least 12 plants) for representative samples.
- The demonstrated storage stability of 24 months -18 °C in dried commodity groups (wheat straw) by JMPR 2014 covers the storage period of 212–344 days (9.4–11.3 months) for maize whole plants and maize stover in study VV-872218.
- The modification of HPLC-MS/MS method GRM042.03A is reduced validated for the determination of benzovindiflupyr in maize whole plants and maize stover in the range 0.01–3.0 mg/kg and SYN 546039 (including conjugates) in the range 0.01–0.1 mg/kg. The benzovindiflupyr and SYN 546039 (including conjugates) concentrations in study VV-872218 are covered by the validation of this analytical method.

Sugar beet tops

The Meeting received 22 supervised residue trial data on sugar beets conducted outdoors in the United States in 2017 and 2018 and Canada in 2017 and 2018 [Dorsey, 2019, VV-547512; Shepard, 2019, VV-547573]. Sugar beets were treated with two applications of a WG or EC formulation in the range between 0.072–0.083 kg ai/ha for each application, using 93–410 L/ha water. The first application was performed as an in-furrow or banded soil application at sowing/planting (BBCH 00). The second application was

performed at BBCH 30–32 as a banded foliar application, except United States trials TK0296310 -03 and -05 where a broadcast foliar application was performed and Canadian trials TK03034334-03 and -04 where the second application was at BBCH 19–32 and BBCH 12–32, respectively. The foliar application was made in conjunction with either a non-ionic surfactant (NIS) or crop oil concentrate (COC) tank mix adjuvant. The applications were made by handheld, backpack, tractor- or ATV-mounted sprayers (ATV = all-terrain vehicle). Information on rain within 24 hours after each application was not stated in the report.

Sampling: From the United States trials at least 12 sugar beet plants were collected at normal commercial harvest (BBCH 47–50). Sugar beet plants in trial TK0296310-07 were harvested at BBCH 39. Sugar beet plants were separated into tops and roots. Two replicate samples were collected from each plot. Sample weights were not stated in the report.

The sample weights for the 12 tops from the immature sugar beet plants from trial TK0296310-07 were 2.0–2.5 kg (4.5–5.5 lbs) for each of the replicate samples [Answers to questions, July 2021].

Sugar beet plants from the Canadian trials were collected at maturity (BBCH 49); sugar beet plants in trial TK03043334-03 (at DAT 69) were harvested at BBCH 39–49. Sugar beet plants were separated into tops and roots. Two replicate samples were collected from each plot. The sample weights and number of sampled sugar beet plants were not stated in the report.

In the Canadian trials 12 sugar beet plants were harvested for each replicate sample. The small roots from the immature sugar beet plants from trial TK03043334-03 weighted 5.6–9.4 kg for each of the replicate samples at each pre-harvest interval. The tops from the immature sugar beet plants from trial TK03043334-03 weighted 2.5–4.4 kg for each of the replicate samples at each pre-harvest interval [Answers to questions, July 2021].

Storage: Samples were frozen and stored for 2.0–14.2 months at -10 °C or lower.

Analysis: Benzovindiflupyr and metabolite SYN 546039 (including its conjugates) were determined in the sugar beet tops using a modification of HPLC-MS/MS method GRM042.03A with an LOQ of 0.01 mg/kg for each analyte. Individual concurrent recoveries in sugar beets tops ranged from 88–107 percent at 0.01-0.1 mg/kg for benzovindiflupyr and 81–112 percent at 0.01–0.1 mg/kg for SYN 546039. Residues in the control samples were < LOQ (n=22) for each analyte.

The results for replicate field samples and their average are shown in Table 10. The average benzovindiflupyr concentrations in sugar beet tops range between <0.01-0.055 mg/kg. Highest residue in an individual sample was 0.079 mg/kg benzovindiflupyr (TK0296310–14). SYN 546039 (including conjugates) residues were < 0.01 mg/kg in each individual sugar beet top sample, except in:

- trial TK0304334-01 (St. Marc sur Richelieu, QC, Canada) where SYN 546039 was found at a mean level of 0.015 mg/kg at DAT 42 (individual 0.013/0.017 mg/kg), 0.014 mg/kg at DAT 47 (individual 0.012/0.016 mg/kg), <0.01 mg/kg at DAT 53, 0.012 mg/kg at DAT 59 (individual 0.011/0.014 mg/kg) and 0.01 mg/kg at DAT 63 (individual <0.01/0.010 mg/kg);
- Trial TK0304334-03 (Taber, AB, Canada) where SYN 546039 was found at a mean level of 0.013 mg/kg at DAT 69 (individual 0.012/0.014 mg/kg) and < 0.01 mg/kg at DAT 74, 78, 84, 91.

Remarks by the reviewer:

- Two of the Canadian trials, TK-0304334-04 and -06 took place at the same location. As the planting and application differed by 30 days, these trials are considered to be independent;
- Sample sizes in the United States study VV-547512 and the Canadian study VV-547573 are compliant with the recommended sample size in the FAO manual (at least 12 plants);

- In trial TK0296310-07, the sugar beet plants were harvested at BBCH 39 and in trial TK03043334-03, the sugar beet plants were harvested at BBCH 39–49. Although BBCH 39 reflects immature plants, sample weights were at least 5.6 kg for these 12 roots (460 g/root) and at least 2.5 kg for these 12 tops and can thus be considered representative for MRL derivation;
- The demonstrated storage stability of 24 months -18 °C in high water commodity groups (spinach) by JMPR 2014 covers the storage period of 2.0–14.2 months for sugar beet tops in study VV-547512;
- The modification of HPLC-MS/MS method GRM042.03A is reduced validated for the determination of benzovindiflupyr and SYN 546039 (including conjugates) in sugar beet tops in the range 0.01-1.0 mg/kg. The benzovindiflupyr and SYN 546039 (including conjugate) concentrations in studies VV-547512 and VV-547573 are covered by the validation of this analytical method.

Kipp, AB, Canada, 2017 (SV36152RR)	EC [a]	2 (46)	0.078 0.072	banded soil + directed foliar; 12 Jul; BBCH 31	62	<0.01, <0.01; (<0.01)	<0.01, <0.01; (<0.01)	[Shepard, 2019 VV-547573], trial TK0304334-08 Soil: sand clay loam

Notes:

[a] For the foliar applications crop oil concentrates (COC) or non-ionic surfactants (NIS) were added to the tank mix. **COC**: Superb HC 0.5 percent-1.0 percent v/v (United States trial 01, 06, 08); Prime oil 0.5-1.0 percent v/v (United States trial 03, 05, 13, 14), Chem Spray 1 percent v/v (United States trial 04), Herbimax 0.6 percent v/v (United States trial 09), **NIS**: Preference 0.25 percent v/v (United States, trial 02, 12), Induce 0.12 percent v/v (United States trial 07, Kinetic 0.3 percent v/v (United States trial 10), R-11 0.13 percent v/v (United States trial 11), Agral 90 0.2 percent v/v (Canada trial 01, 02, 03, 04, 05, 06, 07, 08).

[b] Samples used in the sugar beet root processing study.

Additional metabolite information

The Meeting received new toxicological information on metabolites and the relevance of these metabolites for the residue definition was therefore re-assessed. Field samples from all trials were analysed for SYN 546039 (including its conjugates) and field trials from pulses and oilseeds were additionally analysed for SYN545720, using validated analytical methods, summarized and assessed by the 2014 and 2016 JMPR. As the 2016 JMPR did not summarize the residue information on the metabolites, the JMPR 2016 supervised trials data were re-summarized. Also the JMPR 2014 and 2019 trials were reproduced below. The results of the JMPR 2022 trials were included in the conclusion below.

Presence of SYN 546039 (hydroxy-benzovindiflupyr) including its conjugates:

- Pome fruit (apple and pear, Table 11, Table 12). SYN 546039 was not detected (< 0.01 mg/kg) in any of the apple and pear trials at 30 and 60 days after the last application (DALA). In two apple trials conducted at 5× exaggerated rates. SYN 546039 ranged from <0.01–0.012 mg/kg at 30 DALA;
- Berries and other small fruit (blueberries, grapes, Table 5, Table 13). SYN 546039 was found in most grape trials. Levels ranging from <0.01–0.057 mg/kg were found at 21 DALA and < 0.01–0.22 mg/kg at 45 DALA. In two grape trials conducted at 5× exaggerated rates SYN 546039 ranged from 0.071–0.12 mg/kg at 21 DALA. SYN 546039 was not analysed in the blueberry trials;
- Bulb vegetables (bulb onions, green onions, Table 14, Table 15). SYN 546039 was not detected (<0.01 mg/kg) in any of the bulb onion trials. It was detected in most of the green onion trials at levels ranging from < 0.01–0.049 mg/kg;
- Cucurbits (cucumbers, summer squashes and melons, Table 16, Table 17, Table 18). SYN 546039 was not detected (< 0.01 mg/kg) in most cucurbit trials at PHI 0 days, except for one summer squash trial and one melon trial. In these two trials SYN 546039 ranged from < 0.01–0.020 mg/kg in summer squashes and <0.01–0.018 mg/kg in melons. In another decline trial on melons, SYN 546039 ranged from 0.013–0.014 mg/kg at longer PHIs of 7–14 days;
- Fruiting vegetables other than cucurbits (sweet peppers, chili peppers, tomatoes, Table 19, Table 20, Table 21). SYN 546039 was not detected (<0.01 mg/kg) in any of the pepper trials at PHI 0–21 days. SYN 546039 was found in one tomato trial at PHI 0 days at 0.014–0.021 mg/kg and it was found in two tomato trials at a longer PHI of 14 days where it ranged from <0.01–0.016 mg/kg;
- Pulses (beans, soya beans, peas, Table 22, Table 23, Table 24). SYN 546039 was not detected (<0.01 mg/kg) in any of the dry bean trials at PHI 0–21 days or dry soya bean trials at PHI 0–35 days. SYN 546039 was found in one dry pea trial at 14 days at <0.01–0.037 mg/kg; in all other dry pea trials SYN 546039 was not detected (<0.01 mg/kg) at PHI 0–21 days;
- Root and tuber vegetables (ginseng, sugar beet roots, potato, Table 6, Table 7, Table 25). SYN 546039 was not detected (<0.01 mg/kg) in any of the ginseng trials at PHI 0–21 days, in any of the sugar beet trials at PHI 42–122 days and in any of the potato trials at PHI 0–29 days;
- Cereal grains (barley, wheat, maize, sweet corn, Table 26, Table 27, Table 8, Table 28, Table 29). SYN 546039 was not detected (< 0.01 mg/kg) in most grain trials at PHI 16–52 days for barley, PHI 10–61 days for wheat, PHI 6–22 days for maize and PHI 6–7 days for sweet corn, except for four barley trials and one wheat trial. In these trials SYN 546039 ranged from <0.01–0.040 mg/kg in barley grain at PHI 23–52 days and 0.011 mg/kg at PHI 41 days for wheat grain. In one barley or two wheat trials conducted at 5× exaggerated rate, SYN 546039 ranged from 0.088–0.091 mg/kg at PHI 26 days for barley grain and <0.01–0.017 mg/kg at PHI 34–41 days for wheat grain;
- Sugar cane canes (Table 30): SYN 546039 was not detected (<0.01 mg/kg) in any of the trials at PHI 20–40 days;
- Oilseeds (rapeseed, cottonseed, peanuts, Table 31, Table 32, Table 33): SYN 546039 was not detected (<0.01 mg/kg) in any of the rapeseed trials at normal rate at PHI 25–40 days or any of the peanut trials at PHI 7–44 days. It was however found in several of the cotton seed trials in the range <0.01–0.034 mg/kg at PHI 40–48 days. In addition it was found in the trials conducted at 5x exaggerated rate in the range <0.01–0.12 mg/kg (n=2) at PHI 44–45 days for cottonseed and in the range 0.011–0.046 mg/kg (n=2) at PHI 31 days for rapeseeds;

- Coffee beans (Table 34): SYN 546039 was not detected (<0.01 mg/kg) in most of the green coffee bean trials at PHI 21–35 days. In one trial SYN 546039 was found at 0.02 mg/kg at PHI 21 days;
- Legume forage (pea vines, soya forage, Table 35, Table 36): SYN5456039 was found in all pea vine trials in the range 0.039–0.77 mg/kg at PHI 0–21 days and in all soya forage trials in the range 0.028–0.53 mg/kg at PHI 0–14 days. Trials on peanut forage were not conducted;
- Legume fodder (pea hay, soya fodder, peanut hay, Table 37, Table 38, Table 39): SYN5456039 was detected in all pea hay trials in the range 0.074–4.4 mg/kg at PHI 0–21 days, all soya hay trials in the range 0.091–4.6 mg/kg at PHI 0–14 days and in almost all peanut hay trials in the range <0.01–1.8 mg/kg at PHI 30 days;
- Cereal forage (wheat forage, sweet corn/maize forage, Table 40, Table 41, Table 42): SYN 546039 was found in almost all wheat forage trials in the range <0.01–0.38 mg/kg at PHI 0–14 days and many of the sweet corn and maize forage trials at <0.01–0.055 mg/kg at PHI 1–17 days. Trials on barley forage were not conducted;
- Cereal fodder (barley hay/straw, wheat hay/straw, sweetcorn/maize stover, Table 43, Table 44, Table 45, Table 46, Table 47, Table 48): SYN 546039 was found in all barley hay and straw trials in the range 0.01–1.0 mg/kg at PHI 0–52 days and in almost all wheat hay and straw trials in the range <0.01–1.3 mg/kg at PHI 0–61 days. SYN 546039 was found in many of the sweet corn and maize stover trials in the range <0.01–0.16 mg/kg at PHI 2–17 days;
- Oilseed forage/fodder (Cotton seed gin trash, Table 49): SYN 546039 was found in all gin trash trials in the range 0.11–1.1 mg/kg at PHI 45–49 days. Trials on rapeseed peanut forage were not conducted. Peanut hay is listed under legume hay;
- Sugar beet tops (Table 10). SYN 546039 was not detected (< 0.01 mg/kg) in most sugar beet tops at PHI 48–122 days, except in two trials where SYN 546039 was found at <0.01–0.017 mg/kg at PHI 42–69 days;

  Presence of SYN545720 (cleavage product) in seeds of pulses, oilseeds and coffee beans:

- Pulses (beans, soya beans, peas, Table 22, Table 23, Table 24). SYN545720 was not detected (<0.01 mg/kg) in any of the dry bean seed trials at PHI 0–21 days and dry soya bean seed trials at PHI 0–28 days. SYN545720 was found in one dry pea trial at PHI 14 days at 0.017–0.026 mg/kg; in all other dry pea trials SYN545720 was not detected (<0.01 mg/kg) at PHI 0–22 days;
- Oilseeds (rapeseed, cotton seed, peanuts, Table 31, Table 32, Table 33). SYN545720 was not detected (<0.01 mg/kg) in any of the cottonseed trials at PHI 35–56 days, peanut trials at PHI 7–44 days and rapeseed trials at PHI 25–40 days;
- Coffee beans (Table 34). SYN545720 was not detected (<0.01 mg/kg) in any of the green coffee bean trials at PHI 21–35 days.

Pome fruit

Residue information apples and pears was reproduced from the JMPR 2016 evaluation and extended with the additional metabolite information.

Notes:

$ Coffee berries were dried (21 days in a greenhouse at room temperature (AMA), 3 days in a dryer at 38°C (JJB1, JJB2), by the sun (RWC1, RWC2, RWC3)) Dried coffee berries were peeled to get the green coffee beans.

Legume vines/forage

Residue information on pea vines and soya bean forage was reproduced from the JMPR 2016 evaluation and extended with additional metabolite information. SYN545720 was not analysed in pea vines or soya bean forage. Information on soya bean forage from trials in Brazil is not available (JMPR 2014). Trials on peanut forage were not conducted.

Notes:

** The residue levels detected in wheat forage samples from site T922 (samples T922-02 and T922-03) appear to be unexpectedly low (<0.01 ppm); samples were analysed to confirm below LOQ values. These duplicate samples may have been collected from the check plot but it cannot be confirmed.

Sweet corn and maize forage

No trials were selected for sweet corn forage or maize forage from the United States.

Note from the reviewer: Report TK0002562: Sweet corn forage and stover samples were each at the same location and received each the same treatment at the same day. Ears were picked by hand and part of the stalks without ears were harvested as “sweet corn forage” at the same day as the sweet corn ears. The remaining stalks were left in the field and were harvested at a later date as “sweet corn stover”. The growth stage at harvest for sweet corn forage and stover was not stated in the study report.

Sweet corn and maize stover

No trials were selected for sweet corn stover or maize stover from the United States.

Note from the reviewer: Report TK0002562: Sweet corn forage and stover samples were each at the same location and received each the same treatment at the same day. Ears were picked by hand and part of the stalks without ears were harvested as "sweet corn forage" at the same day as the sweet corn ears. The remaining stalks were left in the field and were harvested at a later date as "sweet corn stover". Report TK0002562 marks these samples as stover DALA 7. For some of these samples, the actual harvest date was much later than 7 days. For some samples the DALA was indeed 7 days; these samples must be considered replicates of sweet corn forage.

Fate of residues in storage and processing

In processing

Processing factors (PF) are defined as the residue in the processed commodity divided by the residue in the corresponding raw agricultural commodity (RAC). The residue used to calculate the processing factor is benzovindiflupyr as defined in the residue definition for enforcement and dietary risk assessment. Residues < LOQ were assumed to be at the LOQ for calculation purposes. Processing factors in the tables were rounded to two figures, but were calculated using unrounded figures reported in the study.

Sugar beet processing study

The Meeting received two processing trials on sugar beets [Dorsey, 2019, VV-547512]. Plots located in the United States were treated twice with an exaggerated rate of 0.38–0.40 kg ai/ha using a WG formulation. The first application was performed as an in-furrow soil application at sowing/planting (BBCH 00). The second application was performed as a banded foliar application at BBCH 30–32. Details of the trials used for processing are presented in Table 7 (trials TK0296310 -01 and -02).

Sugar beet plants for processing were collected at normal commercial harvest (BBCH 47–50). Sugar beet plants were separated into tops and roots. Samples were collected and stored frozen prior to shipment to the processing facility. Sugar beet roots were processed into dried pulp, refined sugar and molasses within 1 day after harvest following methods representative of commercial practice.

Processing into dried pulp, molasses and refined sugar consisted of the following steps:

- Cleaning: Sugar beet roots (222.6; 207.3 lbs = 101; 94.0 kg) were cleaned prior to processing. Heavy deposits of soil were removed with a brush and water, and loose leaves and foreign matter were separated from beets to obtain cleaned beets (216.9; 200.7 lbs = 98.4; 91.0 kg).
- Slicing: A portion of the cleaned beets (92.5; 93.2 lbs = 42.0; 42.3 kg) were mechanically sliced into cossettes using a Hobart food chopper.
- Diffusion: Cossettes were first exposed to heated water at 88–92 °C (190–198 °F) for 30–45 seconds and then diffused in 5 kettles containing warm water at 68–74 °C (155–165 °F) for 9 minutes in each kettle. The diffusion water from the 5 kettles was screened (US 100 mesh sieve) to remove any remaining small pieces of beet (cossettes). The diffusion water and the diffused cossettes were collected separately.
- Pressing: Diffused cossettes were dewatered (pressed) in a filter bag and hydraulic press to obtain pressed wet pulp (39.1; 45.0 lbs = 17.7; 20.4 kg). The press water was collected and added to the diffusion water to obtain raw juice.
- Wet pulp drying: The pressed wet pulp was dried in an oven at 54–71 °C (130–160 °F) to achieve a final moisture content of 15 percent or less. The resulting dried pulp (4.3; 4.6 lbs = 1.95; 2.09 kg) was collected.
- Phosphatizing step 1: Raw juice was mixed and the temperature increased to 80–85 °C (176–185 °F). A 20 percent calcium oxide solution was added until the pH was 10.5. If the pH was above 11.2, the pH was lowered to 11.2 with phosphoric acid (3M). A precipitate or mud was formed. Centrifugation separated the mud and phosphatized juice.
- Phosphatizing step 2: The phosphatized juice was mixed and heated to 80–85 °C (176–185 °F). The pH was reduced to 9.1–9.3 with phosphoric acid (3M). After the pH was achieved, the juice was centrifuged and vacuum filtered to separate mud and clear juice. The clear juice was mixed and heated to 80–85 °C (176–185 °F) and the pH was reduced to 8.8–9.0 with sodium bisulphite to obtain thin juice (115.2 lbs).
- Evaporation: The thin juice was evaporated under vacuum until a 50–60 percent solids thick juice was achieved. The temperature was maintained below 85°C (185F). After evaporation, the thick juice was filtered over cotton. The filtered thick juice (6.392 kg) was evaporated under vacuum until a 70–80 percent solids syrup was achieved.
- Crystallisation and centrifugation: A solution of white sugar was added to the syrup and the syrup was allowed to cool. After this 'seeding' step sugar crystals were formed. Crystallised sugar and molasses were separated by centrifugation. Steam was added during centrifugation to remove all residual molasses from the crystallised sugar. Molasses (3.625; 3.764 kg) was collected. Crystallised sugar was dried in an oven at 54–77 °C (130–170 °F) to obtain refined sugar with a final moisture content of 1.0 percent (0.763; 0.625 kg)

Moisture content was determined as 39.92 percent and 43.94 percent in molasses and 3.28 percent and 3.05 percent in dried pulp. The dry matter content (100 percent–moisture content) is therefore 60.08 percent and 56.06 percent in molasses and 96.72 percent and 96.95 percent in dried pulp.

Storage: Samples were frozen and stored for 6.7–7.6 months at -10 °C or lower.

Analysis: Benzovindiflupyr and metabolite SYN 546039 (induding its conjugates) were determined in sugar beet and its processed commodities using a modification of HPLC-MS/MS method GRM042.03A with an LOQ of 0.01 mg/kg for each analyte. Mean concurrent recoveries in sugar beet and its processed commodities ranged from 76–111 percent at 0.01–2.0 mg/kg for benzovindiflupyr and 77–

100 percent at 0.01–1.0 mg/kg for SYN 546039. Residues in the control samples were < LOQ (n=2) for each analyte and matrix.

Processing results for benzovindiflupyr in sugar beet commodities are shown in Table 50. Residues for SYN 546039 (including its oonjugates) were < 0.01 mg/kg in each sample. The results of the two processing trials on sugar beet indicate a concentration of residues of benzovindiflupyr in dried pulp (median PF = 7.1) and a reduction of residues of benzovindiflupyr in refined sugar and molasses (best estimate PF < 0.46).

Remarks by the reviewer:

- No storage stability information is available for processed sugar beet commodities (molasses, dried pulp, sugar). The JMPR 2014 concluded that benzovindiflupyr and SYN546039 (free) are stable for at least 24 months at -18 ºC in crop commodities representative of the high water, high acid, high starch, high protein and high oil commodity groups as well as in wheat straw and for at least 24 months at -10 ºC in various processed commodities such as flour (maize, soya), meal (maize), oil (maize, soya), soya milk, dried fruits (grape, apple) and fruit juice (apple). As storage stability was shown in such a wide range of commodities, storage stability results can be extrapolated to processed sugar beet commodities (molasses, dried pulp, sugar).
- The modification of HPLC-MS/MS method GRM042.03A is reduced validated for the determination of benzovindiflupyr and SYN 546039 (including conjugates) in sugar beet commodities (roots, dried pulp, molasses, refined sugar) in the range 0.01–1.0 mg/kg. The benzovindiflupyr and SYN 546039 (including conjugate) concentrations in study VV-547512 are covered by the validation of this analytical method.
- The pressed wet pulp yields of 19–22 percent and dried pulp yields of 4.6–4.9 percent represent commercial practice. However, the yields for sugar (1.5–1.8 percent) and molasses (8.6–8.9 percent) do not represent commercial practice. Normally, a yield of 14–16 percent refined sugar and up to 3.5 percent molasses (dm 72 percent) is obtained from sugar beets containing 17 percent sucrose. The manufacturer indicates that the study was not set up as a mass balance study and that losses occurring during processing, some of the inputs into the processing procedure, and fractions that were discarded along the process were not weighed/measured [Answers to questions, July 2021]. The processing was conducted according to commercial practices adapted for small-scale equipment in a “batch process". It is not a continuous looping process where, for example, molasses or pulp could be run through the process multiple times to increase overall sugar yield while reducing yield of other components. In addition, the GLP processing lab is working with the beets derived from the field trials, which can vary in water content and sugar content from trial to trial, field to field, and year to year. Commercial production is focused on maximizing sugar output, whereas GLP batch processing is focused on generating representative samples of several commodities (pulp, refined sugar, and molasses) for subsequent residue analysis [Answers to questions, July 2021]. Based on this argumentation, the current reviewer considers the samples representative for the purpose of deriving processing factors.

Table 50 Residues of benzovindiflupyr in sugar beet processed commodities

Maize processing study

Maize processing trials have been summarized and evaluated by the JMPR 2016. An overview of the processing factors is given in Table 51.

Overall conclusion on processing factors

An overview of processing factors for benzovindiflupyr in sugar beets and maize are listed in Table 51.

Table 51 Overview of processing factors for sugar beets and maize

	PF – parent only	PF median or best estimate
Sugar beet dried pulp	5.5, 8.7	median 7.1 (n=2)
Sugar beet refined sugar	<0.46, <0.67	best estimate <0.46 (n=2)
Sugar beet molasses	<0.46, <0.67	best estimate <0.46 (n=2)
Maize meal (JMPR 2016)	<0.25	best estimate <0.25 (n=1)

Maize grits (JMPR 2016)	<0.25	best estimate <0.25 (n=1)
Maize refined oil (dry processing) (JMPR 2016)	<0.25	best estimate <0.25 (n=1)
Maize refined oil (wet processing) (JMPR 2016)	0.50	best estimate 0.50 (n=1)
Maize starch (JMPR 2016)	<0.25	best estimate <0.25 (n=1)
Maize gluten (JMPR 2016)	0.75	best estimate 0.75 (n=1)
Maize bran (JMPR 2016)	0.50	best estimate 0.50 (n=1)
Maize milled by-product (JMPR 2016)	<0.25	best estimate <0.25 (n=1)

APPRAISAL

Benzovindiflupyr is a broad-spectrum fungicide first evaluated by JMPR in 2013 for Toxicology and in 2014 for Residues. The compound was re-evaluated in 2016, 2018 and 2019 for additional uses.

An ADI of 0–0.05 mg/kg bw and an ARfD of 0.1 mg/kg bw were established by the 2013 JMPR. The 2014 JMPR Meeting recommended the residue definition for plant and animal commodities (for compliance with MRLs and for estimation of dietary intake) as: benzovindiflupyr. The residue is fat soluble.

Benzovindiflupyr was scheduled at the Fifty-first Session of the CCPR for evaluation of additional uses by the 2021 JMPR and rescheduled for evaluation by the 2022 JMPR. The Meeting received additional information from the manufacturer on the toxicity of metabolites, method of residue analysis, use patterns, supervised residue trials (blueberries, dried ginseng, sugar beets and maize) and processing studies on sugar beets.

Chemical Names

Table 52 Metabolites referred to in this appraisal

Code	Structural formula, short name, IUPAC name	JMPR 2014 conclusions
SYN 546039	 hydroxy-benzovindiflupyr CSCD695908 IUPAC: N-[(1RS,2RS,4SR)-9-(dichloromethylene)-2-hydroxy-1,2,3,4-tetrahydro-1,4-methanonaphthalen-5-yl]-3-(difluoromethyl)-1-methyl-1H-pyrazole-4-carboxamide	JMPR 2014: Found in rat goat (milk, liver, kidney, muscle, fat) hen (eggs, liver, muscle, skin with fat) tomato fruit wheat forage/hay/straw wheat grains soya bean forage/hay soya bean seeds rotational crops: lettuce leaves, turnip roots/leaves, wheat forage/hay/straw
SYN 508272	 pyrazole amide CSCC210616 IUPAC: 3- difluoromethyl-1-methyl-1H-pyrazole-4-carboxylic acid amide	JMPR 2014: Found in goat (milk, liver, kidney, muscle, fat) hen (eggs, liver, muscle, skin with fat) wheat hay/straw wheat grains soya bean forage soya bean hay rotational crops: turnip leaves, wheat forage/hay/straw photolysis in water common metabolite with other pyrazole fungicides like bixafen, fluindapyr, fluxapyroxad, inpyrfluxam, isopyrazam and sedaxane

Code	Structural formula, short name, IUPAC name	JMPR 2014 conclusions
NOA 449410	 pyrazole acid CSAA798670 IUPAC: 3-difluoromethyl-1-methyl-1H-pyrazole-4-carboxylic acid	JMPR 2014: Found in: tomato fruit wheat hay/straw wheat grains soya bean forage/hay soya bean seeds rotational crops: lettuce leaves, turnip roots/leaves, wheat forage/hay/straw photolysis in water (not detected in goat and hen commodities) common metabolite with other pyrazole fungicides like bixafen, fluxapyroxad, inpyrfluxam, isopyrazam and sedaxane
SYN 545720	 N-desmethylpyrazole-acid CSCD465008 or R958945, IUPAC: 3-difluoromethyl-1H-pyrazole-4-carboxylic acid CASnr 151734-02-0	JMPR 2014: Found in tomato fruit soya bean forage/hay soya bean seeds rotational crops: lettuce leaves, turnip roots/leaves, wheat forage/hay/straw (not detected in rat, goat and hen commodities) (not found in photolysis in water) common metabolite with other pyrazole fungicides like bixafen, fluxapyroxad, inpyrfluxam, isopyrazam and sedaxane

Methods of analysis

The Meeting received additional validation information for benzovindiflupyr and SYN 546039 in blueberries, dried ginseng roots, sugar beet commodities and maize commodities for analytical methods already considered by the JMPR in 2014. The Meeting concluded that the presented (modified) methods were sufficiently validated and are suitable to quantify benzovindiflupyr and SYN 546039 (including conjugates) in plant commodities.

Stability of pesticide residues in stored analytical samples

The Meeting agreed that the demonstrated storage stability on various representative plant commodities evaluated by the JMPR 2014 covered the residue sample storage intervals used in the field trials and processing studies considered by the current Meeting.

Residue definition

The Meeting received additional toxicological information on hydroxy-benzovindiflupyr (SYN 546039) and the three cleavage products: pyrazole amide (SYN 508272), pyrazole acid (NOA 449410) and N-desmethyl pyrazole acid (SYN 545720). The three cleavage products are common to other pyrazole fungicides like bixafen, fluindapyr, fluxapyroxad, inpyrfluxam, isopyrazam and sedaxane. The 2014 JMPR concluded that

these metabolites were not relevant for the residue definition, because the residue levels were low and/or because the toxicity was much lower than parent.

The current Meeting concluded that the three cleavage products (pyrazole amide, pyrazole acid and N-desmethyl pyrazole acid) are not covered by the health based guidance values of benzovindiflupyr and should be assessed by TTC (Cramer class III).

Hydroxy-benzovindiflupyr (SYN 546039 including conjugates) was found at significant levels in the metabolism studies on legume forage/fodder (9.2–12 percent TRR, 0.34–1.6 mg/kg eq), moderate levels in cereal hay/straw (0.5–3.6 percent TRR, 0.032–0.23 mg/kg eq) and low levels in fruit crops, cereal grains/forage and seeds of pulses/oilseed (0.1–2.1 percent TRR, < 0.01 mg/kg eq).

Actual levels of hydroxy-benzovindiflupyr (including conjugates) in field trials conducted at cGAP were 0.92–3.5 mg/kg in legume hay, 0.15–0.71 mg/kg in legume forage, 0.040–1.2 mg/kg in cereal hay/straw, < 0.01–0.32 mg/kg in cereal forage and 0.018–0.19 mg/kg in grapes. Hydroxy-benzovindiflupyr (including conjugates) levels in other crops were low: < 0.01 mg/kg in pome fruit, bulb onions, dry beans, soya beans, potatoes, sweet corn, sugar cane, rape seed, peanuts, and < 0.01–0.035 mg/kg in fruiting vegetables, dry peas, cereal grains and coffee beans.

Hydroxy-benzovindiflupyr (including conjugates) was found in the livestock metabolism studies evaluated by the 2014 JMPR: mammalian muscle, fat and milk (22 percent–39 percent TRR, < 0.01–0.035 mg/kg eq); mammalian edible offal (22–50 percent TRR, 0.040–0.65 mg/kg eq); and eggs (12–22 percent TRR; 0.014–0.015 mg/kg eq). It was found at low levels in poultry tissues (1.3–5.2 percent TRR, < 0.01 mg/kg eq).

Actual levels of hydroxy-benzovindiflupyr (including conjugates) in feeding studies on lactating cows at the maximum dietary burden were < 0.01 mg/kg in milk and muscle, 0.019 mg/kg in fat and 0.037 mg/kg in mammalian offal. No feeding studies on poultry were available. Based on the metabolism studies, actual levels of hydroxy-benzovindiflupyr (including conjugates) in poultry tissues and eggs are expected to be < 0.01 mg/kg at the maximum dietary burden. The current Meeting concluded that this metabolite is 10 times less toxic than parent.

Because the contribution of hydroxybenzovindiflupyr to the overall dietary risk is low (4.5 percent relative exposure increase), the Meeting confirmed that hydroxy-benzovindiflupyr should not be included in the residue definition for dietary risk assessment for either plant or animal commodities .

The Meeting therefore confirmed its definition of the residue for compliance with the MRL and dietary risk assessment for plant and animal commodities as: benzovindiflupyr.

Results of supervised residue trials on crops

Supervised trials were available for the use of benzovindiflupyr on blueberries, ginseng, sugar beets and maize. Product labels were available from the United States.

Blueberries

Benzovindiflupyr is registered in the United States for a foliar spray on lowbush blueberries with a critical GAP (cGAP) application rate of 2× 0.076 kg ai/ha, a retreatment interval (RTI) of 10 days and a PHI of 1 day.

Because the United States label registered lowbush blueberries only, the Meeting decided that the supervised trials on highbush blueberries could not be matched to this cGAP. Five supervised trials on lowbush blueberries from the United States performed at an application rate of 2× 0.074–0.076 kg ai/ha

with an RTI of 10 days and a PHI of 1 day, approximated this cGAP. Residues of benzovindiflupyr in lowbush blueberries were: 0.48, 0.51, 0.65, 0.69, 0.87 mg/kg (n=5).

The Meeting considered five trials sufficient for the minor crop blueberries and estimated a maximum residue level of 2 mg/kg, a HR of 0.98 mg/kg (individual highest residue) and an STMR of 0.65 mg/kg for benzovindiflupyr in blueberries (FB0020). The recommendation refers to blueberries, as the Codex Classification does not distinguish between lowbush and highbush blueberries (both have code FB0020).

Dried ginseng roots

Benzovindiflupyr is registered in the United States on ginseng with a cGAP rate of 4× 0.076 kg ai/ha, an RTI of 14 days and a PHI of 15 days.

Four supervised trials on ginseng from the United States performed at 4×0.073–0.080 kg ai/ha with an RTI of 13–15 days and a PHI of 15 days approximated this cGAP. Fresh ginseng roots from these trials were dried for 6–8 days until an estimated dry matter content of 70–90 percent was reached. Residues of benzovindiflupyr in dried ginseng roots were: 0.034, 0.068, 0.094, 0.14 mg/kg (n=4), as received.

According to the Codex Classification, ginseng should comply with Codex Standard 295R-2009. This regional standard has been replaced by Codex Standard 321-2015. Codex Standard 321-2015 stipulates that dried ginseng roots should contain no more moisture than 14.0 percent (i.e. have a dry matter content of at least 86.0 percent). The actual dry matter content of the individual dried ginseng root samples from the supervised field trials were not reported, but were estimated at 70–90 percent in the study report.

The Meeting concluded that residues in ginseng roots with an estimated dry matter content of 70–90 percent were not affected by more than 25 percent (100 percent × (86–70) / 86 = 18.6 percent). The Meeting considered four trials sufficient for the minor crop ginseng roots and estimated a maximum residue level of 0.3 mg/kg, a HR of 0.16 mg/kg (highest individual) and an STMR of 0.081 mg/kg for benzovindiflupyr in dried ginseng roots (DV 0604 and DT 0604).

Sugar beet roots

Benzovindiflupyr is registered in the United States on sugar beets with two different GAPs:

A) a single in-furrow or banded soil application at 0.075 kg ai/ha at the 2–8 leaf-stage, followed by a foliar application at 0.075 kg ai/ha up to BBCH 31.

B) two foliar applications at 2× 0.075 kg ai/ha with an RTI of 5 days and the last application applied up to BBCH 31.

The Meeting considered the two foliar applications (GAP B) as cGAP. Because all the supervised trials provided to the Meeting were conducted with the combined soil and foliar treatment (GAP A) with a longer RTI of 25–46 days between the soil and subsequent foliar application, none of the trials matched the cGAP The Meeting decided that the trials were not suitable to derive maximum residue levels.

Maize grains

Benzovindiflupyr is registered in Canada on maize (field corn, popcorn, sweet corn, specialties) with a cGAP of 2× 0.075 kg ai/ha, an RTI of 7 days and a PHI of 7 days. None of the trials provided to the present or previous JMPR Meetings matched with this GAP.

Benzovindiflupyr is registered in the United States on maize (field corn) and popcorn with a cGAP rate of 2× 0.051 kg ai/ha, a retreatment interval (RTI) of 14 days and a PHI of 7 days.

Seven supervised trials on maize from the United States performed at 2× 0.050–0.053 kg ai/ha with an RTI of 13–15 days and a PHI of 6–7 days approximated this cGAP. Residues of benzovindiflupyr in maize grains were: < 0.01 (6), 0.016 mg/kg (n=7).

The Meeting estimated a maximum residue level of 0.02 mg/kg and an STMR of 0.01 mg/kg for benzovindiflupyr in maize (GC 0645). The Meeting decided to extrapolate this MRL to popcorn (GC 0656).

Residues in animal feeds

Maize forage

Benzovindiflupyr is registered in Canada on maize (field corn, popcorn, sweet corn, specialties) with a cGAP of 2× 0.075 kg ai/ha, an RTI of 7 days and a PHI of 7 days. None of the trials provided to the present or previous JMPRs matched with this GAP.

Benzovindiflupyr is registered in the United States on maize (field corn) and popcorn with a cGAP rate of 2× 0.051 kg ai/ha, a retreatment interval (RTI) of 14 days and a PHI of 7 days.

Trials provided as maize forage (whole plant) that could possibly be matched to the United States GAP, were harvested at BBCH 85–89. The Meeting considered these samples not representative for green forage plants, as the plants already lost moisture and thus may have concentrated their residues. The Meeting decided not to derive median and highest residues for maize forage.

Maize stover

Benzovindiflupyr is registered in Canada on maize (field corn, popcorn, sweet corn, specialties) with a cGAP of 2× 0.075 kg ai/ha, a retreatment interval (RTI) of 7 days and a PHI of 7 days. None of the trials provided to the present or previous JMPRs matched with this GAP.

Benzovindiflupyr is registered in the United States on maize (field corn) and popcorn with a cGAP rate of 2× 0.051 kg ai/ha, an RTI of 14 days and a PHI of 7 days.

Seven supervised trials on maize stover (remaining plant) from the United States performed at 2× 0.050–0.053 kg ai/ha with an RTI of 13–15 days and a PHI of 6–7 days approximated this cGAP. Residues of benzovindiflupyr in maize stover were: 0.86, 1.2, 1.3, 1.6, 1.7, 2.3, 2.9 mg/kg (n=7) on an as received basis (assuming a dry matter content of 83 percent derived from the OECD 2018 feed calculator), corresponding to 1.0, 1.5, 1.6, 1.9, 2.0, 2.8, 3.5 mg/kg (n=7) on dry weight basis

The Meeting estimated a maximum residue level of 7 mg/kg, as dry weight and a median residue of 1.6 mg/kg and a highest residue of 2.9 mg/kg as received for maize stover. The Meeting decided to extrapolate these residues to popcorn stover.

Sugar beet leaves and tops

Benzovindiflupyr is registered in the United States on sugar beets with two different GAPs:

A) a single in-furrow or banded soil application at 0.075 kg ai/ha at the 2–8 leaf-stage, followed by a foliar application at 0.075 kg ai/ha up to BBCH 31.

B) two foliar applications at 2× 0.075 kg ai/ha with an RTI of 5 days and the last application applied up to BBCH 31.

The Meeting considered the two foliar applications (GAP B) as cGAP. Because all the supervised trials provided to the Meeting were conducted with the combined soil and foliar treatment (GAP A) with a longer RTI of 25–46 days between the soil and subsequent foliar application, none of the trials matched the cGAP. The Meeting decided that the trials were not suitable to derive maximum residue levels.

Fate of residues during processing

The Meeting received new information on the fate of benzovindiflupyr residues during processing in sugar beet roots. Furthermore, median and highest residues could be derived for maize processed commodities, based on the processing data evaluated by the JMPR 2016.

Table 53 Estimation of processing factors for commodities considered at this and previous Meetings

Raw commodity [STMR/HR]	Processed commodity	Individual processing factors	Mean or best estimate processing factor	STMR-P = STMR-RAC × PF (mg/kg)	HR-P = HR-RAC × PF (mg/kg)
Maize grains [0.01 mg/kg]	Maize meal (JMPR 2016)	< 0.25	< 0.25 (n=1)	0.0025	
	Maize flour (JMPR 2016)	0.25	0.25 (n=1)	0.0025	
	Maize grits (JMPR 2016)	< 0.25	< 0.25 (n=1)	0.0025	
	Maize refined oil (wet processing) (JMPR 2016)	0.50	0.50 (n=1)	0.0050	
	Maize starch (JMPR 2016)	< 0.25	< 0.25 (n=1)	0.0025	
	Maize gluten (JMPR 2016)	0.75	0.75 (n=1)	0.0075	
	Maize bran (JMPR 2016)	0.50	0.50 (n=1)	0.0050	
	Maize milled by-product (JMPR 2016)	< 0.25	< 0.25 (n=1)	0.0025	

Residues in animal commodities

Dietary burdens were calculated for beef cattle, dairy cattle, broilers and laying poultry based on feed items evaluated by the current and previous JMPRs and including maize grains and maize stover. The dietary burdens, estimated using the 2018 update of the OECD feed calculator, are presented in Annex 6 of the 2022 JMPR Report and summarised below.

Table 54 Estimated maximum and mean dietary burdens of farm animals

	Animal dietary burden: benzovindiflupyr, ppm of dry matter diet							
	United States-Canada		European Union		Australia		Japan	
	max	mean	max	mean	max	mean	max	mean
Beef cattle	3.035	1.269	6.894	2.559	14.80	4.200	0.661	0.466
Dairy cattle	8.093	3.012	7.519	3.029	14.33	4.065	3.520	1.830
Poultry – broiler	0.196	0.196	0.270	0.270	0.065	0.065	0.047	0.047
Poultry – layer	0.194	0.194	2.154	0.894	0.065	0.065	0.039	0.039

Notes:

Highest maximum beef or dairy cattle dietary burden suitable for MRL estimates for mammalian tissues.

Highest maximum dairy cattle dietary burden suitable for MRL estimates for mammalian milk.

Highest mean beef or dairy cattle dietary burden suitable for STMR estimates for mammalian tissues.

Highest mean dairy cattle dietary burden suitable for STMR estimates for milk.

Highest maximum poultry dietary burden suitable for MRL estimates for poultry tissues and eggs.

Highest mean poultry dietary burden suitable for STMR estimates for poultry tissues and eggs.

The 2019 JMPR estimated a mean/maximum dietary burden of 5.145/14.80 ppm for beef cattle, 5.145/14.33 ppm for dairy cattle and 0.857/2.075 ppm for layer poultry. The Meeting noted that the contribution of maize grain and maize stover increased the mean dietary burdens for poultry by less than 10 percent. The Meeting therefore confirmed its previous recommendations for maximum residue levels in animal products.

Residue values for exposure calculations

The 2022 JMPR re-evaluated the study reports provided to previous Meetings in order to obtain field trial information for N-desmethyl pyrazole acid (SYN 545720) and Hydroxy-benzovindiflupyr (SYN 546039) (see Annex below). Parent residue values were corrected where necessary (see Annex below). Correct parent residue values were used in the dietary burden calculations, IEDI, IESTI and GECDE estimations conducted by the 2022 JMPR.

Commodity	Compound	Selected residues (mg/kg)
Group of Pome fruit	Parent (corrected values in bold)	**0.020, 0.022**, **0.026**, 0.031, 0.038, 0.039, **0.040**, 0.041, 0.042, 0.044, 0.048, 0.057, **0.058**, **0.060**, 0.062, **0.066**, 0.067, 0.069, 0.074, **0.086**, 0.096, 0.10, 0.16 mg/kg (**n=23**) with HR of 0.17 mg/kg (individual highest residue) and an STMR of 0.057 mg/kg
	SYN 546039including conjugates	< 0.01 (23) mg/kg (n=23) with HR of 0.01 mg/kg and STMR of 0.01 mg/kg

Parent corrected: after re-evaluation of the 2016 JMPR study reports, some parent values were corrected. Bold values in the 2016 JMPR parent data and current parent data indicate which values were corrected.

RECOMMENDATIONS

On the basis of the data obtained from supervised trials, the Meeting concluded that the residue levels listed in Annex 1 are suitable for establishing maximum residue limits and for IEDI, IESTI and GECDE assessments.

Definition of the residue for compliance with the MRL and dietary risk assessment for plant and animal commodities: *benzovindiflupyr*

The residue is fat-soluble.

Table 55 Residue levels suitable for establishing maximum residue limits and for IEDI, IESTI and GECDE assessments

CCN	Commodity	Recommended maximum residue level (mg/kg)		STMR or STMR-P mg/kg	HR or HR-P mg/kg
		New	Previous		
FB 0020	Blueberries	2		0.65	0.98
DV 0604	Ginseng, dried including red ginseng	0.3		0.081	0.16
DT 0604	Ginseng, dried	0.3		0.081	0.16

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The ADI for benzovindiflupyr is 0–0.05 mg/kg bw. The International Estimated Daily Intakes (IEDIs) for benzovindiflupyr were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the 2022 and previous JMPRs. The results are shown in Annex 3 of the 2022 JMPR Report.

The IEDIs ranged from 0.27–1.9 percent of the maximum ADI. The Meeting concluded that long-term dietary exposure to residues of benzovindiflupry from uses considered by the 2022 and previous JMPRs is unlikely to present a public health concern.

Acute dietary exposure

The ARfD for benzovindiflupyr is 0.1 mg/kg bw. The International Estimate of Short Term Intakes (IESTIs) for benzovindiflupyr were calculated for the food commodities and their processed commodities for which HRs/HR-Ps or STMRs/STMR-Ps were estimated by the present Meeting and for which consumption data were available. The results are shown in Annex 4 of the 2020 JMPR Report.

The IESTIs varied from 0–10 percent of the ARfD for children and 0–9 percent of the ARfD for the general population. The Meeting concluded that acute dietary exposure to residues of benzovindiflupyr from uses considered by the present Meeting is unlikely to present a public health concern.

Threshold of toxicological concern (TTC) consideration for metabolites

The three cleavage products (pyrazole amide, pyrazole acid and N-desmethyl pyrazole acid) are common to other pyrazole fungicides like bixafen, fluindapyr, fluxapyroxad, inpyrfluxam, isopyrazam and sedaxane. In the absence of overall information on the uses of all active substances and considering the lack of a specific health-based guidance value, the Meeting decided there was insufficient information to perform a combined risk assessment for residues resulting from use with all active substances leading to formation of these three cleavage products. The Meeting concluded that the three cleavage products (pyrazole amide, pyrazole acid and N-desmethyl pyrazole acid) could be assessed using the TTC approach (Cramer Class III threshold of 1.5 µg/kg bw per day) and that the exposure should be based on the anticipated residues following use of each active substance, separately.

Pyrazole amide (SYN 508272) and pyrazole acid (NOA 449410) were detected at low levels in food crops (<1 percent TRR, < 0.01 mg/kg eq), and animal commodities (< 5 percent TRR, < 0.01 mg/kg eq) in the metabolism studies evaluated by the 2014 JMPR.

N-desmethyl pyrazole acid (SYN 545720, including conjugates) was present at moderate levels in the metabolism studies on seeds of pulses/oilseeds (47 percent TRR, 0.047 mg/kg eq, ratio 47/15 to parent) evaluated by the 2014 JMPR. It was detected at low levels in fruit crops (0.1 percent TRR, < 0.001 mg/kg eq, ratio 0.2/91 to parent). It was not detected in cereals grains or animal commodities.

Actual levels of N-desmethyl pyrazole acid (including conjugates) in field trials conducted at cGAP were < 0.01–0.020 mg/kg in dry pea seeds and < 0.01 mg/kg in dry beans, dry soya bean seeds, rape seeds, peanut nutmeat and green coffee beans.

Based on the benzovindiflupyr uses evaluated by the 2022 and previous JMPRs and the ratios to parent derived from metabolism studies, the Meeting estimated the following dietary exposures:

- Pyrazole amide (SYN 508272): 0.0003–0.0026 µg/kg bw per day (IEDI)
- Pyrazole acid (NOA 449410): 0.0008–0.0045 µg/kg bw per day (IEDI)
- N-desmethyl pyrazole acid (SYN 545720) 0.0075–0.0399 µg/kg bw per day (IEDI). This last estimate could be refined to 0.0052–0.0248 µg/kg bw per day using the field trial information for SYN545720 for pulses, oilseeds and coffee beans (see Annex below).

The Meeting concluded that the estimated dietary exposure to residues of pyrazole amide, pyrazole acid and N-desmethyl pyrazole acid from benzovindiflupyr uses considered by the 2022 and previous JMPRs is below the TTC for Cramer Class III compounds and is unlikely to present a public health concern. Should further benzovindiflupyr uses be considered in the future, these conclusions may need to be re-evaluated.

BENZPYRIMOXAN (325)

First draft prepared by Makoto Irie and Sachiko Yoda, Food and Agricultural Materials Inspection Center, Japan

EXPLANATION

Benzpyrimoxan is an insect growth regulator having biological activity to rice plant hopper larvae (Hemiptera: Delphacidae), without any adulticidal activity. It is registered for the control of sap sucking insects on rice.

At the Fifty-first Session of the CCPR (2019), benzypyrimoxan was scheduled for the evaluation as a new compound in 2020 and rescheduled to the 2022 JMPR. The Meeting received information on identity, physical and chemical properties, animal and plant metabolism, rotational crop study, environmental fate, analytical methods, GAP information, storage stability, processing, supervised residue trials and farm animal feeding study.

IDENTITY

Common name	Benzpyrimoxan
Chemical name	
IUPAC:	5-(1,3-dioxan-2-yl)-4-[4-(trifluoromethyl)benzyloxy]pyrimidine
CAS:	5-(1,3-dioxan-2-yl)-4-[[4-(trifluoromethyl)phenyl]methoxy]pyrimidine
CAS Registry No:	1449021-97-9
CIPAC No:	Not allocated
Synonyms:	NNI-1501
Structural formula:	
	Molecular formula:	C16H15F3N2O3
Molecular weight:	340.30

PHYSICAL AND CHEMICAL PROPERTIES

Pure active ingredient

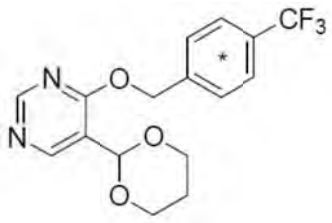
Table 1 Physical and chemical properties of the pure active ingredient

Property	Test material purity	Results	Reference
Appearance (colour, physical state, odour)	99.3%	Pale yellowish white / Powder / Odourless	Ota, 2016 PC-37007, PC-37013, PC-37014
Vapour pressure	99.3%	1.39×10^{-5} Pa at 25 °C	Ota, 2016 PC-37008

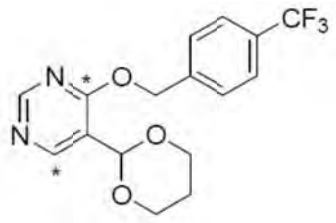
Property	Test material purity	Results	Reference
Henry's Law Constant		Calculation (25 °C) H = 9.39 × 10^{-4} Pa m^3/mol	-
Melting point	99.7%	120.1-121.3°C Capillary tube in a metal block method	Ota, 2016 PC-37016
Boiling point	99.7%	Not confirmed. The test item changed at 225-235 °C Siwoloboff method	Ota, 2016 PC-37017
Thermal stability	99.7%	The test item was stable to about 220 °C. Thermal analysis method	Ota, 2016 PC-37018
Octanol/water partition coefficient	99.3%	log Pow = 3.42 at pH 7.61 Shake Flask method at 24.5 °C	Yonemura, 2017 PC-37033
Solubility in water	99.3%	5.04 mg/L (distilled water) Flask method at 20 ± 0.5 °C pH = 6.79 (24 h), 7.02 (48 h), 6.96 (72 h)	Yaginuma, 2016 PC-37015
Solubility in organic solvents	99.3%	1.95 g/L in heptane 27.9 g/L in methanol 114 g/L in acetone 111 g/L in ethyl acetate 178 g/L in 1,2-dichloroethane 55.8 g/L in *p*-xylene Flask method at 20 ± 0.5 °C	Ota, 2016 PC-37009
Relative density	99.3%	1.440 g/cm^3 at 20 °C	Ota, 2016 PC-37010
Hydrolysis	Radiochemical purity: 99.4% ([phenyl-U-^{14}C]benzpyrimoxan) 98.7% ([pyrimidinyl-4(6)-^{14}C]benzpyrimoxan)	Benzpyrimoxan is hydrolytically stable under neutral and basic conditions (pH 7 and 9, 50 °C), while it is considered to be hydrolytically unstable under acidic conditions (pH 4). Hydrolysis of benzpyrimoxan at pH 4 is highly dependent upon temperature. The degradation half-life of the test substances at pH 4 at 25 °C was 50.4–51.4 days.	Nishimura, 2017 E-37007
Photolysis	Radiochemical purity: 98.2 ([phenyl-U-^{14}C]benzpyrimoxan) 99.3 ([pyrimidinyl-4(6)-^{14}C]benzpyrimoxan)	The DT_{50} of the test substances was 121.6-154.4 days, which were equivalent to 553.2-702.4 days (mean: 627.8 days) under natural sunlight in Tokyo spring.	Murata, 2017 E-37008
Dissociation constant	99.3	pKa = 2.14 Spectrophotometric method	Ota, 2016 PC-37011

METABOLISM AND ENVIRONMENTAL FATE

The metabolism of benzpyrimoxan has been investigated in plants and animals. The fate and behaviour of benzpyrimoxan in plants, animals and the environment were investigated using the [^{14}C] labelled test materials shown in Figure 1



[Phenyl-U-^{14}C]-benzpyrimoxan



[Pyrimidinyl-4(6)-^{14}C]-benzpyrimoxan

Figure 1 [^{14}C]-Labelled test materials used in plant and animal metabolism studies, and the environmental fate studies

The chemical structures of the major metabolite/degradation compounds from the metabolism of benzpyrimoxan are shown in Table 2.

Table 2 Chemical structures of the major degradation compounds from the metabolism of benzpyrimoxan

Compound name		Structure	Found in metabolism studies
Benzpyrimoxan-2-OH DH-04	5-(1,3-dioxan-2-yl)-4-{[4-(trifluoromethyl)phenyl] methoxy}pyrimidin-2-ol MW: 356		Rice Livestock Soil

Plant metabolism

Plant metabolism studies were performed on rice with [Phenyl-U-^{14}C] and [Pyrimidinyl-4(6)-^{14}C]-benzpyrimoxan. Metabolites were identified using multiple chromatographic systems and authentic standards.

Rice

The metabolism of benzpyrimoxan was investigated in paddy rice following foliar spray application. Rice was seeded, transplanted and grown in a pot under paddy condition in a greenhouse. [Phenyl-U-^{14}C] or [Pyrimidinyl-4(6)-^{14}C]-labelled benzpyrimoxan was formulated as a suspension concentrate (SC). The SC formulation containing 2 percent of test substance was diluted 200-fold (100 mg ai/L) and 10 mL of the

diluent was sprayed on a whole test plant three times, which was equivalent to 3× 200 g ai/ha (general planting density for paddy rice: 200,000 plants/ha). For applications starting at the milk stage, the plant was sprayed three times at 7 day intervals, at heading stage (BBCH 55) and milk stage (BBCH 61–65 and 73–75). For applications starting at the ripe stage, the plant was sprayed twice at 7 day intervals, at heading stage (BBCH 55) and milk stage (BBCH 61–65), with the third application at BBCH 87–89, 4 weeks after the second application (Yoshizane, 2018: R-37018).

For both stage samples, the samples were taken 7 days after the last application (DALA). Samples of panicle, foliage and root were collected at milk stage. At ripe stage, panicle, straw and root were collected and then panicle was separated into grain and hull after 14 days air drying.

The surface of collected panicle, foliage, straw and hull samples were rinsed with acetonitrile. Panicle and foliage samples collected at milk stage were homogenized and sequentially extracted with acetonitrile/ distilled water (4/1, E1), acetonitrile/ 0.1 mol/L HCl (4/1, E2), acetonitrile/ 1 mol/L HCl (4/1, E3), acetonitrile/ 0.1 mol/L NaOH (4/1, E4) and acetonitrile/ 1 mol/L NaOH (4/1, E5). Grain (husked rice), hull and straw samples collected at ripe stage were crushed into small pieces and then homogenized and extracted as for milk stage samples. The unextracted residues and roots at both stages were collected and combusted after drying. Total radioactive residue (TRR) was determined to be the total of radioactivity in rinses, extracts and unextracted residues. The unextracted residues containing above 0.05 mg eq/kg or 10 percent TRR were treated sequentially with cellulase (for grain, treated with β-amylase), 6 mol/L HCl and 10 mol/L NaOH to characterize the radioactivity.

For quantification of radioactivity, aliquots of rinse and extracts were mixed with a liquid scintillant and subjected to LSC measurement. The unextracted residues and the root samples were combusted by a sample oxidiser. Aliquots of dried residual solid and root were mixed with cellulose powder prior to combustion to improve combustion efficiency. Radioactivity trapped in scintillation vials with scintillant after combustion was subjected to liquid scintillation counting (LSC) measurement.

For identification and quantification of radioactive residue, aliquots of concentrated rinse and extract were applied to two-dimensional TLC chromatography. To confirm identification of radioactive components, radioactivity in rinse and extract fractions was chromatographed on HPLC.

TRRs in panicle and foliage at milk stage were 1.18–1.40 and 1.83–2.44 mg eq/kg, respectively. TRRs in hull and straw at ripe stage were 2.81–4.68 and 3.29–3.69 mg eq/kg, respectively. Relatively small amounts of radioactive residues were detected in grain (0.10–0.25 mg eq/kg) and root (0.05–0.09 mg eq/kg). The major parts of TRR were recovered in surface rinse, neutral extract (acetonitrile/ distilled water (4/1, v/v; E1)) and the acid extract fractions (acetonitrile/ 0.1 mol/L HCl (4/1, v/v; E2)) in all the plant parts at both stages. Rinses and extracts (E1 to E5) were concentrated and subjected to TLC-radioluminography to determine metabolite constituents. The distribution of radioactivity in the extracts are shown in Table 3.

Notes:

N/A: not applicable; ND: not detected.

The radioactive residues detected in roots were as follows:

Milk stage: 0.08 mg eq/kg ([Phenyl-U-^{14}C]), 0.05 mg eq/kg ([Pyrimidinyl-4(6)-^{14}C]).

Ripe stage: 0.09 mg eq/kg ([Phenyl-U-^{14}C]), 0.09 mg eq/kg ([Pyrimidinyl-4(6)-^{14}C]).

At milk stage, the residues were identified as unchanged benzpyrimoxan and benzpyrimoxan-2-OH (DH-04). Benzpyrimoxan was determined to be 1.00–1.14 mg/kg (81.7–84.7 percent TRR) in panicle and 1.28–1.68 mg/kg (68.8–70.2 percent TRR) in foliage. DH-04 was determined to be 0.05–0.06 mg eq/kg (3.4–4.9 percent TRR) in panicle and 0.20–0.24 mg eq/kg (9.9–10.9 percent TRR) in foliage. Many minor (< 10 percent TRR) metabolites were also detected. After enzyme (-glucosidase and cellulose) hydrolysis of polar metabolites, small amounts (<10 percent TRR) of identified metabolites were detected.

At maturity, the residues were also identified as unchanged benzpyrimoxan and benzpyrimoxan-2-OH (DH-04). Benzpyrimoxan was determined to be 0.05–0.14 mg/kg (48.3–57.2 percent TRR) in grain, 1.68–2.83 mg/kg (59.9–60.6 percent TRR) in hulls and 1.58–1.86 mg/kg (48.2–50.5 percent TRR) in straw. DH-04 was determined to be 0.02–0.04 mg eq/kg (15.4–17.3 percent TRR) in grain, 0.14–

0.24 mg eq/kg (5.0–5.1 percent TRR) in hulls and 0.34–0.39 mg eq/kg (9.3–11.9 percent TRR) in straw. Many minor (<10 percent TRR) metabolites were also detected. After enzyme (-glucosidase and cellulose) hydrolysis of polar metabolites, small amounts (<10 percent TRR) of identified metabolites were detected.

Small amount of radioactivity was liberated from the unextracted residues by decomposing treatment with cellulase (for grain, treated with α-amylase), 6 mol/L HCl and 10 mol/L NaOH, sequentially. Tables 4 and 5 show the metabolites identified in the studies.

Notes:

ND: Not detected.

[1)] Radioactivity was detected up to E2. E3, E4 and E5 were not analysed.

[2)] No individual component exceeded < 0.01 mg eq/kg, 3.6%TRR.

[3)] No individual component exceeded 0.08 mg eq/kg, 3.0%TRR.

[4)] No individual component exceeded 0.11 mg eq/kg, 3.5%TRR.

The metabolites accounting for more than 10 percent TRR were benzpyrimoxan and benzpyrimoxan-2-OH (DH-04) in paddy rice.

Figure 2 shows the proposed pathway for benzpyrimoxan in paddy rice.

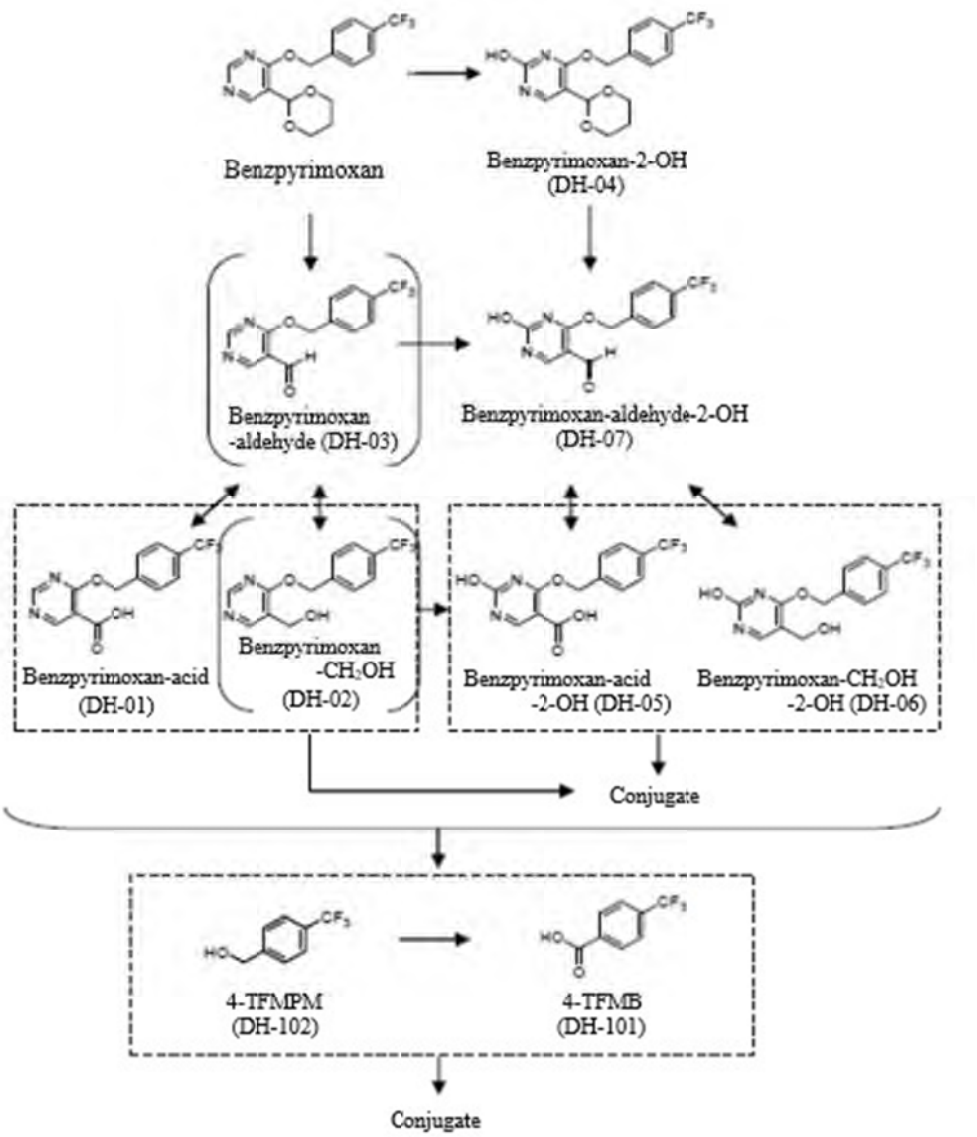

Figure 2 Metabolic Pathway of Benzpyrimoxan in Paddy rice.

Animal metabolism

The Meeting received studies on the metabolism of benzpyrimoxan in rats, lactating goats and laying hens. The metabolism of benzpyrimoxan in laboratory animals (rats) was summarized and evaluated by the WHO Core Assessment Group of the 2022 JMPR.

Lactating goat

The metabolism study in the lactating goat (*Capra hircus*) was conducted with ^{14}C-benzpyrimoxan (Ahn, 2018: R-37010). Lactating goats were dosed with [Phenyl-U-^{14}C]-benzpyrimoxan (1 goat) or [Pyrimidinyl-4(6)-^{14}C]-benzpyrimoxan (1 goat) orally once daily for 5 consecutive days at a nominal 10 ppm in the diet. Doses were contained in cellulose-filled gelatin capsules. The average actual dose was 13.8 ppm for the phenyl label and 14.7 ppm for the pyrimidinyl label.

Milk, faeces and urine were collected twice a day during the treatment period. The goats were sacrificed approximately 6 hours after the last dose for phenyl label and approximately 8 hours after the last dose for pyrimidinyl label.

The TRR values in the urine, cage wash, bile, whole milk, and skim milk were counted directly by LSC. Portions of each feces sample, homogenized gastrointestinal tracts, and blood samples were analysed for ^{14}C residue by combustion. The radioactive residues in liver, kidney, muscle, fat, and milk fat were measured by solubilization of subsamples.

Samples of liver and kidney were extracted twice with acetonitrile/water (1/1) and then once with acetonitrile at room temperature. The individual extracts were collected separately and analysed by LSC. A portion of the combined acetonitrile/water extracts was analysed by both HPLC and two-dimensional (2-D) TLC. Combined acetonitrile/water extracts of liver and kidney were subjected to β-glucuronidase or sulfatase hydrolysis. Treated samples were analysed by both HPLC and 1 D-/2 D-TLC, co-chromatographed with reference standards.

A sample of whole milk (Day 5) was extracted once with acetonitrile, twice with acetonitrile/water (1/1) and then once with acetonitrile at room temperature. The individual extracts were collected separately and analysed by LSC. A portion of the combined acetonitrile/water extracts was analysed by both HPLC and 2-D TLC.

Samples of skim milk and milk fat (Day 5) near the maximum concentration was extracted twice with acetonitrile/water (1/1) and then once with acetonitrile. The individual extracts were collected separately and analysed by LSC. A portion of the combined acetonitrile/water extracts was analysed by both HPLC and 2-D TLC.

For liver, kidney and milk, initial unextracted residue after the neutral extraction was further extracted twice with acetonitrile/0.1 mol/L HCl (4/1). The individual extracts were collected separately and analysed by LSC. For skim milk and milk fat, unextracted residue after the neutral extraction was dissolved in 0.1 mol/L NaOH and radio assayed by LSC.

Combined fat samples from renal, omental, and subcutaneous fat were extracted with hexane/acetone (4/1) and twice with acetone. The individual extracts were collected separately and analysed by LSC. The acetone/hexane extracts obtained from three individual samples were combined and concentrated to near dryness. Warm hexane was added and the sample was partitioned twice with acetonitrile. The hexane and acetonitrile phases were quantified by LSC. The initial unextracted residue after the acetone extraction was combusted for quantification by LSC.

Unextracted residue samples after the acetonitrile/0.1 mol/L HCl extraction in liver and kidney were characterized by additional extractions with protease, 4 mol/L HCl at 50 °C and 10 mol/L NaOH at 50 °C. The radioactivity recovered from the samples are shown in Table 6.

GI tract	-	12.23	-	10.89
Cage rinse	-	0.24	-	0.23
Percent of administered dose		83.32		80.57

The overall recovery of radioactivity was 83.3 percent of the applied dose (AD) for phenyl label and 80.6 percent for pyrimidinyl label, respectively. Radioactivity recovered in the urine, feces, and GI tract accounted for 50.3, 20.2 and 12.2 percent AD for phenyl label, and of 48.5, 19.7 and 10.9 percent AD for pyrimidinyl label, respectively Cage wash contained 0.23-0.24 percent AD. Radioactivity in the tissues accounted for <1.0 percent AD. Liver contained 0.27 and 0.67 percent AD for phenyl and pyrimidinyl labels, respectively, kidney contained 0.04 and 0.03 percent AD, and omental fat contained 0.02 percent AD for phenyl label. Other tissues such as muscle and fat contained ≤0.01 percent AD.

TRRs were measured daily in whole milk (separately skim milk and milk fat). For phenyl label, TRRs in skim milk and milk fat reached a plateau at Days 3–5 and were in a range of 0.051–0.083 mg eq/kg in skim milk, 0.057–0.092 mg eq/kg in milk fat, and 0.052–0.083 mg eq/kg in whole milk. For pyrimidinyl label, TRRs also reached a plateau at Days 3-5 and were in a range of 0.055–0.092 mg eq/kg in skim milk, 0.074–0.120 mg eq/kg in milk fat, and 0.058–0.095 mg eq/kg in whole milk. Table 7 shows the TRRs in the samples after extraction.

Notes:

N/A: Not analysed.

[1)] Neutral solvent extract of liver was treated with β-glucuronidase.

[2)] Neutral solvent extract of milk was partitioned with ethyl acetate, and ethyl acetate was analysed by HPLC and TLC.

In the neutral solvent extract of liver, which was treated with β-glucuronidase, benzpyrimoxan-CH_2OH (DH-02) and its conjugates (in phenyl label, 0.051 mg eq/kg and 21.8 percent TRR; in pyrimidinyl label, 0.019 mg eq/kg and 3.1 percent TRR), benzpyrimoxan-acid-2-OH (DH-05) (in phenyl label, 0.025 mg eq/kg and 10.7 percent TRR; in pyrimidinyl label, 0.039 mg eq/kg and 6.4 percent TRR), and benzpyrimoxan-CH_2OH-2-OH (DH-06) and its conjugate (in phenyl label, 0.036 mg eq/kg and 15.4 percent TRR; in pyrimidinyl label, 0.029 mg eq/kg and 4.8 percent TRR) were identified as major metabolites. Benzpyrimoxan-2-OH (DH-04) was also identified as a minor metabolite. Unknown metabolites in pyrimidinyl label consisted of several metabolites accounting for 0.054 mg eq/kg and 8.9 percent TRR. From the results by LC-MS in ESI positive mode, it was proposed that molecular weight of unknown-1 and unknown-2 was 226.1 ($C_{10}H_{15}O_3N_3$) and 169.1 ($C_{10}H_{16}O_3N_3$), respectively.

In the neutral solvent extract of kidney, benzpyrimoxan-acid (DH-01) accounted for 15.8 percent TRR in phenyl label (0.038 mg eq/kg) and 20.3 percent TRR (0.038 mg eq/kg) in pyrimidinyl label. DH-02 (free and conjugated) accounted for 16.3 percent TRR (0.039 mg eq/kg) in phenyl label and 5.9 percent TRR (0.011 mg eq/kg) in pyrimidinyl label. DH-05 accounted for 54.6 percent TRR (0.131 mg eq/kg) in phenyl label and 39.6 percent TRR (0.074 mg eq/kg) in pyrimidinyl label. DH-06 (free and conjugated) and benzpyrimoxan-benzoly-glycine (DH-402) were identified as minor metabolites.

In the neutral solvent extract of whole milk, skim milk and milk fat, DH-05 was identified as a major metabolite (0.040–0.062 mg eq/kg and 62.5–86.1 percent TRR in phenyl label; 0.036–0.054 mg eq/kg and 49.3–63.5 percent TRR in pyrimidinyl label). DH-06 was a minor residue.

Tables 8 and 9 sumarize the metabolites identified in liver, kidney, fat and milk in both label experiments.

Notes:

N/A: Not applicable, ND: Not detected

Muscle was not analysed because of low concentration of < 0.01 mg eq/kg.

[1] DH-06-conjugate was not detected in milk.

[2] This metabolite was further analysed by LC/MS.

[3] No individual component exceeded 0.007 mg eq/kg (8.5%TRR) in whole milk.

[4] No individual component exceeded 0.043 mg eq/kg (7.1%TRR) and 0.013 mg eq/kg (7.0%TRR) in liver and kidney, respectively

Laying hens

The metabolism study in laying hens (*Gallus gallus domesticus*) was conducted with ^{14}C-benzpyrimoxan (Ahn, 2018: R-37011). Laying hens (2 treatment groups, 10 hens per group) were treated with either [Phenyl-U-^{14}C] or [Pyrimidinyl-4(6)-^{14}C]-benzpyrimoxan by oral administration. Each hen received a single daily dose for 7 consecutive days at a nominal 10 ppm in the diet. Doses were contained in cellulose-filled gelatin capsules. The average actual dose was 11.1 ppm for the phenyl label and 12.8 ppm for the pyrimidinyl label

Eggs and excreta were collected twice a day during the treatment period. The hens were sacrificed at 6 hours after the last dose, and liver, muscle (breast and leg), gastrointestinal tract and fat samples (abdominal and subcutaneous) were collected.

Cage washes were analysed directly by LSC. Portions of each excreta sample and homogenized gastrointestinal tracts were analysed for ^{14}C residue by combustion via oxidizers. The TRRs in liver, muscle, fat and eggs (whole and separated) were solubilised and measured by LSC after addition of scintillation cocktail.

Eggs and all tissues (except for phenyl labeled musle) contained >0.010 mg eq/kg and were subjected to metabolite analysis. Extracted radiolabeled residues were identified by HPLC using cochromatography with authentic reference standards. The identity of residues was confirmed by TLC comparing the Rf values of standards with the sample they were analysed with.

Samples of liver, muscle and egg were extracted with acetonitrile/water (1/1) and then with acetonitrile. Unextracted residues after the neutral extraction were further extracted with acetonitrile/0.1 mol/L HCl (4/1). The remaining unextracted residue after the weak acidic extraction was combusted for quantification by LSC.

Samples of fat were extracted with hexane/acetone (4/1) and then with acetone. The initial unextracted residue after the acetone extraction was combusted for quantification by LSC. The combined acetone/hexane and acetone extracts from the fat tissues was concentrated to near dryness. Hexane was added and the sample was partitioned with acetonitrile. The hexane and acetonitrile phases were quantified by LSC. Combined acetonitrile layers were analysed by both HPLC and 2D-TLC.

Combined acetonitrile/water extracts of liver (pyrimidinyl-label) were concentrated and subjected to hydrolysis with β-glucuronidase and sulfatase. There was no significant difference between enzyme-treated samples and non-treated samples by HPLC analysis, confirmed by TLC. Unextracted samples after the acetonitrile/0.1 mol/L HCl extraction in liver and egg were characterized by additional extractions with protease, 4 mol/L HCl at 50 °C and 10 mol/L NaOH at 50 °C.

The overall recovery of radioactivity from the group of 10 laying hens was 76.34 percent dose for phenyl label and 87.78 percent dose for pyrimidinyl label, respectively. Radioactivity recovered in the excreta and cage washes accounted for 74.54 percent dose and 0.481 percent dose for phenyl label, and for 85.19 percent dose and 0.382 percent dose for pyrimidinyl label, respectively. Radioactivity in the

tissues accounted for <0.1 percent dose for phenyl label and 0.139 percent dose for pyrimidinyl label (Table 10).

TRR were measured daily in eggs (egg white and yolk measured separately). For phenyl label, concentrations of radioactivity both in egg white and yolk reached a plateau at Days 4–7 and were in a range of 0.004–0.008 mg eq/kg in egg white and 0.032–0.053 mg eq/kg in egg yolk. For pyrimidinyl label, concentrations of radioactivity reached a plateau at Days 5–7 and were in a range of 0.006–0.009 mg eq/kg in egg white and 0.134–0.197 mg eq/kg in egg yolk. The extractability of the residues is shown in Table 11.

Notes:

N/A: Not applicable

In the neutral solvent extract of liver, benzpyrimoxan-CH_2OH (DH-02) (in phenyl label, 0.013 mg eq/kg and 21.7 percent TRR; in pyrimidinyl label, 0.011 mg eq/kg and 6.1 percent TRR) and benzpyrimoxan-acid-2-OH (DH-05) (in phenyl label, 0.012 mg eq/kg and 20.0 percent TRR; in pyrimidinyl label, 0.050 mg eq/kg and 27.8 percent TRR) were identified as major metabolites. In addition, benzpyrimoxan-CH_2OH-2-OH (DH-06) was also detected as a minor component.

In the initial extract of fat, benzpyrimoxan (in phenyl label, 0.043 mg/kg and 70.5 percent TRR; in pyrimidinyl label, 0.089 mg/kg and 70.6 percent TRR) and DH-02 (in phenyl label, 0.006 mg eq/kg and 9.8 percent TRR; in pyrimidinyl label, 0.018 mg eq/kg and 14.3 percent TRR) were identified as major components. In the neutral solvent extract of muscle and egg, benzpyrimoxan and DH-02 were identified as major components, but were below 0.01 mg eq/kg.

Tables 12 and 13 summarize the compounds indentified in the experiments.

[1] No individual component exceeded 0.037 mg eq/kg (20.6%TRR) by characterization.

Furthermore, these residues consist of some ninhydrin-positive and protein-related residues by TLC.

[2] No individual component exceeded 0.011 mg eq/kg (15.7%TRR) by characterization.

Furthermore, these residues consist of some ninhydrin-positive and protein-related residues by TLC.

Summary of animal metabolism

The metabolic fate of benzpyrimoxan seems to be similar in the goat and the hen and is proposed in Figure 3.

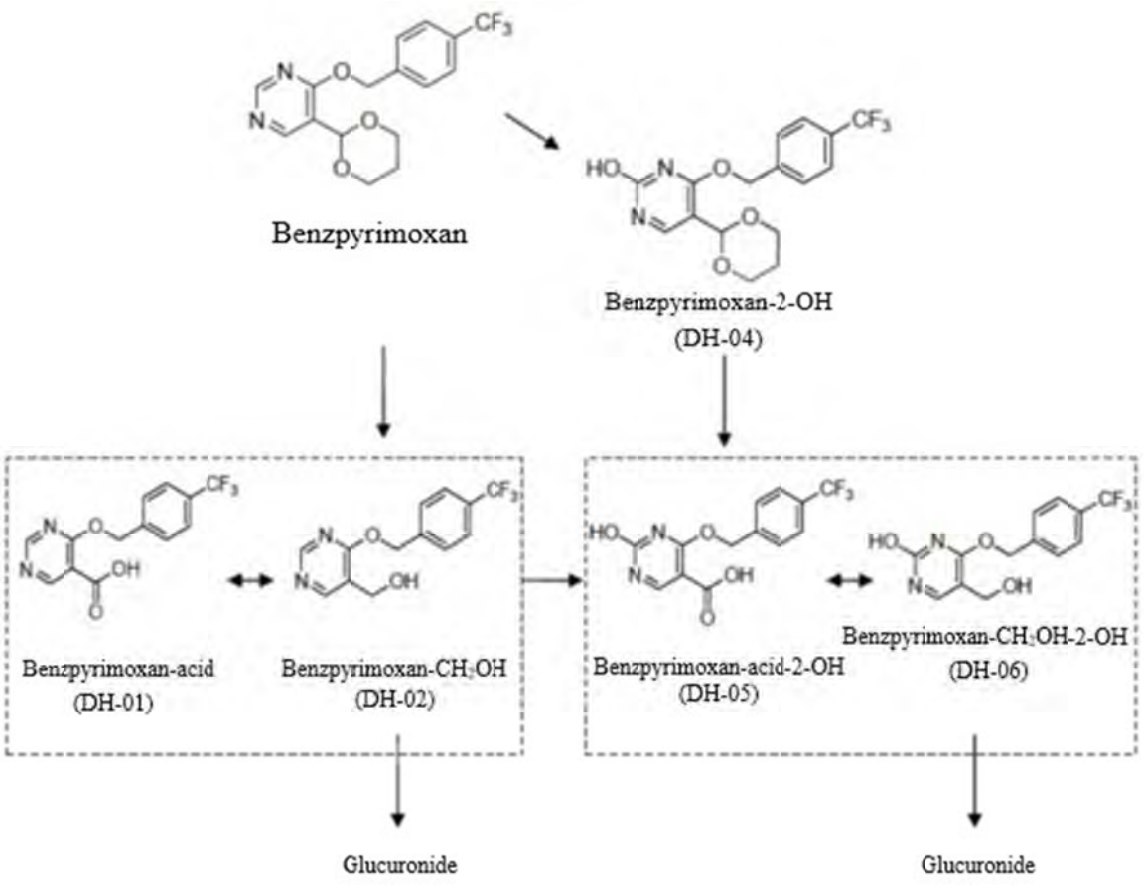

Figure 3 Metabolic pathway of benzpyrimoxan in farm animals

Environmental fate

The Meeting received information on degradation in aerobic soil (paddy and upland), hydrolysis and photodegradation studies.

Degradation in aerobic soil

The soil metabolism study was conducted in aerobic soil under paddy conditions. The test system employed in the study consisted of a 70 g dry weight equivalent of soil flooded with a water layer in a vessel which was connected to a series of traps for organic volatiles and for alkaline volatiles including carbon dioxide using ethylene glycol and 20 percent ethanol amine, respectively. Following a 14-day pre-incubation, [Phenyl-U-^{14}C] and [Pyrimidinyl-4(6)-^{14}C]-benzpyrimoxan were applied at 0.2 mg ai/kg dry soil, which was equivalent to the proposed maximum field application rate (200 g ai/ha) and incubated in the dark at 25±2 °C under aerobic conditions (Tanaka, 2016: E-37003). Table 14 shows the characteristics of the soil used in the study.

Table 14 Paddy soil characteristics (Tanaka, 2016: E-37003)

Origin location	Kochi, Japan
Soil texture (USDA)	Clay loam
percent Sand	20.4
percent Silt	52.0
percent Clay	27.6

Origin location	Kochi, Japan
pH (KCl)	4.6 [21°C]
pH (water)	5.7 [21°C]
Organic carbon (percent)	1.41
Cation exchange capacity ($cmol_c/kg$)	12.3
Maximum water holding capacity (10 g/kg)	72.0
Bulk density (mg/cm^3)	0.97
Microbial biomass (mg/kg)	
At zero day (pre-incubation)	639
After 120 days	512
After 180 days (post-incubation)	466

Soil samples were analysed at 0, 14, 30, 60, 120 and 180 days after application. Water phase of soil sample was removed after decantation and the soil was extracted with neutral extraction solvent (acetonitrile/distilled water, 4/1), two acidic extraction solvents (acetonitrile/0.1 mol/L HCl, 4/1 and acetonitrile/1.0 mol/L HCl, 4/1). Extracts and trap solutions were subjected to LSC. Unextracted radioactivity obtained after extraction by the solvents was subjected to combustion radioanalysis. Total recovery was determined as the sum of radioactivity in extracts (water and soil phase), trap solution and unextracted, and expressed as percent of applied radioactivity (AR) (Table 15). The extracted fractions were analysed by TLC and HPLC. Additionally, characterization of radioactivity in 20 percent ethanolamine trap media (CO_2 fraction) and unextracted was conducted.

Unextracted radioactivity was fractionated as follows: An aliquot of air-dried soils after solvent extraction derived from 180 day and sterilized soil samples was re-extracted with 1 mol/L NaOH solution at about 50 ºC by shaking for 2 hours followed by centrifugation. The obtained precipitate (humin fraction) was weighed. An aliquot was subjected to combustion radioanalysis. The supernatant was acidified to pH 1–2 by addition of.12 mol/L HCl, and resultant insoluble matter was removed by centrifugation. The supernatant and precipitate obtained by centrifuge were designated as fulvic acid and humic acid fractions, respectively. Fulvic acid fraction was filled up to 25 mL and then an aliquot was subjected to radioanalysis. An aliquot of humic acid fraction was subjected to combustion radioanalysis after reconstituting with 1 mol/L NaOH solution.

[3] Sum of organic volatile and carbon dioxide

Radioactivity in trap solution and unextracted accounted for a maximum of 1.9 and 5.3 percent of AR, respectively. Substantial mineralization ($^{14}CO_2$) was observed with both radiolabels, which indicated that benzpyrimoxan was steadily degraded in paddy soil. Fractionation of unextracted revealed that radioactivity was mainly distributed in humin fraction.

Tables 16 and 17 show the degradantes of benzpyrimoxan in paddy soil. The total recoveries were more than 94.3 percent AR for [Phenyl-U-^{14}C] benzpyrimoxan and more than 95.2 percent AR for [Pyrimidinyl-4(6)-^{14}C] benzpyrimoxan. Regardless of incubation time and sterilized or non-sterilized soil, the radioactivity in the solventextracted fraction accounted for more than about 90 percent of AR. Benzpyrimoxan accounted for more than 70 percent of AR, even after 180 days incubation, which implied that benzpyrimoxan degraded in paddy soil very gradually. The laboratory half-life of benzpyrimoxan in paddy soil was over 1 year.

Several identified and unknown degradates were detected, however, none of which accounted for more than 10 percent of AR throughout the study period for both radiolabels. Benzpyrimoxan-2-OH (DH-04) was the major degradate, which was formed at a maximum of 5.3 percent of AR after 120 days incubation. Benzpyrimoxan-acid (DH-01), benzpyrimoxan-aldehyde (DH-03), benzpyrimoxan-acid-2-OH (DH-05), benzpyrimoxan-CH_2OH-2-OH (DH-06), benzpyrimoxan-aldehyde-2-OH (DH-07), 4-TFMB (DH-101) and 4-TFMPM (DH-102) were detected as minor degradates. Under sterilized condition, benzpyrimoxan-acid (DH-01), benzpyrimoxan-aldehyde (DH-03), benzpyrimoxan-enaminealdehyde (DH-08) and 4-TFMPM (DH-102) were also detected. The results are shown in Tables 16 and 17.

In a second study, the soil metabolism study was conducted in upland soil under aerobic conditions. The test system employed in the study consisted of a 50 g dry weight equivalent of soil in a vessel which was connected to a series of traps for organic volatiles and for alkaline volatiles including carbon dioxide using ethylene glycol and 20 percent ethanol amine, respectively. Following a 14-day pre-incubation, [Phenyl-U-^{14}C] and [Pyrimidinyl-4(6)-^{14}C]-benzpyrimoxan were applied at 0.2 mg ai/kg dry soil, which was equivalent to the proposed maximum field application rate (200 g ai/ha) and incubated in the dark at 25 ± 2 ºC under aerobic conditions (Tanaka, 2017: E-37006). Table 18 shows the characteristics of the soil used in the study.

Table 18 Upland soil characteristics (Tanaka, 2017: E-37006)

Origin location	Kochi, Japan
Soil texture (USDA)	Loam
percent Sand	35.8
percent Silt	43.1
percent Clay	21.1
pH (KCl)	5.6 [21 °C]
pH (water)	6.7 [21 °C]
Organic carbon (percent)	1.97
Cation exchange capacity ($cmol_c/kg$)	15.4
Maximum water holding capacity (10 g/kg)	73.0
Bulk density (mg/cm^3)	1.06
Microbial biomass (mg/kg)	
At zero day (pre-incubation)	121
After 120 days	122
After 180 days (post-incubation)	78

Soil samples were analysed at 0, 14, 30, 60, 120 and 180 days after application and extracted with neutral extraction solvent (acetonitrile/distilled water (4/1), two acidic extraction solvents (acetonitrile/0.1 mol/L HCl (4/1) and acetonitrile/1.0 mol/L HCl (4/1 v/v)). Extracts and trap solutions thus obtained were subjected to liquid scintillation counting. Unextracted radioactivity obtained was subjected to combustion radioanalysis. The extracted fractions were analysed by TLC and HPLC. Additionally, characterization of radioactivity in 20 percent ethanolamine trap media (CO_2 fraction) and unextracted was conducted. Total recovery was determined as the sum of radioactivity in extracts, trap solution and unextracted and the results are shown in Table 19.

Radioactivity in unextracted was fractionated as follows: An aliquot of air-dried unextracted derived from 180 days sample and sterilized soil sample was re-extracted with 1 mol/L NaOH solution at about 50 ºC by shaking for 2 hours followed by centrifugation. The obtained precipitate (humin fraction) was weighed. An aliquot was subjected to combustion radioanalysis. The supernatant was acidified to pH ranged from 1–2 using.12 mol/L HCl, and resultant insoluble matter was removed by centrifugation. The supernatant and precipitate obtained by centrifuge were designated as fulvic acid and humic acid fractions, respectively. Fulvic acid fraction was filled up to 25 mL and then an aliquot was subjected to radioanalysis. An aliquot of humic acid fraction was subjected to combustion radioanalysis after reconstituting with 1 mol/L NaOH solution.

Tables 20 and 21 show the degradation data of benzpyrimoxan in upland soil. The total recoveries were more than 91.4 percent AR for [Phenyl-U-^{14}C]-benzpyrimoxan and more than 90.7 percent of AR for [Pyrimidinyl-4(6)-^{14}C]-benzpyrimoxan. The radioactivity of extracted fraction was reduced to about 50 percent of AR at 180 days incubation, although the radioactivity of extracted fraction remained more than 90 percent of AR at 180 days for sterilized soil. Benzpyrimoxan was continuously degraded in soil throughout the incubation period, and reduced to about 30 percent of AR at 180 days. The laboratory half-life of benzpyrimoxan in upland soil under aerobic condition was 124 days.

Radioactivity in trap solution and unextracted accounted for a maximum of 14.4 and 25.2 percent of AR, respectively. Substantial mineralization ($^{14}CO_2$) was observed with both radiolabels, which indicated that benzpyrimoxan was steadily degraded in soil. Fractionation of unextracted revealed that radioactivity was mainly distributed in humin fraction.

Several identified and unknown degradates were detected, none of which accounted for more than 10 percent of AR. Metabolite DH-04 was the major degradate, which was formed at a maximum of 7.8 percent of AR after 14 days incubation. Benxpyrimoxan-CH_2OH (DH-02), benzpyrimoxan-aldehyde (DH-03), benzpyrimoxan-acid-2-OH (DH-05), benzpyrimoxan-aldehyde-2-OH (DH-07), benzpyrimoxan-enaminealdehyde (DH-08), 4-TFMB (DH-101) and 4-TFMPM (DH-102) were detected as minor degradates. In the case of sterilized condition, DH-03, DH-08 and DH-102 were detected, suggested that these degradates were derived from chemical reaction.

In summary, benzpyrimoxan was degraded in aerobic soil under paddy and upland condition, following production of many degradates. Degradates were mainly produced by hydroxylation of pyrimidine ring, cleavage of cyclic acetal and oxidation of carbonyl group. In addition, pyrimidine ring part was cleaved or broken away. Degradates thus produced were further changed other degradates and took in bound residue, consequently mineralized to CO_2. The proposed methabolic pathway is shown in Figure 4.

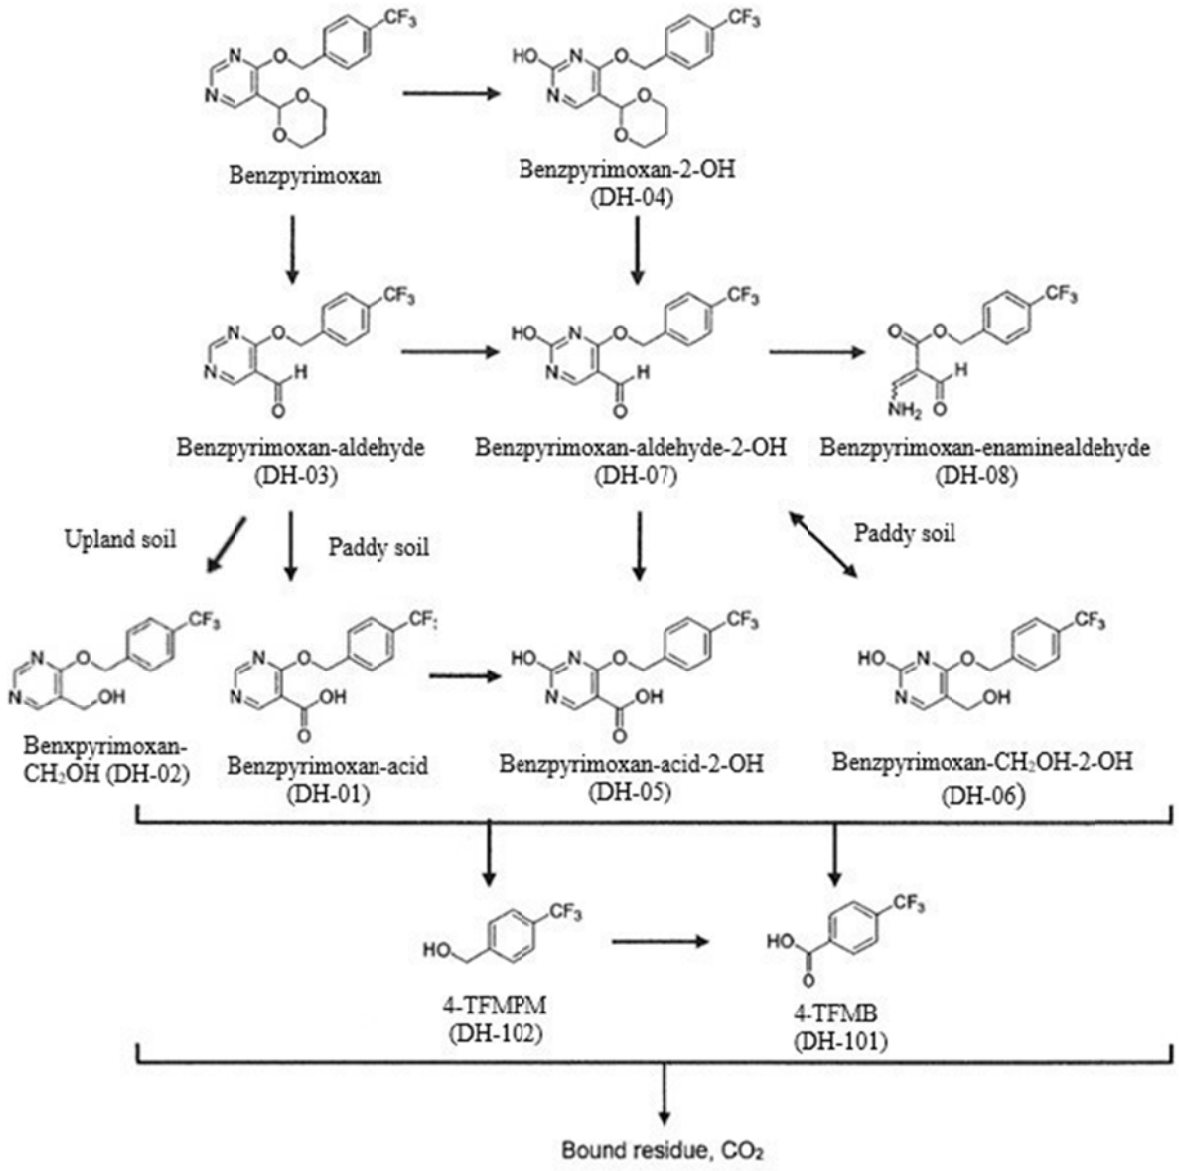

Figure 4 Metabolic pathway of benzpyrimoxan in aerobic soil

Hydrolysis

The hydrolysis of ^{14}C-benzpyrimoxan was studied in buffers solutions (Nishimura, 2017: E-37007).

For the preliminary test (Tier 1 test), hydrolysis of [Phenyl-U-^{14}C]-benzpyrimoxan was tested in aqueous buffer solutions at 50°C at different pHs (pH 4, 7 and 9), with a nominal concentration of 2 mg/L. The solutions were incubated in the dark under sterile conditions. Duplicate samples were taken after 0 and 5 days of inclubation and analysed by radio-HPLC.

After 5 days, 23.9, 98.1 and 98.2 percent AR were identified as unchanged benzpyrimoxan at pH 4, 7 and 9, respectively (Table 22). Benzpyrimoxan was considered to be hydrolytically stable at environmentally relevant temperatures under neutral and basic conditions, while benzpyrimoxan was considered to be hydrolytically unstable under acidic conditions.

Table 22 Proportions of radioactive components in aqueous solutions at pH 4, 7 and 9 at 50 °C after treatment of [Phenyl-U-^{14}C]-benzpyrimoxan, percent of applied radioactivity

[1)] Sum of minor unidentified components, each <5.8 percent AR

For the definitive test (Tier 2 test), hydrolysis of benzpyrimoxan separately labeled with ^{14}C in the phenyl and the pyrimidine rings was tested in buffer solutions at pH 4 at different temperatures (25 °C, 40 °C and 50 °C). Sampling times at 25 °C were 0, 9, 14, 17, 21, 24 and 30 days, at 40 °C were 0, 2, 6, 8, 10, 15 and 20 days, and at 50 °C were 0, 1, 2, 3, 4, 6 and 7 days. The results are shown in Tables 23 and 24.

At 25 °C, environmentally relevant temperature, the recovery during the study was >95 percent AR for all samples. After 30 days, 65.3 and 67.9 percent were identified as unchanged benzpyrimoxan in the [Phenyl-U-^{14}C] and [Pyrimidinyl-4(6)-^{14}C] label treated samples, respectively. The major hydrolysis product at pH 4 was benzpyrimoxan-enaminealdehyde (DH-08) with maximum amounts of 13.2 percent AR (24 DAT, average of both radiolabels). Two minor hydrolysis products were formed and identified, benzpyrimoxan-aldehyde (DH-03, representing a maximum 4.7 percent AR, 14 days, average of both radiolabels) and 4-TFMPM (DH-102, representing a maximum 8.6 percent AR, 30 days, ^{14}C-phenyl label). No other component represented greater than 5.4 percent AR (average of two replicates).

Table 23 Proportions of radioactive components in aqueous solutions at pH 4 at 25 °C after treatment of [Phenyl-U-^{14}C]-benzpyrimoxan, percent of applied radioactivity

[1)] includes DH-200 (NNI-1501-4-OH) and Pyr-Unk-01 (FW: 142, $C_5H_6N_2O_3$)

[2)] includes Pyr-Unk-02 (FW: 114, $C_4H_6N_2O_2$) and Pyr-Unk-03 (FW: 124, $C_5H_4N_2O_2$)

At 40 °C and 50 °C, the recovery during the study was >95 percent AR for all samples (data not shown). At the end of incubation period, benzpyrimoxan represented 16.7 and 14.5 percent AR, at 40 °C and 50 °C, respectively (average of both radiolabels). Three discrete hydrolytic products were formed and identified, namely DH-08 (representing a maximum 43.2 percent AR, 50 °C, 7 days, average of both radiolabels), DH-03 (representing a maximum 9.3 percent AR, 50 °C, 3 days, average of both radiolabels) and DH-102 (representing a maximum 30.7 percent AR, 40 °C, 20 days, ^{14}C-phenyl label). In the ^{14}C-pyrimidinyl label samples, two additional peaks (designated as UP1 and UP2) were detected, both representing a mixture of different compounds. The peak UP1 reached a maximum level of 8.2 percent AR (40 °C, 20 days). The peak UP1 consisted of benzpyrimoxan-4-OH (DH-200) and Pyr-Unk-01. The peak UP2 reached a maximum level of 20.8 percent AR (40 °C, 20 days). The peak UP2 consisted of Pyr-Unk-02 and Pyr-Unk-03.

The DT_{50} at pH 4 at 25 °C was 50.9 days (average of both radiolabels). Hydrolysis of benzpyrimoxan at pH 4 is highly dependent upon temperature (Table 25).

Table 25 Rate constants and DT_{50} values for the hydrolysis of benzpyrimoxan

Radiolabel	pH	Temperature (°C)	DT_{50} (days)
[Phenyl-U-^{14}C]	4	50	2.48
		40	7.56
		25	50.4
		20	97.3[1)]
	7	50	N/A[2)]
	9	50	N/A[2)]

Radiolabel	pH	Temperature (°C)	DT_{50} (days)
[Pyrimidinyl-4(6)-^{14}C]	4	50	2.53
		40	7.98
		25	51.4
		20	99.7[1)]

Notes:

[1)] The estimated values were calculated by using the rate constants at the other temperatures.

[2)] Less than 10 percent degradation was observed in the preliminary test (at 50 °C up to 5 days)

Photodegradation in buffer solutions

The photodegradation fate of [Phenyl-U-^{14}C] or [Pyrimidinyl-4(6)-^{14}C]-benzpyrimoxan was studied in buffer solutions (Murata, 2017: E-37008). The test substances dissolved in buffer solution (pH 7), whose concentration was targeted as 2.0 mg/L (less than one half of its water solubility) were irradiated by artificial sunlight of a xenon arc lamp with filters blocking irradiation below 290 nm at 25.0 °C up to 25 days.

The test substances decreased to 84.6–85.0 percent AR after 25 days irradiation. No significant degradation was observed in the dark condition. The half-lives of the test substances were determined to be 121.6–154.4 days, which were estimated as 553.2–702.4 days (mean: 627.8 days) under natural sunlight in Tokyo spring.

In [Phenyl-U-^{14}C]-benzpyrimoxan samples, 4-TFMB (DH-101) and 4-TFMPM (DH-102) were identified, accounting for a maximum of 3.0 and 3.2 percent AR, respectively. In [Pyrimidinyl-4(6)-^{14}C]-benzpyrimoxan samples, benzpyrimoxan-acid (DH-01) and benzpyrimoxan-4-OH (DH-200) were identified, accounting for a maximum of 0.4 and 6.0 percent AR, respectively. In both [Phenyl-U-^{14}C] and [Pyrimidinyl-4(6)-^{14}C]-benzpyrimoxan samples, several minor degradates were detected, none of which accounted for greater than 10 percent AR through the study. In both [Phenyl-U-^{14}C] and [Pyrimidinyl-4(6)-^{14}C]-benzpyrimoxan samples, organic volatile in the ethanolamine traps was accounted for 0.5–0.9 percent AR at the end of irradiation and was considered to be carbon dioxide.

Rotational crop studies

No rotational crop studies were submitted to the Meeting.

RESIDUE ANALYSIS

Analytical methods

Descriptions of analytical methods together with validation data for residues of benzpyrimoxan and its metabolites in plant and animal matrices were submitted to the Meeting. The methods rely on an initial extraction, usually with acetonitrile/water. After column clean-up, benzpyrimoxan and its metabolites are analysed by LC-MS/MS, at a LOQ of 0.01 mg/kg for both parent and metabolites.

Plant matrices (benzpyrimoxan and DH-04)

Method R-37002 was validated in husked rice, bran, polished rice, washing water and cooked rice. The pulverised rice grain, bran and straw samples were soaked with water. Except washing water, benzpyrimoxan and benzpyrimoxan-2-OH (DH-04) were sequentially extracted twice with acetonitrile/water (4/1) and twice with acetonitrile/0.1 mol/L HCl (4/1). The extract was cleaned-up by C_{18} cartridge, eluted with acetonitrile/water (3/2), and the eluate filtered prior to analysis by LC-MS/MS.

Washing water sample was cleaned-up by C_{18} cartridge, eluted with acetonitrile/water (3/2), the eluate filtered prior to analysis by LC-MS/MS.

In method A-37024, husked rice samples were hydrated with water and extracted with acetonitrile for 5 minutes in a grinder, followed by addition of a QuEChERs salt pouch containing magnesium sulphate, sodium chloride, sodium citrate dibasic sesquihydrate and sodium citrate tribasic dehydrate and extracting for 1 minute in a grinder. After centrifugation, aliquots were diluted into the calibration range with acetonitrile/water (1/1) and analysed by LC-MS/MS. The method was idepedently validated (Munford, 2020; A-35025).

Method validation data and MS/MS transitions for quantification and confirmation on plant matrices are summarized in Tables 26 (benzpyrimoxan) and 27 (benzpyrimoxan-2-OH, DH-04). Mean recoveries of benzpyrimoxan and DH-04 were whithin the range of 70–120 percent and RSD <20 percent. Linearity was obtained in the range of 0.03–2.0 µg/L per analyte using five calibration points, prepared in acetonitrile/water (3/2), and linear correlations were >0.99. LOQ was set at 0.01 mg/kg.

Notes:

MV: Method Validation, ILV: Independent Laboratory Validation, NA: Not Analysed

Animal matrices (benzpyrimoxan, DH-01, DH-02, DH-4, DH-05 and/or DH6)

Method R-37016 was validated in milk, cow muscle, liver, kidney and fat for benzpyrimoxan and metabolites benzpyrimoxan-acid (DH-01), benzpyrimoxan-CH_2OH (DH-02), benzpyrimoxan-2-OH (DH-04), benzpyrimoxan-acid-2-OH (DH-05) and benzpyrimoxan-CH_2OH-2-OH (DH-06). Milk and skim milk samples were weighed into a centrifuge tube, purified by PLS-2 SPE cartridge, eluted with acetonitrile, the eluate filtered and diluted prior to analysis for benzpyrimoxan, DH-04, and DH-05. Another aliquot of milk was treated with β-glucuronidase for 24 hours, cleaned up by PLS-2 SPE cartridge, eluted with acetonitrile, the eluate filtered and diluted prior to DH-06.analysis.

Tissue (muscle, liver and kidney) and milk cream samples were extracted twice with acetonitrile/water (1/1), an aliquot was cleaned up by C_{18} cartridge, eluted with acetonitrile, the eluate diluted and filtered prior to analysis for benzpyrimoxan, DH-01, DH-04, and DH-05. An additional aliquot was treated with β-glucuronidase, cleaned up by PLS-2 SPE cartridge, eluted with acetonitrile, the eluate filtered and diluted prior to analysis for DH-02 and DH-06.

Cow fat samples were extracted twice, first with hexane/acetone (4/1) and second with acetonitrile/water (1/1). The two phases were allowed to separate and the lower (acetonitrile/acetone) layer collected. The upper layer was extracted with acetonitrile and collected. The collected lower layers was adjusted, then an aliquot was cleaned up by C_{18} cartridge and eluted with acetonitrile. The eluate was then diluted and filtered prior to analysis for benzpyrimoxan, DH-01, DH-04, and DH-05. An additional aliquot was treated with β-glucuronidase, then cleaned up by PLS-2 SPE cartridge and eluted with acetonitrile. The eluate was filtered and diluted prior to analysis for DH-02 and DH-06. Analysis of all analytes was performed by LC-MS/MS, and the method validated at a LOQ of 0.01 mg/kg.

Method R-37017 was validated for egg and hen muscle and liver. Samples were extracted twice with acetonitrile/water (1/1). A small aliquot was purified by C_{18} cartridge, eluted with acetonitrile, the eluate was diluted and filtered prior to analysis for benzpyrimoxan, DH-02 and DH-05.

Hen fat samples were extracted twice, first with hexane/acetone (4/1) and second with acetonitrile/water (1/1). The extracts were combined in a separatory funnel, then collected the lower hydro-organic layer. The upper layer was extracted with acetonitrile and the acetonitrile combined with previously collected hydro-organic layer. A small aliquot was cleaned up by C_{18} cartridge, eluted with acetonitrile. The eluate was diluted and filtered prior to analysis for benzpyrimoxan, DH-02 and DH-05. Analysis of all analytes was performed by LC-MS/MS.

Validation data for methods R-37016 and R-37016 on animal matrices and mass transitions are summarized in Table 28 for benzpyrimoxan and Tables 29 to 32 for the metabolites.

STABILITY OF PESTICIDE RESIDUES IN STORED ANALYTICAL SAMPLES

The Meeting received data on the storage stability of benzpyrimoxan and its metabolites in samples for plant and animal commodities stored frozen.

Plant matrices

The storage stability of benzpyrimoxan and metabolite benzpyrimoxan-2-OH (DH-04) in rice grain, husked rice and rice straw was tested (Morita, 2016, 2017, 2018: R-37002, R-37004, R-37009). Homogenised samples were fortified with benzpyrimoxan and DH-04 in acetonitrile at 0.5 mg/kg, and the samples were stored in at -20 ± 6 °C. Duplicate samples were analysed at each sampling time. Benzpyrimoxan and DH-04 were analysed using method in rice residue studies by LC-MS/MS (LOQ of 0.01 mg/kg). The results are shown in Tables 34 and 35. Benzpyrimoxan and DH-04 were found to be stable upon frozen storage in rice commodities for at least 2.5 months (rice grain: 77 days, husked rice: 75 days, straw: 82 days).

Animal matrices

The storage stability of benzpyrimoxan and metabolites benzpyrimoxan-acid (DH-01), benzpyrimoxan-CH_2OH (DH-02), benzpyrimoxan-2-OH (DH-04), benzpyrimoxan-acid-2-OH (DH-05) and benzpyrimoxan-CH_2OH-2-OH (DH-06) in cow milk and tissues was tested in feeding study (VanMiddlesworth, 2018: R-37016). Control samples of milk and tissues were fortified with benzpyrimoxan and metabolites at 0.1 mg/kg and stored under freezer conditions for at least as long as the longest storage interval (harvest to extraction) from the feeding study samples. The aged samples were extracted alongside freshly fortified control matrix samples. The conversion of DH-01 to DH-05 in aged liver, kidney and fat samples is measured as DH-05 and reported as DH-01 equivalent using the molecular weight ratio of DH-01 to DH-05 to calculate the equivalent residue of DH-01 in mg/kg and percent recovery. Benzpyrimoxan and metabolites were analysed using method in cow feeding study by LC-MS/MS (LOQ of 0.01 mg/kg). The results are shown in Tables 36 to 40.

85**			91, 92	77, 81								

Notes:

* Procedural recovery.

** DH-01 was found to degrade quantitatively to DH-05 and was presented as DH-01 equivalent recoveries in parenthesis. The DH-05 residue can be converted to DH-01 equivalent residue through the ratio of the DH-01 to DH-05 molecular weights. The resulting residue can be summed with the measured DH-01 residue to give a DH-01 equivalent percent recovery.

Table 39 Recovery of benzpyrimoxan, DH-01, DH-02, DH-04, DH-05 and DH-06 from stored fortified samples of cow kidney at 0.1 mg/kg (R-37016 VanMiddlesworth, 2018)

Notes:

* Procedural recovery

** DH-01 was found to degrade quantitatively to DH-05 and were presented as DH-01 equivalent recoveries in parenthesis. The DH-05 residue can be converted to DH-01 equivalent residue through the ratio of the DH-01 to DH-05 molecular weights. The resulting residue can be summed with the measured DH-01 residue to give a DH-01 equivalent percent recovery.

The storage stability of benzpyrimoxan and metabolites benzpyrimoxan-CH_2OH (DH-02) and benzpyrimoxan-acid-2-OH (DH-05) in hen eggs was tested in feeding study (VanMiddlesworth, 2018: R-37017). Egg control samples were fortified with benzpyrimoxan and metabolites at 0.1 mg/kg and stored under freezer conditions for at least as long as the longest storage interval (harvest to extraction) from the feeding study samples. After the appropriate storage interval the aged samples are extracted alongside freshly fortified control matrix samples. Recoveries of both aged and freshly fortified samples are determined. Benzpyrimoxan, DH-02 and DH-05 were extracted from eggs with acetonitrile/water (1/1). Extracts were cleaned up on a C_{18} SPE cartridge, filtered and analysed by LC-MS/MS (LOQ of 0.01 mg/kg. The results are shown in Table 41

Table 41 Benzpyrimoxan, DH-02 and DH-05 from stored fortified hen egg samples at 0.1 mg/kg (R-37017 VanMiddlesworth, 2018)

USE PATTERN

Benzpyrimoxan is an insecticide having biological activity to rice plant hoppers (Hemiptera: Delphacidae). The Meeting received label for use in rice in Japan (Table 42).

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received information on benzpyrimoxan supervised field trials conducted in Japan using SC formulation on paddy rice and rice straw.

Conditions of the supervised residue trials were generally well reported. Most field reports provided data on the applicators used, plot size, field sample size and sampling date.

Laboratory reports included method validation with procedural recoveries from spiking at residue levels similar to those occurring in samples from the supervised trials. Date of analyses and duration of residue sample storage were also provided. Although trials included control plots, no control data are recorded in the tables except when residues were found in samples from control plots. Residue data are not corrected for percent recovery.

Each of the field trial sites generally consisted of untreated control plot and treated plot. Application rates and residue concentrations have generally been rounded to two significant figures. Residue values from the trials, which have been used for the estimation of maximum residue levels, STMRs and HRs, are underlined.

The residue concentrations are reported for benzpyrimoxan and benzpyrimoxan-2-OH (DH-04), expressed as parent compound equivalents (conversion factor = 0.955).

Total residues for estimation of maximum residues levels and STMRs are calculated by summing up the concentrations of benzpyrimoxan and DH-04, expressed as benzpyrimoxan, as illustrated below.

Benzpyrimoxan	DH-04	Total
<0.01	<0.01	<0.02 (0.01 + 0.01)
<0.01	0.025	0.035 (0.01+0.025)
0.019	0.058	0.077 (0.019+0.058)

Rice cereals

The Meeting received 8 decline trials on paddy conducted in Japan (Morita, 2016, 2017, 2018: R-37002, R-37004, R-37009). Applications were made between booting/heading and harvest with treatment intervals of 6–14 days. Mature rice plants were harvested at 7 days after last application (DALA) as well as 14 and 21 DALA and dried naturally for 3–7 days on a drying pole protected from rain. Rice grain (paddy rice) was collected at threshing. Samples of husked rice and hulls were collected upon husking. The samples were then transported under cooled conditions to the analytical laboratory within 1–2 days.

Samples were analysed for residues of benzpyrimoxan and benzpyrimoxan-2-OH (DH-04) following analytical method in study R-37002. The LOQs for both benzpyrimoxan and DH-04 were 0.01 mg/kg. The overall mean recoveries from concurrent fortifications for benzpyrimoxan and DH-04 in

matrices were within 70–120 percent. Samples were stored deep frozen until extraction for a maximum of 61 days for rice grain and 56 days for husked rice. The results are shown in Table 43.

Notes:

[1)] Re-treatment interval is given in parenthesis.

[2)] [Total residue = parent + 3 × DH-04 expressed as parent]: the toxicity of DH-04 is three times higher than that of parent.

Rice straw

The Meeting received 8 decline trials on paddy rice conducted in Japan (Morita, 2016, 2017, 2018: R-37002, R-37004, R-37009). Applications were made between booting/heading and harvest with treatment intervals of 6–14 days. Mature rice plants were harvested at 7 DALA as well as 14 and 21 DALA and dried naturally for 3–7 days on a drying pole in a facility to prevent rain. Straw was collected at threshing. The samples were then transported under cooled conditions to the analytical laboratory within 1–2 days.

Samples were analysed for residues of benzpyrimoxan and benzpyrimoxan-2-OH (DH-04) following analytical method R-37002. The LOQs for both benzpyrimoxan and DH-04 were 0.01 mg/kg. The overall mean recoveries from concurrent fortifications for benzpyrimoxan and DH-04 in matrices were within 70–120 percent. Samples were stored deep frozen until extraction for a maximum of 63 days. The results are shown in Table 44.

FATE OF RESIDUES IN STORAGE AND PROCESSING

The Meeting received information on high temperature hydrolysis of benzpyrimoxan and the fate of benzpyrimoxan residues during the processing of rice.

High temperature hydrolysis

The hydrolysis of [^{14}C]-benzpyrimoxan was studied in sterile buffered solutions of pH 4, 5 and 6 (Ihara, 2017: E-37004). [Phenyl-U-^{14}C] and [Pyrimidinyl-4(6)-^{14}C]-benzpyrimoxan were incubated in aqueous buffered solutions at a nominal concentrations of 1.0 mg/L at three pH values. The conditions of incubation were as follows: pH 4 ± 0.1 at 90 ± 5 °C for 20 minutes, representing pasteurization; pH 5 ± 0.1 at 100 ± 5 °C for 60 minutes, representing brewing, baking and boiling; pH 6 ± 0.1 at 120 ± 5 °C for 20 minutes, representing sterilization.

At the end of the incubation periods, the solutions were measured for their total radioactivity by LSC for the recovery (mass valance) and analysed by normal phase TLC-RLG (radioluminography) to determine the proportions of benzpyrimoxan and any radiolabelled breakdown products. To confirm

identification of radioactive components, radioactivity in the samples were chromatographed on HPLC equipped with a fraction collector.

The total radioactivity recovery (based on the applied radioactivity percent AR) was 99.0–100.7 percent AR, 104.4–105.7 percent AR, and 96.0–99.6 percent AR for the pH 4, pH 5, and pH 6 hydrolysis samples, respectively (Table 45).

Table 45 Recoveries of radioactivity from processed buffered solutions

Conditions	Recovery of Applied Radioactivity [1.0 mg/L]	
	[Phenyl-U-^{14}C]	[Pyrimidinyl-4(6)-^{14}C]
pH 4, 90°C, 20min	100.7	99.0
pH 5, 100°C, 60 min	104.4	105.7
pH 6, 120°C, 20 min	99.6	96.0

The predominant residue was unchanged benzpyrimoxan. Benzpyrimoxan-aldehyde (DH-03), benzpyrimoxan-enamine-aldehyde (DH-08) and benzpyrimoxan-benzyl alcohol (DH-102) were identified with up to 7.4 percent TRR. The summary of the results are shown in Table 46

Rice processing

Two brown rice (husked rice) samples obtained from field trials in Ibaraki and Niigata (R-37004 and R-37009) were used as treated raw agricultural commodity (Hamasaka, 2020: R-37021). Since residues of benzpyrimoxan and benzpyrimoxan-2-OH (DH-04) in these samples were determined to be greater >LOQ of 0.01 mg/kg (10 times higher), samples were considered suitable for determination of rice processing factors.

Samples were processed through polishing and cooking. A schematic chart of processing procedure is illustrated in Figure 5.

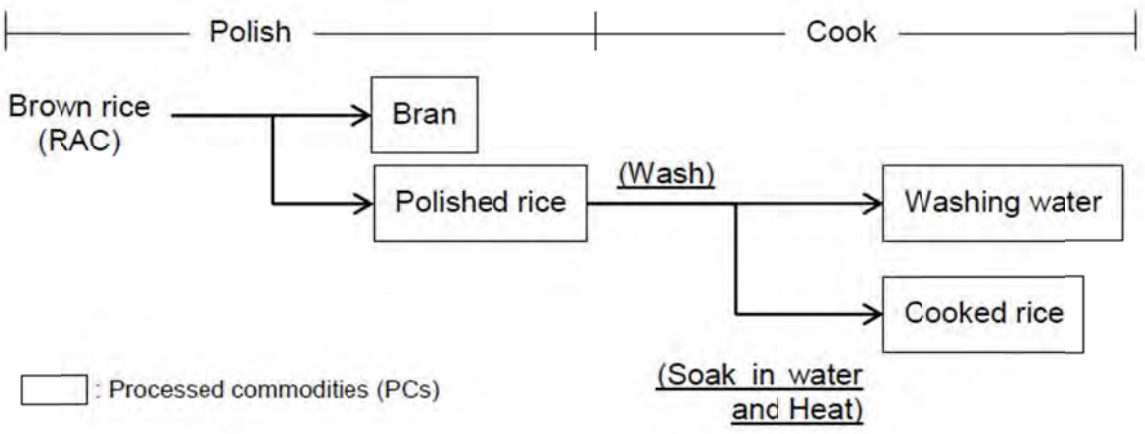

Figure 5 Processing of brown rice

For polishing, a small scale automated rice polishing machine was employed. The polished rice and the bran were stored frozen until analysis. For rice cooking, polished rice was rinsed three times with water. The cloudy washing water was brought to volume with acetonitrile and stored in a refrigerator until analysis. The washed rice was cooked in a small scale automatic rice cooker. The cooked polished rice was homogenised and stored in a freezer until analysis.

Husked rice, polished rice and bran samples were pulverised and soaked in distilled water before extraction, while the cooked rice was immediately subjected to extraction. The samples were extracted twice with acetonitrile/water (80/20) and the extracts combined. The remaining solid materials were extracted twice with acetonitrile/0.1 mol/L HCl (80/20), neutralised with 0.06 mol/L NaOH and acetonitrile was evaporated. Samples were dissolved in distilled water, cleaned-up on C18 cartridges (conditioned with acetonitrile) and the eluates were collected and brought to volume with acetonitrile. The purified samples were analysed by LC-MS/MS. Also, aliquots of the rice washing water were purified on C18 cartridges and subjected to LC-MS/MS analysis.

For method validation, untreated samples of husked rice, bran, polished rice, cooked rice and washing water were fortified with either benzpyrimoxan or DH-04 at levels of 0.01, 0.1, 0.2, 0.5 or 3.5 mg/kg. Mean recoveries were all between 70–120 percent, with RSDs <10 percent. Concurrent recoveries for both analytes in all processed matrices were 86–96 percent. The maximum storage interval from processing until extraction and analysis was 5–8 days.

The results are shown in Table 47.

Table 47 Residues of benzpyrimoxan and DH-04 in processed commodities of rice treated 3 times at 0.01 kg ai/hL in Japan

Year, Location (variety)	DALA	Commodity	Residues, mg/kg			Processing Factor

RESIDUES IN ANIMAL COMMODITIES

Farm animal feeding studies

The Meeting received lactating dairy cow and laying hens feeding studies.

Lactating dairy cow

Fourteen Holstein dairy cows were treated orally with gelatin capsules fortified with benzpyrimoxan once daily for 28 consecutive days (VanMiddlesworth, 2018: R-37016) at four dose levels equal to 0 (Control, 2 cows), 8 (1×, 3 cows), 24 (3×, 3 cows), and 80 (10×, 6 cows) ppm diet (dry-weight basis. One control and three animals from the 10× dose group were randomly assigned for use in the depuration phase of the study.

During the acclimation and treatment periods, the cows were milked twice daily and samples were pooled to yield a single milk sample per day per animal. Milk samples were retained from the control and treated cows on Dose Days -1 (pre-dose) and days 1, 3, 7, 10, 14, 21 and 28. Additional samples were collected on 3 separate days throughout the depuration phase (Study days 31, 35 and 42). For each cow within a dose group, a daily composite was prepared from milk collected in the morning and evening on Days -1 through Day 28. Extra pooled milk on Days 14 and 28 were separated into cream and skim milk from a single control cow, three cows in the 1× dosing group, three cows in the 3× dosing group, and three cows in the 10× dosing group.

Upon completion of the 28-day dosing period, ten animals (one control, three 1×, three 3× and three 10×) were humanely terminated within 24 hours of receiving the final dose, on the morning of Day 29. Muscle (flank and loin), liver, kidney and fat (subcutaneous, omental and perirenal) were collected from each animal to yield samples of approximately 1 kg weight each, where available. All analytical samples were kept frozen for analysis.

Analytical methods for the analysis of benzpyrimoxan and the metabolites were validated prior to use in bovine milk, muscle, liver, kidney, and fat for benzpyrimoxan, DH-01, DH-02, DH-04, DH-05, and DH-06 at a LOQ of 0.01 mg/kg (Tables 28 to 32).

The longest period of milk storage prior to extraction was 42 days. For skim milk and cream the longest storage interval was 78 days. The longest period of storage for muscle, liver, kidney and fat was 41, 83, 69 and 68 days, respectively.

The results for milk, cream and skin milk are shown in Tables 48 and 49. There was a transfer of residue of benzpyrimoxan, DH-05 and DH-06 to milk, skim milk, and cream, during 28 days of consecutive dosing, reaching a plateau in milk after 3 days of dosing which remained for the remainder of the 28 day dosing schedule. After dosing is complete, DH-05 was found in the 3 day post dose sampling event at

80 ppm, but is not found in the 7 day or 14 day post dose sampling event. There is a very rapid decline after cessation of dosing.

The results for tissues are shown in Table 50. There was no appreciable residue transfer or preferential accumulation to the bovine muscle. For liver and kidney, residues of benzpyrimoxan and metabolites were detected on the first day after cessation of dosing (day 28 sampling event) from cows administered at the 1×, 3× and 10× dosing levels. Benzpyrimoxan and DH-05 were found in the liver of the 10× dosing level in the 3 day post dose sampling event during the depuration phase, but not in the subsequent sampling events. For perirenal, omental and subcutaneous fat, residues of benzpyrimoxan, DH-02, DH-04 and DH-05 were detected on the first day after cessation of dosing (day 28 sampling event) from cows administered at the 1×, 3×, and 10× dosing levels. Fat residue in the 10× dosing level was <0.01 mg/kg by the 3 day post dose sampling event.

Laying hen

ISA Husked (Gold Star) laying hens (*Gallus gallus domesticus*) were treated orally with gelatin capsules fortified with benzpyrimoxan once daily for 29 consecutive days (VanMiddlesworth, 2018: R-37017). Sixty egg laying hens were dosed at four dose levels equal to 0 ppm (Control,), 3 ppm (1×), 9 ppm (3×), and 30 ppm (10×) diet (dry-weight basis). Birds chosen for the study were randomly assigned to one of five

treatment groups: control (12 hens in 3 subgroups of 4 hens each: 1A, 1B, and 1C), 1× (12 hens in 3 subgroups of 4 hens each: 2A, 2B, and 2C), 3× (12 hens in 3 subgroups of 4 hens each: 3A, 3B, and 3C) and 10× (24 hens in 6 subgroups of 4 hens each: 4A, 4B, 4C, 4D, 4E, 4F). One control subgroup (subgroup 1C) and three subgroups from the 10× dose group (subgroups 4D, 4E, and 4F) were assigned for use in the depuration phase of the study.

During the acclimation and treatment periods, the eggs were collected twice daily and the samples were pooled to yield a single sample per day per subgroup. Egg samples were retained from the control and treated hens on Dose Days -1 (pre-dose) and days 1, 3, 7, 10, 14, 17, 21, 24 and 28. Additional samples were collected on 3 separate days throughout the depuration phase (Study days 32, 36 and 43). For each subgroup within a dose group, a daily composite was prepared from eggs collected in the morning and evening on Days -1 through Day 28. The pooled egg samples on Days 14 and 28 were separated into egg yolk and egg white from a single control (group 1, subgroup 1C), three subgroups in the 1× dosing group (group 2, subgroups 2A, 2B, and 2C), three subgroups in the 3× dosing group (group 3, subgroups 3A, 3B, and 3C), and three subgroups in the 10× dosing group (group 4, subgroup 4D, 4E, and 4F).

Upon completion of the 29-day dosing period, eleven subgroups (two controls: subgroups 1A and 1B, three 1×: subgroups 2A, 2B, and 2C, three 3×: subgroups 3A, 3B, 3C, and three 10×: subgroups 4A, 4B, 4C) were humanely terminated at the in-life facility within 6 hours of receiving the final dose. 100–150 g of muscle (thigh and breast combined), the entire liver, and 50 g of fat (subcutaneous and abdominal combined) were collected from each bird to yield samples. All analytical samples were kept frozen until analysis.

Analytical methods for the analysis of benzpyrimoxan and the metabolites were validated at a LOQ of 0.01 mg/kg for benzpyrimoxan, benzpyrimoxan-CH_2OH (DH-02), and benzpyrimoxan-acid-2-OH (DH-05). Average recoveries for both quantitation and confirmation ion transitions were in the acceptable range for all analytes (Tables 28, 30 and 32). The longest storage period for egg was 36 days. Tissue samples of muscle, liver, and fat were analysed within 30 days.

The results for eggs, egg yolk and whites are shown in Tables 51 and 52. There was transfer of residue of benzpyrimoxan, DH-02, and DH-05 to egg, egg yolk, or egg white during 29 days of consecutive dosing, but rapidly declined within 3 days following the final dose. There were no residues found in whole eggs when benzpyrimoxan is delivered in the feed at the anticipated livestock dietary exposure levels.

Table 51 Benzpyrimoxan and metabolites residues in whole eggs (mg/kg)

Table 53 shows the rsults for hen tissues. There was no appreciable residue transfer or preferential accumulation to the hen muscle. For liver and fat, the residues of benzpyrimoxan (fat), DH-02 (liver and fat), and DH-05 (liver) were found the last day of dosing from hens administered at the 1× (liver), 3× (liver and fat), and 10× (liver and fat) dosing level. After cessation of the dose, there were no residues measured in the liver or fat.

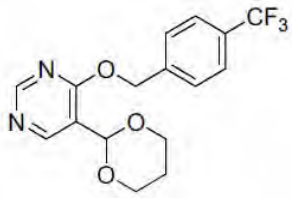
APPRAISAL

Benzpyrimoxan is an insecticide (insect growth regulator) with activity on juvenile stages of the rice plant hopper (Hemiptera: Delphacidae). Benzpyrimoxan is highly active against nymphal stages of rice plant hoppers without any adulticidal activity. It is registered for the control of sap sucking insects on rice.

At the Fifty-first Session of the CCPR (2019), it was scheduled for the evaluation as a new compound in 2020 and rescheduled to the 2022 JMPR. The Meeting received information on identity, physical and chemical properties, animal and plant metabolism, rotational crop study, environmental fate, analytical methods, GAP information, storage stability, processing, supervised residue trials and farm animal feeding study.

The IUPAC name for benzpyrimoxan is 5-(1,3-dioxan-2-yl)-4-[4-(trifluoromethyl)benzyloxy]pyrimidine.



The following abbreviations are used for the major metabolites discussed in Table 1 below.

Table 54 Metabolites and their codes referred to in the appraisal

Code	Name and Matrix	Structure
Benzpyrimoxan-2-OH DH-04	5-(1,3-dioxan-2-yl)-4-{[4-(trifluoromethyl)phenyl] methoxy}pyrimidin-2-ol Rice, Soil	Benzpyrimoxan-acid-2-OH DH-05	2-hydroxy-4-{[4-(trifluoromethyl)phenyl] methoxy}pyrimidine-5-carboxylic acid Goat, Hen	Benzpyrimoxan-CH_2OH DH-02	(4-{[4-(trifluoromethyl)phenyl] methoxy}pyrimidin-5-yl)methanol Goat, Hen	Benzpyrimoxan-CH_2OH-2-OH DH-06	5-(hydroxymethyl)-4-{[4-(trifluoromethyl)phenyl] methoxy}pyrimidin-2-ol Goat, Hen	Benzpyrimoxan-acid DH-01	4-{[4-(trifluoromethyl)phenyl] methoxy}pyrimidine-5-carboxylic acid Goat	Benzpyrimoxan-benzoyl-glycine DH-402	N-[4-(trifluoromethyl)benzoyl]glycine Goat	Benzpyrimoxan-aldehyde DH-03	4-{[4-(trifluoromethyl)phenyl] methoxy}pyrimidine-5-carbaldehyde High temperature hydrolysis	Benzpyrimoxan-enamine-aldehyde DH-08	[4-(trifluoromethyl)phenyl] methyl (2E)-3-amino-2-formylprop-2-enoate High temperature hydrolysis	4-TFMPM DH-102	[4-(trifluoromethyl)phenyl] methanol High temperature hydrolysis	
Physical and chemical properties

Benzpyrimoxan is not volatile. It has a higher solubility in organic solvents (up to 178 g/L in dichloromethane) in comparison to water (5 mg/L). The octanol/water partition coefficient log P_{ow} of 3.4

for benzpyrimoxan suggests a potential to partition into fat. Benzpyrimoxan is hydrolytically stable under natural and basic conditions while it is considered to be moderately persistent under acidic conditions (pH 4), with DT_{50} value at 25 °C of about 50 days. It is stable to photolysis.

Plant metabolism

The Meeting received plant metabolism studies for after foliar application on paddy rice with benzpyrimoxan labelled at [Phenyl-U-^{14}C] and [Pyrimidinyl-4(6)-^{14}C].

[^{14}C]-benzpyrimoxan was applied to rice grown pots under paddy conditions in a greenhouse at a rate of 0.20 kg ai/ha (1× GAP). In one experiment, the plant was sprayed three times at 7 day intervals, at heading stage (BBCH 55) and milk stage (BBCH 61–65 and 73–75). In a second experiment, the plant was sprayed twice with an interval of 7 days, at heading stage (BBCH 55) and milk stage (BBCH 61–65), with the third application at BBCH 87–89, 4 weeks after the second application. Samples were taken at 7 days after treatment (DAT). Samples of panicle, foliage and root were collected at milk stage. At ripe stage, panicle, straw and root were collected and then panicle was separated into grain and hulls after 14 days of air drying.

Total radioactive residues (TRR) in panicle and foliage at milk stage were 1.2–1.4 and 1.8–2.4 mg eq/kg, respectively. The TRRs in hull and straw at ripe stage were 2.8–4.7 and 3.3-3.7 mg eq/kg, respectively. Relatively small amounts of radioactive residues were detected in grain (0.10–0.25 mg eq/kg) and root (0.05–0.09 mg eq/kg). At least 77 percent TRR of [Pyrimidinyl-4(6)-14C] label) were recovered from the samples in the surface rinse with acetonitrile (15–49 percent TRR), acetonitrile/water (45–86 percent TRR) and acetonitrile/0.1 mol/L HCl (1.4–9.4 percent TRR) in all the plant parts at both stages. The post-extraction solids (PES) of all samples were characterized by enzyme, and acidic or alkaline hydrolyses, which released an additional 2–19 percent TRR.

Benzpyrimoxan was the predominant residue in all samples at milk and ripe stages, at levels of 0.05–0.14 mg/kg (48–57 percent TRR) in grain, 1.7–2.8 mg/kg (60–61 percent TRR) in hull and 1.6–1.9 mg/kg (48–51 percent TRR) in straw. Benzpyrimoxan-2-OH (DH-04) was the major metabolite in all samples at both stages, at 0.02–0.04 mg eq/kg (15–17 percent TRR) in grain, 0.14–0.24 mg eq/kg (5.0–5.1 percent TRR) in hull and 0.34–0.39 mg eq/kg (9.3–12 percent TRR) in straw.

Minor (< 10 percent TRR) metabolites were also detected. Benzpyrimoxan-CH_2OH (DH-02) conjugate was identified in hulls (3.1–3.8 percent TRR; 0.11–0.15 mg eq/kg) and straw (2.6–4.4 percent TRR, 0.09–0.16 mg eq/kg). Benzpyrimoxan-acid-2-OH (DH-05) (free and conjugated) was identified in hulls (1.1–1.7 percent TRR, 0.05 mg eq/kg) and straw (4.4–4.8 percent TRR, 0.15–0.18 mg eq/kg). Benzpyrimoxan-CH_2OH-2-OH (DH-06) (free and conjugated) was found in hulls (1.2 percent TRR, 0.03 mg eq/kg) and straw (3.4–3.5 percent TRR, 0.11–0.13 mg eq/kg).

Conclusions

Parent benzpyrimoxan is the main residue in rice. The potential metabolic pathway in rice is hydroxylation of a pyrimidine ring to benzpyrimoxan-2-OH (DH-04), followed by hydrolysis of an acetal moiety to form a hydroxymethyl moiety and carboxylic acid moiety.

Animal metabolism

The Meeting received animal metabolism studies on rats, lactating goats and laying hens where animals were dosed with [^{14}C]-benzpyrimoxan. The metabolism and distribution of benzpyrimoxan in farm animals were investigated using the [Phenyl-U-^{14}C] and the [Pyrimidinyl-4(6)-^{14}C]-benzpyrimoxan.

Rats

The metabolism of benzpyrimoxan in rats was reviewed in the framework of the toxicological evaluation by the WHO Core Assessment Group of the 2022 JMPR.

Lactating goats

Lactating goats received daily oral dosing of [^{14}C]-benzpyrimoxan for 5 consecutive days at 14 ppm in the diet for [Phenyl-U-^{14}C]-benzpyrimoxan and at 15 ppm in the diet for [Pyrimidinyl-4(6)-^{14}C]-benzpyrimoxan. The goats were sacrificed 6 hours after the last dose for the phenyl label and 8 hours after the last dose for the pyrimidinyl label.

TRR were highest in the liver (0.22–0.69 mg eq/kg) and kidney (0.18–0.25 mg eq/kg), followed by muscle (0.008–0.010 mg eq/kg) and fat (0.008–0.015 mg eq/kg). The concentration of radioactivity in the milk reached a plateau of 0.052–0.095 mg eq/kg by day 3–5.

Liver and kidney were extracted with acetonitrile/water and acetonitrile, fat with hexane/acetone and acetone and milk (Day 5) with acetonitrile and acetonitrile/water. Liver, kidney and milk were further extracted with acetonitrile/0.1 mol/L HCl. Muscle was not analysed due to low concentration (< 0.01 mg eq/kg). Most of radioactive residues (78–93 percent TRR) in milk and tissues were extracted (neutral solvent: 57–93 percent TRR, ACN/HCl: < 1.2–3.8 percent TRR).

Benzpyrimoxan was not detected in any sample except in liver (2.3 percent TRR, 0.014 mg/kg). Benzpyrimoxan-acid-2-OH (DH-05) was found as a predominant metabolite in kidney (40–47 percent TRR, 0.074–0.11 mg eq/kg) and milk (59–86 percent TRR, 0.048–0.062 mg eq/kg) and as a major metabolite in liver (6.4–11 percent TRR, 0.025–0.039 mg eq/kg).

Benzpyrimoxan-CH_2OH (DH-02) (free and conjugated) was found as a major metabolite in liver (3.1–22 percent TRR, 0.019–0.051 mg eq/kg) and kidney (5.9–16 percent TRR, 0.011–0.039 mg eq/kg). Benzpyrimoxan-CH_2OH-2-OH (DH-06) (free and conjugated) was the major metabolite in liver (4.8–15 percent TRR, 0.029–0.036 mg eq/kg) and benzpyrimoxan-acid (DH-01) in kidney (16–20 percent TRR, 0.038 mg eq/kg).

Benzpyrimoxan-2-OH (DH-04) was identified as a minor metabolite in liver (2.6–3.1 percent TRR, 0.006–0.019 mg eq/kg) and benzpyrimoxan-benzoyl-glycine (DH-402) in kidney (7.9 percent TRR, 0.019 mg eq/kg).

Laying hens

Laying hens received daily oral dosing for 7 consecutive days of [Phenyl-U-^{14}C]-benzpyrimoxan at a rate equivalent to 11 ppm in the diet and of [Pyrimidinyl-4(6)-^{14}C]-benzpyrimoxan at 13 ppm. The hens were sacrificed 6 hours after the last dose.

TRRs in tissues were highest in liver (0.066–0.19 mg eq/kg) and subcutaneous fat (0.065–0.18 mg eq/kg), followed by abdominal fat (0.042–0.063 mg eq/kg) and leg and breast muscle (0.003–0.014 mg eq/kg). Residue levels in egg white reached a plateau of 0.006–0.009 mg eq/kg by days 4–7 and those in egg yolk reached a plateau of 0.13–0.20 mg eq/kg by day 5–7.

Liver, muscle and egg were extracted with acetonitrile/water and acetonitrile, and fat with hexane/acetone and acetone. Liver, muscle and egg were further extracted with acetonitrile/0.1 mol/L HCl. Good extractability was achieved for fat samples (95–96 percent TRR). Over 50 percent TRR was extracted from liver and muscle samples (neutral solvent: 54–79 percent TRR, ACN/HCl: 1.7–2.2 percent

TRR), and 34–73 percent TRR from eggs (neutral solvent: 31–67 percent TRR, ACN/HCl: 2.9–6.7 percent TRR).

Benzpyrimoxan was the predominant component in muscle (43 percent TRR, 0.006 mg/kg) and fat (71 percent TRR, 0.043–0.089 mg/kg), a minor residue in eggs (5.7–13 percent TRR, 0.002–0.004 mg/kg) and was not detected in liver.

DH-05 was identified as a major metabolite in liver (20–28 percent TRR, 0.012–0.050 mg eq/kg). DH-02 was a major metabolite in liver (6.1–22 percent TRR, 0.011–0.013 mg eq/kg), fat (9.8–14 percent TRR, 0.006–0.018 mg eq/kg)and was identified as a major metabolite in muscle (14 percent TRR) and egg (13–27 percent TRR), but at levels below 0.01 mg eq/kg. DH-06 was found as a minor component in liver (3.3 percent TRR, 0.002–0.006 mg eq/kg). No other metabolites were identified.

Conclusions

Parent benzpyrimoxan is the minor residue or no residue in animal commodities except hen muscle and fat. The major metabolites of benzpyrimoxan in farm animals are formed by hydrolysis of the acetal moiety to form a hydroxymethyl moiety (DH-02 and DH-06) and its resulting carboxylic acid moiety (DH-01 and DH-05), followed by conjugation to glucuronides. Hydroxylation of a pyrimidine ring are also observed.

Environmental fate

The Meeting received aerobic soil (paddy and upland) metabolism, aqueous hydrolysis and aqueous photolysis studies for benzpyrimoxan.

In the aerobic paddy soil metabolism study conducted in a vessel with phenyl and pyrimidinyl radiolabelled benzpyrimoxan, benzpyrimoxan was degraded in paddy soil very gradually with a DT_{50} of > 1 year at 25 °C. Benzpyrimoxan was detected with 73–95 percent AR during 180 days incubation period. Several identified and unknown degradates were detected, however, none of which accounted for more than 10 percent of AR throughout the study period for both radiolabels.

In the aerobic upland soil metabolism study conducted in a vessel with phenyl and pyrimidinyl radiolabelled benzpyrimoxan, benzpyrimoxan was gradually degraded in upland soil with a DT_{50} of 124 days at 25 °C. Benzpyrimoxan was detected as the major component with 33 percent AR after 180 days incubation. Several identified degradants were detected but accounted for less than 10 percent of AR and did not accumulate

In conclusion, benzpyrimoxan was gradually degraded in soil, and the breakdown products also moderately degraded to form unextracted residue and CO_2. Benzpyrimoxan is persistent in soil.

In the aqueous hydrolysis study, benzpyrimoxan was hydrolytically stable at pH 7 and 9 at 50 °C but decomposed at pH 4 with a DT_{50} of 50–51 days at 25 °C. The hydrolysis product was benzpyrimoxan-enamine aldehyde (DH-08) with maximum amounts of 13 percent AR. Several identified and unknown hydrolysis products accounted for less than 10 percent of AR. Hydrolysis is unlikely to be a major route of environmental degradation.

In the aqueous photolysis study, benzpyrimoxan was photolytically stable at 25 °C for 25 days. Photolysis in water is unlikely to be a major route of environmental degradation.

Rotational crop metabolism

No rotational crop studies were provided to the Meeting.

The Meeting noted that residue of benzpyrimoxan may be taken up by follow-on and rotational crops since this compound is persistent in soil,

The Meeting considered that information on the agricultural practice for paddy rice cultivation and International Harmonised Guidelines (OECD TG504) indicated potential crop rotation for paddy rice.

The Meeting could not conclude on the residues related to benzpyrimoxan in rotational crops.

Methods of analysis

The Meeting received information on analytical methods for benzpyrimoxan and its metabolites in plant and animal matrices.

Plant matrices

In the method for determination of benzpyrimoxan and benzpyrimoxan-2-OH (DH-04) in rice matrices (grain, husked rice, polished rice, cooked rice, bran and straw), samples were extracted with acetonitrile/water and acetonitrile/0.1 mol/L HCl (. After SPE clean-up, residues were determined by LC-MS/MS. The method was validated with an LOQ of 0.01 mg/kg for each analyte.

A QuEChERS method was also validated for benzpyrimoxan and DH-04 in husked rice with an LOQ of 0.01 mg/kg for each analyte.

The Meeting concluded that the presented methods were sufficiently validated and are suitable to measure benzpyrimoxan and DH-04 in rice commodities.

Animal matrices

In the method for determination of benzpyrimoxan, benzpyrimoxan-acid (DH-01), benzpyrimoxan-CH_2OH (DH-02), benzpyrimoxan-2-OH (DH-04), benzpyrimoxan-acid-2-OH (DH-05) and benzpyrimoxan-CH_2OH-2-OH (DH-06), cow tissues (muscle, liver, kidney) and cream samples were extracted with acetonitrile/water and cleaned up by SPE. Fat samples were extracted with hexane/acetone and acetonitrile/water, the hexane layer extracted with acetonitrile followed by SPE clean-up. Milk and skin milk samples were centrifuged and provided to SPE. An aliquot of each sample was treated with -glucuronidase. The residues were determined by LC-MS/MS .

The method recoveries of DH-01 in liver were < 70 percent due its conversion to DH-05, although the sum of DH-01 and DH-05 recovery was within the acceptable range.

In the method for the analysis of benzpyrimoxan, DH-02 and DH-05 in hen commodities, egg, muscle and liver samples were extracted twice with acetonitrile/water and purified by SPE. Fat samples were extracted with hexane/acetone and acetonitrile/water, the lower layer collected, the hexane layer extracted with acetonitrile and the hydro-organic layer combined. The extract was cleaned up by SPE. The residues were analysed by LC-MS/MS at a LOQ of 0.01 mg/kg

The Meeting concluded that the presented methods were sufficiently validated at a LOQ of 0.01 mg/kg and are suitable to measure benzpyrimoxan, DH-01 (except liver), DH-02 (free and conjugated), DH-04, DH-05 and DH-06 (free and conjugated) in animal commodities. DH-4 and DH-06 (free and conjugated) were not validated in hen commodities.

Stability of pesticide residues in stored analytical samples

The Meeting received information on storage stability of benzpyrimoxan and benzpyrimoxan-2-OH (DH-04) in rice grain (paddy rice), brown rice and straw fortified at 0.5 mg/kg and stored at -20 °C.

Benzpyrimoxan and DH-04 were stable for at least 2.5 months in rice grain, husked rice and straw, which covered the residue sample storage intervals used in the field trials considered by the current Meeting.

The Meeting received information on storage stability of benzpyrimoxan, DH-01, DH-02, DH-04, DH-05 and/or DH-06 in animal commodities fortified at 0.1 mg/kg and stored at -20 °C.

Benzpyrimoxan, DH-04 and DH-06 were stable for at least 3 months in milk, muscle and liver, at least 2.5 months in fat, and at least 1 month in kidney, DH-05 was stable for at least 1 month in milk, muscle, liver, kidney, fat and egg and DH-02 was stable for at least 3 months in muscle and liver, for at least 2.5 months in fat, and for at least 1 month in kidney and egg.

The Meeting noted that DH-01 was unstable in liver, kidney and fat, quantitatively degrading to DH-05 within 1 month of frozen storage. DH-01 was stable for at least 3 months in muscle.

Definition of the residue

Plant commodities

In plant metabolism studies on benzpyrimoxan in rice, benzpyrimoxan (48–61 percent TRR) was a major component in all rice commodities (grains, hull and straw). DH-04 (5.0–17 percent TRR) was identified at 0.02–0.39 mg eq/kg in all rice commodities. DH-02 conjugate, DH-05 (free and conjugated), DH-06 (free and conjugated) were detected at > 0.01 mg eq/kg and not greater than 4.5 percent TRR in feed commodities (panicle, foliage, hull and straw).

The Meeting decided that the suitable analyte for enforcement purposes is parent benzpyrimoxan in rice commodities.

In deciding which compounds should be included in the residue definition for dietary risk assessment, the Meeting considered the toxicological properties of the candidate DH-04 (benzpyrimoxan-2-OH). The Meeting agreed that DH-04 was approximately 3 times more toxic than parent.

The Meeting decided that the suitable analytes for dietary risk assessment are benzpyrimoxan and benzpyrimoxan-2-OH.

Animal commodities

In animal metabolism studies, benzpyrimoxan was the predominant component in hen muscle (43 percent TRR, 0.006 mg eq/kg) and hen fat (71 percent TRR, 0.043–0.089 mg eq/kg), but the minor residue in goat liver (2.3 percent TRR, 0.014 mg/kg) and eggs (5.7–13 percent TRR, 0.002–0.004 mg/kg), and not detected in hen liver, goat kidney, goat muscle, goat fat and milk.

Benzpyrimoxan-acid-2-OH (DH-05) was the predominant component of the residue in goat kidney (40–47 percent TRR) and milk (59–86 percent TRR), and the major residue in liver (goat: 6.4–11 percent TRR, hen: 20–28 percent TRR).

Benzpyrimoxan-acid (DH-01) was only found in goat kidney (16–20 percent TRR) and it may be converted to DH-05 in liver, kidney and fat during storage and/or analysis. The Meeting considered that interconversion of DH-01 to DH-05 may have occurred in the matrices due to the storage interval between sampling and extraction of 24–50 days in animal metabolism studies.

The Meeting decided that the suitable analytes for enforcement purposes are parent benzpyrimoxan, DH-01 and DH-05 in animal commodities.

The metabolism and feeding studies for ruminant show that total residues of benzpyrimoxan, DH-01 and DH-05 in skim milk are 1.5 times higher than in cream. Laying hen metabolism study shows that total residues in fat are higher than in muscle, but the ratio does not show a clear fat solubility.

The Meeting considered the residues of benzpyrimoxan not to be fat-soluble.

In deciding which compounds should be included in the residue definition for dietary risk assessment, the Meeting considered the likely occurrence of the compound and the toxicological properties of the candidates DH-01, DH-02 (free and conjugated), DH-05 and DH-06 (free and conjugated).

DH-02 (free and conjugated) was a major metabolite in only goat liver (3.1–22 percent TRR, 0.019–0.051 mg eq/kg) and kidney (5.9–16 percent TRR, 0.011–0.039 mg eq/kg) and DH-06 (free and conjugated) only in goat liver (4.8–15 percent TRR, 0.029–0.036 mg eq/kg).

Since liver and kidney contributes little to the total dietary exposure and an ARfD for benzpyrimoxan was not considered necessary, the Meeting concluded that these metabolites should not be included in the residue definition for dietary risk assessment.

The Meeting concluded that the toxicities of DH-01 (benzpyrimoxan-acid) and DH-05 (benzpyrimoxan-acid-2-OH) were covered by the health-based guidance values for parent compound.

The Meeting decided to define the residue for dietary risk assessment for animal commodities as the sum of benzpyrimoxan, benzpyrimoxan-acid and benzpyrimoxan-acid-2-OH, expressed as benzpyrimoxan.

The Meeting recommended the following residue definitions for benzpyrimoxan:

Definition of the residue for compliance with the MRL for rice commodities: *Benzpyrimoxan*

Definition of the residue for dietary risk assessment for rice commodities: *Sum of benzpyrimoxan and 3 × benzpyrimoxan-2-OH, expressed as benzpyrimoxan*

Definition of the residue for compliance with the MRL and dietary risk assessment for animal commodities: *Sum of benzpyrimoxan, benzpyrimoxan-acid and benzpyrimoxan-acid-2-OH, expressed as benzpyrimoxan*

The Meeting considers the residue not to be fat-soluble.

Results of supervised residue trials on crops

Supervised trials were available for the use of benzpyrimoxan on rice.

Product labels were available from Japan.

Total residues for estimation of dietary exposure from food commodities are calculated by summing up the concentrations of benzpyrimoxan and 3 × benzpyrimoxan-2-OH (expressed as benzpyrimoxan equivalents), because benzpyrimoxan-2-OH is three times higher toxicity than parent benzpyrimoxan. The method of calculation is illustrated below.

Example of the method for calculation of total residues (mg/kg) for dietary exposure

Benzpyrimoxan	Benzpyrimoxan-2-OH (DH-04)	Total
< 0.01	< 0.01 × 3	< 0.04
< 0.01	0.025 × 3	0.085

For the purpose to calculating the livestock animal dietary burden, no factor of 3 is applied to the residue levels of the metabolite. Total residues are benzpyrimoxan + benzpyrimoxan-2-OH, expressed as benzpyrimoxan.

As no studies on residues in follow-on and rotational crops were provided to the Meeting, no estimations for maximum residue levels, STMR and median residues levels in annual crops sown/planted after rice cultivation could be made. The supervised residue trials with direct application and studies on rotational crops will be evaluated together at a future meeting when all results will be available.

Rice

The critical GAP for rice in Japan allows three spray applications of 0.01 kg ai/hL with a PHI of 7 days. Data were available from supervised trials on rice in Japan matching Japanese GAP.

Benzpyrimoxan residues in rice grain with husk were (n=5): 1.2, 1.6, 1.9, 2.0 and 3.4 mg/kg.

Total residues in rice grain were (n=5): 1.7, 2.8, 3.7, 3.9 and 5.6 mg/kg.

For the purposes to calculate the livestock animal dietary burden residues (benzpyrimoxan plus DH-04, expressed as benzpyrimoxan) in rice grain were (n=5): 1.4, 2.0, 2.5, 2.6 and 4.1 mg/kg.

As indicated no recommendation could be made for rice. Benzpyrimoxan residues in husked rice were (n=8): 0.06, 0.10, 0.20, 0.30, 0.32, 0.33, 0.44 and 0.46 mg/kg.

Total residues in husked rice were (n=8): 0.15, 0.19, 0.41, 0.72, 0.74, 0.75, 0.79 and 0.89 mg/kg.

As indicated no recommendation could be made for rice, husked.

Residues in animal feeds

Rice, hay and/or straw

The critical GAP for straw of rice in Japan allows three spray applications of 0.01 kg ai/hL with a PHI of 7 days. Data were available from supervised trials on rice in Japan matching the GAP.

Benzpyrimoxan residues in rice straw were (n=8): 4.2, 4.7, 5.6, 5.8, 7.2, 7.8, 8.1 and 9.0 mg/kg on dry weight basis.

Total residues (benzpyrimoxan plus DH-04, expressed as benzpyrimoxan) in rice straw were (n=8): 5.5, 6.2, 6.8, 7.2, 9.0, 9.7, 10 and 11 mg/kg on dry weight basis.

No recommendation could be made for rice straw until the contribution of residues from direct application as well as uptake through the soil can be assessed.

Fate of residues during processing

High temperature hydrolysis

The hydrolysis of [^{14}C]-benzpyrimoxan was studied in sterile buffered solutions of pH 4, 5 and 6. [Phenyl-U-^{14}C] and [Pyrimidinyl-4(6)-^{14}C]-benzpyrimoxan were incubated at 1.0 mg/L in aqueous buffered solutions to simulate common processing practices (pasteurization, baking/boiling and sterilization).

At pH 4, 5 and 6 with heating, the predominant residue was parent benzpyrimoxan (92–100 percent AR). Some minor degradation products (benzpyrimoxan-aldehyde (DH-03), benzpyrimoxan-enamine-aldehyde (DH-08) and benzpyrimoxan-benzyl alcohol (DH-102)) were identified with up to 7.4 percent AR.

Benzpyrimoxan residue is stable during processing and no DH-04 residue is expected.

Residues in processed commodities

The Meeting received information on the fate of total residues of benzpyrimoxan and benzpyrimoxan-2-OH (DH-04) during processing in rice, husked. Calculated processing factors are summarised in the following table.

Table 55 Processing factors for rice, husked and STMR-P values

Raw commodity	Processed commodity	Calculated processing factor[#] [best estimate]
Rice, husked = Brown rice	Bran	8.6, 9.5 [9.1]
	Polished rice	0.41, 0.43 [0.42]
	Cooked polished rice	0.068, 0.095 [0.082]

[#] Each value represents a separate study. The factor is the ratio of the residue in processed commodity divided by the residue in the RAC.

Residues in animal commodities

Farm animal feeding studies

The Meeting received a lactating dairy cow and a laying hen feeding studies, which provided information on likely residues resulting in animal commodities, milk and eggs from benzpyrimoxan in the animal diet.

Lactating dairy cows

Holstein dairy cows were dosed with benzpyrimoxan for 28 days at the equivalent of 8, 24 and 80 ppm in the diet. Residues of benzpyrimoxan, and benzpyrimoxan-acid-2-OH (DH-05) in milk, and residues of benzpyrimoxan, benzpyrimoxan-acid (DH-01) and DH-05 in tissues (liver, kidney, muscle and fat) were determined.

For whole milk, no benzpyrimoxan residue was detected at all feeding levels. DH-05 residue was detected at all feeding level and achieved a plateau concentration of 0.012–0.034 mg/kg at the 8 ppm (1 ×) feeding level after 3 days of dosing.

For liver, residues of benzpyrimoxan and DH-05 were detected at all feeding levels (benzpyrimoxan: < 0.01–0.15 mg/kg, DH-05: 0.011–0.25 mg/kg). No residue of DH-01 was found at any feeding level.

For kidney, benzpyrimoxan residues were found at the 80 ppm feeding level (1 cow: 0.031 mg/kg). DH-01 residue was detected with < 0.01–0.032 mg/kg at the 24 and 80 ppm feeding levels. DH-05 residue was detected with 0.032–0.30 mg/kg at all feeding levels.

For fat, benzpyrimoxan residue was detected with < 0.01–0.031 mg/kg at the 80 ppm feeding level. DH-05 residue was detected with < 0.01–0.18 mg/kg at all feeding levels. No DH-01 residue was found at any feeding level.

For muscle, no residues (< 0.01 mg/kg) were found at any feeding level.

Laying hens

Laying hens were dosed with benzpyrimoxan for 29 days at the equivalent of 3, 9 and 30 ppm in the diet. Residues of benzpyrimoxan and DH-05 were determined in eggs, liver, muscle and fat.

For eggs, DH-05 residue was found (< 0.01–0.011 mg/kg) at the 30 ppm feeding level. Benzpyrimoxan residue was below the LOQ (< 0.01 mg/kg) at any feeding level.

For liver, DH-05 residue was detected with < 0.01–0.067 mg/kg at all feeding levels. No benzpyrimoxan residue was found at any feeding level.

For fat, benzpyrimoxan residue was detected with 0.012–0.015 mg/kg at the 30 ppm feeding level. No DH-05 residue was found at any feeding level.

For muscle, no residues (< 0.01 mg/kg) were found at any feeding level.

Farm animal dietary burden

The Meeting noted that the studies on residues in follow-on and rotational crops were not provide to the Meeting, and decided not to estimate maximum residue levels and STMRs on annual crops that may lead to animal feeds. The estimations will be made in the future when the studies are available.

RECOMMENDATIONS

Definition of the residue for compliance with the MRL for plant commodities: *Benzpyrimoxan*

Definition of the residue for dietary risk assessment for plant commodities: *Sum of benzpyrimoxan and benzpyrimoxan-2-OH, expressed as benzpyrimoxan*

Definition of the residue for compliance with the MRL and dietary risk assessment for animal commodities: *Sum of benzpyrimoxan, benzpyrimoxan-acid and benzpyrimoxan-acid-2-OH, expressed as benzpyrimoxan*

The residue is not fat-soluble.

FUTURE WORK OR INFORMATION

Desirable information:

- Submission of existing soil dissipation studies.
- Information on residues in rotational crops (confined rotational crop study and/or field residue trials on rotational crops)

DIETARY RISK ASSESSMENT

The Meeting could not make any recommendations for residue levels in crops since information on the residues in follow-on and rotational crops was not provided to the Meeting. Furthermore, no dietary exposure assessment was conducted.

BIFENTHRIN (178)

First draft prepared by Dr G Ye, Ministry of Agriculture and Rural Affairs, Beijing, Republic of China

EXPLANATION

Bifenthrin is a pyrethroid insecticide and miticide. It was first evaluated for residues and toxicology by the JMPR in 1992. Bifenthrin was evaluated under periodic review programme in 2009 (T) and 2010 (R), and subsequently evaluated in 2015 and 2019 for additional MRLs.

An ADI of 0–0.01 mg/kg bw and an ARfD of 0.01 mg/kg bw were established by the 2009 JMPR. The residue definition for compliance with the MRL and for estimation of dietary intake (for animal and plant commodities) is bifenthrin (sum of isomers). The residue is fat-soluble.

Bifenthrin was scheduled at the Fifty-first Session of the CCPR for the evaluation of additional MRLs by the 2021 JMPR, which was delayed to the 2022 JMPR.

The Meeting received information on GAPs and supervised residue trials for apple, peach, avocado, pomegranate, peppers (bell, non-bell), melon, spinach, and peanut, as well as the processing studies on apple and peanut.

METHODS OF RESIDUE ANALYSIS

A number of analytical methods (for enforcement and data collection) for plant and animal matrices were evaluated by the 2010, 2015 and 2019 Meeting. Residue analytical methods consisted of extraction with acetone or hexane, cleaning-up with SPE, and determination by GC-ECD and GC-MSD. Typical LOQs achieved for plant and animal commodities fall in the range of 0.01–0.05 mg/kg.

The Meeting received descriptions and concurrent recovery data for analytical methods for residues of bifenthrin used in supervised trials. The methods used in trials are either similar to or slight modification of methods evaluated by previous JMPRs. These methods are characterized by acetone extraction, partitioning of residues into hexane, clean-up using Florisil, and analysis by GC-ECD

Method P-3526 (Culligan J.F. 2001, report no. P-526): Samples were homogenised and extracted by shaking in 15 mL of acetone for 15 minutes, and partitioned twice with hexane. An aliquot was cleaned up with silica gel solid phase extraction column. Bifenthrin was quantified by GC-ECD. The LOQ was of 0.05 mg/kg for bifenthrin in the apple matrix (fruit, juice and pomace), peach fruit, avocado fruit and pomegranate.

Method P-2132M (Ridler, J.E., 1989, P-2132M P.42): Samples were homogenised and extracted with acetone, and partitioned twice with hexane, cleaned-up with Florisil solid phase extraction column. Bifenthrin is quantified by GC-ECD. The LOQs were of 0.1, 0.055, 0.048 and 0.05 mg/kg for bifenthrin in cantaloupe, bell pepper, non-bell pepper and spinach.

Method P-2715 (Kim, I., 1992): Homogenised samples were extracted twice with acetone, partitioned with hexane and were cleaned up with a Florisil solid phase extraction column. Bifenthrin is quantified by GC-ECD. The LOQ of 0.05 mg/kg was validated for bifenthrin in spinach.

Method P-3457(Chen A., 2000): Homogenised samples were extracted with acetone and sodium chloride solution, partitioned with hexane, concentrated under nitrogen and were cleaned up with Florisil solid phase extraction column. Bifenthrin is quantified by GC-MSD. The LOQ was of 0.05 mg/kg for bifenthrin in peanut meat.

Method P-0130 (Winkler, D, A, 1992, MRID # 41492605; evaluated by the 2010 JMPR): Samples were homogenised and extracted by ultrasonicating with acetone, partitioned with cyclohexane and were cleaned up with a silica gel solid-phase extraction column. Bifenthrin is quantified by GC-ECD. The LOQ was of 0.05 mg/kg for bifenthrin in peanut meat and hay, 1.0 mg/kg in peanut vine and 2.0 mg/kg in peanut hay.

Method P-2763 (Kim, I., 1992, P-2763; evaluated by 2010 JMPR): Nutmeat and meal samples of processed peanut were extracted with acetone followed by ultrasonication, and further extracted with acetonitrile. Oil samples were extracted with acetonitrile, partitioned with cyclohexane and were cleaned up with a silica gel cartridge solid phase extraction. Bifenthrin is quantified by GC-ECD. The LOQ was of 0.05 mg/kg for bifenthrin in peanut nutmeat, meal and refined oil.

Concurrent recovery data for the methods used for determination of bifenthrin residues in plant commodities for which supervised trial data were submitted to the current Meeting are summarized below.

Table 1 The concurrent recoveries of analytical method for bifenthrin in related commodities

Crop	Fortification (mg/kg)	n	Range Recovery (percent)	Mean recovery (percent)	CV percent	Reference
Apple, fruit	0.05 0.125 0.5 5	10 1 14 3	69-84 86 73-85 76-77	75 84 79 77	4 4	P-3526

STABILITY OF PESTICIDE RESIDUES IN STORED ANALYTICAL SAMPLES

The maximum storage intervals in the residue trials were covered by storage stability of at least 18 months in high acid, 49 months in high water, 36 months in high oil and high starch, and 15 months in high protein commodities stored at -18 ˚C concluded by 2010 and 2015 JMPR.

USE PATTERNS

Bifenthrin is registered for use in avocado, pome fruit, peach, pomegranate, melon, spinach, peanut, and okra in the United States. Registered use patterns are summarised in Table 2.

Table 2 Registration information on foliar applications of bifenthrin (EC formulation) in the United States

Crop	Formulation	Application				PHI (days)	Remark
	kg ai/L	Rate (kg ai/ha)	Water (L/ha)	RTI (min, days)	Max no.		
Pome fruit*	0.24	0.0448-0.224	1870 (ground dilute spray)/ 467 (ground conc. spray)/ 93(aerial)	30	3	14	Do not apply more than 0.56 kg ai./ha per year with no more than 0.51 kg ai/ha applied after petal fall (BBCH 69). Do not graze livestock in treated orchards or cut treated cover crops for feed
Peach subgroup**	0.24	0.0448-0.224		30	3	14	
Avocado	0.111 g/kg (bifenthrin) + 0.037 g/kg (zeta cypermethrin)	0.062 (bifenthrin) 0.021(zeta-cyp)	884 (ground)/93 (air)	14	5	1	Do not apply more than 0.31 (bifenthrin）+0.104(zeta-cypermethrin) kg ai/ha per year
Pomegranate	0.24	0.112-0.224	467	14	3	14	Do not apply more

Crop	Formulation	Application				PHI (days)	Remark
	kg ai/L	Rate (kg ai/ha)	Water (L/ha)	RTI (min, days)	Max no.		
							than 0.561 kg ai./ha per year
Melon	0.24	0.0448-0.112	187(ground)/ 47 (air)	7	3	3	Do not apply more than 0.336 kg ai./ha per year no more than 2 applications after bloom
Pepper/eggplant (subgroup 8-10B)***	0.24	0.0336-0.112	93 (ground/ 19 (air)	7	2	7	Do not apply more than 0.224 kg ai/ha per season
Spinach	0.24	0.0336-0.112	47-470 (air)/93-47-0(ground)	7	4	40	Do not apply more than 0.45 kg ai/ha per year
Peanut	0.24	0.0336-0.112	93 (ground/ 19 (air)	14	5	14	Do not apply more than 0.56 kg ai/ha per year Do not feed green immature plants and peanut hay to livestock

Notes:

*Pome fruit (US group 11-10) includes: Apple, Azarole, Crabapple, Loquat, Mayhaw, Medlar, Pear, Pear, Asian, Quince, Tejocote.

**Peach subgroup ((US subgroup 12-12B) includes: Peach; Nectarine.

***Pepper/eggplant (US subgroup 8-10B) includes: African eggplant; bell pepper; eggplant; martynia; non-bell pepper; okra; pea eggplant; pepino; roselle; scarlet eggplant.

Supervised field residues trials

The Meeting received information on supervised field trials for bifenthrin on pome fruit (apple and pear), peach, avocado, pomegranate, melon, bell and non-bell pepper, spinach and peanut

Crop	Table No.
Apple	3
Peach.	4
Avocado	5
Pomegranate	6
Melon	7
Bell pepper	8
Non-bell pepper	9
Spinach,	10, 11
Peanut,	12, 13
Peanut vine, hay, hull	14

Trials were generally documented with laboratory and field reports. Laboratory reports included method validation with procedural recoveries from spiking at residue levels similar to those occurring in samples from the supervised trials. Dates of analyses or duration of residue sample storage were also provided. Although trials included control plots, no control data are recorded in the tables except where residues in control samples exceeded the LOQ. Unless stated otherwise, residue data are recorded unadjusted for recovery.

Residue values from the trials conducted according to maximum GAP have been used for the estimation of maximum residue levels. Those results included in the evaluation are underlined.

Conditions of the supervised residue trials were generally included in field reports. Trial designs used non-replicated plots. Field reports provided data on the sprayers used, plot size, field sample size and sampling date.

In trials where replicate field samples were taken from a single plot and analysed separately, or where duplicate analyses of the same sample were made, the average of residue values from the trials conducted according to the ± 25 percent of maximum total seasonal application rate according to the GAP has been used for the estimation of maximum residue levels. Those results included in the tables are underlined.

Pome Fruits (002)

Apple

Twelve supervised trials on apple were conducted in the United States during 2013-2014 growing seasons (Samoil, K.S., 2015a, IR-4 PR No. 11016). Apples were treated with 3 foliar applications of 25 percent bifenthrin EC, retreatment interval of 19–23 days, except one trial (C001) with 4 foliar applications. The first application targeted a rate of 0.11 kg ai/ha and the second and third applications targeted a rate of 0.22 kg ai/ha. All applications were made using appropriate spray equipment. Adjuvants were used in the application. Duplicate samples were harvested 13-15 days after the last application (DALA), and for decline trials 7, 10–11, 17–18, and 21 DALA. The maximum storage intervals for field-treated samples were 469 days (fruit), 482 days (juice), and 466 days (pomace), which were covered by the storage stability studies. Residues of bifenthrin were determined using Method P-3526. Results of the trials are summarized in Table 3.

[7] Cream Ridge (Red Delicious) application date: 2013-07-29, 08-20, 09-10.

* The second application was mistakenly made at 0.111 g ai/ha; an additional application at 0.112 g ai/ha was made one day after the second. A fourth application was made 19 days after the third at the correct rate of 0.224 g ai/ha.

Stone fruit (003)

Peach

Twelve supervised trials on peach were conducted in the United States during 2013-2014 growing seasons (Samoil, K.S., 2015b, IR-4 PR No. 11017). Peaches were treated with 3 foliar applications of 25 percent bifenthrin EC, retreatment interval of 20–23 days except one trial (AR09) with 4 foliar applications. The first application targeted a rate of 0.11 kg ai/ha and the second and third applications targeted a rate of 0.22 kg ai/ha. All applications were made using appropriate spray equipment. Adjuvants were used in the application. Samples were harvested 10–15 DALA, and in the decline trial at 6, 10–11, 17 and 21 DALA. The maximum storage interval for field-treated samples (12 months) was covered by the storage stability studies. Residues of bifenthrin were determined using Method P-3526. Results of the trials are summarized in Table 4.

Assorted Tropical and Sub-Tropical Fruits – Inedible Peel (006)

Avocado

Six supervised trials on avocado were conducted in the United States during 2013 growing seasons (Samoil, K.S., 2015c, IR-4 PR No. 10578). Avocados were treated with 5 foliar applications of 25 percent bifenthrin EC, retreatment interval of 14-17 days. The application rates were 0.081–0.091 kg ai/ha. All applications were made using appropriate spray equipment. Adjuvants were used in the application. Duplicate samples were harvested 1 DALA and at 0, 1, 3, 6 and 10 DALA in the decline trials. The maximum storage interval for field-treated samples (17 month) was covered by storage stability studies. Residues of bifenthrin were determined using Method P-3526. Results of the trials are summarized in Table 5.

Pomegranate

Four supervised trials on pomegranate were conducted in the United States during 2014 growing season (Samoil, K.S., 2016, IR-4 PR No. 11249). The pomegranates were treated with 3 foliar applications of 25 percent bifenthrin EC, retreatment interval of 14 days. The first application targeted a rate of 0.11 kg ai/ha and the second and third applications targeted a rate of 0.22 kg ai/ha. All applications were made using appropriate spray equipment. Adjuvants were used in the application. Duplicate samples were harvested 14 DALA or at 6, 11, 14, 18 and 21 DALA for the decline trials. The maximum storage interval for field-treated samples (13 months) was covered by storage stability studies. Residues of bifenthrin were determined using Method P-3526. Results of the trials are summarized in Table 6.

Cucurbits – inedible peel, melons, except watermelon (011B)

Melon (cantaloupe)

Seven supervised trials on cantaloupe were conducted in the United States during 1990 growing seasons (Biehn, W.L., 1996, IR-4 PR No. 4151). Cantaloupe were treated with 3 foliar applications at a rate of 0.112 kg ai/ha of 25 percent bifenthrin EC The second applications were conducted 30-39 days after first application except one trial (Test 05, 52 days), and the third applications 7-8 days after second application except 38 days in one trial (Test 07). All applications were made using appropriate spray equipment. No adjuvants were used in the application. Duplicate samples were harvested 0, 3 and 7–8 days after the last application. The maximum storage intervals for field-treated samples (17 months) were covered by storage stability studies. Residues of bifenthrin were determined using Method P-213M. Results of the trials are summarized in Table 7.

Notes:

* Fruits were harvested that were not mature and were only 2-4 inches in diameter (not marketable).

Fruiting vegetables, other than Cucurbits, peppers (012A)

Pepper, sweet

The following trials on bell pepper were previously reported by the 2010 JMPR. Five supervised trials on pepper, sweet (bell pepper) were conducted in the United States during 1994 growing seasons (Samoil, K.S., 1999a, IR-4 PR No. 05281). Bell peppers were treated with 2 foliar applications at rates of 0.097–0.119 kg ai/ha of 25 percent bifenthrin EC, retreat interval of 7-8 days. All applications were made using appropriate spray equipment. No adjuvants were used in the application. Duplicate samples were harvested 7–8 days after the last application. The maximum storage intervals for field-treated samples (3 months) were covered by storage stability studies. Residues of bifenthrin were determined using Method P-213M. Results of the trials are summarized in Table 8.

Pepper, chilli

Trials on pepper, chilli (non-bell pepper) were previously reported by the 2010 JMPR. Seven supervised trials on non-bell pepper were conducted in the United States during 1994 growing seasons (Samoil, K.S., 1999b, IR-4 PR No. 05280). Non-bell peppers were treated with 2 foliar applications at rates of 0.084–0.112 kg ai/ha of 25 percent bifenthrin EC, retreat interval of 6–8 days. All applications were made using appropriate spray equipment. No adjuvants were used in the application. Duplicate samples were harvested 6–7 days after the last application. The maximum storage intervals for field-treated samples (4 months) were covered by storage stability studies. Residues of bifenthrin were determined using Method P-213M with the LOQ of 0.05 mg/kg. Results of the trials are summarized in Table 9.

Leafy Vegetables (including brassica leafy vegetables) (013)

Spinach

The following trials on spinach were previously reported by the 2015 JMPR. Seven supervised trials on spinach were conducted in the United States during 1999 growing seasons (Samoil, K.S., 2001, IR-4 PR No. 07088). Spinach was treated with 1 foliar application at rates of 0.448–467 kg ai/ha of 25 percent bifenthrin EC All applications were made using appropriate spray equipment. No adjuvants were used in the application. Duplicate samples were harvested 37–41 days after application. The maximum storage intervals for field treated samples (2 months) were covered by storage stability studies. Residues of bifenthrin were determined using Method P-2132M with the LOQ of 0.05 mg/kg. Results of the trials are summarized in Table 10.

[3] Weslaco (Olympia) application date 1999-03-25.

Three supervised trials on spinach were conducted in the United States during 1992-1993 growing seasons (Kim, I., 1993a, FMC Study No. 182SPI92R1). Spinach was treated with 4 foliar applications at rates of 0.112 kg ai/ha of 25 percent bifenthrin EC, retreat interval of 4–12 days All applications were made using appropriate spray equipment. No adjuvants were used in the application. Duplicate samples were harvested 20–40 days after the last application. The maximum storage intervals for field-treated samples (5months) were covered by storage stability studies. Residues of bifenthrin were determined using Method P-2715 with the LOQ of 0.05 mg/kg. Results of the trials are summarized in Table 11. Residues of 4'-hydroxy-bifenthrin were also analysed but all residues were below LOQ (< 0.05 mg/kg).

Oilseed (023)

Peanut

Four supervised trials on peanut were conducted in the United States during 2003 growing seasons (Morris, R.T., 2004, FMC Study No. 182PNT03R1). Peanut was treated with a soil application at rate of 0.28 kg ai/ha with 1.15G and a foliar application at rate of 0.28 kg ai/ha of bifenthrin 2EC 7days after soil application. All applications were made using appropriate spray equipment. No adjuvants were used in the application. Duplicate samples were harvested 14 days after the last application in 3 trials and 3, 7, 15 and 17 days in one trial. The maximum storage intervals for field-treated samples (6months) were covered by storage stability studies. Residues of bifenthrin were determined using Method P-3457 with the LOQ of 0.05 mg/kg. Results of the trials are summarized in Table 12.

Notes:

* One soil treatment of 0.28 kg ai/ha plus 0.28 kg ai/ha at the interval of 7 days.

Four supervised trials on peanut were conducted in the United States during 1992 growing seasons (Kim, I., 1993b, FMC Study No. 182PNT92R1). Peanut was treated with 5 foliar applications at rate of 0.112 kg ai/ha of bifenthrin 2EC, at premature seedling, early bloom, pegging, early nut maturity and mature nuts, with retreat interval of 9–35 days. All applications were made using appropriate spray equipment. No adjuvants were used in the application. Duplicate samples were harvested 0 and 7days after the last application. The maximum storage intervals for field-treated samples (6 months) were covered by storage stability studies. Residues of bifenthrin were determined using Method P-0130 with the LOQ of 0.05 mg/kg. Results of the trials are summarized in Table 13.

Animal feed

Four supervised trials on peanut were conducted in the United States during 1992 growing seasons (Kim, I., 1993b, FMC Study No. 182PNT92R1). Peanut was treated with 5 foliar applications at rate of 0.112kg ai/ha of bifenthrin 2EC, at premature seedling, early bloom, pegging, early nut maturity and mature nuts, with retreat interval of 9-35 days. All applications were made using appropriate spray equipment. No adjuvants were used in the application. Duplicate samples were harvested 1, 7, 10, 14 and 21 days after the last application The maximum storage intervals for field-treated samples (6 months) were covered by storage stability studies. Residues of bifenthrin were determined using Method P-0130 with the LOQ of 0.05 mg/kg. Results of the trials are summarized in Table 14.

Fate of residues during processing

The Meeting received trials on the processing of apple and peanut.

Apple

Apples treated with three foliar applications of bifenthrin at approximately rate of 2.80 kg ai/ha/season, an adjuvant was added to the spray mixture. Apple samples were harvested 15 days after the last application at commercial maturity. Samples were shipped under ambient conditions to the processing facility where samples were processed to juice and pomace (Samoil, K.S. 2015a, IR-4 PR No. 11016).

Apples were tub washed in cold tap water for 5 minutes, were crushed by a hammermill to a unform pulp consistency. The crushed apple pulps were placed in a swept surface kettle and heated with low pressure steam until the temperature reaches 40–50 °C. The pectic enzyme treated apple pulp was pressed using a hydraulic style apple press. The collected fresh juice was filtered through US#40 screen prior to packaging a fresh juice sample and/or further refining processes of pasteurized, clarified and/or concentrated apple juice samples. The wet pomace collected from the pressing process was analysed for moisture content and sampled as the wet pomace fraction. The raw juice was reheated to 93 °C for 15–30 seconds to deactivate the pectic enzymes and was then placed in the cooler to allow the solids to settle overnight. The clear juice was racked and the solids were discarded. The juice was vacuum filtered through diatomaceous earth to improve clarification. The filtered juice is pasteurized by heating to 93$\pm$3 °C and packed in cans while hot. The cans were sealed and inverted, then cooled using cold water. Residues of bifenthrin were determined using Method P-3526 with the LOQ of 0.05 mg/kg. Results of the trials are summarized in Table 15.

Table 15 Residues of bifenthrin in apple and its processed commodities following application of bifenthrin WSB (IR-4 PR No. 11016)

Location, Country/Year (variety)	Matrix	Application rate (kg ai/ha)	DALA (days)	Residues (mg/kg) (individual values)	Processing factor
Twin Falls, ID, United States, 2013 (Red Delicious)	Fruit	0.561, 1.11 and 1.12	15	1.07 (1.22, 0.928)	--
	Juice			<0.05 (<0.05, <0.05)	<0.048
	Pomace			2.66 (3.77, 1.55)	2.5

Residues of bifenthrin are not concentrated in juice but are concentrated in pomace.

Peanut

Peanuts treated with three foliar applications at rate of 0.336 kg ai/ha (total approximately 1.008 kg ai/ha/season) bifenthrin EC, no adjuvant was added to the spray mixture. Peanut samples were collected 13 days after the last application at commercial maturity (Culligan, J.F. 1996, FMC Study No. 182PNT95R2). The samples were processed following the below scheme. The residues of bifenthrin were determined using Method P-2814 with the LOQ of 0.05mg/kg. Results of the trials are summarized in Table 16.

As residues in nutmeat (raw commodity) and all the processed commodities were below the LOQ (except that one value for refined oil was at the LOQ), processing factors could not be calculated.

Table 16 Residues of bifenthrin in peanut and its processed commodities following application of bifenthrin WSB (FMC Study No. 182PNT95R2)

Location, Country/Year (variety)	Application rate (kg ai/ha)	DALA	Matrix	Residues (mg/kg)	Processing factor
Sunsweet, GA, United States, 1995 (Florunner)	3×0.336	13	Nutmeat, field	<0.05, <0.05, <0.05, <0.05	--
			Nutmeat, pre-processing	<0.05, <0.05, <0.05, <0.05	--
			Meal	<0.05, <0.05, <0.05, <0.05	NC
			Refined oil	<0.05, <0.05, 0.05, <0.05	NC

Notes:

NC: Not Calculated because average residues in RAC and processed commodity were <LOQ.

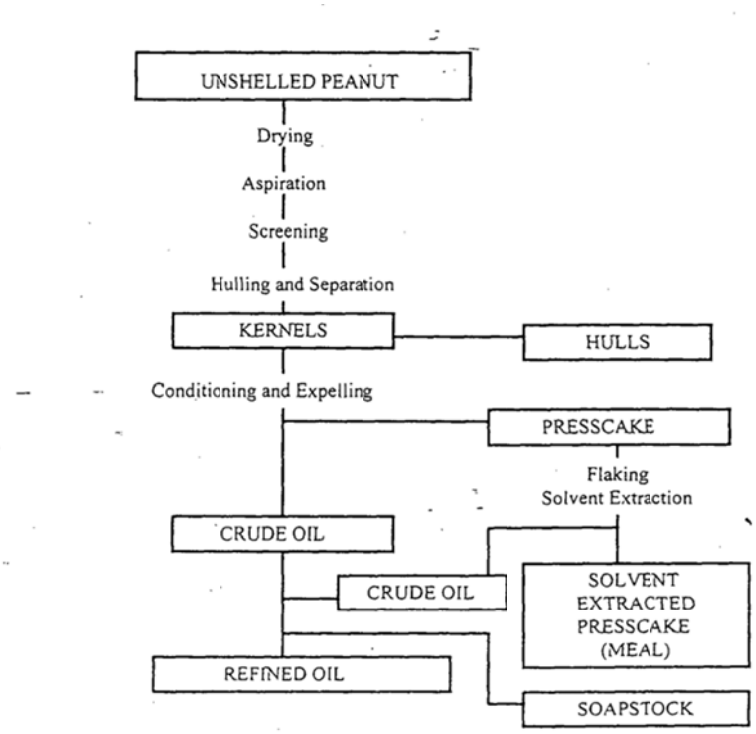

Figure 1 Flow scheme for processing peanut nutmeat into processed parts

APPRAISAL

Bifenthrin is a pyrethroid insecticide and miticide. It was first evaluated for residues and toxicology by the JMPR in 1992. Bifenthrin was evaluated under the periodic review programme in 2009 (T) and 2010 (R), and subsequently evaluated in 2015 and 2019 for additional MRLs.

An ADI of 0–0.01 mg/kg bw and an ARfD of 0.01 mg/kg bw were established by the 2009 JMPR. The definition of the residue for compliance with the MRL and for dietary risk assessment for animal and plant commodities is *bifenthrin* (sum of isomers). The residue is fat-soluble.

Bifenthrin was scheduled at the Fifty-first Session of the CCPR for the evaluation of additional uses by the 2021 Extra JMPR and was re-scheduled to the 2022 JMPR.

The current Meeting received information on new GAPs and supervised residue trials for apple, peach, avocado, pomegranate, pepper (bell, non-bell), melon, spinach, and peanut, as well as processing studies on apple and peanut.

Methods of analysis

The Methods used in residue trials were similar to or slight modifications to the method evaluated by previous Meetings. In general, the data generation methods considered by this Meeting involved extraction with acetone and cleaning-up with SPE. Final determination was achieved using GC-ECD or GC-MSD. The methods were considered suitable for analysis of bifenthrin in trials.

Stability of pesticide residues in stored analytical samples

The 2010 and 2015 JMPR evaluated the stability of bifenthrin in analytical samples stored under frozen conditions and concluded that bifenthrin is stable for at least 18 months in high acid, 49 months in high water, 36 months in high oil and high starch, and 15 months in high protein commodities under frozen conditions. The maximum frozen storage intervals in the supervised trials provided to the current Meeting were shorter than the storage intervals indicated above.

Results of supervised residue trials on crops

The Meeting received information on supervised trials of bifenthrin on apple, peach, avocado, pomegranate, melon, peppers (sweet and chili), spinach and peanut.

Pome fruit, except Japanese persimmon

Apple

The GAP for bifenthrin is in the United States for the US pome fruit group, consisting of foliar applications at 0.224 kg ai/ha with re-treatment intervals (RTIs) of not less 30 days and a PHI of 14 days, no more than 3 applications and a total application rate not more than 0.56 kg ai/ha per year with no more 0.51 kg ai/ha applied after petal fall (BBCH 69). Given the annual rate limitation, the cGAP is an initial application at 0.112 kg ai/ha followed by 2 applications, each at 0.224 kg ai/ha.

In independent trials approximating the cGAP but with retreatment intervals of 20 rather than 30 days, residues of bifenthrin in fruits were (n=8): 0.10, 0.11, 0.13, 0.19, 0.20, 0.24, 0.29, and 0.42 mg/kg.

Noting that the residue decline studies on apple and peach showed no significant changes in concentration between 7 and 21 days after the final application, the Meeting agreed that the difference in retreatment intervals between the trials and the cGAP would not affect residues by more than 25 percent and agreed to use the data from the trials to estimate a maximum residue level.

The Meeting estimated a maximum residue level of 0.7 mg/kg, an STMR of 0.195 mg/kg and an HR of 0.45 mg/kg (highest individual result) for bifenthrin in apple. Noting that the registration is for the US pome fruit group, which does not include Japanese persimmon, the Meeting agreed to extrapolate the estimates for apple to the group of pome fruit, except persimmon, Japanese.

The Meeting noted that acute dietary exposure assessment for apple and pear exceeded the ARfD of 0.01 mg/kg bw (*apple: 250 percent for children in China; pear: 310 percent for children in Canada*). No alternative GAP was available.

Peach

The critical GAP for bifenthrin is in United States for the US Peach subgroup 12-12B, consisting of foliar applications at 0.22 kg ai/ha with RTI of not less 30 days and a PHI of 14 days, no more than 3 application and the total application rate less than 0.56 kg ai/ha per year with no more 0.51 kg ai/ha applied after petal fall (BBCH 69). Given the annual rate limitation, the cGAP is an initial application at 0.12 kg ai/ha followed by 2 applications, each at 0.22 kg ai/ha.

In independent trials approximating the cGAP, residues of bifenthrin in fruit without stone were (n=11): 0.12, 0.12, 0.17, 0.20(2), 0.22, 0.24, 0.26, 0.30, 0.38 and 0.41 mg/kg.

Noting that the residue decline studies on apple and peach showed no significant changes in concentration between 7 and 21 days after the final application, the Meeting agreed that the difference in retreatment intervals between the trials and the cGAP would not affect residues by more than 25 percent.

Furthermore, the 2017 JMPR concluded that for stone fruit, based on the weight of the stone relative to the whole fruit, residues measured in fruit without stones would overestimate whole-fruit residues by about 10 percent and that correcting for this factor would lead to the same maximum residue level estimation. Therefore, the Meeting agreed to use the data from the trials to estimate a maximum residue level.

The Meeting estimated a maximum residue level of 0.8 mg/kg, an STMR of 0.22 mg/kg and an HR of 0.49 mg/kg (highest individual result) for bifenthrin in peach and agreed to extrapolate to the subgroup of peaches.

The Meeting noted that acute dietary exposure assessment showed that residues in peach, apricot, and nectarine exceeded the ARfD of 0.01 mg/kg bw (*peach: 230 percent for children in Japan; apricot: 110 percent for children in Germany; nectarine: 210 percent for children in The Netherlands (Kingdom of the*)). No alternative GAP was available.

Avocado

The critical GAP for bifenthrin on avocado in the United States is foliar applications at 0.062 kg ai/ha with an RTI of not less 14 days and a PHI of 1 day, no more than 5 applications.

Five independent trials were conducted on avocado in the United States with 5 foliar applications at rates of 0.081–0.091 kg ai/ha, and RTIs of 13–17 days, the total application rates of 0.40–0.44 kg ai/ha and a PHI of 1 day. The residues of bifenthrin in fruits (without stone) were (n=5): 0.076, 0.08, 0.11, 0.26 and 0.30 mg/kg. The scaled residues using the scaling factors of 0.73–0.77 (last application rate in trial/GAP) were (n=5): 0.056, 0.058, 0.089, 0.20 and 0.22 mg/kg.

Based on the scaled residue data, the Meeting estimated a maximum residue level of 0.5 mg/kg (assuming the pit constitutes 15 percent of the whole fruit weight), an STMR of 0.089 mg/kg and an HR of 0.23 mg/kg (highest individual result) for bifenthrin in avocado.

Pomegranate

The critical GAP for bifenthrin on pomegranate in the United States is foliar applications at 0.22 kg ai/ha with RTI of not less 14 days and a PHI of 14 days, no more than 3 application and the total application rate less than 0.56 kg ai/ha per year. Given the annual rate limitation, the cGAP is an initial application at 0.12 kg ai/ha followed by 2 applications, each at 0.22 kg ai/ha.

In independent trials matching the cGAP, residues of bifenthrin in pomegranate were (n=4): 0.11, 0.16, 0.17 and 0.18 mg/kg.

The Meeting estimated a maximum residue level of 0.5 mg/kg, a STMR of 0.165 mg/kg and an HR of 0.22 mg/kg (highest individual result) for bifenthrin in pomegranate.

Melon (cantaloupe)

The critical GAP for bifenthrin on melon in the United States is 3 foliar applications at 0.11 kg ai/ha at RTI of not less 7 days and a PHI of 3 days, with no more than two applications after bloom.

In independent trials matching the cGAP, residues of bifenthrin in fruits were (n=4): < 0.1(2), 0.11 and 0.12 mg/kg.

The Meeting agreed that four trials were insufficient to make a recommendation for melon.

Peppers

The critical GAP for bifenthrin in the United States is for the US crop group covering use on peppers and eggplant and consists of 2 foliar applications at 0.11 kg ai/ha with RTI of not less 7 days and a PHI of 7 days, no more than 2 applications.

Five independent trials on pepper, sweet were conducted in the United States approximating the GAP. The residues of bifenthrin in fruits were (n=5): < 0.055, 0.06, 0.10, 0.14 and 0.17mg/kg.

Seven independent trials on pepper, chilli were conducted in the United States approximating the GAP. The residues of bifenthrin in fruits were (n=7): < 0.05, 0.08, 0.10 0.14, 0.15, 0.18 and 0.29 mg/kg.

The ranked order of the combined bifenthrin residues in sweet pepper and pepper, chilli were (n=12): < 0.05, < 0.055, 0.06, 0.08, 0.10(2), 0.14(2), 0.15, 0.17, 0.18, and 0.29 mg/kg.

The Meeting noted that the provided trials were previously evaluated by the 2010 JMPR under a registered use on peppers and that the current registration is for peppers and eggplant. The Meeting estimated a maximum residue level of 0.4 mg/kg, an STMR of 0.12 mg/kg, and an HR of 0.31 mg/kg (from a single sample) for bifenthrin in the Subgroup of peppers (except okra, martynia and roselle) to replace its previous recommendation. The Meeting agreed to extrapolate those estimates to the Subgroup of eggplants.

For estimating residues in dried chili peppers, the Meeting used the data from chili peppers and a default processing factor of 7. On that basis, the Meeting estimated a maximum residue level of 4 mg/kg an STMR of 0.98 mg/kg, and an HR of 2.2 mg/kg for bifenthrin in chili pepper, dried to replace its previous recommendation of 5 mg/kg.

Spinach

The critical GAP for bifenthrin on spinach in the United States is 4 foliar applications at 0.11 kg ai/ha at RTI of not less 7 days and a PHI of 40 days.

In independent trials on spinach approximating the cGAP, residues of bifenthrin in spinach were (n=4): 0.05 (2) and 0.15 mg/kg (2).

The Meeting agreed that four trials were insufficient to make a recommendation for spinach.

Peanut

The critical GAP for bifenthrin on peanut in the United States is five foliar applications at 0.11 kg ai/ha with RTI of not less 14 days and a PHI of 14 days.

In four trials involving one soil application (0.28 kg ai/ha) and one foliar application (0.28 kg ai/ha), with harvest 3–17 DALA, the residues of bifenthrin in nutmeat were (n=4): < 0.05 (4) mg/kg.

In four trials with 5 foliar applications at 0.11 kg ai/ha, with RTIs between last two sprays of 9–35-days and harvest 0–8 DALA, residues of bifenthrin in nutmeat were (n=4) < 0.05 (4) mg/kg.

In a trial to obtain samples for processing studies, 3 foliar applications were made at 0.34 kg ai/ha, and RTIs of 11–47 days, with harvest 13 DALA, the bifenthrin residue in nutmeat was < 0.05 mg/kg.

None of the available trials matched the cGAP. Noting the residues from all trials, including the trials with exaggerated rates, were < 0.05 mg/kg, the Meeting agreed to estimate a maximum residue level of 0.05(*) and an STMR of 0.05 mg/kg for bifenthrin in peanut.

Residues in animal feeds

Peanut vine, hay and hull

The only GAP provided for peanuts was from the United States. There is a label restriction in the United States which excludes the feeding of green immature plants and peanut hay to livestock. The Meeting did not make new estimates for residues in animal commodities and confirmed its previous recommendation.

Fate of residues during processing

The Meeting received processing studies for apple and peanut.

Estimated processing factors for apple considered at this Meeting are summarised below.

Table 17 Processing factors for estimation of STMR

RAC	Processed commodity	Median or best estimate processing factor	STMR-P =$STMR_{RAC}$ × PF (mg/kg)
Apple (STMR = 0.2 mg/kg)	Juice	< 0.048	0.0096
	Wet pomace	2.5	0.5

For peanut, four nutmeat samples were obtained from a trial with three applications of bifenthrin at 0.336 kg ai/ha. Residues in all samples of nutmeat and meal were < 0.05 mg/kg. In oil, bifenthrin residues were < 0.05 mg/kg in three samples and 0.05 mg/kg in one sample. A processing factor for oil could not be calculated due to the non-quantifiable residue in the nutmeat.

Noting that the dosing in the trial was at a 1.8× rate and that when scaled to a cGAP rate the expected residues in meal and refined oil would be < 0.05 mg/kg, the Meeting agreed to estimate the median-P for meal at 0.05 mg/kg and the STMR-P for refined oil at 0.05 mg/kg.

Farm animal dietary burden

Dietary burdens were calculated for beef cattle, dairy cattle, broilers and laying poultry based on feed items evaluated by the JMPR. The dietary burdens, estimated using the 2018 OECD Feed diets listed in Appendix XIV Electronic attachments to the 2016 Edition of the FAO manual, are presented in Annex 6.

The maximum total dietary burdens calculated in 2019 were 8.3 ppm (beef cattle), 7.4 ppm (dairy cattle), 0.59 ppm (poultry broiler) and 2.0 ppm (poultry layer). The only animal feed evaluated by the current Meeting is apple pomace. Maximum total dietary burdens calculated by the current Meeting using the OECD diets were unchanged or slightly less than those derived by the 2019 Meeting. The Meeting therefore confirmed its previous recommendations for residue levels in animal products.

RECOMMENDATIONS

On the basis of the data obtained from supervised trials, the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessments.

Table 18 Residue levels suitable for establishing maximum residue limits and for IEDI and IESTI assessments

CCN	Commodity	Recommended Maximum residue level (mg/kg)		STMR or STMR-P mg/kg	HR mg/kg
		New	Previous		
FI 0326	Avocado	0.5		0.089	0.23

CCN	Commodity	Recommended Maximum residue level (mg/kg)		STMR or STMR-P mg/kg	HR mg/kg
		New	Previous		
VO 20046	Eggplant, Subgroup of	0.4		0.12	0.31
SO 0697	Peanut	0.05*		0.05	
HS 0444	Pepper, chilli, dry	4	5	0.98	2.2
FS 2001	**Peaches, Subgroup of #**	0.8#		0.22	0.49
VO 0051	Peppers, Subgroup of (except okra, martynia and roselle)	0.4	0.5	0.12	0.31
FI 0355	Pomegranate	0.5		0.165	0.22
FP 0009	Pome fruits, Group of (except persimmon, Japanese)#	0.7#		0.195	0.45
JF 0226	Apple juice			0.0096	
OR 0697	Peanut oil, edible			0.05	
	Apple, wet pomace	--	--	0.5	--

Notes:

On the basis of information provided to the JMPR it was concluded that the estimated acute dietary exposure to residues of bifenthrin for the consumption of Peaches, Subgroup of and Pome fruit, Group of (except Japanese persimmon) may present a public health concern.

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The ADI for bifenthrin is 0–0.01 mg/kg bw. The International Estimated Daily Intakes (IEDIs) for bifenthrin were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the JMPR. The results are shown in Annex 3 of the 2022 JMPR Report. The IEDIs ranged from 10–40 percent of maximum ADI of 0.01 mg/kg bw. The Meeting concluded that the long-term dietary exposure to residues of bifenthrin from uses considered by the current Meeting is unlikely to present a public health concern.

Acute dietary exposure

The ARfD for bifenthrin is 0.01 mg/kg bw, the International Estimate of Short-Term Intakes (IESTIs) was calculated for food commodities and their processed commodities for which HRs/HR-Ps or STMRs/STMR-Ps were estimated by the present Meeting and for which consumption data were available. The results are shown in Annex 4 of the 2022 JMPR report.

The IESTIs were less than 100 percent of the ARfD, except for apple (up to 230 percent for children in China), pear (up to 310 percent for children in Canada), peach (up to 260 percent for children in Japan), apricot (up to 110 percent for children in Germany), and nectarine (up to 210 percent for children in the Netherlands). The Meeting concluded that acute dietary exposure to residues of bifenthrin may present a public health concern for those commodities.

BROFLANILIDE (326)

First draft prepared by Dr J Heidler, Federal Institute for Risk Assessment, Berlin, Germany

EXPLANATION

Broflanilide is a meta-diamide insecticide for the control of chewing-insect pests. It is the pro-insecticide to its active form desmethyl broflanilide, which acts by binding to the GABA receptor, resulting in a block of inhibitory neurotransmission and death of target insects. At the Fifty-first Session of the CCPR, broflanilide was scheduled for evaluation as a new compound in 2020 and rescheduled to the 2022 JMPR.

The Meeting received information on identity, physicochemical properties, metabolism (plant, confined rotational crops and animals), environmental fate, field rotational crops, methods of residue analysis, freezer storage stability, registered use patterns, supervised residue trials in bulb vegetables (green onion, leek), brassica vegetables (cabbage, Chinese cabbage), tomato, root vegetables (radish, Japanese radish, turnip, potato), cereals (wheat, barley), maize, sweet corn and coffee, fate of residues in processing, and livestock feeding studies.

IDENTITY

ISO common name	Broflanilide
IUPAC name	*N*-[2-bromo-4-(perfluoropropan-2-yl)-6-(trifluoromethyl)phenyl]-2-fluoro-3-(*N*-methylbenzamido)benzamide
CA nomenclature	3-(benzoylmethylamino)-*N*-[2-bromo-4-[1,2,2,2-tetrafluoro-1-(trifluoromethyl)ethyl]-6-(trifluoromethyl)phenyl]-2-fluorobenzamide
Synonyms	BAS 450 I, MCI-8007, MLP-8607, Reg.No. 5672774, LS 5672774, LSP5672774
CAS No.	1207727-04-5
CIPAC No.	994
Structural formula	Molecular formula	$C_{25}H_{14}BrF_{11}N_2O_2$
Molecular mass	663.3 g/mol

Notes:

[a.] ε is molar absorption coefficient (dm3.mol-1.cm-1). λmax is absorption wavelength maxima (nm). Maxima below 220 nm were disregarded as these are below the low wavelength cut-off of the solvents employed.

Formulations

Broflanilide is applied formulated alone or in combination with other active substances. It is formulated as aerosol dispenser (AE), bait (RB), emulsifiable concentrate (EC), flowable concentrate for seed treatment, (FS), suspension concentrate (SC), water dispersible granules (WG), and smoke generator (FU) products.

Table 2 Examples of formulations registered containing broflanilide as active ingredient

Formulation	Broflanilide content	Formulation	Broflanilide content
AE	0.0045% w/w	EC	1.5% w/w
AE	0.125% w/w	FS	300 g/L
AE	0.2% w/w (with insecticide)	FS	16.7 g/L (with fungicides)
RB	0.005% w/w	FU	10% w/w
RB	0.02% w/w	SC	100 g/L
RB	0.025% w/w	SC	5% w/w
RB	0.25% w/w	SC	12 % w/w
EC	5% w/w	SC	20 % w/w
EC	0.5% w/w	WG	5% w/w

METABOLISM AND ENVIRONMENTAL FATE

Metabolism studies were conducted using ^{14}C-labelled broflanilide. The position of the label for the test substances is presented in Figure 1:

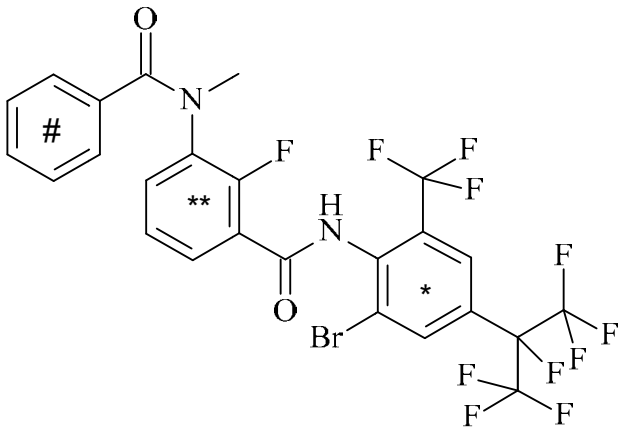

Figure 1 Structure of broflanilide and position of radiolabels

Notes:

* Denotes [B-ring-U-^{14}C] radiolabelled material.

# Denotes [C-ring-U-^{14}C] radiolabelled material.

** Denotes [A-ring-U-^{14}C] radiolabelled material.

Chemical names, structures and code names of metabolites and degradation products of broflanilide are shown in Table 3.

DC-DM-(A6-OH)-8007	3-amino-*N*-[2-bromo-4-(perfluoropropan-2-yl)-6-(trifluoromethyl)phenyl]-2-fluoro-4-hydoxybenzamide		Animals (goat (liver, kidney)
DM-(C2-OH)-8007	*N*-2-bromo-4-(perfluoropropan-2-yl)-6-(trifluoromethyl)phenyl]-2-fluoro-3-(2-hydoxybenamido)benzamide		Animals (goat (liver, kidney)
B-urea (Reg. No 6065386)	[2-bromo-4-(perfluoropropan-2-yl)-6-(trifluoromethyl)phenyl]urea	 Molar mass: 451.1 g/mol	Confined rotational crop (wheat (forage, hay & straw), lettuce (immature & mature), radish (leaves))
B-oxam-acid (Reg. No 6066332)	*N*-[2-bromo-4-(perfluoropropan-2-yl)-6-(trifluoromethyl)phenyl]oxamic acid	 Molar mass: 480.1 g/mol	Confined rotational crop (wheat (forage, hay & straw), radish (leaves))
Hippuric acid	N-benzoylglycine		Animals (goat skim milk, kidney, liver)
H-U27B (and related but not fully elucidated H-U27C)	Hydroxyl cysteine conjugate of DM-8007		Animals (hen liver)

Plant metabolism

The metabolic fate in plants was investigated following application of [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide to cabbage, tomato, Japanese radish, soya bean, rice, wheat and tea.

Cabbage

A metabolism study with cabbage (variety "Copenhagen Market") was performed outdoors with [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide (Estigoy, 2017, BROFLAN_017). Cabbage plants received two foliar applications at nominal rates of 0.025 kg ai/ha each. The first application occurred on immature cabbage (BBCH 45) and the second application 7 days later (BBCH 46). Immature cabbage (BBCH 46) was harvested 6 days after application 1, while mature cabbage (BBCH 49) was harvested 21 days after application 2.

Upon arrival in the laboratory, the outer leaves of the cabbage plants were separated from the inner leaves. Only the outer leaves received a surface rinse with acetonitrile, before all samples were homogenized by blending with dry ice. The radioactive content in the samples was determined by combustion, followed by liquid scintillation counting (LSC). The radioactive content in the surface rinse was directly determined by LSC. Portions of the rinsed outer leaves and the inner leaves were subjected to extraction with acetonitrile (twice) and acetonitrile:water (1+1) (once). Radioactive components in the acetonitrile rinses and solvent extracts were determined by LSC and characterized/identified by co-chromatography with authentic reference standards using reverse phase HPLC, LC-MS and TLC.

Table 4 shows similar TRR levels for both labels with the majority of the radioactivity found in the outer cabbage leaves.

Table 4 Total radioactive residues in cabbage after two foliar applications of [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide

Matrix	DAT	TRR determined (values are from the rinse + combustion of inner and outer leaves of cabbage plants [mg/kg]	TRR calculated [mg/kg] [1]
[B-ring-U-^{14}C]-broflanilide			
Cabbage (inner and outer leaves)	6 DAT1	0.352	0.306
Cabbage (inner and outer leaves)	21 DAT2	0.181	0.146
[C-ring-U-^{14}C]-broflanilide			
Cabbage (inner and outer leaves)	6 DAT1	0.304	0.264
Cabbage (inner and outer leaves)	21 DAT2	0.305	0.266

Notes:

[1] Sum of the residues in the surface rinses, acetonitrile:water extracts and PES.

The radioactivity extracted from homogenized cabbage is presented in Table 5. Inner leaves taken 21 DAT 2 were not extracted due to their low radioactivity (0.000-0.005 mg eq/kg). Extracted radioactivity was similar for both labels ranging between 92–95 percent TRR, while the PES accounted for 6–8 percent TRR (Table 5).

Table 5 Extractability of radioactive residues from cabbage samples after two foliar applications of [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide

TRR[2]	0.264	100	0.266	100.1
TRR[2]/TRR[1]	86.8		87.2	

Notes:

[1] TRR determined (values are from the rinse + combustion of inner and outer layers of cabbage plants).

[2] TRR was calculated as the sums of the residues in the surface rinses, acetonitrile:water extracts and PES.

[3] Samples were not extracted (values are based on the combustion data).

The distribution of radioactivity in cabbage is presented in Table 6. Parent broflanilide was the major identified residue in immature and mature cabbage accounting for 66–84 percent TRR (0.10–0.25 mg eq/kg). Additionally two minor metabolites were identified, namely S(PFP-OH)-8007 and DM-8007 accounting for 3.8–7.6 percent TRR (0.01–0.012 mg eq/kg) and 2.9–7.9 percent TRR (0.009–0.021 mg eq/kg), respectively. The unextracted residue was not further characterized.

Tomato

A metabolism study with tomato (variety "Marglobe") was performed outdoors with [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide (Estigoy, 2017, BROFLAN_018). Rain shelters constructed from galvanized pipe, lumber and clear greenhouse plastic were placed over the planter boxes for the duration of the study to protect them from thunderstorms. Tomato plants received two foliar applications at nominal rates of 0.025 kg ai/ha each. The first application occurred at the pre-bud stage (approx. BBCH 49-50) and the second application 83 days later at the beginning ripening stage (approx. BBCH 79-81). Immature tomatoes and leaves (BBCH 75) were harvested 71 days after application 1, while mature tomatoes and leaves (~BBCH 88) were harvested 10 days after application 2.

Upon arrival in the laboratory, samples were immersed in acetonitrile to remove surface residues. The rinsed tomatoes and leaves were homogenized by blending with dry ice and the radioactive content in

the samples was determined by combustion, followed by liquid scintillation counting (LSC). Portions of the tomato leaves from harvest 2 were subjected to extraction with acetonitrile (twice) and acetonitrile:water (1+1) (once). Radioactive components in the acetonitrile rinses and solvent extracts were determined by LSC and characterized/identified by co-chromatography with authentic reference standards using reverse phase HPLC, LC-MS and TLC. The PES of the tomato leaves from harvest 2 was further characterized by treatment with 0.01M Na2-EDTA solution, followed by incubation in a water bath (30 °C) for 23 hours (pectin extraction) and with dimethyl sulfoxide followed by incubation in a water bath (80 °C) for 48 hours (lignin extraction). Tomato fruits from both harvests and immature tomato leaves from harvest 1were not extracted, due to the low amount of radioactivity present (< 0.001 mg eq/kg).

TRR was very low or non-detectable in samples taken at harvest 1 (Table 7), while in samples from harvest 2 similar TRR levels were found for both labels, with the majority of the radioactivity detected in the leave surface rinse samples.

Table 7 Total radioactive residues in tomato fruits and leaves after two foliar applications of [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide

The radioactivity extracted from homogenized tomato fruits and leaves taken at harvest 2 is presented in Table 8. Extracted radioactivity was similar for both labels ranging between 96–99 percent TRR in tomato leaves and 70–80 percent TRR in tomato fruit. The PES in tomato fruit accounted for 20–30 percent TRR, but was < 0.003 mg eq/kg in absolute concentration.

Notes:

[1] TRR determined (values are from the rinse + combustion of tomato fruits and leaves).

[2] TRR was calculated as the sums of the residues in the surface rinses, acetonitrile:water extracts and PES.

The distribution of radioactivity in tomato fruits and leaves is presented in Table 9. Parent broflanilide was the major identified residue, accounting for 87–89 percent TRR (0.76–1.3 mg eq/kg) in tomato leaves and 60–68 percent TRR (0.006–0.007 mg eq/kg) in tomato fruit. Additionally, metabolites S(PFP-OH)-8007 and DM-8007 were identified in tomato leaves and fruit at minor levels of 3.0–3.4 percent TRR (0.0003–0.051 mg eq/kg) and 3.4–4.0 percent TRR (0.0004–0.060 mg eq/kg), respectively. Further characterization of the PES from tomato leaves treated with [B-ring-U-^{14}C]-labelled broflanilide allocated 0.3 percent TRR to pectin and 2.5 percent TRR to lignin.

Japanese radish

A metabolism study with Japanese radish (variety Karayoshi, *Raphanus sativus* L. *var. longipinnatus*) was performed indoors (glass green house) with [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide (Hayashi, 2017, BROFLAN_019). The first treatment was applied to the soil at a rate of 0.4 kg ai/ha immediately after seeding, and a second treatment was applied foliar 41 days later at a rate of 0.225 kg ai/ha, 29 days before the final harvest. Plants (leaves and root) were collected at three sampling points: 40DAT1 (intermediate harvest-1), 14DAT2 (intermediate harvest-2) and 29DAT2 (final harvest).

Upon arrival in the laboratory, the leaves were surface-rinsed with acetonitrile (except the intermediate harvest-1) and the root was further separated into peel and flesh. All samples were homogenized by blending with dry ice. Portions of the samples were subjected to extraction with acetonitrile:water (8+2) (twice) and acetonitrile:0.1M HCl (8+2) (once). The extract were pooled and the radioactive content determined by LSC, while the PES was combusted first and then the radioactivity determined by LSC. The leaf extract at the intermediate harvest-2 and the final harvest contained feasible amounts of radioactivity for further characterization/identification. These extracts were fractionated by solid phase extraction (SPE), followed by quantification of the radioactive components by co-

chromatography with authentic reference standards using reverse phase HPLC and TLC. All other samples were not further analysed.

The TRR was calculated as the sum of the rinse/extracts and the PES for each matrix, rather than by direct combustion (Table 10). TRR was generally < 0.01 mg eq/kg for both labels in samples taken at the intermediate harvest 1. In samples from the intermediate harvest-2 and from the final harvest, the TRR was at least two orders in magnitude higher in the leaves compared to the root, but similar among each matrix for both time points and labels.

Table 10 Total radioactive residues in radish leaves and roots after treatment with [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide

Matrix	Intermediate harvest-1 (40DAT1) mg eq/kg	Intermediate harvest-2 (14DAT2) mg eq/kg	Final harvest (29DAT2) mg eq/kg
[B-ring-U-^{14}C]-broflanilide			
Leaves	0.0059	3.868	4.178
Roots	0.0038	0.0113	0.0036
[C-ring-U-^{14}C]-broflanilide			
Leaves	0.0069	4.443	3.608
Roots	0.0075	0.0112	0.0119

The radioactivity extracted from homogenized radish leaves ranged between 95–99 percent TRR, except for leaves from intermediate harvest 1 for the C-ring label with 70 percent TRR (Table 11). In these samples the radioactivity in the PES accounted for 30 percent TRR, but was < 0.0021 mg eq/kg in absolute concentration. In radish roots, the sum of the radioactivity found in peel and flesh extracts ranged between 54–96 percent TRR, while 4.3–47 percent TRR remained in the PES. However, absolute concentrations in the PES were throughout < 0.0056 mg eq/kg.

The distribution of radioactivity in radish leaves is presented in Table 13. Parent broflanilide was the major identified residue, accounting for 77–82 percent TRR (2.8–3.6 mg eq/kg). Additionally, metabolites S(PFP-OH)-8007 and DM-8007 were identified at minor levels of 1.7–2.9 percent TRR (0.067–0.12 mg eq/kg) and 2.5–3.3 percent TRR (0.11–0.13 mg eq/kg), respectively. The radioactive residue in radish roots was not further characterized.

Soya bean

A metabolism study with soya bean (variety "Woodruff") was performed outdoors with [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide (Estigoy, 2017, BROFLAN_020). Rain shelters constructed from galvanized pipe, lumber and clear greenhouse plastic were placed over the planter boxes for the duration of the study to protect them from thunderstorms. Soya plants received two foliar applications at nominal rates of 0.025 kg ai/ha each. The first application occurred at bud formation (approx. BBCH 49–51) and the second application 77 days later at the beginning of the pod and seed ripening stage (approximately BBCH 79–81). Soya bean forage and hay samples were harvested 21DAT1 (BBCH 69) and 35DAT1 (BBCH 74), respectively. The mature soya bean seeds were harvested 12DAT2.

Upon arrival in the laboratory, soya bean forage and hay were surface-rinsed with acetonitrile and the radioactivity determined by LSC. Subsequently all samples were homogenized by blending with dry ice and their radioactive content determined by combustion, followed by LSC. Portions of soya bean forage and hay were subjected to extraction with acetonitrile (twice) and acetonitrile:water (1+1) (once). The extract were pooled and the radioactive content determined by LSC. The extracts were further

characterized/identified by co-chromatography with authentic reference standards using reverse phase HPLC, LC-MS and TLC. The PES of soya bean hay were further characterized by treatment with 0.01M Na2-EDTA solution, followed by incubation in a water bath (30 °C) for 23 hours (pectin extraction) and with dimethyl sulfoxide followed by incubation in a water bath (80 °C) for 48 hours (lignin extraction). Soya bean seeds were not further analysed due to the low amount of radioactivity present.

Table 14 shows similar TRR levels for both labels with the highest levels found in soya bean forage. In soya bean seeds, the detected radioactivity was < 0.01 mg eq/kg for both labels.

Table 14 Total radioactive residues (mg eq./kg) in soya bean forage, hay and seeds after treatment with [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide

Notes:

[1] TRR determined (values are from the direct determination of rinse + combustion).

[2] TRR was calculated as the sums of the residues in the surface rinses, extracts and PES.

The distribution of radioactivity in soya bean forage and hay is presented in Table 16. Parent broflanilide was the major identified residue, accounting for 75–76 percent TRR (0.32–0.34 mg eq/kg) in soya bean forage and 67–71 percent TRR (0.19 mg eq/kg) in soya bean hay. Additionally, metabolites S(PFP-OH)-8007 and DM-8007 were identified in soya bean forage and hay at minor levels of 3.8–5.6 percent TRR (0.010–0.021 mg eq/kg) and 5.1–8.3 percent TRR (0.022–0.023 mg eq/kg), respectively. Further characterization of the PES from soya bean hay treated with [C-ring-U-^{14}C]-labelled broflanilide allocated 3.0 percent TRR to pectin and 4.3 percent TRR to lignin (Table 16).

Rice

A metabolism study with rice (variety Koshihikari, *Oryza sativa* L.) was performed indoors (glass green house) with [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide (Hayashi, 2017, BROFLAN_021). The first treatment was applied to the flooding water at a rate of 0.3 kg ai/ha immediately after transplantation of the rice seedlings, and a second treatment was applied foliar at a rate of 0.15 kg ai/ha 73 days later. The rice plants were collected at 13DAT2 (intermediate harvest: foliage) and 32DAT2 (the final harvest: brown rice, hulls, straw and root).

Upon arrival in the laboratory, only the foliage from the intermediate harvest was surface-rinsed with acetonitrile, before all samples were homogenized by blending with dry ice. Portions of the foliage, brown rice, straw and hulls were subjected to extraction with acetonitrile:water (8+2) (twice). The extract were pooled and the radioactive content determined by LSC, while the radioactivity in the PES was determined by combustion analysis. Further characterization of the extracts was accomplished by SPE fractionation, followed by identification of the radioactive components by co-chromatography with authentic reference standards using reverse phase HPLC, TLC and LC-TOF-MS. The PES of brown rice was further characterized by washing with a 50 mM KH_2PO_4/NaOH buffer (pH 6.9), followed by enzymatic treatment with α-amylase (starch fraction) and protease (protein fraction) and acidic hydrolysis with 6 N H_2SO_4.The PES of hulls and straw was further characterized by sequential extraction with 0.1 M HCl solution, 1 percent Na2-EDTA (pectin fraction), dimethylsulfoxide (lignin fraction), 24 percent KOH solution (hemicellulose fraction) and 72 percent sulfuric acid solution (cellulose fraction).

The TRR was calculated as the sum of the rinse (foliage only), extracts and the PES for each matrix, except for root, where the radioactivity was directly determined via combustion Table 17. TRR was generally similar for both labels with the highest levels found in rice hulls and straw. In brown rice levels were at least one order in magnitude lower and levels differed significantly between labels (B-ring label about 1/5 of C-ring label). The higher radioactivity in the brown rice using the C-ring label was explained by the possible generation of $^{14}CO_2$, followed by incorporation through photosynthesis.

Table 17 Total radioactive residues (mg eq./kg) in rice forage, brown rice, hulls, straw and root after treatment with [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide

Matrix	DAT	TRR measured	TRR calculated[1]
[B-ring-U-^{14}C]-broflanilide			
Foliage	13DAT2	n/a	1.1491
Brown rice	32DAT2	n/a	0.0207

Straw		n/a	4.8864
Root		1.6821	n/a
[C-ring-U-^{14}C]-broflanilide			
Foliage	13DAT2	n/a	1.9096
Brown rice	32DAT2	n/a	0.1114
Hulls		n/a	6.7494
Straw		n/a	4.1665
Root		0.7560	n/a

Notes:

[1] TRR calculated as the sum of surface rinse (foliage only), extracts and PES.

The extracted radioactivity from rice forage, brown rice, hulls and straw ranged between 85–98 percent TRR, except for brown rice for the C-ring label with 18 percent TRR (Table 18). In these samples the radioactivity in the PES accounted for 82 percent TRR. Since the absolute measured radioactivity in the extracts was similar for both labels, it was assumed that the higher radioactivity in the PES from C-ring label was due to incorporation of $^{14}CO_2$, into the plant matrix.

The distribution of radioactivity in rice forage, brown rice, hulls and straw is presented in Table 19. Parent broflanilide was the major identified residue, accounting for 84-87 percent TRR (1.0-1.6 mg eq/kg) in rice foliage, 83–90 percent TRR (4.6–8.1 mg eq/kg) in hulls and 85–87 percent TRR (3.6–4.1 mg eq/kg) in straw. In brown rice relative amounts of parent broflanilide differed significantly

between the two labels, accounting for 64 percent TRR using the B-ring label and 13 percent TRR using the C-ring label. However, absolute numbers were comparable at 0.013–0.014 mg eq/kg. Additionally, metabolites S(PFP-OH)-8007 and DM-8007 were identified in all matrices at minor levels of 1.0–8.5 percent TRR (0.002–0.28 mg eq/kg) and 0.8–5.4 percent TRR (0.001–0.26 mg eq/kg), respectively (Table 19).

Wheat

A metabolism study in wheat (variety Thasos) after seed treatment was performed with [B-ring-U-^{14}C]-labelled broflanilide indoors (Rosenbaum, 2017, BROFLAN_022). Wheat seeds were coated with broflanilide in an FS formulation prior sowing at a nominal application rate of 10 g ai/100 kg seeds. The actual applied amount of the test item corresponds to an actual application rate of 0.022 kg ai/ha. Immature wheat plants (wheat forage) were collected at growth stage BBCH 39 (77 DAT). Half of the forage was allowed to dry for 8 days at room temperature (wheat hay). Mature wheat plants were harvested at growth stage BBCH 89 (154 DAT) and were separated into straw and grains.

Upon arrival in the laboratory, samples were homogenized by blending with dry ice and their radioactive content determined by combustion, followed by LSC. Portions of wheat straw and grains were subjected to extraction with acetonitrile:water (1+1) (twice), followed by acetonitrile (once). The extract were pooled and the radioactive content determined by LSC. The straw extracts were further characterized by liquid-liquid partitioning with ethyl acetate, followed by fractionation using SPE. Identification of the radioactivity present in the straw extracts was accomplished by co-chromatography with authentic reference standards using reverse phase HPLC and LC-MS. The PES of wheat straw and

grains were further characterized by enzyme solubilization using macerozyme, tyrosinase and amylase. Wheat forage and hay were not further analysed due to the low amount of radioactivity present.

TRR levels in wheat matrices were generally low, with the highest level measured in wheat straw at 0.029 mg eq/kg. A summary of the radioactive residues found in present in Table 20.

Table 20 Total radioactive residues (mg eq./kg) in wheat matrices after seed treatment with [B-ring-U-^{14}C]-labelled broflanilide

Notes:

[1] Corresponds to the re-dissolved precipitate from acetonitrile/water extract.

The distribution of radioactivity in wheat straw and grains is presented in Table 22. No individual components could be identified in either matrix. In wheat straw one unknown component was detected accounting for 14 percent TRR, but was detected at < 0.01 mg eq/kg in absolute numbers. The overall fraction of characterized radioactivity accounted for 81 percent TRR in wheat straw and 53 percent TRR in wheat grain.

Tea

A metabolism study with tea (variety Japanese small leaf tea) was performed outdoors with [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide (Fleischmann, 2017, BROFLAN_023). Tea plants received two foliar applications at nominal rates of 0.1 kg ai/ha each with a RTI of 14 days. Tea leaves were harvested at 7DAT2 and 14DAT2.

Upon arrival in the laboratory, tea leaves were surface-rinsed with acetonitrile and the radioactivity in the rinse determined by LSC. Subsequently, the samples were homogenized by blending with dry ice and their radioactive content determined by combustion, followed by LSC. Portions of the tea leaves were subjected to extraction with acetonitrile (twice) and acetonitrile:water (1+1) (once). The extracts were pooled and the radioactive content determined by LSC. Further characterization/identification of the extract was accomplished by co-chromatography with authentic reference standards using reverse phase HPLC, LC-HRMS and TLC. The PES was not further characterized.

The TRR in tea leaves was calculated as the sum of the rinse, extracts and the PES (Table 23). The TRR was generally similar for both labels ranging between 15–20 mg eq/kg.

Table 23 Total radioactive residues (mg eq./kg) calculated[1] in tea leaves after two foliar application with [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide

The distribution of radioactivity in tea leaves is presented in Table 25. Parent broflanilide was the major identified residue, accounting for 96–97 percent TRR (14–19 mg eq/kg). Additionally, metabolites S(PFP-OH)-8007 and DM-8007 were identified at minor levels of 1.0–1.4 percent TRR (0.14–0.27 mg eq/kg) and 0.0–1.0 percent TRR (0.007–0.20 mg eq/kg), respectively (Table 25).

Notes:

[1] 1-15 metabolites <1%TRR.

[2] 1-9 metabolites <1.05%TRR.

In order to investigate the translocation of broflanilide in plants, the radioactivity in leaves on a stem above and below a treated leaf was determined. Results showed that 92–97 percent of the TRR remained on the treated leaf. Distribution of the radioactive residues on leaves above the treated leaf were 0.1–3.3 percent TRR and on leaves below the treated leaf were between 2.3–5.0 percent TRR.

Summary plant metabolism

In all plant metabolism studies, broflanilide was moderately degraded into DM-8007 via demethylation or into S(PFP-OH)-8007 via oxidative defluorination (substitution of fluorine with hydroxy group). Parent broflanilide was the major identified component in all matrices, while both metabolites were detected at minor amounts only.

The proposed metabolic pathway of broflanilide is shown in Figure 2.

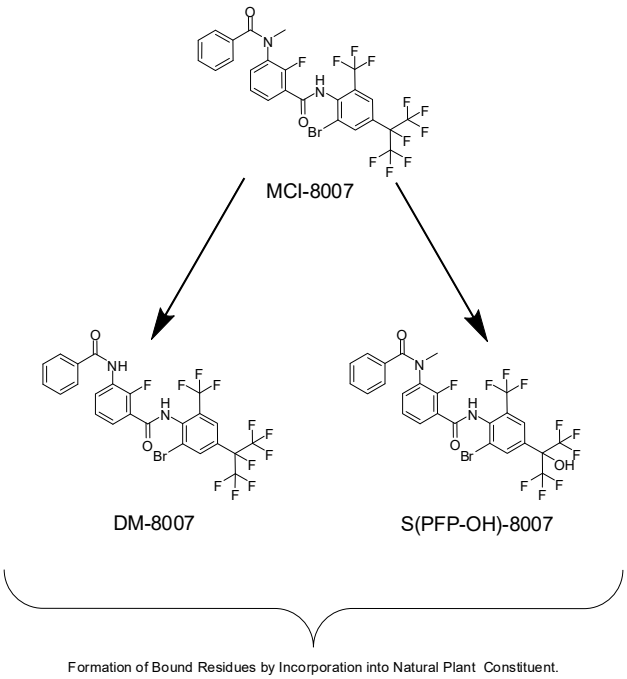

Figure 2 Proposed metabolic pathway of broflanilide in primary crops (cabbage, tomato, Japanese radish, soya bean, rice, tea)

Animal metabolism

Metabolism studies were provided for lactating goats and laying hens using [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide.

Laboratory animals

The evaluation of the metabolism studies in laboratory animals was carried out by the WHO Core Assessment Group.

Lactating goats

A metabolism study with lactating goats was performed with [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide (Estigoy, 2017, BROFLAN_024). The compound was administered orally once daily (after morning milking) for 10 consecutive days to one lactating goat per label. Administered doses were 19 ppm (0.62 mg/kg bw day) and 20 ppm (0.73 mg/kg bw) for the B- and C-label, respectively. Animals were milked twice daily, with urine and faeces being collected twice daily. Tissue samples were collected after sacrifice, which occurred 12 hr after the last dose for the [B-ring-U-^{14}C]-labelled broflanilide and 8 hours after the last dose for the [C-ring-U-^{14}C]-labelled broflanilide. Samples collected at sacrifice included flank and loin muscles, omental, subcutaneous, and renal fats, liver, kidney, as well as whole blood, bile, the gastrointestinal tract.

The total radioactivity in milk, bile, urine, and cage wash was directly measured by LSC. Faeces, gastrointestinal tract, and whole blood samples were subjected to combustion prior to the determination of total radioactivity by LSC. Muscles (flank and loin), milk, fat (omental, subcutaneous and renal), liver, and kidney were dissolved in tissue solubiliser followed by LSC.

Tissues were homogenized in the presence of dry ice followed by sequential solvent extraction:

Samples of flank and loin muscles were extracted twice with acetonitrile/water (1+1) and then once with 100 mL of acetonitrile. The extracts were pooled and the radioactive content determined by LSC. Characterization/identification of the extract was accomplished by co-chromatography with authentic reference standards using reverse phase HPLC and TLC analysis. The PES were combusted and radioactive content measured by LSC.

Milk was separated into milk fat and skim milk by centrifugation. Subsequently, the skim milk was extracted twice with acetone:water (1+1) and once with acetone. The corresponding milk fat was extracted twice with 1:4 acetone/hexane (1+4) and then once with acetone. The extracts were pooled and the radioactive content determined by LSC. The milk fat was concentrated and partitioned with acetonitrile and the acetonitrile layers were measured by LSC. The hexane layer, which contained the fat, stuck to the separating funnel and was not measured. Characterization/identification of the extract was accomplished by co-chromatography with authentic reference standards using reverse phase HPLC, TLC and LC-MS analysis. The PES were combusted and radioactive content measured by LSC.

Fat samples were extracted identically to the milk fat. Liver and kidney samples were twice with acetonitrile/water (1+1) and then once with acetonitrile. The radiocarbon content of each extract was measured by LSC. The PES was combusted, and radiocarbon measured by LSC. The acetonitrile/water extracts were combined, concentrated and centrifuged prior to LSC analysis. To improve concentration recoveries, the solid precipitates from the concentration were rinsed with either acetonitrile or acetonitrile:water (1+1). The rinses were radioassayed by LSC, combined with the concentrated extract and analysed by HPLC, TLC and/or LC-MS analysis. Samples of liver (B and C-ring label) and kidney (B-ring label only) containing high PES were re-extracted using the SPEX Sample Prep (Geno/ Grinder) to improve extractability of bound radioactive residues. The PES from these samples was further characterized by enzyme solubilization using protease and lipase, followed by incubations with 1N HCl and 1 N NaOH. The extracts and solubilizates were also treated with β-glucuronidase in order to cleave conjugates to their respective aglycones.

The total recovery of the administered radioactivity was good for both labels ranging between 87–92 percent. The majority of the radioactivity was found in faeces at 51–75 percent AR. In urine, the recovered radioactivity of [C-ring-U-^{14}C]-labelled broflanilide was at 24 percent AR, while only 0.7 percent AR was found of [B-ring-U-^{14}C]-labelled broflanilide. A higher fraction of metabolites from [C-ring-U-^{14}C]-labelled broflanilide excreted via urine was suggested. A summary of the recovered radioactivity is presented in Table 26.

Table 26 Recovered radioactive residues after oral administration of [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide for 10 consecutive days to lactating goats

Total	91.7		87.0	

Notes:

[1] Levels were calculated based on the average dpm/g of Day 1 pm to Day 10 pm samples.

[2] Total recovered in Skim Milk and Milk Fat.

In milk the total radioactivity both labels increased rapidly after the first administration and ranged over the course of the study between 0.123-0.381 mg eq/kg for [B-ring-U-^{14}C]-labelled broflanilide and between 0.130-0.429 mg eq/kg for [C-ring-U-^{14}C]-labelled broflanilide. Residue levels reached a plateau after approximately 6 days and 2 days [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide, respectively (Figure 3). In milk fat, levels of broflanilide were for both labels ~2 orders in magnitude higher compared to skim milk, reaching a level of up to 4.1 mg eq/kg. The results are summarised in the following Table 27.

Table 27 Recovered radioactive residues in milk after oral administration of [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide for 10 consecutive days to lactating goats

Figure 3 shows the time course of the concentrations of [^{14}C]- broflanilide in milk.

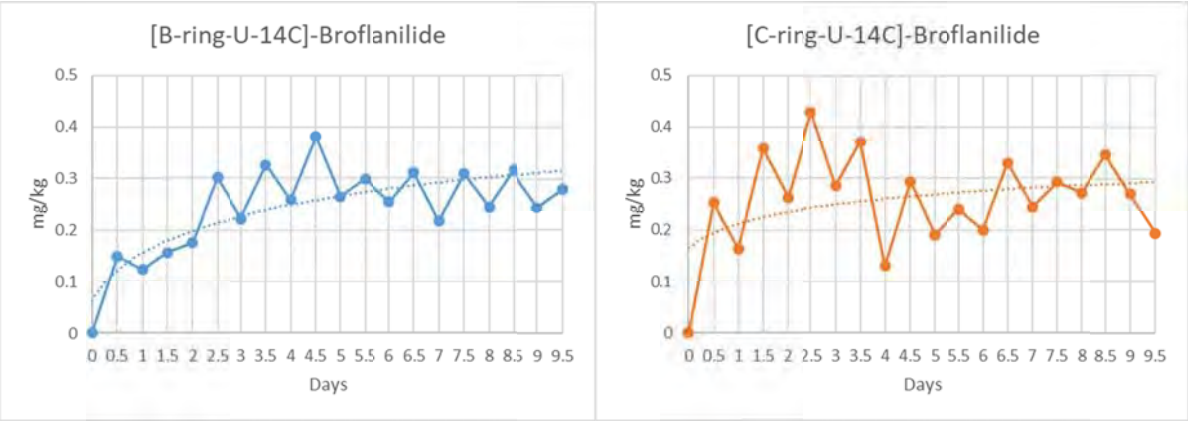

Figure 3 Time course of the concentrations of [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide in milk

Extraction solvents released at least 88 percent TRR from most matrices, except for liver and kidney at 42-68 percent TRR (both labels) and 76 percent TRR (B-ring label), respectively. A summary of the results is presented in Table 28 and Table 29.

Notes:

[1] TRR determined by combustions.

[2] TRR was calculated as the sum of the residues in the extract and PES.

The distribution of radioactivity in lactating goats is presented in Tables 30 to 32. Parent broflanilide was only detected as a minor residue in muscle, kidney and liver at 0.5–6.7 percent TRR (0.005–0.022 mg eq/kg) and was not detected in all other matrices. A major identified metabolite using both labels was metabolite DM-8007 in muscle, milk (skim and fat), fats, liver (only C-label) and kidney at 21–100 percent TRR (0.01–3.4 mg eq/kg). In the B-label treated goat only, metabolite DC-DM-8007 was detected at major proportions in muscle, milk (skim and fat), fats, liver and kidney at 29–67 percent TRR (0.017–2.3 mg eq/kg), while in the C-label only, hippuric acid was detected in skim milk, liver and kidney at 19–69 percent TRR (0.018–0.13 mg/kg). Also, hydroxylated and conjugated DC-DM-(A4-OH)-8007, DC-DM-(A6-OH)-8007 and DM-(C2-OH)-8007 were identified in liver and kidney (B-label only), accounting for up to 15 percent TRR (0.32 mg eq/kg), 11 percent TRR (0.24 mg eq/kg) and 17 percent TRR (0.078 mg eq/kg). The proposed metabolic pathway of broflanilide in lactating goat is shown in Figure 4.

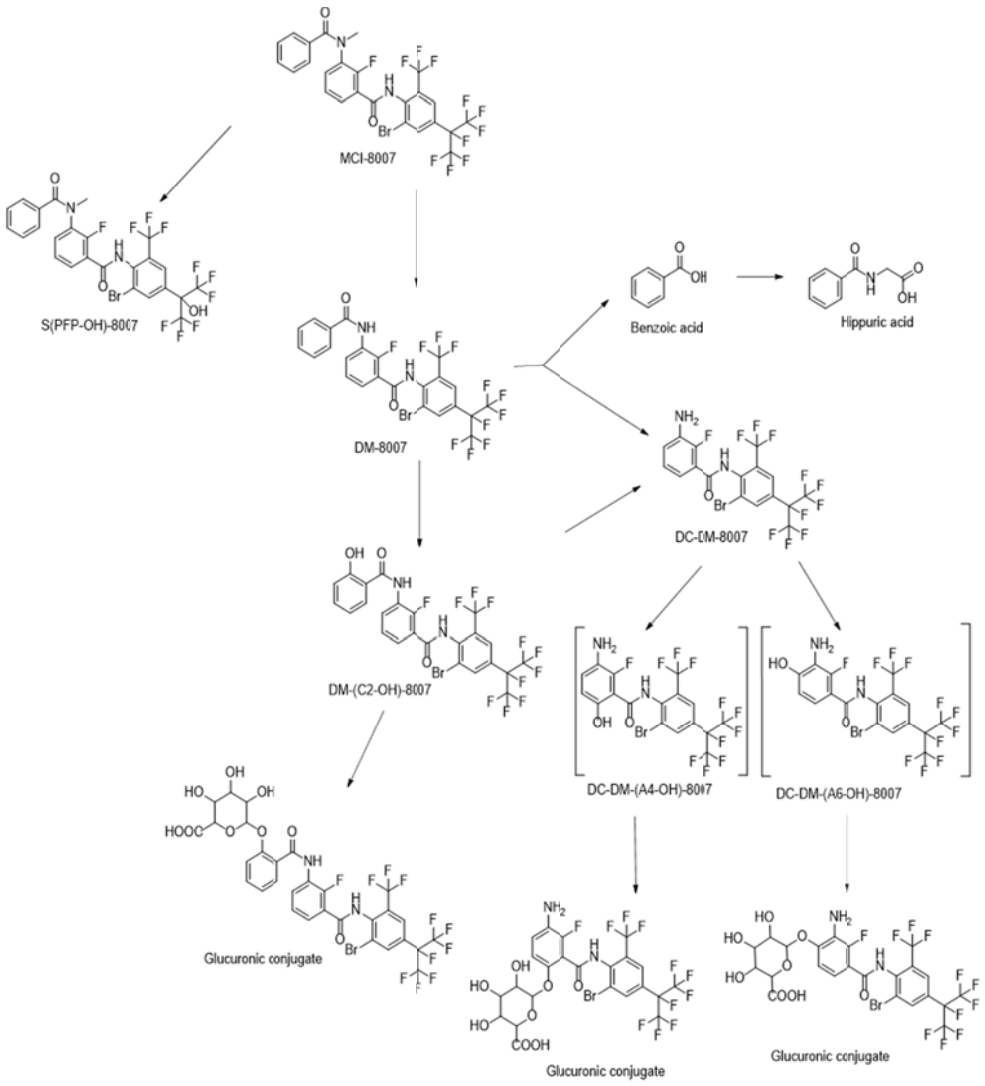

Figure 4 Proposed metabolic pathway of broflanilide in lactating goat

Laying hens

A metabolism study with laying hens was performed with [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide (Estigoy, 2017, BROFLAN_025). The compound was administered orally in cellulose-filled gelatin capsules once daily after the morning collection of eggs and excreta for 14 consecutive days to 10 laying hens per label. Two additional hens per label received a single dose only, used for blood kinetic analysis. Administered doses were 14 ppm (0.86 mg/kg bw day) and 15 ppm (0.84 mg/kg bw) for the B- and C-label, respectively. Eggs and excreta samples were collected twice daily, at approximately 12 hour intervals. Samples of breast muscle, thigh (leg) muscle, abdominal and subcutaneous fat, liver and the entire gastrointestinal tract were collected after sacrifice, which occurred 6 hr after the last dose. Blood

samples were collected for blood kinetic analysis at nine intervals (0.5, 1, 2, 4, 6, 8, 10, 12, and 24 hours) after the first dose.

The total radioactivity in cage wash was directly measured by LSC. Excreta, gastrointestinal tract, and whole blood samples were subjected to combustion prior to the determination of total radioactivity by LSC. Egg white, egg yolk, fats (abdominal and subcutaneous), muscles (breast and thigh), and liver were dissolved in tissue solubiliser followed by LSC.

Tissues were homogenized in the presence of dry ice followed by sequential solvent extraction. Egg white, egg yolk, and muscle samples were extracted twice with acetonitrile/water (1+1) and then once with acetonitrile. The extracts (except thigh muscle) were pooled and cleaned up by solid phase extraction on a silica cartridge to remove fat.

Fat samples were extracted twice with 50 mL acetone/hexane (1:4, v:v) then once with 50 mL acetone. The extracts were pooled, the acetone removed by evaporation, followed by liquid-liquid portioning of the remaining hexane phase with acetonitrile.

Liver samples were initially extracted three times with acetonitrile:water (1:1, v:v) and then once with acetonitrile. For some liver samples additional extractions were performed with weak base (1 mol/L aqueous sodium hydroxide) and strong base (25 percent aqueous sodium hydroxide). The PES of hen liver from both radiolabels (B and C-ring) were further incubated and extracted with protease, followed by lipase enzyme. After enzymatic extraction, the post extracted solids were further extracted with weak acid (1 mol/L hydrochloric acid) and weak base (1mol/L aqueous sodium hydroxide).

The radioactive content is all extracts/fractions was determined by LSC. Characterization/identification of the extract was accomplished by co-chromatography with authentic reference standards using reverse phase HPLC, TLC and/or HPLC/MS analysis. The PES were combusted and radioactive content measured by LSC.

The total recovery of the administered radioactivity was good for both labels ranging between 73–79 percent and 92–95 percent if normalized for percent equivalent mass weight of muscle and fat. The majority of the radioactivity was found in excreta at 56–65 percent AR. In edible tissues radioactivity was highest in fat at 15–19 mg eq/kg, followed by egg yolk at 3.4–3.6 mg eq/kg and liver at 1.8–2.6 mg eq/kg. A summary of the recovered radioactivity is presented in Table 33.

Table 33 Recovered radioactive residues after oral administration of [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide for 14 consecutive days to laying hens

Matrix	[B-ring-U-^{14}C]-broflanilide		[C-ring-U-^{14}C]-broflanilide	
	% AR	mg eq/kg	% AR	mg eq/kg
Total	73.1 (92.0)[1]		79.4 (94.7)[1]	

Notes:

[1] Normalized value based on percent equivalent mass weight of muscle and fat in the administered animals (taken from *New Zealand Journal of Agricultural Research, 1998, Vol. 41: 555-559*).

Incorporation of radioactivity into egg whites reached steady state within 3–4 days, while no plateau was reached in egg yolks. The concentration ratio of between egg yolk and egg white increased over the time course by a factor >400. A summary of the recovered radioactivity is presented in Table 34.

Extraction with solvents released at least 89 percent TRR from all matrices, except for liver where 65–72 percent TRR (both labels) were released. Additional sequential treatments with enzymes, hydrochloric acid and sodium hydroxide, or treatment with sodium hydroxide alone resulted in overall extraction efficiency for liver of 99–100 percent. A summary of the results is presented in Table 35 and Table 36.

Table 35 Extractability of residues from egg white, egg yolk, thigh muscle and breast muscle after oral administration of [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide for 14 consecutive days to laying hens

Notes:

[1] TRR measured.

[2] TRR was calculated as the sum of the residues in the extracts and PES.

The distribution of radioactivity in laying hens is presented in Table 37 to Table 39. Parent broflanilide was only tentatively identified in egg white from the B-label at 2.1 percent TRR (0.0004 mg eq/kg). The predominant identified residue for both labels was metabolite DM-8007 in all

matrices at 57–100 percent TRR (0.013–19 mg eq/kg). As a minor metabolite only occurring with the B-label, DC-DM-8007 was detected in all matrices, accounting for up to 3 percent TRR (0.56 mg eq/kg) in subcutaneous fat (in egg white the TRR was with 16 percent higher, but absolute amount with 0.003 mg eq/kg lower). Additionally in liver only, H-U27B (B-label), a hydroxyl cysteine conjugate of DM-8007 and the similar, but structurally not fully elucidated compound H-U27C (C-label), were identified at levels of 5.3 percent TRR (0.131 mg eq/kg) and 3.3 percent TRR (0.061 mg eq/kg).

Summary livestock metabolism

In lactating goats the transfer of radioactivity into milk and tissues was low. In edible tissue, highest the TRRs were found in fat and milk fat. Parent broflanilide was only detected in minor amounts in muscle, kidney and liver, demonstrating extensive metabolism. The main transformation products of Broflanilide in milk and tissues were metabolites DM-8007, DC-DM-8007 and glucuronide conjugates. Glucuronide conjugation was observed for metabolite DM-(C2-OH)-8007, which was previously formed by hydroxylation of metabolite DM-8007. Conjugation was also observed for metabolites DC-DM-(A4-OH)-8007 and DC-DM-(A6-OH)-8007, which were previously formed by hydroxylation of metabolite DC-DM-

8007. Additionally, broflanilide was also further metabolized to hippuric acid which was detected in skim milk, liver, kidney

In laying hens transfer of radioactivity into tissues and eggs was moderate. In edible tissues, highest TRR levels were found in fat, followed by egg yolk. Parent broflanilide was only tentatively identified in egg white demonstrating as well extensive metabolism. The main transformations of broflanilide in the hen tissues were to metabolites DM-8007, DC-DM-8007 and hydroxyl cysteine conjugate of DM-8007 (H-U27).

In all studies, TRR levels in fat were at least one order in magnitude higher compared to meat, indicating fat solubility.

The proposed metabolic pathway of broflanilide in laying hens is shown in Figure 5.

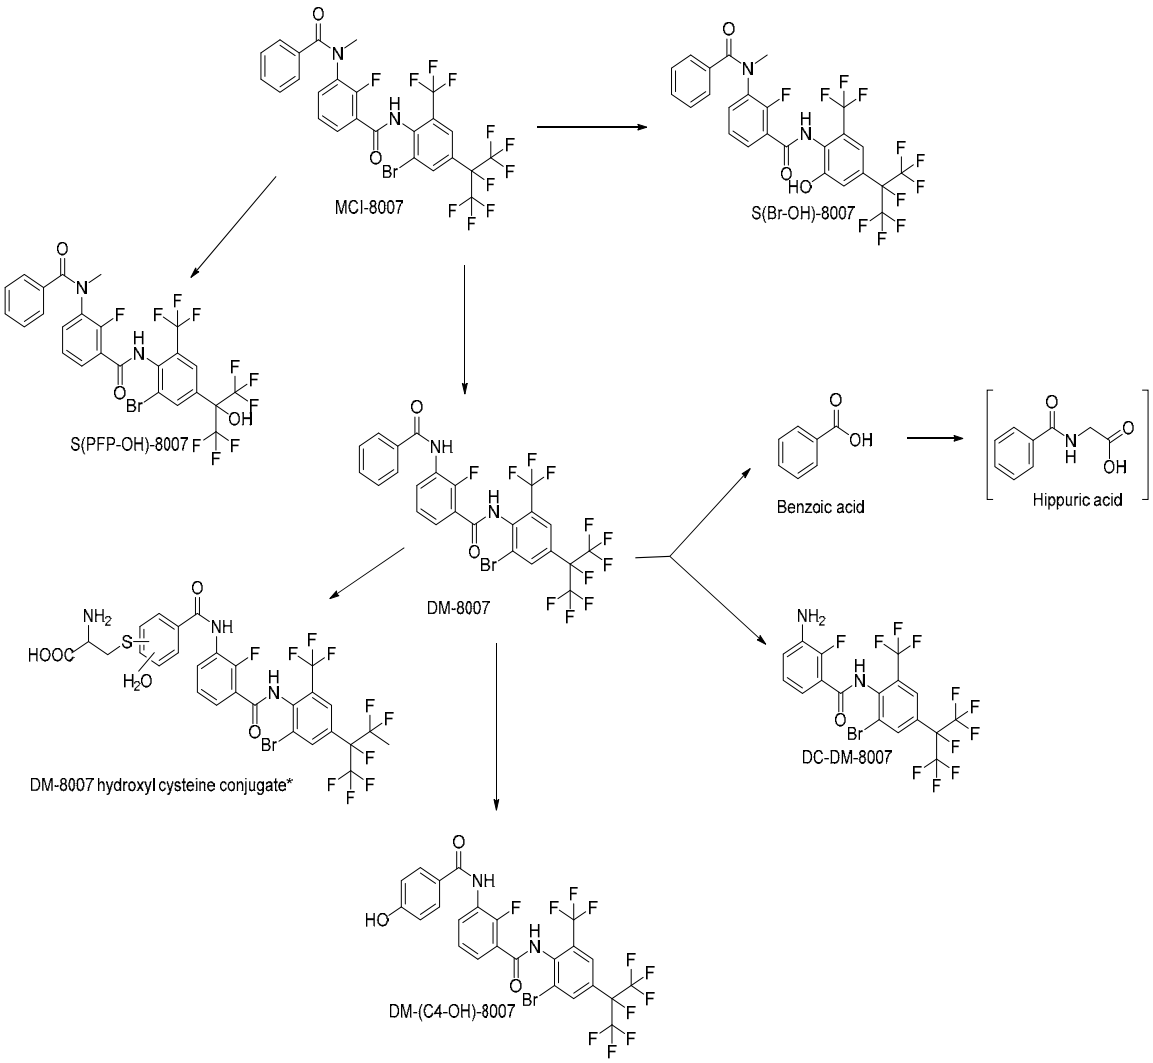

Figure 5 Proposed metabolic pathway of broflanilide in laying hens

Bioaccumulation in fish

A bioaccumulation study in rainbow trout (*Oncorhynchus mykiss*) was performed with [B-ring-U-^{14}C]-labelled broflanilide (Dodd, 2017, BROFLAN_026). Fish were exposed in a flow through system to broflanilide at nominal concentrations of 1.0 µg/L (mean measured: 0.9 µg/L) and 10 µg/L (mean measured: 8.6 µg/L) over a 28 day exposure period, followed by 10 days depuration. Water samples were taken daily and there was no notable degradation of broflanilide in tank water over the course of the study. Fish were sampled at day 0, 1, 3, 7, 14, 21 and 27 during the exposure phase and day 1, 3, 7 and 10 during the depuration phase. The fish were separated into fillet (edible), skeleton and viscera (non-edible) stored at ≤-15 °C until taken for analysis.

The radioactive content in the samples was determined by combustion, followed by LSC. Homogenized samples were subjected to extraction with acetonitrile (twice) and acetonitrile:water (1+1). The lipid content was determined by sequential extraction with chloroform/methanol (1:2), chloroform and water. The chloroform layer was evaporated to dryness and the weight of the dried lipid residue determined. Radioactive components in the solvent extracts were determined by LSC and characterized/identified by co-chromatography with authentic reference standards using reverse phase HPLC and TLC.

After an initial accumulation of radioactive residues to day 7 (low level) or day 3 (high level), steady state was considered to have been achieved. Mean concentrations of radioactivity were highest for both exposure level in the non-edible fish portion. Mean concentrations of radioactivity in the edible portion at steady state were 0.188-0.297 mg eq/kg for the low level and 1.39-1.94 mg eq/kg for the high level. The corresponding steady state measured bioconcentration factors for total radioactivity were for the edible fish portion 241 (low level), 174 (high level), for the non-edible fish portion 470 (low level), 345 (high level) and for the whole fish 366 (low level), 267 (high level). Depuration was rapid for both exposure levels with ~50 percent of the radioactivity eliminated after 1 day and >95 percent elimination after 7 days (Table 40).

Table 40 Mean concentration of radioactivity (mg eq./kg ± sd) and bioconcentration factors (BCF; steady state) for the radioactivity during exposure of fish in water treated with ^{14}C-Broflanilide (B-label) at 1 or 10 mg/L and percent depuration

Parent broflanilide accounted in the edible portion at steady state for 31.4–36.8 percent (low level), 31.5–40.2 percent (high level) and in the non-edible portion 29.9–33.0 percent (low level), 33.4–38.5 percent (high level). DM-8007 was the only additional compound identified, accounting at steady state for 53.4–62.6 percent (low level), 55.7–64.8 percent (high level) and in the non-edible portion 56.7–63.3 percent (low level), 57.9–62.8 percent (high level) (Table 41).

At the low exposure level, mean concentrations of broflanilide at steady state were 0.077 mg/kg (edible), 0.143 mg/kg (non-edible) and 0.112 mg/kg (whole fish). The corresponding steady state bioconcentration factors for broflanilide were 84 (edible), 157 (non-edible) and 123 (whole fish). At the high exposure level, mean concentrations of broflanilide at steady state were 0.589 mg/kg (edible), 1.18 mg/kg (non-edible) and 0.893 mg/kg (whole fish). The corresponding steady state bioconcentration factors for broflanilide were 68 (edible), 135 (non-edible) and 102 (whole fish) (Table 42).

For metabolite DM-8007 at the low exposure level, mean concentrations at steady state were 0.137 mg eq/kg (edible), 0.273 mg eq/kg (non-edible) and 0.209 mg eq/kg (whole fish). At the high exposure level, mean concentrations of DM-8007 at steady state were 0.994 mg eq/kg (edible), 1.975 mg eq/kg (non-edible) and 1.508 mg eq/kg (whole fish) (Table 42). Mean steady state bioconcentration factors for broflanilide were 68-84 (edible), 135-157 (non-edible) and 102-123 (whole fish).

There was no apparent increase in the lipid content of the fish during the course of the study. Whole fish lipid content expressed as percent tissue weight was 2.97 percent at Day 0, 2.62 percent at the termination of exposure and 2.66 percent at termination of the depuration phase

Table 42 Concentrations of [^{14}C]-broflanilide and metabolite DM-8007 (mg eq/kg) in fish tissues during exposure and depuration phase. BFC= bioconcentration factor

The calculation of the lipid-normalized bioconcentration factors (steady state) for total radioactivity during exposure to tank water treated with [^{14}C]-Broflanilide is shown in Table 43. Lipid normalized steady state bioconcentration factors were 517-720 for total radioactivity and 198-242 for broflanilide.

Table 43 Lipid-normalized bioconcentration factors (steady state) for total radioactivity in whle fish during exposure to tank water treated with [^{14}C]-Broflanilide. Results are normalized to 5 percent lipid content

Environmental fate

For the investigation of the environmental fate of broflanilide, the Meeting received studies on aerobic soil metabolism and degradation, soil photolysis and on the behaviour in confined and field rotational crops.

Aerobic soil degradation

The rate of degradation of broflanilide was studied in one fresh aerobic soil (moisture adjusted to 50 percent maximum water holding capacity) using [A-ring-U-^{14}C]-, [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide at a nominal application rate of 0.2 mg/kg, corresponding to 50 g ai/ha (Ta, 2017, BROFLAN_027). Soil characteristics are shown in Table 45.

Table 45 Soil characteristics (BROFLAN_027)

Soil Name	Texture	Soil series	pH (water)	Cation exchange capacity [meq/100g]	Maximum Water Holding Capacity (g/100 g dry soil)	Organic C [percent]
Soil Ca	Sandy Clay Loam	Centerville clay	7.6	23.2	46.5	0.87

The test system was maintained in the dark at a nominal temperature of 20 2 C for 365 days. Volatile organics and CO_2 were trapped with ethylene glycol and 1 mol/L NaOH, respectively. Samples were taken at 0, 7, 14, 30, 59, 91, 120, 177, 269, and 365 days after application.

The soil samples were sequentially extracted with methanol, followed by two extractions with methanol/water (7/3). The 365 DAT samples were further extracted with ethyl acetate, hexane, and dioxane. Extracts were analysed by HPLC against reference standards to identify parent and metabolites. Confirmation of the identity of the metabolites was done for selected samples by LC/MS. The radioactivity in extracts and traps was quantified by LSC. The soil remaining after the extraction was combusted followed by LSC.

Broflanilide declined from 102–108 percent AR to 75–86 percent AR over the study time. The only identified metabolite were DM-8007 and S(PFP-OH)-8007, accounting for up to 1.6 percent AR and 1.1 percent AR, respectively (Table 46). The radioactivity in the bound residues increased over time from 0.9–1.1 percent AR to 5.7–8.0 percent AR.

Table 46 Biotransformation of radiolabelled broflanilide, expressed as of applied radioactivity percentage (mean from duplicate samples)

Notes:

LOQ= 0.3 percent AR (for CO_2 and volatiles organics); 0.5 percent AR (all others).

Degradation endpoints were derived from the best-fit kinetic models for broflanilide. The degradation results are given in Table 47.

Table 47 Half-life calculation for broflanilide in soil under aerobic conditions (BROFLAN_028)

Data set	Kinetic model	Estimated parameter [d^{-1}]	DT_{50} [d]
Full 365 day	SFO	k: 0.0006	1126 [a]
Truncated 120 day	SFO	k: 0.0012	596

Notes:

[a] If DT_{50} > 1000 days, KinGUII does not output estimated value. In these cases, DT_{50} was back-calculated according to ln(2)/k, where k was the SFO rate constant optimized during the kinetic fitting.

In a second study, the degradation of broflanilide was investigated in three fresh aerobic soils (moisture adjusted to 50 percent maximum water holding capacity) using [B-ring-U-^{14}C]-labelled broflanilide at a nominal application rate of 0.2 mg/kg, corresponding to a proposed maximum field application rate of 50 g ai/ha (Ta, 2017, BROFLAN_028). Soil characteristics are shown in Table 48. “Processed soil” was sieved through a 2 mm sieve before use, while intact soil cores were directly placed in Plexiglas boxes. The moisture content of the soils were maintained at approximately 50 percent maximum water holding capacity (MWHC).

Table 48 Soil characteristics

Soil Name	Texture	Soil series	pH (water)	Cation exchange capacity [meq/100g]	Maximum Water Holding Capacity (g/100 g dry soil)	Organic matter [percent]
Soil IL	Silty clay	Drummer silty clay loam	4.8	22.5	54.4	0.87
Soil NC	Sandy loam	Norfolk	5.9	4.7	31.3	1.7
Soil TN	Silt loam	Falaya silt loam	7.0	5.7	34.5	1.3

Both test systems were kept in the dark at nominal temperature of 25 2 C for 365 days. CO2 was trapped with 1 mol/L NaOH. Duplicate samples were taken at 0, 15, 30, 58, 86, 120, 177, 259 and 365 days after application.

The soil samples were sequentially extracted with acetonitrile, acetonitrile:water (1/1), and methanol:water (1/1) with the exception of 259 DAT samples of replicate 2 and 365 DAT samples of both replicates. The 259 DAT samples of replicate 2 and 365 DAT samples of both replicates were extracted with methanol, methanol:water (7/3), and methanol:water (7/3). Further, the "processed" 365 DAT samples were extracted with ethyl acetate, hexane, and dioxane. Extracts were analysed by two different HPLC methods (method 1 & method 2) against reference standards to identify parent and metabolites. The radioactivity in extracts and traps was quantified by LSC. The soil remaining after the extraction was combusted followed by LSC.

The mass balances of broflanilide in intact soil cores and processed soil are presented in Tables 49 and 50. In all soils, the extracted radioactivity declined from 97.5–99.6 percent AR to 59–90 percent AR, while the unextracted radioactive increased from <LOQ-1.2 percent AR to 8–41 percent AR. Further analysis of the bound residues from 365 DAT showed that fulvic acid, humic acid and humin, accounted for 1.2–6.6 percent AR, 3.9–23 percent AR and 1.7–6.8 percent AR, respectively. The fraction detected as CO_2 accounted for up to 4 percent AR.

LOQ= 0.3 percent AR (for CO_2); 1.3 percent AR.

The fraction of identified broflanilide and its metabolites is presented in Tables 51 to 62. For all soils (intact and processed) and methods, parent broflanilide declined from 95–99 percent to 52–87 percent over the study time. Identified metabolites were S(PFP)-OH-8007 at up to 1.2 percent AR, DC-DM-8007 at up to 2.3 percent AR, DM-8007 at up to 4.9 percent AR, DC-8007 at up to 0.5 percent AR and unknowns/others at up to 5.5 percent AR.

Notes:

[a] SFO model was selected as representative model for all evaluations. DT_{50} units are days.

[b] Endpoint exceeds 1000 days. Therefore, 1000 days proposed as a practical, conservative approximation.

In a third study, the soil dissipation/accumulation of broflanilide under field conditions was studied using bare ground plots at five sites in the United States (NC, FL, CA, WA, ND) (Mitchell, 2017, BROFLAN_029). Top soil characteristics are shown in Table 64. A suspension concentrate (SC)

formulation of broflanilide (100 g ai/L) was applied at 2×25 g ai/ha at 7-day intervals for the NC, FL, and CA sites and 1×50 g ai/ha for the WA and ND sites.

Table 64 Top soil (0-6 inches) characteristics (BROFLAN_029).

Soil Name	Texture	Soil series	pH (water)	Cation exchange capacity [meq/100g]	Organic matter [percent]
Soil NC	Loamy sand	Wickham	5.7	3.4	0.66
Soil FL	Sand	Basinger-Smyrna	7.3	4.4	1.4
Soil CA	Loamy sand	Hanford	7.1	4.5	0.53
Soil WA	Sand	Quincy	8.1	8.8	0.26
Soil ND	Clay	Hegne-Fargo	6.9	29.7	3.2

The proposed sampling schedule for soil cores was as follows: prior to and immediately after each test substance application (two applications in NC, FL, and CA; one application in WA and ND) and then 3, 5, 10, 20, 50, 90, 180, 270, 360, 450, and 540 days after last application. Due to the frozen ground, soil samples were not taken at 180 DALT in ND. Due to flooding from Hurricane Matthew, soil samples were not taken at 540 DALT in NC. Soil cores were sectioned into segments of 0–2, 2–4, 4–6, 6–12, 12–18, 18–24, 24–30, 30–36, and 36–42 inches. The top three segments had a length of two inches and all deeper segments had a six-inch length. Core segments were composited by depth within each replicate.

Soil samples were extracted with methanol, followed by methanol/water (7+3). The extracts were combined, diluted 1:5 with methanol/water (1+1) and analysed for broflanilide and its metabolites DM-8007, DC-DM-8007, DC 8007, and S(PFP-OH)-8007 using LC-MS/MS. The limit of quantitation (LOQ) for residues of Broflanilide in soil was 0.001 mg/kg and the limit of detection (LOD) was 0.0002 mg/kg, for each analyte. Mean procedural recoveries from control soil samples fortified with broflanilide and metabolites at 1×, 100× and 600× LOQ were within the acceptable range of 70 to 120 percent.

The measured levels of broflanilide declined from 0.044-0.122 mg/kg at 0 DALT to 0.0002–0.0069 mg/kg at 450–521 DALT, with a few exceptions exclusively found at the 0–5 cm depth. Quantified metabolites were DM-8007 at up to 0.0024 mg/kg and S(PFP)-OH-8007 at up to 0.0008 mg/kg. Concentrations of DC-DM-8007 and DC-8007 were consistently below LOD. The results are shwon in Table 65 to 69.

Degradation endpoints were derived from the best-fit kinetic models for broflanilide and metabolite DM-8007. The degradation results are given in Table 70.

Table 70 Dissipation DT_{50} and DT_{90} values for broflanilide and metabolite DM-8007

Site	Soil Profile	Analyte	Model	DT_{50} (d)	DT_{90} (d)
NC soil	0-42 inches	Broflanilide	DFOP	4.3	88.5
		DM-8007	SFO	21.4	71.0
FL soil	0-42 inches	Broflanilide	FOMC	6.0	189.5
		DM-8007	FOMC	7.8	43.5
CA soil	0-42 inches	Broflanilide	FOMC	18.2	390.4
		DM-8007	SFO	37.7	125.1
WA soil	0-42 Inches	Broflanilide	DFOP	5.6	62.3

Site	Soil Profile	Analyte	Model	DT_{50} (d)	DT_{90} (d)
		DM-8007	SFO	16.8	55.7
ND soil	0-42 inches	Broflanilide	DFOP	3.3	392.3
		DM-8007	SFO	91.3	303.3

Soil photolysis

The soil surface photolytic behaviour of broflanilide was investigated in a non-sterile silt loam soil using [A-ring-U-^{14}C]-, [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide at a nominal application rate of 4.7 mg/kg (dry weight), equivalent to 75 g ai/ha. (Ponte, 2017 BROFLAN_030). Soil characteristics are shown in Table 71.

Table 71 Soil characteristics in the United States (BROFLAN_030)

Soil Name	Texture	Soil Origin	Organic matter [percent]	Cation exchange capacity [meq/100g]	pH
IL soil	Silt loam	Carlyle, Illinois,	3.4	11.8	5.9

Soil samples (~2mm thick) were prepared on quartz/Pyrex dishes and subjected to continuous irradiation for 14 days (equivalent to ~38 US solar days or ~32 OECD solar days) at 20 2.6 C using a xenon irradiation source with filters to eliminate infrared light and wavelengths of 290 nm. Dark control samples were prepared in parallel. Volatile organics and CO2 were trapped with ethylene glycol and 10 percent aqueous NaOH solution, respectively. Soil samples were taken at 0, 16h, 24h or 40h, 3, 6, 9 and 14 days.

The soil samples were extracted once with acetonitrile/water (7+3), followed by two times with acetonitrile/0.5 mol/L aqueous HCl (7+3). Extracts were combined and analysed by LSC and HPLC. Selected samples were analysed by TLC to confirm results. The soil remaining after extraction was combusted followed by LSC.

The percentage recovery of the applied radioactivity in moist soil is presented in Tables 72 to 74. Only minor degradation of parent broflanilide was observed from 95–101 percent to 91–95 percent over the irradiation time, while dark controls at 14 days were within the same range at 95 percent. Metabolite DM-8007 occurred only at minor amounts at up to 4.2 percent in C-ring labelled broflanilide, before declining to 2.6 percent at day 14. Unextracted radioactivity increased slightly from 0.8-1.0 percent to 1.5–2.4 percent at day 14.

Table 72 Phototransformation of [A-ring-U-^{14}C]-labelled broflanilide, expressed as percentage (mean of duplicate) of applied radioactivity, on moist irradiated soil samples

Based on the decline rate observed for all three labels, a half-life time (DT_{50}) of 3466 hours under continuous artificial light was estimated (single 1st order kinetics) for broflanilide, equivalent to 389 US solar days, or 347 OECD solar days.

Confined rotational crops

A confined rotational crop study in the United States of America was conducted with [A-ring-U-^{14}C]- and [B-ring-U-^{14}C]-labelled broflanilide, each applied at a rate of 0.15 kg ai/ha to a sandy loam soil (Fleischmann, 2017, BROFLAN_031). After plant-back intervals (PBIs) of 30, 120 and 270 days, the nature and level of radioactive residues were investigated in lettuce (variety Salad Bowl), radish (variety Crimson Giant) and wheat (variety Blanca Royale).

Soil cores were collected from plots on same day of planting crops 30 days, 120 days and 270 days after treatment, as well as at the final harvest and segmented. Crops planted at the 30, 120 and 270 days after treatment intervals were harvested at different stages of maturity. Lettuce was sampled at immature and mature stages of growth. Radish was sampled at maturity dividing the plant into root

(tuber) and foliage. Wheat plants were harvested at growth stages of forage, hay and at maturity where wheat was divided into straw and grain samples.

Liquid samples such as extracts were directly measured by LSC, while samples not amenable to direct radioanalysis were combusted prior to the determination of total radioactivity by LSC. Crop matrices with a TRR ≥ 0.01 mg/kg determined by combustion analysis were extracted two times with acetonitrile/water (8:2), followed by one time with acetonitrile. Representative portions of combined extracts were concentrated to remove acetonitrile, before partitioned against ethyl acetate. Various HPLC methods, TLC and LC-MS were applied for the characterization and identification of the radioactivity. To identify conjugates possibly present in the aqueous extract of B-ring 30 DAT straw samples were hydrolysed by either β-glucosidase, 1 mol/L KOH or 1 mol/L HCl.

At all planting intervals, the majority of the applied radioactivity remained in the 0–6 cm soil horizon. For 30 DAT, radioactive residues in the 0-6 cm soil horizon ranged between 0.043-0.121 mg eq/kg and increased to 0.099–0.139 mg eq/kg at 120 DAT and 0.145–0.158 mg eq/kg at 239 DAT, before declining to 0.052–0.083 mg eq/kg at 270 DAT and 0.049–0.050 mg eq/kg at 338 DAT (Table 75).

Radioactivity for both labels in all matrices was comparable, with consistently higher levels found for the B-ring label. TRR levels were highest in wheat hay and straw for all PBIs, with the tendency to be higher at later PBIs. A summary of all TRRs found is presented in Table 76. Samples containing total radioactive residues >0.01 mg eq/kg were further investigated by solvent extraction and chromatography.

The radioactivity found in the fractions from the acetonitrile/water extractions, including partitioning behaviour, as well as in the unextracted remainder is presented in Table 77. Extractabilities ranged between 71–92 percent in radish foliage, 77–94 percent TRR in lettuce (immature and mature), 88–92 percent in wheat forage, 36–70 percent TRR in wheat hay, 59–77 percent TRR in straw and 22–85 percent TRR in grain. The radioactivity remaining in the PES was highest at 0.025 mg eq/kg for wheat straw from the treatment with B-labelled broflanilide. No additional characterization of the PES fractions was performed.

Table 77 Extractability of radioactive residues from rotational crops after application of [A-ring-U-^{14}C]- and [B-ring-U-^{14}C]-labelled broflanilide to bare soil at 0.15 kg ai/ha

Notes:

[1] TRR determined by combustion/LSC.

[2] TRR determined by calculation (ACN/H_2O (=organic partition + aqueous partition) + PES).

For the 30 day PBI, the results of the identification and characterization of radioactive residues are presented in Table 78. Residues >0.01 mg eq/kg were found in wheat hay and straw only. Parent broflanilide was identified as a minor component ranging between 4.3–10.2 percent TRR (0.001–

0.003 mg eq/kg). Identified metabolites for both labels were DM-8007, ranging between ND–3.7 percent TRR (ND-0.002 mg eq/kg). For the B-label only, additional identified metabolites were B-urea, ranging between 9.7–13.9 percent TRR (0.004–0.005 mg eq/kg) and B-oxam-acid, ranging between 12.5–20 percent TRR (0.004–0.011 mg eq/kg). Other unknown metabolites detected for the B-label were Uk3B-org at up to 12.5 percent TRR (0.007 mg eq/kg) and for the A-label Uk3A-org up to 31.5 percent TRR (0.009 mg eq/kg).

For the 120 day PBI, the results of the identification and characterization of radioactive residues are presented in Table 79. Residues > 0.01 mg eq/kg were found in lettuce (immature and mature), as well as for wheat forage, hay and straw. Parent broflanilide was identified in varying relative amounts, ranging between ND–45.7 percent TRR, while absolute amounts were consistently < 0.01 mg eq/kg (ND–0.008 mg eq/kg). For the B-label only, additional identified metabolites were B-urea in immature lettuce and wheat matrices, ranging between 11.1–26.6 percent TRR (0.001–0.010 mg eq/kg) and B-oxam-acid in wheat matrices, ranging between 5.4–13.4 percent TRR (0.001–0.006 mg eq/kg). Other unknown metabolites detected for the B-label were Uk3B-org up to 13.8 percent TRR (0.001 mg eq/kg) in immature lettuce and 8.2 percent TRR (0.004 mg eq/kg) in wheat hay as well as for the A-label Uk13A up to 26.8 percent TRR (0.006 mg eq/kg) in wheat straw.

Notes:

[1)] TRR determined by combustion/LSC.

[2)] Sum of combined extracts + PES.

For the 270 day PBI, the results of the identification and characterization of radioactive residues are presented in Table 80 and Table 81. Residues > 0.01 mg eq/kg were found in lettuce (immature and mature) and radish leaves, as well as for wheat forage, hay, straw and grain. Parent broflanilide was identified in varying relative amounts, ranging between ND–46.6 percent TRR, while absolute amounts were consistently < 0.01 mg eq/kg (ND–0.006 mg eq/kg). For the B-label only, additional identified metabolites were DM-8007 in radish leaves and wheat straw at 1.8–2.6 percent TRR (< 0.001–0.001 mg eq /kg), B-urea in all matrices (except wheat grain) at 11.8–35.6 percent TRR (0.004–0.010 mg eq/kg) and B-oxam-acid in radish leaves and wheat matrices (except grain), ranging between 11.3–35.6 percent TRR (0.002–0.024 mg eq/kg). Other unknown metabolites detected for the B-label were Uk10B up to 43.9 percent TRR (0.006 mg eq/kg) in wheat grain and for the A-label Uk13A up to 19.4 percent TRR (0.005 mg eq/kg) in wheat hay.

The proposed metabolic pathway of broflanilide in rotational crops is shown in Figure 6.

Field rotational crop studies

In two field rotational crop trials conducted during the 2016/17 growing seasons in the United States, broflanilide was applied once to bare soil a rate of 0.05 kg ai/ha (1x rate) (Bledsoe, 2019, BROFLAN_032). Wheat, lettuce and radish were planted 30, 60, 90 and 360 DAT and sampled at normal crop maturity.

Parent broflanilide and its metabolites S(PFP-OH)-8007 and DM-8007 were analysed by according to modified method D1417/01, while metabolites B-oxam-acid and B-urea were analysed according to method D1703/01. Homogenized plant samples were extracted after hydration (if necessary), by shaking with acetonitrile. A mixture of salts (magnesium sulfate, sodium chloride, disodium citrate sesquihydrate, and trisodium citrate dihydrate) is then added, followed by mixing with a vortexer and separation by centrifuge. For broflanilide and its metabolites S(PFP-OH)-8007 and DM-8007, an aliquot of the resulting organic layer is diluted in acetonitrile:water (50:50, with 0.1 percent formic acid). Quantification of parent and metabolites was performed by LC-MS/MS with a LOQ of 0.01 mg/kg. Mean procedural recoveries for parent broflanilide and metabolites spiked at 0.01 and 0.1 mg eq/kg to wheat, lettuce and radish matrices were mostly within 70-120 percent and a RSD of <20 percent. Mean recoveries outside this range were found for broflanilide at 0.1 mg/kg in wheat forage (126 percent) and radish top (123 percent), for S(PFP-OH)-8007 at both levels in wheat forage (129 and 125 percent) and for DM-8007 at 0.1 mg eq/kg in wheat forage (131 percent, RSD 27 percent).

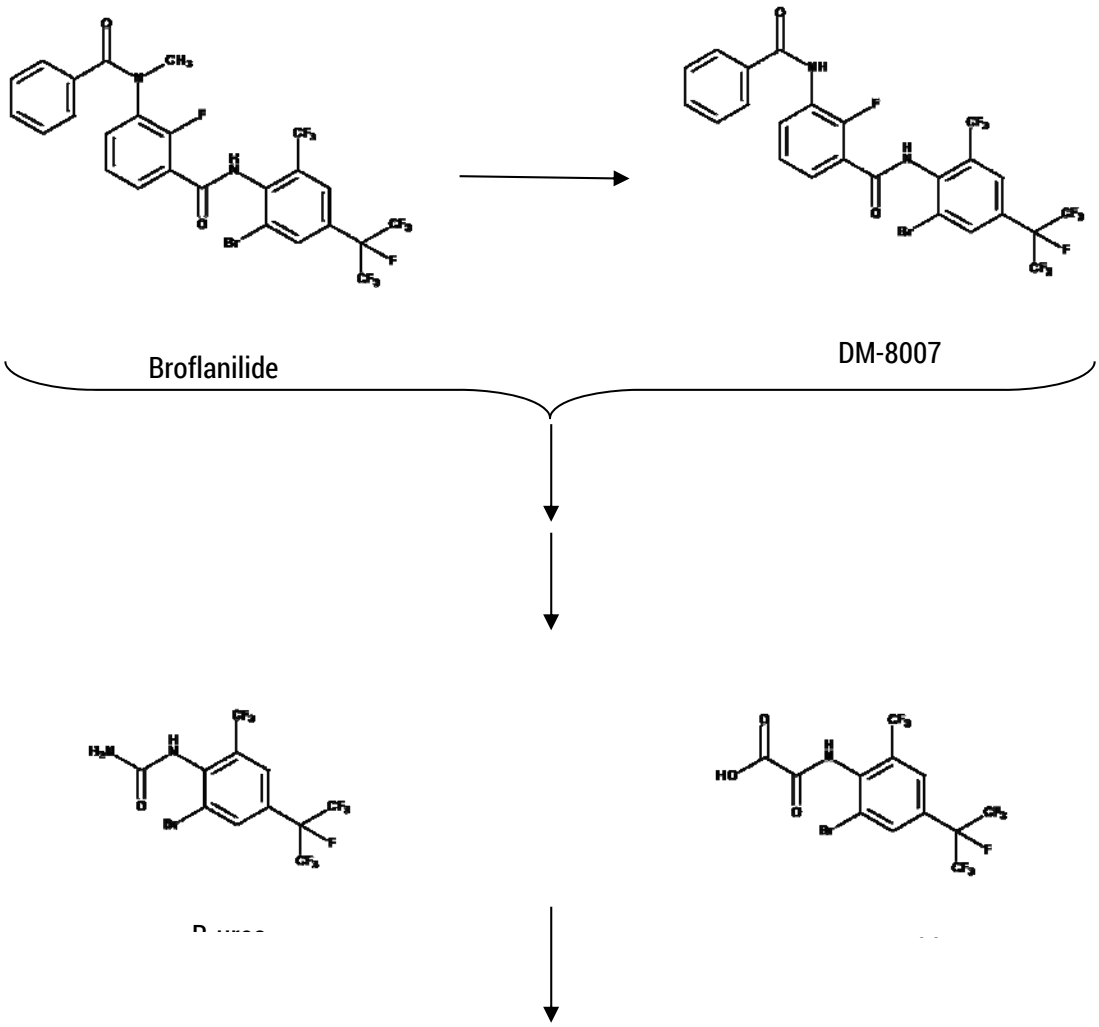

Figure 6 Proposed metabolic pathway of broflanilide in confined rotational crops

The results of the field rotational crop study are provided in Table 82. In general, residues of broflanilide were <LOQ, with the exception of parent broflanilide in lettuce planted at 30 days PBI at 0.013 mg/kg.

Notes:

[1] At each location, two treated samples (Rep. A and B) per matrix were collected at each sampling interval from the treated plot. Mean of two replicates is presented.

[2] Mean of multiple analyses of the same sample (range: < 0.01-0.018 mg/kg).

RESIDUE ANALYSIS

Analytical methods

For the analysis of broflanilide and metabolites in various plant and animal matrices, analytical methods suitable for enforcement and data generation purposes were submitted. In the following table an overview of these methods is presented.

Table 83 Overview of analytical methods for broflanilide and metabolites

Method	Matrix	Extraction	Clean-Up	Analyte, Detection, LOQ
Plant materials				
D1417/01 (according to QuEChERS) ILV available	Dry, high starch (wheat grain); dry high protein (bean seed), high water content (tomato), high acid content (citrus), high fat content (soya bean seed), difficult (coffee bean)	Acetonitrile/water (1/1) + buffer salts	Dispersive solid phase extraction with PSA	LC-MS/MS Broflanilide: m/z 663→643, 665→645 S(PFP-OH)-8007: m/z 661→641, 663→643 DM-8007: m/z 649→242, 649→629 LOQ: 0.001 mg/kg
D1703/01 (according to QuEChERS)	Dry, high starch (wheat grain); dry high protein (bean seed), high water content (lettuce), high acid content (orange), high fat content (soya bean seed)	Acetonitrile/water (1/1) + buffer salts	Dispersive solid phase extraction with PSA (optional)	LC-MS/MS B-urea: m/z 451→431, 453→433 B-oxam acid: m/z 478→406, 480→408 LOQ: 0.01 mg/kg
Japanese crop residue method	High water content (radish root and leaves, turnip root and leaves, leek)	Acetonitrile/water (80/20)	Solid phase extraction on C18	LC-MS/MS Broflanilide: m/z 665→645 S(PFP-OH)-8007: m/z 661→641 DM-8007: m/z 649→242 LOQ: 0.01 mg/kg
Korean crop residue method	High water content (cabbage, Chinese cabbage, radish root and leaves, green onion,	Acetonitrile	Partitioned with saturated saline solution, water and dichloromethane;	GC-ECD or HPLC-UV LOQ: 0.02-0.1 mg/kg LC-MS/MS

Plant materials

Method D1417/01 (Jose, 2017, BROFLAN_033 & Jose, 2017, BROFLAN_034)

The method is based on the citrate buffered QuEChERS method. The residues of broflanilide and its metabolites S(PFP-OH)-8007 and DM-8007 are extracted from crop matrices by shaking with acetonitrile and then in the presence of various salts ($MgSO_4$; NaCl; sodium citrate sesquihydrate and sodium citrate dehydrate). For high oil/dry matrices samples, water is previously added before extraction with acetonitrile. An aliquot of the resulting extract is treated with magnesium sulfate and PSA to remove the excess water and fatty acids, respectively. An aliquot is then diluted with 0.1 percent formic acid acetonitrile:water (50:50).

Final determination is accomplished by LC-MS/MS in positive ionization mode, using a BEH C18 column and monitoring ion transitions m/z 663→643, 665→645 for broflanilide, m/z 661→641, 663→643 for S(PFP-OH)-8007 and m/z 649→242, 649→629 for DM-8007. Quantitation was done with external standards in solvent, except dry beans where matrix matched standards were used. The results are shown in Table 84.

Table 84 Recovery data for method D1417/01 measuring broflanilide and its metabolites S(PFP-OH)-8007 and DM-8007 in various plant matrices using LC-MS/MS

Matrix	Analyte	Fortification Level [mg/kg]	n	Recoveries,%	Mean, %	SD, %	RSD, %

Independent laboratory validation of method D1417/01 (Jutson, 2017, BROFLAN_035):

The sample extraction, clean-up and method of determination was mostly identical to D1417/01, with modifications applied to some samples in a second trial (use of a larger amount of buffer salts for some potato, grape and lettuce samples; omitting the clean-up step for grape and lettuce). The results are shown in Table 85.

Table 85 Recovery data for the ILV of method D1417/01, measuring broflanilide and its metabolites S(PFP-OH)-8007 and DM-8007 in various plant matrices

Method D1703/01 (Downs, 2017, BROFLAN_036)

The method is based on the citrate buffered QuEChERS method. The residues of the metabolites B-urea and B-oxam acid are extracted from crop matrices by shaking with acetonitrile (for dry matrices addition of water), followed by shaking with a salt solution ($MgSO_4$; NaCl; sodium citrate sesquihydrate and sodium citrate dehydrate). Optional clean-up with PSA. An aliquot of the extract is then diluted with 0.1 percent formic acid in acetonitrile:water (50:50) and analysed.

Final determination is accomplished by LC-MS/MS using a BEH Phenyl column. B-oxam acid was analysed in negative ionization mode and monitoring the ion transitions m/z 478→406, 480→408, while B-urea was quantified in positive ionization mode and monitoring the ion transitions m/z 451→431, 453→433. Quantitation was done with external standards in matrix or solvent. The results are shown in Table 86.

Table 86 Recovery data for method D1703/01 measuring metabolites B-urea and B-oxam acid in various plant matrices by LC-MS/MS

Japanese crop residue method (Kawaguchi, 2020, BROFLAN_037)

The study contains a compilation of validation data from multiple field trials. The homogenized sample materials are extracted with acetonitrile/water (80/20). After filtration an aliquot of the extract is cleaned up by SPE on a C18 cartridge. Analytes are eluted with acetonitrile/water/formic acid (80/20/1/v). If necessary, the eluate is further diluted with acetonitrile/water/formic acid (80/20/1/v).

Final determination is accomplished by LC-MS/MS in positive electrospray ionization using a C18 column and monitoring ion transition m/z 665→645 for broflanilide, m/z 649→242 for DM-8007 and m/z 661→641 for S(PFP-OH)-8007. Quantitation is done with external standards in solvent. The results are shown in Table 87.

Korean crop residue method (Hiraki, 2020, BROFLAN_038; Hiraki, 2020, BROFLAN_039)

The studies contain compilations of validation data from multiple field trials. The homogenized sample materials are extracted with acetonitrile. After filtration the extract is partitioned with saturated saline solution, water and dichloromethane. The organic phase is dried on anhydrous sodium sulfate and concentrated by evaporation. Clean-up of the extract is performed on a NH_2 SPE cartridge. Analytes are eluted with n-hexane/acetone (80:20).

Final determination in study BROFLAN_038 is accomplished by GC-ECD using a DB-5 column or equivalent (cabbage, radish, tomato) or by HPLC-UV at 226 nm and using a C18 column (Chinese cabbage, green onion, tomato, radish). In study BROFLAN_039, final determination is accomplished by HPLC-UV at 226 nm and using a C18 column (Chinese cabbage, tomato, green onion, radish (broflanilide & DM-8007)) and by LC-MS/MS in positive electrospray ionization mode and monitoring the transitions m/z 661→ 621, 661→ 641 (radish for S(PFP-OH)-8007). Quantitation is done in both studies with external standards in solvent. The results are shown in Tables 88 and 89..

Animal materials

Method D1604/01 (Malinsky, 2017, BROFLAN_040)

Residues of broflanilide in the livestock commodity samples of milk, egg, liver, kidney and muscle are extracted with acetonitrile followed by acetonitrile/water (80:20). Liver, kidney and muscle are further partitioned with a salt solution ($MgSO_4$; NaCl; sodium citrate sesquihydrate and sodium citrate dehydrate), followed by clean-up with PSA. Samples of fat are extracted with acetone/hexane (20/80), followed by acetone. An aliquot of the extracts from all commodities are then diluted with 0.1 percent formic acid in acetonitrile/water (1:1).

Final determination is accomplished by LC-MS/MS in positive ionization mode, using a BEH C18 column and monitoring ion transitions m/z 663→643, 665→645 for broflanilide, m/z 545→525, 547→527 for DC-DM-8007 and m/z 649→242, 651→242 for DM-8007. Quantitation was done with external standards in solvent. The results are in Table 90.

Notes:

[1)] Average of more than one value.

Independent laboratory validation of method D1604/01 (Sheng & Wrigley, 2017, BROFLAN_041):

The sample extraction, clean-up and method of determination were identical to D1604/01. Recovery data are in Table 91.

Table 91 Recovery data for the ILV of method D1604/01, measuring broflanilide and its metabolites DC-DM-8007 and DM-8007 in various animal matrices

Stability of pesticides in stored analytical samples

Plant matrices

The storage stability of parent broflanilide and its metabolites S(PFPOH)-8007 and DM-8007 under frozen conditions in lettuce, kidney bean, soya bean, potato and grape was determined over a period up to 24 month. (Delinsky, 2020, BROFLAN_042).

Each analyte was added to homogenized samples at 0.01 mg/kg and stored deep frozen at approximately -20 °C. Storage durations of approximately 0, 3, 5, 9, 12, 15, 18, and 24 months were tested for broflanilide and DM-8007. Metabolite S(PFP-OH)-8007 in potato was tested at storage intervals of 0, 1, 2, 6, 9, 12, 15, 21, and 24 months, while in lettuce, kidney bean, soybean, and grape S(PFP-OH)-8007 has been tested at 0, 1, 2, 6, 7, 9, 15, 21, and 25 months (except for lettuce and kidney bean where the final timepoint was 28 months instead of 25). Due to a fortification error at the first fortification event with S(PFP-OH)-8007, the fortification had to be repeated. All samples were analysed in triplicates according to method D1417/01. The results are in Table 92 to 94.

Notes:

na Not applicable

[1)] The duplicate concurrent recovery sample was spiked at the incorrect level and the data were rejected.

[2)] Data from the third fortification event of storage stability samples. All other data are from the second fortification event.

The storage stability of metabolites B-oxam-acid and B-urea under frozen conditions in lettuce, grape, wheat grain, soya bean dried seed and kidney bean dried seed was determined over a period up to 16 month (Delinsky, 2019, BROFLAN_043). In addition, the storage stability of broflanilide and metabolites S(PFP-OH)-8007, DM-8007, B-oxam-acid and B-urea in bee related matrices (honey and pollen) was investigated. The results are shown in Table 93

Each analyte was added separately to homogenized samples at 0.1 mg/kg (honey and pollen: 0.01 mg/kg), stored deep frozen at approximately -20 °C and analysed after storage durations of approximately 0. 2, 5, 9, 12-13, and 16 months. The plant commodity samples were analysed for B-oxam-

acid and B-urea residues using BASF Method D1703/01, while the bee related matrices were analysed according to method L0334/02 (validation not available).

The storage stability of parent broflanilide and its metabolites S(PFPOH)-8007 and DM-8007 under frozen conditions in Chinese cabbage, cabbage, tomato, radish (root & leaves) and green onion was determined over a period up to 6 month (Hiraki, 2020, BROFLAN_044, Hiraki, 2020, BROFLAN_045).

Each analyte was added to homogenized samples at a rate of 0.1, 0.2, 0.4 or 0.5 mg/kg, stored deep frozen at -20°C and analysed after 20, 104, 119 and 178 days (BROFLAN_044) and 7, 17, 23, 33, 34 and 35 days (BROFLAN_045). All samples were analysed according to the Korean residue method. The results are shown in Table 95

The storage stability of parent broflanilide and its metabolites S(PFPOH)-8007 and DM-8007 under frozen conditions in radish (root & leaves), turnil (root and leaves) and leek was determined over a period up to 7 month (Kawaguchi, 2020, BROFLAN_046).

Each analyte was added to homogenized samples at a rate of 0.5 mg/kg, stored frozen at -20 °C and analysed after 19 to 206 days of storage. All samples were analysed according to the Japanese residue method. The results are shown in Table 96

Animal matrices

The storage stability of parent broflanilide and its metabolites DM-8007 and DC-DM-8007 under frozen conditions in muscle, liver, kidney, milk and fat was determined over a period up to 2 month with a dairy cow feeding study. (Xu, 2019, BROFLAN_082).

For each freezer storage interval, duplicate samples were fortified at 0.01 mg/kg (milk, fat) or 0.1 mg/kg (muscle, liver, kidney), placed in the freezer at -20 ºC and analysed after 0, 1 and 2 months. All samples were analysed in duplicates according to method D1604/01. The results are shown in Table 97.

Coffee	Colombia	100 g/L	SC	Foliar spray	18 g ai/ha		2 (30 days)	45

RESULTS OF SUPERVISED RESIDUE TRIALS ON CROPS

Residue levels were reported as measured. Application rates were always reported as broflanilide equivalents. When residues were not detected they are shown as below the LOQ, e.g., < 0.01 mg/kg. Application rates, spray concentrations and mean residue results have generally been rounded to two significant figures. Values from the trials conducted according to maximum GAP have been used for the estimation of maximum residue levels. These results are underlined.

Laboratory reports included method validation including procedural recoveries with spiking at residue levels similar to those occurring in samples from the supervised trials. Duration of residue sample storage were also provided. Field reports provided data on the sprayers used and their calibration, plot size, residue sample size and sampling date. Although trials included control plots, no control data are recorded in the tables except where residues in control samples exceeded the LOQ. Residue data are recorded unadjusted for percent recovery. A summary of the residue trials is shown in Table 98.

Bulb vegetables

Green onion (Welsh onion)

Two greenhouse trials were conducted with green onion in the Republic of Korea in the 2017 growing season (BROFLAN_047, BROFLAN_048). Plants received 3 spray applications of broflanilide at nominal rates of 2.5 g ai/hL (37.5-50 g ai/ha) with a 7 day interval between applications. Green onions were collected at 0, 7 and 14 DALA (in one trial samples were also taken additionally at 21 DALA). Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using the Korean residue method with a validated limit of quantification of 0.1 mg/kg and a limit of detection of 0.01 mg/kg.

Additionally, a total of three field trials were conducted with green onion in Japan in the 2013 and 2014 growing seasons (BROFLAN_049, BROFLAN_050). Plants received 3 spray applications of broflanilide at nominal rates of 2.5 g ai/hL with a 7±1 day interval between applications. Leeks were collected at 1, 3 and 7 DALA. Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using the Japanese residue method with a LOQ of 0.01 mg/kg. The results are shown in Table 100.

Leek

A total of three field trials were conducted with leek in Japan in the 2013 and 2014 growing seasons (BROFLAN_049, BROFLAN_050). Plants received 3 spray applications of broflanilide at nominal rates of 2.5 g ai/hL with a 7±1 day interval between applications. Leeks were collected at 1, 3 and 7 DALA. Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using the Japanese residue method with a LOQ of 0.01 mg/kg. The results are shown in Table 101.

[1] Mean from 2 analytical replicate samples. The values of each metabolite were converted to the value of MCI-8007 (Conversion factor; DM-8007: 1.02, S(PFP-OH)-8007: 1.00).

Brassica vegetables

Cabbage

A total of 10 field trials were conducted with cabbage in Canada and the United States during the 2015 and 2016 growing seasons (BROFLAN_051). Plants received 2 spray applications of broflanilide at nominal rates of 25 g ai/ha (water volume ranged from 283–446 L/ha) with a 6–8 day interval between applications. Samples were collected at 1 day after the last application. Additionally, in one decline trial, plants were also collected at 0, 1, 3, 7 and 14 DALA. Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using method D1417/01 with a LOQ of 0.001 mg/kg.

One greenhouse trial was conducted with cabbage in Republic of Korea in the 2018 growing season (BROFLAN_052). Plants received 3 spray applications of broflanilide at nominal rates of 37.5–50 g ai/ha (water volume: 2000 L/ha) with a 7 day interval between applications. Plants were collected at 7, 14, 21, and 30 DALA. Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using the Korean residue method with a validated limit of quantification of 0.1 mg/kg and a limit of detection of 0.01 mg/kg.

A total of 24 field trials were conducted with cabbage in China during the 2015–2018 growing seasons (BROFLAN_053, BROFLAN_054, BROFLAN_055, BROFLAN_056). Plants received 2 or 3 spray applications of broflanilide at nominal rates of 22.5–45 g ai/ha (water volume: 750–900 L/ha), with a 7 day interval between applications. Plants were collected at (0, 1, 2), 3, 5 and 7 DALA. Additionally, some decline trials were performed with 1 application at 33.8 or 45 g ai/ha, were samples were collected at various time points, up to 21 days. Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using a method similar to D1417/01 with a LOQ of 0.01 mg/kg for broflanilide and 0.001 mg/kg or 0.01 mg/kg for metabolites DM-8007 and S(PFP-OH)-8007. The results are in Table 102.

GS= growth stage; RTI= repeated treatment interval, days

[1] Mean values from duplicate or triplicate field samples. The values of each metabolite were converted to the value of MCI-8007 (Conversion factor; DM-8007: 1.02, S(PFP-OH)-8007: 1.00).

[2] Same location and year, but different formulation and therefore considered independent.

Chinese cabbage

Two greenhouse trials were conducted with Chinese cabbage in the Republic of Korea in the 2017 and 2018 growing seasons (BROFLAN_057, BROFLAN_058). Plants received 2 spray applications of broflanilide at nominal rates of 37.5–50 g ai/ha (water volume: 2000 L/ha) with a 7 or 9 day interval between applications. Plants were collected at 7, 14 and 21 DALA (one trial additionally at 30 DALA). Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using the Korean residue method using HPLC-UV with a LOQ of 0.1 mg/kg and a limit of detection of 0.01 mg/kg.

A total of 10 field trials were conducted with Chinese cabbage in China during the 2015-2016 and 2018 growing seasons (BROFLAN_059, BROFLAN_060). Plants received 2 or 3 spray applications of broflanilide at nominal rates of 25, 30 or 45 g ai/ha (water volume: 600-900 L/ha), with a 7 day interval between applications. Plants were collected at 5 and 7 DALA, and some trials additionally at 0, 3 and 10 DALA. Additional decline trials were performed with 1 application at 45 g ai/ha and samples were collected at 0, 1, 2, 3, 7, 14, 21, 28 and 42 DALA. Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were extracted with acetonitrile, followed by addition of sodium chloride. The supernatant was diluted with methanol-water (1:1) and determined by LC-MS/MS with a LOQ of 0.001 mg/kg. The results are shown in Table 103.

[1] Mean values from duplicate or triplicate field samples. The values of each metabolite were converted to the value of MCI-8007 (Conversion factor; DM-8007: 1.02, S(PFP-OH)-8007: 1.00).

Fruiting vegetables, other than cucurbits

Tomatoes

A total of 20 field trials were conducted with tomatoes (3 with cherry tomatoes) in the United States during the 2015 growing season (BROFLAN_061). Plants received 2 foliar spray applications of broflanilide at nominal rates of 25 g ai/ha with a 7±1 day interval between applications. Samples were collected at 1 days after the last application. Additionally, in two decline trial, plants were also collected at 0, 1, 3, 7 and 10 DALA. Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using method D1417/01 (according to QuEChERS) with a LOQ of 0.001 mg/kg.

Additionally, two greenhouse trials were conducted with tomatoes in the Republic of Korea in the 2018 and 2019 growing seasons (BROFLAN_062, BROFLAN_063). Plants received 2 or 3 spray applications of broflanilide at 2.5 g ai/hL with a 7 day interval between applications. Plants were collected at 0, 1, 3, 5 and 7 DALA. Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using the Korean residue method with a validated limit of quantification of 0.1 mg/kg and a LOQ of 0.01 mg/kg. The results are shown in Table 104.

[1] Mean values from duplicate or triplicate field samples, individual values in parentheses. The values of each metabolite were converted to the value of MCI-8007 (Conversion factor; DM-8007: 1.02, S(PFP-OH)-8007: 1.00).

Root and tuber vegetables

Radish

Two greenhouse trials were conducted with radishes in the Republic of Korea in the 2018 and 2019 growing seasons (BROFLAN_064, BROFLAN_065). Plants received 3 spray applications of broflanilide at 2.5 g ai/hL with a 7–9 day interval between applications. Plants were collected at 7, 14, 21 and 30 DALA or 0, 7, 14 DALA. Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using the Korean residue method with a LOQ of 0.1 mg/kg and a LOD of 0.01 mg/kg. The results are shown in Table 105.

Japanese radish

A total of six field trials were conducted with Japanese radish in Japan in the 2013 and 2014 growing seasons (BROFLAN_066, BROFLAN_067). Plants received 3 foliar spray applications of broflanilide at nominal rates of 2.5 g ai/hL (37.5–75 g ai/ha) with a 7±1 day interval between applications. Radish roots and tops were collected at 1, 3 and 7 DALA. Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using the Japanese residue method with a LOQ of 0.01 mg/kg (Table 106)

Potato

A total of 21 field trials were conducted with cabbage in Canada and the United States during the 2015–16 growing seasons (BROFLAN_069). Two treatments were applied: 1) Plants received 2 spray applications of broflanilide at nominal rates of 25 g ai/ha with a 6–8 day interval between applications. Samples were collected at 13-14 days after the last application. Additionally, in one decline trial, plants were also collected at 0, 7, 14, 18 and 21 DALA. 2) One in-furrow application, at planting at 50 g ai/ha. Samples were collected at 80–146 days after the application. Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using method D1417/01 with a LOQ of 0.001 mg/kg (Table 108). The procedural recoveries ranged from 70.3-118 percent at 0.001 & 0.1 mg/kg and the samples were stored at a maximum of 450 days before analysis.

Notes:

GS= growth stage; RTI= repeated treatment interval, days

[1] Mean values from duplicate field samples, individual values in parentheses. The values of each metabolite were converted to the value of MCI-8007 (Conversion factor; DM-8007: 1.02, S(PFP-OH)-8007: 1.00).

* Crop maturity.

Cereal grains

Wheat

A total of 25 field trials were conducted on winter or spring wheat in Canada and the United States during the 2015/16 growing season (BROFLAN_070). The seeds were treated with broflanilide at a nominal concentration of 100 g ai/ton of seed. The treated seeds were planted at a rate of 84.0–134.4 kg/ha, (target rate 100 kg/ha), resulting in an actual test substance application rate of 8.14–13.3 g ai/ha. Samples were collected at 83–274 days after planting. Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using method D1417/01 with a LOQ of 0.001 mg/kg. Procedural recoveries: range from 66-137 percent at 0.001 and 0.1 mg/kg and the samples were stored up to 444 days. The results are shown in Table 109.

[1] Mean values from duplicate field samples, individual values in parentheses. The values of each metabolite were converted to the value of MCI-8007 (Conversion factor; DM-8007: 1.02, S(PFP-OH)-8007: 1.00).

[2] Average of several re-analyses.

Barley

A total of 16 field trials were conducted on barley in Canada and the United States during the 2015 and 2016 growing seasons (BROFLAN_071). The seeds were treated with broflanilide at a nominal concentration of 100 g ai/ton of seed. The treated seeds were planted at a rate of 95.2 to 107 kg/ha, (target rate 100 kg/ha) resulting in an actual test substance application rate of 9.52–10.7 g ai/ha. Barley grain was harvested at maturity (BBCH 87-90). Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using method D1417/01 with a LOQ of 0.001 mg/kg. Procedural recoveries ranged from 88- to 133 percent at 0.001 and 0.1 mg/kg, and samples were stored up to 585 days before analysis. The results are shown in Table 110

Notes:

[1] Mean values from duplicate field samples, individual values in parentheses. The values of each metabolite were converted to the value of MCI-8007 (Conversion factor; DM-8007: 1.02, S(PFP-OH)-8007: 1.00).

Maize

A total of 25 field trials were conducted on maize (20) and sweet corn (5) in Canada and the United States during the 2015 and 2016 growing seasons (BROFLAN_072). Plants received one in-furrow application, at planting at 50 g ai/ha. Sweet corn kernel + cob with husk removed (K+CWHR) were collected 62–94 DAA, while maize gain samples were collected 112–164 days after application (DAA). Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using method D1417/01 with a LOQ of 0.001 mg/kg. A reduced validation set (n=3) for corn grain at two levels (0.001 and 0.1 mg/kg) had acceptable mean recoveries within the range of 70–120 percent with an RSD <20 percent for all analytes, while the reduced validation set for K+CWHR had somewhat higher mean recoveries at up to 129 percent. Procedural recoveries: 83–163 percent at 0.001 & 0.1 mg/kg. Samples were stored up to 267 days for grain and up to 357 days for K+CWHR. The results are showing in Table 111

Table 111 Residues of broflanilide in sweet corn kernel + cob with husk removed (K+CWHR) and maize grain following in-furrow treatment at planting in Canada and the United States (Study 2016/7006467, Wyatt, 2017, BROFLAN_072)

Seeds for beverages and sweets

Coffee

A total of nine field trials were conducted on coffee in Brazil and Colombia during the 2016 and 2018/19 growing seasons, respectively (BROFLAN_073, BROFLAN_074). Plants received 2 foliar applications of broflanilide at nominal rates of 18 g ai/ha with an RTI of up to 30 days. Coffee cherries were harvested at 45, 60, 75 and 90 DALA. Coffee cherries sampled in Colombia were de-pulped, dried and threshed. For the coffee cherries sampled in Brazil only threshing is mentioned for all trials, while drying and de-pulping is mentioned for some trials only. Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using method D1417/01 with a LOQ of 0.001 mg/kg (Table 112).

Notes:

GS= Growth stage.

RTI= repeated treatment interval, days.

[1] The values of each metabolite were converted to the value of MCI-8007 (Conversion factor; DM-8007: 1.02, S(PFP-OH)-8007: 1.00).

[2] Mean of several measurements.

Feed commodities

Turnip tops

A total of 3 greenhouse trials were conducted with turnip in Japan in the 2014/15 growing season. Plants received 3 foliar spray applications of broflanilide at nominal rates of 2.5 g ai/hL with a 7±1 day interval between applications. Turnip tops were collected at 1, 3 and 7 DALA. Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using the Japanese residue method with a LOQ of 0.01 mg/kg (Table 113).

Wheat forage, hay and straw

A total of 25 field trials were conducted on winter or spring wheat in Canada and the United States during the 2015–16 growing seasons (BROFLAN_070). The seeds were treated with broflanilide at a nominal concentration of 100 g ai/t of seed (8.14–13.3 g ai/ha). Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using method D1417/01 (according to QuEChERS) with a validated limit of quantification of 0.001 mg/kg. A reduced validation set (n=3) for wheat forage at two levels (0.001 and 0.1 mg/kg) had acceptable mean recoveries within the range of 70–120 percent with an RSD < 20 percent for broflanilide, while for metabolites DM-8007 and S(PFP-OH)-8007 mean recoveries at the 0.1 mg/kg level were outside of this range at 125 percent and 144 percent, respectively. Procedural recoveries for all analytes were consistently > 120 percent at the 0.1 mg/kg level. Samples were stored up to 44 days before analysed. The results are shown in Table 114.

[2] Average of several re-analyses.

Maize forage and stover

A total of 25 field trials were conducted on maize in Canada and the United States during the 2015 and 2016 growing seasons (BROFLAN_072). Plants received one in-furrow application, at planting at 50 g ai/ha. Maize forage was collected at 62–110 DAA and maize stover from 99-164 DAA. Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using method D1417/01 (according to QuEChERS) with a LOQ of 0.001 mg/kg. Procedural recoveries ranged from 66 -186 percent at 0.001 and 0.1 mg/kg> Samples were stored for up to 315 days (forage) and for up to 672 days (stover) before analysis. The results are shown in Table 115.

Notes:

[1] Mean values in parentheses. The values of each metabolite were converted to the value of MCI-8007 (Conversion factor; DM-8007: 1.02, S(PFP-OH)-8007: 1.00).

Barley hay and straw

A total of 16 field trials were conducted on barley in Canada and the United States during the 2015 and 2016 growing seasons (BROFLAN_071). The seeds were treated with broflanilide at a nominal concentration of 100 g ai/ton of seed (9.52–10.7 g ai/ha). Barley hay was harvested at early milk to soft dough stage (BBCH 73 to 85) and allowed to field dry to 10 to 20 percent moisture content before being collected. Barley straw was harvested at grain maturity (BBCH 97–90) Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using method D1417/01 (according to QuEChERS) with a LOQ of 0.001 mg/kg. Procedural recoveries ranged from 96–133 percent at 0.001 and 0.1 mg/kg. Samples were stored for up to 604 days (hay) or 561 days (straw) before analysed. The results are shown in Table 116.

FATE OF RESIDUES IN STORAGE AND PROCESSING

Nature of residue during processing

[B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide were incubated in aqueous citrate buffer solutions over the concentration range 0.1 to 1.5 mg/L under three sets of conditions, each designed to simulate an appropriate process: 90 °C (pH 4, 20 minutes) to simulate pasteurization, 100 °C (pH 5, 60 minutes), to simulate boiling, baking and brewing, and 120 °C (pH 6, 20 minutes) to simulate sterilization (Strathdee, 2017, BROFLAN_075; Amendment 1: BROFLAN_076).

Total recovered radioactivity was measured for each test solution by LSC. Radioactive components were characterized by fractionation and co-chromatography with authenticated reference compounds using HPLC-UV and TLC. Selected samples were also analysed by LC-MS to identify components.

Preliminary solubility testing was performed in aqueous media buffered to pH 4, 5 and 6 using ^{14}C-radiolabeled forms of Broflanilide over the concentration range 0.1 to 1.5 mg/L. The recovery of radioactivity indicated that Broflanilide in aqueous media adsorbed to glassware over these concentration ranges with 51.3 to 66.5 percent of the radioactivity recovered from the aqueous media. Subsequent adsorption to glassware testing indicated that the majority of radioactivity could be recovered by soaking

vessels with acetonitrile following removal of the [^{14}C]-buffered media with a total of ≥ 85.0 percent of the applied radioactivity recovered from the buffered media and acetonitrile washes (Table 117).

Table 117 Hydrolysis of broflanilide under simulated processing conditions, in percent of total applied radioactivity (Percent TAR)

Test Material	[C-ring-U-^{14}C]-Broflanilide			[B-ring-U-^{14}C]-Broflanilide		
	pH 4, 90 °C (20 min)	pH 5, 100 °C (60 min)	pH 6, 120 °C (20 min)	pH 4, 90 °C (20 min)	pH 5, 100 °C (60 min)	pH 6, 120 °C (20 min)

[4)] Mean of two replicates.

Residues after processing

The fate of broflanilide during processing of raw agricultural commodity (RAC) was investigated in tomato, potato, maize, wheat and coffee. As a measure of the transfer of residues into processed products, a processing factor was used, which is defined as:

Processing factor = Residue in processed product (mg/kg) ÷ Residue in raw agricultural commodity (mg/kg)

If residues in the RAC were below the LOQ, no processing factor could be derived. In case of residues below the LOQ in the processed product, the numeric value of the LOQ was used for the calculation and the PF was expressed as “less than” (e.g. < 0.5).

Tomato

The transfer of residues of broflanilide into processed commodities was investigated in tomato from three supervised field trials conducted in the United States during the 2015 growing season (Reeves, 2020, BROFLAN_077). The trials were performed with two foliar applications at an exaggerated rate of 125 g ai/ha + spray adjuvant (non-ionic surfactant) at BBCH 86–89) with a RTI of 6-7 days and harvest at 1 DALA. Tomatoes were processed into the commodities of blanched tomatoes, blanching water, canned tomatoes, ketchup after pasteurization, paste, peeled tomatoes, puree, raw juice, sundried tomatoes, tomato peel, vegetable stock, wash water, washed tomatoes and wet pomace, using common commercial practices.

Tomato juice, paste and puree: Tomatoes were chopped, passed through an initial screen, heated to 91–97 °C and passed through another screen. The pulp material not passing was collected as wet pomace. The resultant tomato juice was further processed to puree and paste by evaporating water under heat.

Sun-dried tomatoes were obtained by slicing tomatoes and drying them in a dehydrator at 49–54 °C for 24–26 hours.

Canned tomatoes were produced by blanching tomatoes with steam for 1–3 minutes, followed submerging into water for removal of the skin. Tomatoes were placed in cans with heated tomato juice, sealed and pressure cooked for 50–60 minutes.

Blanched tomatoes were placed into boiling water for 30–60 seconds.

Peeled tomatoes were obtained by peeling by hand. The remaining peeled tomatoes were blended and sieved. The material passing through the sieve was collected as raw juice. Alternatively, raw juice was produced by using a juicer.

Ketchup was produced by evaporation of tomato juice to a solid content of 30–35 percent, followed by adding vinegar, sugar and salt. After stirring, the mixture was passed through a sieve. The material passing through was ketchup.

Vegetable stock was produced by cooking diced and cored tomatoes with water for 45–60 minutes, followed by sieving. The material passing through was vegetable stock.

Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using method D1417/01 with a LOQ of 0.001 mg/kg. Procedural recoveries for all analytes in the RAC and all processed commodities ranged between 71.2–130 percent.

Residue of broflanilide in the RAC and processed commodities are presented in Table 130. Residues of metabolites S(PFP-OH)-8007 and DM-8007 in tomato RAC samples were below LOQ (< 0.001 mg/kg). In processed fractions, residues of metabolite S(PFP-OH)-8007 were below LOQ (< 0.001 mg/kg) in all samples except for sun-dried tomatoes (up to 0.0045 mg/kg), tomato peel (up to 0.0015 mg/kg) and wet pomace (up to 0.0024 mg/kg). Residues of metabolite DM-8007 were below LOQ (< 0.001 mg/kg) in all processed fraction samples except for sun-dried tomatoes (up to 0.0054 mg/kg), tomato peel (up to 0.0013 mg/kg) and wet pomace (up to 0.0016 mg/kg) (Table 118).

Notes:

RAC: Raw agricultural commodity.

* Mean of two replicate samples.

Potato

The transfer of residues of broflanilide into processed commodities was investigated in potato from three supervised field trials conducted in the United States during the 2015 growing season (Crawford, 2017, BROFLAN_078). The trials were performed with one in-furrow application at planting, followed by one foliar application 14 days prior to harvest (BBCH 45–48) at exaggerated rates of 126–128 g ai/ha for the first application and 125–149 g ai/ha for the second application + adjuvant. Potato samples were collected at 14 DALA and for trial R150085 at 23 DALA. Potatoes were processed into peeled potatoes, wet peel, boiled potatoes, microwave boiled potatoes, baked potatoes, fried potatoes, crisps, chips, granules/flakes, process waste, ensiled, starch, dried pulp and protein using simulated commercial processing procedures. Samples were stored frozen for a maximum of 344 days (11.3 months).

Potato flakes were produced by removing the peel by using a steam peeler. Peels were collected and pressed. The peeled potatoes were cut into slabs, washed to remove starch and steam cooked for 35–45 minutes. The wash water was filtered and centrifuged to obtain the starch sample. The cooked slices were mashed, followed by mixing with additives and drying the potato mash in a single drum dryer. The resultant sheet is broken up and fed into a hammer mill for a uniform sizing of the finished flakes.

Potato crisp and fried potatoes were produced by peeling washed potatoes with Hobart peeler, and cut to slices. After washing to remove free starch, the slices were fried in oil at 163–191 °C for 90–100 seconds (crisps) or 3 minutes (fried potatoes).

Boiled potatoes (hand peeled) and microwave boiled potatoes (unpeeled) were obtained by boiling in water until an internal temperature of 88–92 °C was reached. Baked potatoes were placed in an oven at 210 °C till the same internal temperature was reached.

Fresh fries were produced by slicing washed unpeeled potatoes into strips, followed by deep frying for 2.5–3.0 minutes at 177–191 °C

Potato pulp and protein were produced by milling washed potatoes, followed by pressing. The pressed wet pulp was placed in a dryer for dehydration to obtain the dried pulp. The potato fruit water collected in pressing was centrifuged and filtered, followed by thermal processing at ~90 °C while adjusting the pH to ~4 with sulphuric acid to precipitate the protein. To obtain ensiled potatoes, an aliquot of the milled potatoes was placed in a bag silo, sealed and kept at room temperature for 3 weeks.

Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using method D1417/01 with a LOQ of 0.001 mg/kg. Procedural recoveries for all analytes in the RAC and all processed commodities ranged between 55.6–129 percent.

Residue of broflanilide in the RAC and processed commodities are presented in Table 131. Residues of metabolites S(PFP-OH)-8007 and DM-8007 in potato field RAC and processor RAC samples were below LOQ (< 0.001 mg/kg), except for trial R150085, where residues of DM-8007 were at 0.001 mg/kg. In processed fractions, residues of metabolite S(PFP-OH)-8007 were below LOQ (< 0.001 mg/kg) in all samples. Residues of metabolite DM-8007 were below LOQ (< 0.001 mg/kg) in all processed fraction samples except for wet peel (up to 0.005 mg/kg), dried pulp (up to 0.003 mg/kg) and potato protein (up to 0.0014 mg/kg) (Table 119)

Notes:

RAC: Raw agricultural commodity.

Maize

The transfer of residues of broflanilide into processed commodities was investigated in maize from 3 supervised field trial conducted in Brazil during the 2015 growing season (Jordan, 2017, BROFLAN_079). The trials were performed with two foliar applications at an exaggerated rate of 90 g ai/ha + oil adjuvant at BBCH 85 and 87 with a RTI of 10 days and harvest at maturity, 14 DALA. At one site, due to a calculation error by the field investigator, the corn was treated at 9 g ai/ha (Trial R150325), one-tenth the targeted rate due to an oversight by the field investigator. Maize was processed to bran, dry milling grits, dry milling meal, dry milling flour, flour-wet process, germ, germ-wet milling, gluten, gluten feed meal, milled by-products, wet milling RBD oil, dry milling RBD oil, wet milling starch using common commercial practices. Samples were stored frozen for a maximum of 205 days (7 months).

Before processing, whole corn samples were dried (if necessary), followed by cleaning by means of aspiration and screening. Screening and light impurities were combined to produce milled by-products.

Dry milling process: cleaned whole corn was moisture conditioned to 20–22 percent, followed by milling. The corn stock from the mill was dried and screened using sieves of various sizes to obtain bran,

germ, and large grits from grits, meal and flour. The germ was dried and flaked, followed by extraction with hexane in a batch extractor. Resulting factions from the solvent extraction were miscella and solvent extracted germs. Miscella was passed through a laboratory vacuum evaporator to separate the crude oil and hexane. The crude oil was alkali refined, resulting in soapstock and alkali refined oil. While the soapstock was discarded, the alkali refined oil was beached, filtered and steam bathed at 220–230 °C to obtain refined bleached-deodorized oil (RBD oil).

Wet milling process: cleaned whole corn was steeped in 49–54 °C water containing 0.1–0.2 percent sulfur dioxide (sulphurous acid), followed by milling and removal of germ and hull using a hydroclone. Germ and hull were dried and separated by screening. The germ was further processed as described for dry milling. The corn stock was screened. The material not passing through was discarded, while the process water (with starch and gluten) passing through the screen was batch centrifuged to separate the starch and gluten. Both fractions were dried subsequently.

Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using method D1417/01 with a LOQ of 0.001 mg/kg. Procedural recoveries for all analytes in the RAC and all processed commodities ranged between 68–132 percent.

Residue of broflanilide in the RAC and processed commodities are presented in Table 132. Residues of metabolites S(PFP-OH)-8007 and DM-8007 in maize grain RAC and processed commodities were below LOQ (< 0.001 mg/kg) (Table 120).

Wheat

The transfer of residues of broflanilide into processed commodities was investigated in wheat from 3 supervised field trial conducted in Brazil during the 2015 growing season (Jordan, 2017, BROFLAN_080). The trials were performed with two foliar applications at an exaggerated rate of 90 g ai/ha + non-ionic adjuvant at BBCH 73 and 77–83 with a RTI of 10 days. Wheat grain was harvested at maturity, 14 DALA. Wheat grains were processed into wheat meal, bran, flour, middlings, shorts and germ and various other wheat processed fractions, according to simulated commercial procedures. Samples were stored frozen for a maximum of 351 days (~12 months).

Before processing, whole wheat grain samples were dried (if necessary), followed by cleaning by means of aspiration and screening. Screening and light impurities were combined to produce milled by-products.

For germ production a sample of the cleaned wheat grain was moisture adjusted and passed through a disc mill, followed by sieving. The material on top of the sieve was aspirated to remove the bran from the germ fraction. The germ and reduced endosperm was separated by sieving with multiple screens The germ material was aspirated once more to remove additional bran and endosperm.

For flour production, breaking of a sample of cleaned, moisture adjusted wheat grain was accomplished by three break rolls. The material passing through the break rolls was fed onto a break sifter screen. The material passing through the 120 screen is Break flour, while the material not passing was passed through the 25 screen. The material passing through the 25 screen is middlings, while the material exiting is bran. The middlings were fed into a reduction system, using two reductions rolls. After passing through the reduction rolls, the material was fed onto a reduction sifter screen. The material passing through is reduction flour, while the material not passing through is shorts. Representative amounts of break and reduction flours were combined to receive white flour.

For production of whole meal flour and whole meal bread, cleaned wheat grains were milled in a pin mill. The resultant whole meal flour was used to bake bread using a bread machine.

For production of gluten, gluten feed meal and starch, break flour was mixed with water. The resultant dough was kneaded as water washed away the starch, leaving the gluten behind. The starch was

separated from the water using centrifugation and dried in a dehydrator. For gluten feed meal, reduction flour is used instead of break flour, but the same procedure is utilized.

Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using method D1417/01 with a LOQ of 0.001 mg/kg. Procedural recoveries for all analytes in the RAC and all processed commodities ranged between 66–137 percent.

Residue of broflanilide in the RAC and processed commodities are presented in Table 133. Residues of metabolites S(PFP-OH)-8007 and DM-8007 in wheat grain RAC and processed fractions, were below LOQ (< 0.001 mg/kg) in all samples, except for milled by-products (up to 0.0079 mg/kg for S(PFP-OH)-8007; 0.0049 mg/kg for DM-8007), germ (up to 0.0013 mg/kg for S(PFP-OH)-8007; 0.0015 mg/kg for DM-8007) and gluten (up to 0.0015 mg/kg for S(PFP-OH)-8007; 0.0023 mg/kg for DM-8007) (Table 121)

Coffee

The transfer of residues of broflanilide into processed commodities was investigated in coffee beans from three supervised field trial conducted in Brazil during the 2018 growing season (José, 2019, BROFLAN_081). The trials were performed with two foliar applications at an exaggerated rate of 90 g ai/ha + non-ionic adjuvant at BBCH 75 and 81 with a RTI of 30 days. Sampling was done at 45 DALA. Coffee beans were dried and processed into concentrated liquor, instant coffee and roasted and ground beans. Samples were stored frozen for a maximum of 263 days (~9 months).

To produce roasted coffee, the green beans were placed in a roster and roasted for 20 minutes at 200 °C. After equilibration for > 18 hours, the roasted beans were grinded in a cone mill.

For liquor extract coffee, beans were roasted for 80–90 minutes at 180 °C. After equilibration for > 18 hours, the bean were broken up in a cone mill and sieved for fines removal. The ground coffee was extracted in columns with 92±4 °C hot water for 15±2 minutes. The extract was dried using a spray dryer for the production of instant coffee.

Residues of broflanilide and metabolites DM-8007 and S(PFP-OH)-8007 were determined using method D1417/01 with a LOQ of 0.001 mg/kg. Procedural recoveries for all analytes in the RAC and all processed commodities ranged between 70.5–134 percent.

Residue of broflanilide in the RAC and processed commodities are presented in Table 134. Residues of metabolites S(PFP-OH)-8007 and DM-8007 in coffee beans (RAC) and processed fractions, were below LOQ (< 0.001 mg/kg) in all samples, except for dried coffee cherry (up to 0.0091 mg/kg for S(PFP-OH)-8007; 0.0058 mg/kg for DM-8007). The results are shown in Table 122.

RESIDUES IN ANIMAL COMMODITIES

Farm animal feeding studies

Lactating cows

The transfer of residues of broflanilide into animal matrices was investigated in a study with dairy cows for 43 consecutive days in order for milk residues to reach plateau (Xu, 2019, BROFLAN_082). The experimental design is presented in Table 124.

Table 124 Dosing regimen for broflanilide in lactating cows

Treatment group	Actual dose [ppm feed (DM basis)] [1)]	Dose amount (mg/day)[2)]	Average dose mg ai/kg bw/ day[3)]
Control	0	0	0
I	0.015	0.33	0.00062
II	0.152	3.7	0.00672
III	1.50	34.7	0.06468
IV	10.1	239.2	0.43586

Notes:

[1)] Based on average mg Broflanilide received per day and the body weight of each animal during the dosing period.

[2)] Dose was calculated as mean over all 6 weeks of dose amount mg/kg day (actual dose mg/kg feed DM multiplied by dry feed intake in kg/day).

[3)] Average dose (mg ai/kg bw) was calculated by dose amount (mg/kg day) divided by mean body weight of animals per group. The body weights were calculated as mean per dose group from page 352 (Control: 514.5 kg, Group I: 534.5 kg, Group II: 551 kg, Group III: 536.5 kg, Group IV: 548.8 kg).

Three cows per treatment group (+ three cows for depuration at 10 ppm) were dosed via oral bolus with broflanilide in gelatin capsules once daily. Milk samples were collected twice daily and pooled on study days (-1), 1, 4, 7, 10, 13, 16, 20, 22, 25, 27, 30, 34, 37, and 41. Additional milk samples were taken on the depuration cows on study days 44, 48, and 55. Cream and whey samples were taken from all the study animals on study day 22 and additionally from the depuration cows on their necropsy days on study days 41, 44, 48, and 55. All cows were sacrificed within 24 hours of administration of the last dose, except the three depuration cows, which were necropsied at 3, 7, and 14 days following the last dose. Samples of liver, kidney, muscle, perirenal fat, mesenterial fat and subcutaneous fat were collected and taken for analysis.

Samples were analysed for parent broflanilide as well as metabolites DM-8007 and DC-DM-8007 using method D1604/01 with a LOQ of 0.001 mg/kg for milk and 0.01 mg/kg for tissues. Procedural recoveries for all matrices and analytes ranged between 75.9–118 percent. LOD for residues in livestock samples was set at 20 percent of the LOQ, equivalent to 0.0002 mg/kg for milk per analyte and 0.002 mg/kg for fat, liver, kidney and muscle. Maximum storage time for milk was 43 days, muscle 28 days, liver and kidney 36 days and fat 42 days.

Residues of parent broflanilide above LOQ were detected in milk only in the highest treatment group (10 ppm) at up to 0.0018 mg/kg (mean over 41 days at 0.001 mg/kg). A plateau in milk was reached after 7 days. In cream, broflanilide was detected >LOQ in the 1.5 and 10 ppm treatment groups, while in skim milk, broflanilide was consistently below LOD (Table 125).

Residues of metabolite DM-8007 were detected at levels >LOQ in milk samples from cows dosed at 0.15 ppm, 1.5 ppm and 10 ppm. A plateau in milk was reached after 7 days in cows dosed at 10 ppm. In cream, DM-8007 was detected at levels >LOQ in all dosing groups (Table 126). Residues of DC-DM-8007 were only sporadically found above LOQ in milk from the 10 ppm dose group. In cream, DC-DM-8007 was detected >LOQ in the 1.5 and 10 ppm treatment groups, while in skim milk, it was consistently below LOD (Table 127).

In tissues, mean levels of broflanilide and of DC-DM-8007 were < LOQ in all treatment groups (Table 128). Metabolite DM-8007 was detected above LOQ in all tissues from the 10 ppm dosing group with a maximum of 0.79 mg/kg in mesenterial fat, while in the lower dose groups DM-8007 was not consistently found in all tissues (Table 128).

Laying hens

The transfer of residues of broflanilide into animal matrices was investigated in a study with laying hens (Ray, 2017, BROFLAN_083). The experimental design is presented in Table 128.

Table 129: Dosing regimen for broflanilide in laying hens

Treatment group	Dose (ppm)	Average mg ai/kg dry feed	Average mg as/kg bw
1× Group	0.02	0.021	0.00117
5× Group	0.10	0.102	0.00551
25× Group	0.50	0.509	0.02734

The hens in the treatment groups (12 animals per group + 12 hens for depuration at 0.5 ppm) were treated orally with broflanilide in a gelatin capsule once daily. Eggs were collected for sampling at selected intervals in the evening after dosing and on the following morning before the next dose and combined. Hens were sacrificed on the day after the last dose (control and 1× group on day 29, 5× group on day 36 and 25× group on day 50). Additionally, the hens from the depuration subgroups were sacrificed at day 53, 57 and 64. Samples of liver, muscle (thigh, breast) and fat (abdominal, subcutaneous) were collected and taken for analysis.

Samples were analysed for parent broflanilide as well as metabolites DM-8007 and DC-DM-8007 using method D1604/01 with a LOQ of 0.01 mg/kg for egg and tissues. Procedural recoveries for all matrices and analytes ranged between 75–113 percent. The method limitation of detection (LOD) for residues in egg and tissue samples was set at 20 percent of the LOQ, equivalent to 0.002 mg/kg. Maximum storage time of egg and tissues was 12 and 15 days, respectively.

In the egg samples, residues of broflanilide and metabolite DC-DM-8007 were < 0.002 mg/kg (<LOD) over the entire dosing period at the 0.02, 0.10 and 0.50 ppm dose levels. Residues of metabolite DM-8007 were < 0.002 mg/kg (<LOD) in the 0.02 and 0.10 mg/kg dose levels as well, but were found at up to 0.023 mg/kg in the 0.5 ppm dose level (Table 130). A plateau in eggs was not reached (Figure 7).

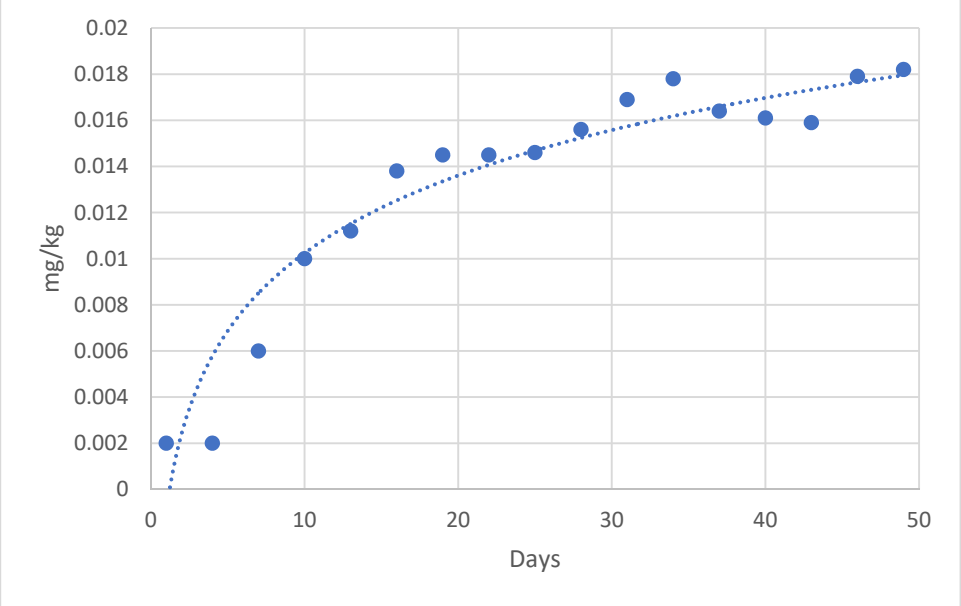

Figure 7 Time course of the concentrations of metabolite DM-8007 in eggs

In the tissue samples, residues of broflanilide and metabolite DC-DM-8007 were <LOQ over the entire dosing period at the 0.02, 0.10 and 0.50 ppm dose levels. Residues of metabolite DM-8007 were found in liver >LOQ only at the highest dose at up to 0.021 mg/kg, while in muscle levels never reached LOQ level. On the other hand, levels of DM-8007 in fat increased from 0.01 mg/kg at the lowest dose level to up to 0.15 mg/kg at the highest dose level (Table 131).

APPRAISAL

Broflanilide is a meta-diamide insecticide for the control of chewing-insect pests. It is the precursor to its active form desmethyl broflanilide, which acts by binding to the GABA receptor, resulting in a block of inhibitory neurotransmission and death of target insects. At the Fifty-first Session of the CCPR, broflanilide was scheduled for evaluation as a new compound in 2020 and rescheduled to the 2022 JMPR.

The Meeting received information on identity, physicochemical properties, metabolism (plant, confined rotational crops and animals), environmental fate, field rotational crops, methods of residue analysis, freezer storage stability, registered use patterns, supervised residue trials, fate of residues in processing, and livestock feeding studies.

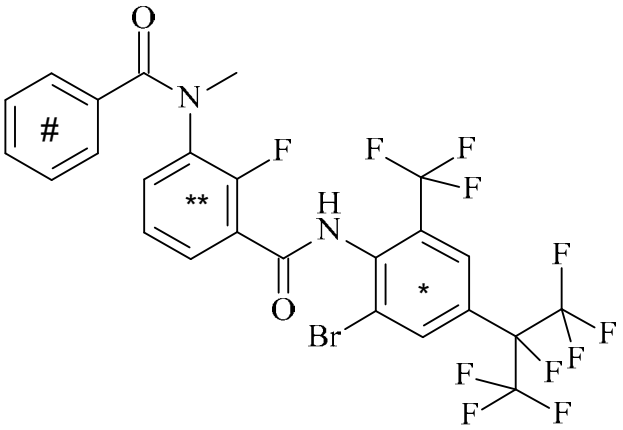

Figure 8 Chemical structure of broflanilide (IUPAC name: *N*-[2-bromo-4-(perfluoropropan-2-yl)-6-(trifluoromethyl)phenyl]-2-fluoro-3-(*N*-methylbenzamido) benzamide). Molecular weight of 663.3 g/mol. * B-ring; # C-ring; ** A-ring

Physical and chemical properties

Parent broflanilide and metabolites DM-8007, S(PFP-OH)-8007 and DC-DM-8007 have low solubility in water, but at least broflanilide has a good solubility in organic solvent. The logP_{OW} at 20 or 25 °C and at pH of 4, 7 and 10 ranges between 3.8–5.9 for these compounds, suggesting that the parent and metabolites have the potential to partition into fat. Parent broflanilide was shown to be hydrolytically stable at pH 4, 7 and 9. Broflanilide was not prone to photodegradation in water pH 7 (DT_{50}: 69–89 days), but showed slow degradation at pH 5 (DT_{50}: 14–20 days) and moderately fast degradation at pH 9 (DT_{50}: 3–6 days). The vapour pressure indicates that broflanilide is not volatile.

Plant metabolism

The metabolic fate in plants was investigated following application of [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide to cabbage, tomato, Japanese radish, soya bean, rice, wheat and tea.

Cabbage

Cabbages grown outdoors received two foliar applications of [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide at nominal rates of 0.025 kg ai/ha each at immature stage (BBCH 45) and 7 days later (BBCH 46). Immature cabbage (BBCH 46) was harvested 6 days after application 1, while mature cabbage (BBCH 49) was harvested 21 days after application 2.

TRRs were highest in cabbage (inner and outer leaves) taken at 6 DAT1 ranging between 0.304–0.352 mg eq/kg. In cabbage (inner and outer leaves) taken at 21 DAT2, about half of the previous TRR for the B-ring was found, while levels for the C-ring remained the same.

The outer leaves received a surface rinse with acetonitrile before homogenization, which released 55–66 percent of the TRR. Homogenized samples of the rinsed outer leaves and the inner leaves were subjected to extraction with acetonitrile (twice) and acetonitrile:water (1+1) (once). Extracted radioactivity was similar for both labels ranging between 92–95 percent TRR, while the PES accounted for 6–8 percent TRR.

Parent broflanilide was the major identified residue in immature and mature cabbage (inner and outer leaves) accounting for 66–84 percent TRR (0.10–0.25 mg/kg). Additionally, two minor metabolites were identified, namely S(PFP-OH)-8007 and DM-8007 accounting for 3.8–7.6 percent TRR (0.01–

0.012 mg eq/kg) and 2.9–7.9 percent TRR (0.009–0.021 mg eq/kg), respectively. The unextracted residue was not further characterized

Tomato

Tomato grown outdoors received two foliar applications of [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide at nominal rates of 0.025 kg ai/ha each. The first application occurred at the pre-bud stage (approx. BBCH 49–50) and the second application 83 days later at the beginning ripening stage (approximately BBCH 79–81). Immature tomatoes and leaves (BBCH 75) were harvested 71 days after application 1, while mature tomatoes and leaves (approximately BBCH 88) were harvested 10 days after application 2.

TRR was very low or non-detected in tomato leaves and immature fruits form harvest 1. In samples from harvest 2, radioactivity was highest in leaves, ranging between 0.904–1.596 mg eq/kg while in tomato fruits, levels were significantly lower at 0.01 mg eq/kg. Samples of tomato leaves and fruits received a surface rinse with acetonitrile before homogenization, which released 70–80 percent TRR.

Portions of the tomato leaves from harvest 2 were subjected to extraction with acetonitrile (twice) and acetonitrile:water (1+1) (once). Extracted radioactivity was similar for both labels ranging between 96–99 percent TRR in tomato leaves and 70–80 percent TRR in tomato fruit. The PES in tomato fruit accounted for 20–30 percent TRR, but was < 0.003 mg eq/kg in absolute concentration and not further analysed.

Parent broflanilide was the major identified residue, accounting for 87–89 percent TRR (0.76–1.3 mg/kg) in tomato leaves and 60–68 percent TRR (0.006–0.007 mg eq/kg) in tomato fruit. Additionally, metabolites S(PFP-OH)-8007 and DM-8007 were identified in tomato leaves and fruit at minor levels accounting for 3.0–3.4 percent TRR (0.0003–0.051 mg eq/kg) and 3.4–4.0 percent TRR (0.0004–0.060 mg eq/kg), respectively.

Japanese radish

Japanese radish grown indoors received two applications of [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide. The first treatment was applied to the soil at a rate of 0.4 kg ai/ha immediately after seeding, and a second treatment was applied foliar 41 days later at a rate of 0.225 kg ai/ha, 29 days before the final harvest. Plants (leaves and root) were collected at three sampling points: 40DAT1 (intermediate harvest-1), 14DAT2 (intermediate harvest-2) and 29DAT2 (final harvest).

TRRs were highest in radish leaves ranging between 3.6–4.4 mg eq/kg for the 14DAT2 and 29 DAT2 sampling time points. In radish roots, the TRR was at least two orders in magnitude lower, ranging between 0.0036–0.0119 mg eq/kg.

Radish leaves were surface-rinsed with acetonitrile (except the intermediate harvest-1) and the root was further separated into peel and flesh. All samples were homogenized by blending with dry ice. Portions of the samples were subjected to extraction with acetonitrile:water (8+2) (twice) and acetonitrile:0.1M HCl (8+2) (once).

The extracted radioactivity in radish leaves ranged between 95–99 percent TRR, except for leaves from intermediate harvest 1 for the C-ring label (70 percent TRR). In these samples the radioactivity in the PES accounted for 30 percent TRR, but was < 0.0021 mg eq/kg in absolute concentration. In radish roots, the sum of the radioactivity found in peel and flesh extracts accounted for 54–96 percent TRR, while 4.3–47 percent TRR remained in the PES. However, absolute concentrations in the PES were throughout < 0.0056 mg eq/kg.

Parent broflanilide was the major identified residue in radish leaves, accounting for 77–82 percent TRR (2.8–3.6 mg/kg). Additionally, metabolites S(PFP-OH)-8007 and DM-8007 were identified at minor levels, accounting for 1.7–2.9 percent TRR (0.067–0.12 mg eq/kg) and 2.5–3.3 percent TRR (0.11–0.13 mg eq/kg), respectively. Residues in roots were not further investigated.

Soya bean

Soya bean grown outdoors received two foliar applications of [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide at nominal rates of 0.025 kg ai/ha each. The first application occurred at bud formation (approx. BBCH 49–51) and the second application 77 days later at the beginning of the pod and seed ripening stage (approx. BBCH 79–81). Soya bean forage and hay samples were harvested at 21DAT1 (BBCH 69) and 35DAT1 (BBCH 74), respectively. The mature soya bean seeds were harvested at 12DAT2.

Similar TRR levels were found for both labels, with the highest levels in soya bean forage ranging between 0.460–0.433 mg eq/kg. In soya bean seeds, the detected radioactivity was < 0.01 mg eq/kg for both labels and was not further analysed.

Portions of soya bean forage and hay were subjected to extraction with acetonitrile (twice) and acetonitrile:water (1+1) (once). The extracted radioactivity was similar for both labels ranging between 92–93 percent TRR in soya bean forage and 89–91 percent TRR in soya bean hay.

Parent broflanilide was the major identified residue, accounting for 75–76 percent TRR (0.32–0.34 mg/kg) in soya bean forage and 67–71 percent TRR (0.19 mg eq/kg) in soya bean hay. Additionally, metabolites S(PFP-OH)-8007 and DM-8007 were identified in soya bean forage and hay at minor levels accounting for 3.8–5.6 percent TRR (0.010–0.021 mg eq/kg) and 5.1–8.3 percent TRR (0.022–0.023 mg eq/kg), respectively.

Rice

Rice grown indoors received two applications of [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide The first treatment was applied to the flooding water at a rate of 0.3 kg ai/ha immediately after seed transplantation, followed by a foliar application at a rate of 0.15 kg ai/ha 73 days later. The rice plants were collected at 13DAT2 (intermediate harvest: foliage) and at 32DAT2 (the final harvest: husked rice, hulls, straw and root).

The TRR (sum of foliage surface rinse, extracts and PES) was generally similar for both labels, with the highest levels found in rice hulls and straw at 5.5–6.8 mg eq/kg and 4.2–4.9 mg eq/kg, respectively. In husked rice, levels were at least one order in magnitude lower at 0.021 mg eq/kg for the B-ring label and 0.11 mg eq/kg for the C-ring label.

Only the foliage from the intermediate harvest was surface-rinsed with acetonitrile. Portions of the foliage, husked rice, straw and hulls were subjected to extraction with acetonitrile:water (8+2) (twice), followed by SPE fractionation of the extracts.

The extracted radioactivity from rice forage, husked rice, hulls and straw ranged between 85–98 percent TRR, except for husked rice for the C-ring label (18 percent TRR). In this sample the radioactivity in the PES accounted for 82 percent TRR Further characterization of the PES using acid/enzyme treatments showed that 21 percent TRR accounted for the starch fraction and 7.2 percent TRR for the protein fraction. Since the absolute measured radioactivity in the extracts was similar for both labels, it was assumed that the higher radioactivity in the PES from C-ring label was due to incorporation of $^{14}CO_2$, into the plant matrix.

Parent broflanilide was the major identified residue, accounting for 84–87 percent TRR (1.0–1.6 mg/kg) in rice foliage, 83–90 percent TRR (4.6–8.1 mg/kg) in hulls and 85–87 percent TRR (3.6–4.1 mg/kg) in straw. In husked rice, although the relative amounts of parent broflanilide differed between the two labels, accounting for 64 percent TRR using the B-ring label and 13 percent TRR using the C-ring label, the radioactive residue levels were similar (0.013–0.014 mg eq/kg). Additionally, metabolites S(PFP-OH)-8007 and DM-8007 were identified in all matrices accounting for 1.0–8.5 percent TRR (0.002–0.28 mg eq/kg) and 0.8–5.4 percent TRR (0.001–0.26 mg eq/kg), respectively.

Wheat

Wheat grown indoors received seed treatment of [B-ring-U-^{14}C]-labelled broflanilide applied at 10 g ai/100 kg seeds, corresponding to actual application rate of 0.022 kg ai/ha. Immature wheat plants (wheat forage) were collected at growth stage BBCH 39 (77 DAT), and half of the forage was allowed to dry for 8 days at room temperature to produce wheat hay. Mature wheat plants were harvested at growth stage BBCH 89 (154 DAT) and were separated into straw and grains.

TRR levels in wheat matrices were generally low, with the highest level measured in wheat straw at 0.029 mg eq/kg, while the TRR in wheat grain was up to 0.011 mg eq/kg.

Portions of wheat straw and grains were subjected to extraction with acetonitrile:water (1+1) (twice), followed by acetonitrile (once). The straw extracts were further partitioned with ethyl acetate, followed by fractionation using SPE. The PES of wheat straw and grains were characterized by enzyme solubilization using macerozyme, tyrosinase and amylase.

Extractability with solvents was higher in straw (79 percent TRR) compared to grains (29 percent TRR). Further characterization of the PES released additionally 6.7 percent TRR from wheat straw and 24 percent TRR from wheat grain. No individual components could be identified in either matrix. In wheat straw, one unknown component accounted for 14 percent TRR, but the level was < 0.01 mg eq/kg.

Tea grown outdoors received two foliar applications of [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide at nominal rates of 0.1 kg ai/ha each with a RTI of 14 days. Tea leaves were harvested at 7days after the second application (7DAT2) and 14DAT2.

The TRR was generally similar for both labels and harvest times, ranging between 15–20 mg eq/kg. Tea leaves were surface-rinsed with acetonitrile followed by extraction with acetonitrile (twice) and acetonitrile:water (1+1) (once). The extracted radioactivity from tea leaves ranged between 99.3–99.6 percent TRR, with over 97 percent radioactive being removed by the acetonitrile rinse.

Parent broflanilide was the major identified residue, accounting for 96–97 percent TRR (14–19 mg/kg). Additionally, metabolites S(PFP-OH)-8007 and DM-8007 were identified at minor levels of 1.0–1.4 percent TRR (0.14–0.27 mg eq/kg) and up to 1.0 percent TRR (0.20 mg eq/kg), respectively.

Summary of plant metabolism

In all plant metabolism studies, broflanilide was degraded into DM-8007 via demethylation or into S(PFP-OH)-8007 via oxidative defluorination (substitution of fluorine with hydroxy group). Parent broflanilide was the major identified component in all matrices, while both metabolites were detected at minor levels.

Animal metabolism

The Meeting received studies on the metabolism of broflanilide in laboratory animals, lactating goats and laying hens. The evaluation of the metabolism studies in laboratory animals was carried out by the WHO Core Assessment Group.

Lactating goats

In lactating goats, the metabolic fate of broflanilide was investigated using [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide. The compound was administered orally once daily (after morning milking) for 10 consecutive days at 19 ppm (0.62 mg/kg bw day) and 20 ppm (0.73 mg/kg bw) for the B-ring and C-ring label, respectively.

The majority of the radioactivity was found in faeces, at 51–75 percent of the applied radioactivity (AR). In urine, 24 percent AR was found in the C-ring treatment, while only 0.7 percent AR was found in the B-ring treatment. In edible tissues, the highest TRRs were found in fats (omental, subcutaneous and renal), ranging from 2.6–3.4 mg eq/kg for both labels and in liver, ranging from 0.46 mg eq/kg (C-ring) to 2.2 mg eq/kg (B-ring). In muscle and kidney, TRRs were lower for both labels, ranging between 0.22–0.37 mg eq/kg and 0.25–0.27 mg eq/kg, respectively.

In whole milk, the radioactive residues ranged between 0.12–0.43 mg eq/kg for both labels. Residue levels reached a plateau after approximately 6 days and 2 days for the B-ring and C-ring labels, respectively. In milk fat, residues were ~2 orders in magnitude higher compared to skim milk for both labels, reaching up to 4.1 mg eq/kg.

Samples of flank and loin muscles, liver and kidney were extracted twice with acetonitrile:water (1:1) and once with acetonitrile. Skim milk was extracted twice with acetone:water (1:1) and once with acetone. Fats and milk fat were extracted twice with acetone/hexane (1+4) and once with acetone. Solvent extraction released at least 88 percent TRR from most matrices, except for liver (42–68 percent TRR, both labels) and kidney (76 percent TRR, B-ring label).

The PES from liver (B and C-ring labels) and kidney (B-ring label only) were further characterized by enzyme solubilization using protease and lipase, followed by incubations with 1 mol/L HCl and 1 mol/L NaOH, which released additionally 16–59 percent TRR. The extracts and solubilizates were also treated with *β*-glucuronidase in order to cleave conjugates to their respective aglycones.

Parent broflanilide was only detected as a minor residue in muscle, kidney and liver, accounting for 0.5–6.7 percent TRR (0.005–0.022 mg/kg). A major identified metabolite using both labels was DM-8007 in muscle, milk, fats, liver (only C-label) and kidney, accounting for 21.3–99.9 percent TRR (0.01–3.4 mg eq/kg). In the B-label treated goat only, metabolite DC-DM-8007 was detected at major proportions in muscle, milk, fats, liver and kidney, ranging from 29–67 percent TRR (0.017–2.3 mg eq/kg), while in the C-label only, hippuric acid was detected in skim milk, liver and kidney at 19–69 percent TRR (0.018–0.13 mg/kg). Also, hydroxylated and conjugated DC-DM-(A4-OH)-8007, DC-DM-(A6-OH)-8007 and DM-(C2-OH)-8007 were identified in liver, accounting for up to 15 percent TRR (0.32 mg eq/kg), 11 percent TRR (0.24 mg eq/kg) and 17 percent TRR (0.078 mg eq/kg), respectively, and in kidney (B-label only), accounting for less than 10 percent TRR (0.007 to 0.019 mg eq/kg).

Laying hens

In laying hens, the metabolic fate of broflanilide was investigated using [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide. The compound was administered orally once daily for 14 consecutive days to 10 laying hens per label, at 14 ppm (0.86 mg/kg bw day) and 15 ppm (0.84 mg/kg bw) for the B- and C-label, respectively. Eggs and excreta samples were collected twice daily, at approximately 12 hour intervals. Samples of breast muscle, thigh (leg) muscle, abdominal and subcutaneous fat, liver and the entire gastrointestinal tract were collected after sacrifice, which occurred 6 hr after the last dose.

The majority of the radioactivity was found in excreta at 56–65 percent AR. In edible tissues radioactivity was highest in fat at 15–19 mg eq/kg, followed by egg yolk at 3.4–3.6 mg eq/kg and liver at

1.8–2.6 mg eq/kg. Incorporation of radioactivity into egg whites reached steady state within 3–4 days, while no plateau was reached in egg yolks.

Egg white, egg yolk, and muscle samples were extracted twice with acetonitrile:water (1:1) and then once with acetonitrile. Fat samples were extracted twice with acetone:hexane (1:4) then once with acetone. Liver samples were initially extracted three times with acetonitrile:water (1:1) and then once with acetonitrile. Extraction with solvents released at least 89 percent TRR from all matrices, except for liver where 65–72 percent TRR were released. The PES of hen liver from both radiolabels were further characterized by enzyme solubilization using protease and lipase, followed by incubations with 1 mol/L HCl and 1 mol/L NaOH, which released additionally 29–36 percent TRR.

Parent broflanilide was only tentatively identified (TLC analysis) in egg white from the B-label at 2.1 percent TRR (0.0004 mg/kg). The predominant identified residue for both labels was metabolite DM-8007 in all matrices, accounting for 57100 percent TRR (0.013–19 mg eq/kg). As a minor metabolite only occurring with the B-label, DC-DM-8007 was detected in all matrices, accounting for up to 3 percent TRR (0.55 mg eq/kg) in subcutaneous fat. In egg white, DC-DM-8007 accounted for 16 percent TRR, but residues were low (0.003 mg eq/kg). H-U27B (B-label), a hydroxyl cysteine conjugate of DM-8007 and the similar, but structurally not fully elucidated compound H-U27C (C-label) were identified in liver only, accounting for 5.3 percent TRR (0.131 mg eq/kg) and 3.3 percent TRR (0.061 mg eq/kg), respectively.

Summary of livestock metabolism

Generally, the transfer of radioactivity into animal food and feed matrices was low. The metabolism in lactating goats and laying hens is similar, starting with N-demethylation of parent broflanilide to form the main metabolite DM-8007, which is either hydroxylated and conjugated, or cleaved to DC-DM-8007 (identified using the B-label) and hippuric acid (identified using the C-label), via the intermediate benzoic acid. DC-DM-8007 is subsequently hydroxylated, followed by conjugation.

Environmental fate in soil

The Meeting received studies on aerobic soil degradation, soil photolysis, confined rotational crop metabolism and field rotational crops.

In two aerobic soil degradation studies performed with fresh soil under laboratory conditions, ^{14}C-labelled broflanilide (A-ring, B-ring, or C-ring), was very persistent with estimated half-lives in various soils ranging between 288 to 1000 days. Identified metabolites were DM-8007 (up to 4.9 percent AR), S(PFP-OH)-8007 (up to 1.2 percent AR) and DC-DM-8007 (up to 2.3 percent AR). On the contrary, in a soil dissipation study under field conditions, broflanilide and metabolite DM-8007 were not, or only moderately persistent with estimated half-lives, ranging from 3.3 to 18 days and from 8 to 91 days, respectively. Therefore, the Meeting concluded that broflanilide does not have the potential to accumulate in soil.

Half-life of ^{14}C-labelled broflanilide for soil photolysis was estimated (single 1st order kinetics) to 389 US solar days, or 347 OECD solar days. The only identified metabolite was DM-8007 at up to 4.2 percent AR. The Meeting concluded that photolysis does not represent a significant degradation pathway for broflanilide.

A confined rotational crop metabolism study was conducted with [A-ring-U-^{14}C]- and [B-ring-U-^{14}C]-labelled broflanilide, each applied at a rate of 0.15 kg ai/ha to a sandy loam soil. After plant-back intervals (PBIs) of 30, 120 and 270 days, the nature and level of radioactive residues were investigated in lettuce, radish and wheat.

Radioactivity for both labels in all matrices was comparable, with consistently higher levels found for the B-ring label. TRR levels were highest in wheat hay and straw for all PBIs, ranging between 0.014–0.067 mg/eq kg and 0.022–0.075 mg eq/kg, respectively, with the tendency to be higher at later PBIs.

Crop matrices with TRRs ≥0.01 mg/kg were extracted two times with acetonitrile/water (8:2), followed by one time with acetonitrile. Extractabilities ranged between 71–92 percent in radish foliage, 77–94 percent TRR in lettuce (immature and mature), 88–92 percent in wheat forage, 36–70 percent TRR in wheat hay, 58–77 percent TRR in straw and 22–84 percent TRR in grain. The highest radioactivity remaining in the PES was found in wheat straw from the treatment with B-labelled broflanilide (0.025 mg eq/kg), but no further characterization was performed.

In food matrices, parent broflanilide was identified in lettuce (immature and mature) at 19.6–46.6 percent TRR (0.002–0.008 mg/kg) at 120 and 270 day PBI and in radish leaves at 2.8–18.1 percent TRR (< 0.001–0.002 mg/kg) for the 270 day PBI only. In feed matrices, parent broflanilide was identified as a minor component in wheat forage, hay and straw, accounting for 4.3–16.7 percent TRR (0.001–0.004 mg/kg) in all PBIs.

Metabolite DM-8007 was a minor residue in wheat hay and straw and in radish leaves ranging between 1.5–3.7 percent TRR (< 0.001–0.002 mg eq/kg) at 30 and 270 day PBIs.

For the B-label only, an additional identified metabolite was B-urea, accounting for 9.7–30.2 percent TRR (0.004–0.010 mg eq/kg) in wheat forage, hay and straw in all PBIs, for 31.9 percent TRR (0.004 mg eq/kg) for the 270 day PBI only in radish leaves, for 26.6–34.5 percent TRR (0.003–0.005 mg eq/kg) at 120 and 270 day PBIs in immature lettuce and for 35.6 percent TRR (0.004 mg eq/kg) for the 270 day PBI only in mature lettuce. Once again for the B-label only, metabolite B-oxam-acid was identified in wheat forage, hay and straw, accounting for 5.4–35.6 percent TRR (0.001–0.024 mg eq/kg) and in radish leaves, accounting for 14.9 percent TRR (0.002 mg eq/kg) for the 270 day PBI only

In two field rotational crop trials, conducted during the 2016/17 growing seasons in the United States, broflanilide was applied once to bare soil at 0.05 kg ai/ha. Wheat, lettuce and radish were planted 30, 60, 90 and 360 DAT and sampled at normal crop maturity.

Residues of broflanilide as well as metabolites S(PFP-OH)-8007, DM-8007, B-oxam-acid and B-urea were < LOQ (0.01 mg eq/kg), with the exception of parent broflanilide in lettuce planted at 30 days PBI (0.013 mg/kg).

Summary of environmental fate in soil

The Meeting concluded that residues of broflanilide are not very persistent under field conditions and does not have the potential to accumulate in soil. From rotational crop studies, the Meeting concluded that significant carry-over of broflanilide residues in succeeding crops is unlikely.

Methods of analysis

The Meeting received analytical methods for the determination of broflanilide and metabolites S(PFP-OH)-8007, DM-8007, B-urea and B-oxamic acid in plant matrices and for broflanilide and metabolites DC-DM-8007 and DM-8007 in animal matrices.

For matrices of plant origin, a method for all analytes based on QuEChERS employed extraction with acetonitrile/water + buffer salts, followed by clean-up using dispersive solid phase extraction (dSPE) with PSA (optional for B-urea and B-oxamic acid). All analytes were determined by LC-MS/MS with an LOQ of 0.001 for broflanilide and metabolites S(PFP-OH)-8007 and DM-8007, and 0.01 mg/kg for B-urea and B-oxamic acid. Two additional methods employed extraction with acetonitrile or acetonitrile/water, followed

by clean-up using liquid-liquid extraction and/or SPE. Final determination was done by LC-MS/MS, GC-ECD or HPLC-UV with LOQs ranging between 0.01–0.1 mg/kg.

For animal matrices, the method employed extraction with acetonitrile, followed by acetonitrile/water for milk, egg, liver, kidney and muscle. Samples of fat were extracted with acetone/hexane, followed by acetone. Liver, kidney and muscle were further partitioned with a salt solution (MgSO4; NaCl; sodium citrate sesquihydrate and sodium citrate dehydrate), followed by clean-up with PSA. Final determination for all analytes was accomplished by LC-MS/MS with an LOQ of 0.001 mg/kg for milk and 0.01 mg/kg for all other matrices.

The Meeting concluded that suitable methods are available to measure residues of broflanilide and metabolites S(PFP-OH)-8007, DM-8007, B-urea and B-oxamic acid in plant matrices as well as broflanilide and metabolites DC-DM-8007 and DM-8007 in animal matrices.

Stability of pesticide residues in stored analytical samples

The Meeting received information on the storage stability of broflanilide and its metabolites S(PFPOH)-8007, DM-8007, B-oxam-acid and B-urea in a variety of plant matrices stored under frozen conditions. Samples were fortified at levels ranging from 0.01 to 0.5 mg/kg.

Residues of broflanilide and metabolite DM-8007 were stable in high acid matrices (grapes), high protein matrices (kidney beans), high water matrices (lettuce), high starch matrices (potato) and high oil matrices (soya been seed) for at least 24 months.

Residues of metabolite S(PFP-OH)-8007 were stable for at least 25 months in high acid matrices (grapes) and high oil matrices (soya been seed), for at least 28 months in high protein matrices (kidney beans) and high water matrices (lettuce), and for at least 24 months in high starch matrices (potato).

Residues of B-oxam-acid and B-urea were stable in high acid matrices (grapes), high protein matrices (kidney beans), high water matrices (lettuce), high starch matrices (wheat grain) and high oil matrices (soya been seed) for at least 16 months.

All samples from field trials were analysed within the tested storage stability time.

For animal matrices, the Meeting received information on the storage stability of broflanilide and its metabolites DM-8007 and DC-DM-8007 in muscle, liver, kidney, milk and fat stored at -20 °C. Samples were fortified at 0.01 mg/kg.

Residues of broflanilide and metabolite DM-8007 were stable in all tested matrices for at least 2 months. Metabolite DC-DM-8007 was not stable in muscle and kidney, but stable up to one month in liver and at least 2 months in milk and fat. Samples were analysed within this time frame, except for the analysis of DC-DM-8007 in muscle (maximum storage 28 days) as well as in kidney and liver (maximum storage 36 days).

Definition of the residue

In food commodities from plant metabolism studies conducted on cabbage, Japanese radish, tomato, soya bean, rice and tea, the predominant residue was parent broflanilide, accounting for 66–84 percent TRR in cabbage, 77–82 percent TRR in Japanese radish leaves, 60–68 percent TRR in tomato fruit, 13–64 percent TRR in husked rice and 96–97 percent TRR in tea. In studies with wheat (seed treatment) and in Japanese radish root, TRR levels were too low for identification. In feed matrices, residues of broflanilide accounted for 75–76 percent TRR in soya bean forage, 67–71 percent TRR in soya bean hay, 83–90 percent TRR in rice hulls and 85–87 percent TRR in rice straw.

The Meeting concluded that parent broflanilide is a major residue in plants and is a suitable marker compound for compliance with MRLs.

Analytical methods are available for monitoring broflanilide in all plant matrices.

On deciding which compounds should be included in the residue definition for risk assessment, the Meeting considered the likely occurrence of the compounds and the toxicological properties of the metabolites S(PFP-OH)-8007 and DM-8007.

The Meeting concluded that S(PFP-OH)-8007 is covered by the health based guidance value of broflanilide, but is toxicologically 3 times more potent. In plant metabolism studies, S(PFP-OH)-8007 was identified as a minor metabolite (< 10 percent TRR), with levels between 3 and 33 times lower than parent. The metabolite was analysed in various food and feed commodities from supervised field trials and residues above LOQ were detected occasionally, but always at least one order in magnitude lower compared to parent. Taking into account its higher potency, its contribution to the overall dietary exposure was still insignificant compared to parent residues (+0.1 percent relative), due to the low concentrations found in treated commodities.

Metabolite DM-8007 was identified in plant metabolism studies as a minor metabolite (< 10 percent TRR), with levels between 8 to 2500 times lower than the parent. Additionally, the metabolite was analysed in various food and feed commodities from supervised field trials and residues above the LOQ were only detected occasionally, but always at least one order in magnitude lower, compared to parent. The Meeting concluded that metabolite DM-8007 is of no greater toxicity than parent broflanilide and is covered by the toxicological reference values of the parent.

The Meeting noted that broflanilide represents the major part of the residues in plant commodities, sufficiently addressing the overall potential dietary exposure from plant commodities and agreed to set the definition of the residue for dietary risk assessment for plant commodities as parent broflanilide.

In animal metabolism studies performed with lactating goats and laying hens, the predominant metabolic pathway is N-demethylation of parent broflanilide to form DM-8007. Its subsequent cleavage results in DC-DM-8007 (identified using the B-label) and hippuric acid (identified using the C-label), via the intermediate benzoic acid. Depending on the label and tissue, some percentages may appear higher/lower than truly present due to the selective radiodetection.

Parent broflanilide was only detected as a minor residue in muscle, kidney and liver from lactating goats (0.5–6.7 percent TRR) and tentatively in egg white (2.1 percent TRR). In a cow feeding study, residues of broflanilide were detected in milk from the 10 ppm feeding level (approximately 7 times higher than the maximum dietary burden) at up to 0.0018 mg/kg and in cream from the 1.5 ppm (approximatley maximum dietary burden) and the 10 ppm feeding levels at up to 0.016 mg/kg. In all other tissues broflanilide was not detected. The Meeting noted that broflanilide is not a suitable marker for the residue definition for compliance with the MRL for animal commodities alone.

The predominant identified residue in metabolism studies was metabolite DM-8007, accounting for 21–100 percent TRR (0.01–3.4 mg eq/kg) in lactating goat matrices and for 57–100 percent TRR (0.013–19 mg eq/kg) in laying hen matrices. In a cow feeding study, residues of DM-8007 were detected in milk (up to 0.12 mg/kg), cream (up to 1.3 mg/kg), fats (up to 0.79 mg/kg), liver (up to 0.078 mg/kg) and in muscle and kidney (up to 0.08 mg/kg). In matrices from laying hens, residues of DM-8007 were found in eggs, liver and fat at up to 0.023 mg/kg, 0.021 mg/kg and 0.15 mg/kg, respectively.

Hence, the Meeting decided to include parent broflanilide and metabolite DM-8007 into the residue definition for compliance with MRLs.

Analytical methods are available for measuring broflanilide and DM-8007 in animal matrices.

In muscle and fat tissues of all animals investigated, residue concentrations of the sum of broflanilide and DM-8007 were 8–60 times higher in fat compared to muscle. Similarly, levels were approximately 200–300 times higher in milk fat compared to skim milk and approximately 400 times higher in egg yolk compared to egg white. The log P_{ow} of DM-8007 is 5.8 in pH 7 buffer solution. The Meeting concluded that residues according to the residue definition are fat-soluble.

On deciding which compounds should be additionally included in the residue definition for risk assessment, the Meeting considered the likely occurrence and toxicological properties for the candidates DC-DM-8007 and hippuric acid as well as the hydroxylated and conjugated metabolites DC-DM-(A4-OH)-8007, DC-DM-(A6-OH)-8007 and DM-(C2-OH)-8007.

In goat metabolism study (20 ppm dose level), DC-DM-8007 was detected in muscle, milk, fats and kidney at similar proportions as DM-8007 (13–67 percent TRR), but higher proportion in liver. In laying hens (15 ppm dose level), DC-DM-8007 occurred mostly at minor proportions in all matrices (0.8–3.0 percent TRR), with the exception of egg white (16 percent TRR). In the cow feeding study, DC-DM-8007 residues above LOQ were only occasionally found at the 1.5 and 10 ppm feeding levels in milk (up to 0.0015 mg/kg) and in cream (up to 0.015 mg/kg), but levels were at least one order in magnitude lower compared to DM-8007. In all cow tissues, as well as in any matrices from a laying hen feeding study, DC-DM-8007 was < LOQ. The Meeting concluded that DC-DM-8007 does not significantly contributes to the dietary exposure and is covered by the toxicological reference value of the parent.

In goat metabolism study, hippuric acid accounted for 19–69 percent TRR in skim milk, liver and kidney. Compared to DM-8007, the residue levels were similar (kidney, liver) or higher (~3 fold in skim milk), but the metabolite was not analysed in the livestock feeding studies. In rat metabolism studies hippuric acid was found in urine at levels of 11 percent AD and is commonly found in mg or g/l concentrations in human urine. Hippuric acid is of no toxicological concern. Hence, the Meeting decided to not include hippuric acid into the residue definition for dietary risk assessment for animal commodities.

In addition, the hydroxylated and conjugated metabolites DC-DM-(A4-OH)-8007, DC-DM-(A6-OH)-8007 and DM-(C2-OH)-8007 were identified in liver and kidney from goats (15, 11 and 17 percent TRR, respectively), at lower or similar levels or higher relative to DM-8007. However, they were not detected in muscle, milk and fat. The Meeting concluded that these metabolites do not significantly contribute to dietary exposure and are covered by the toxicological reference values of the parent.

The Meeting decided to include broflanilide and metabolite DM-8007 in the residue definition for dietary exposure purposes for animal commodities

Definition of the residue for compliance with the MRL and for dietary risk assessment for plant commodities: *Broflanilide*

Definition of the residue for compliance with the MRL and for dietary risk assessment for animal commodities: *Sum of broflanilide plus 3-benzamido-N-[2-bromo-4-(perfluoropropan-2-yl)-6-(trifluoromethyl)phenyl]-2-fluorobenzamide (DM-8007), expressed as broflanilide.*

The residue is fat-soluble.

Results of supervised residue trials on crops

Supervised trials were available for the use of broflanilide on green onion (Welsh onion), leek, cabbage, Chinese cabbage, tomatoes, radish, Japanese radish, turnip, potato, wheat, barley, maize and coffee. No trials according to GAP were provided on turnip.

Green onions, Subgroup of

The critical GAP for green onions in Japan allows three foliar applications of broflanilide at 2.5 g ai /hL with a PHI of 1 day.

Field trials with green onion in Japan were performed according to the GAP (±25 percent). The ranked order of broflanilide residues was (n=3): 0.38, 0.46, 1.32 mg/kg.

Field trials with leek in Japan were performed according to the GAP (±25 percent). The ranked order of residues was (n=3): 0.10, 0.20, 0.22 mg/kg.

The Meeting noted that residues in green onion and leek belong to different populations and could not be combined.

The Meeting concluded that the number of trials is insufficient to estimate maximum residue levels for broflanilide in green onions and leek.

Cabbage and Chinese cabbage

The critical GAP for cabbage and Chinese cabbage in Japan allows three foliar applications of broflanilide at 2.5 g ai /hL, and PHI of 14 days. No trials were provided matching this GAP.

A GAP for cabbage and Chinese cabbage in China allows a maximum of one foliar application of broflanilide at 24 g ai/ha and PHI of 5 days.

A total of 12 field trials conducted with cabbage in China were provided. In trials conducted at 33.8 g ai/ha, broflanilide residues were (n=6): < 0.01, 0.03, 0.11, 0.12, 0.16 and 0.42 mg/kg. In trials conducted at 45 g ai/ha, residues were (n=6): 0.12, 0.31, 0.33, 0.48 and 1.6 (2) mg/kg.

The proportionality approach was used in both datasets, and scaling factors of 0.71 or 0.53 were applied, giving residues in ranked order (n=12): < 0.01, 0.02, 0.06, 0.08, 0.09, 0.11, 0.17 (2), 0.26, 0.30 and 0.84 (2) mg/kg.

In field trials conducted with Chinese cabbage (n=4) in China at 45 g ai/hg, the ranked order of residues was (n=4): 0.39, 0.41, 0.99, 1.8 mg/kg. By applying the scaling factor of 0.53, residues were: 0.21, 0.22, 0.53 and 0.95 mg/kg.

The Meeting recognized that the residue population from trials on cabbage and Chinese cabbage were not significantly different according to the Kruskal-Wallis H-test and decided to combine the data sets. The ranked order of residues for estimating maximum residue levels and dietary risk assessment was (n=16): < 0.01, 0.02, 0.06, 0.08, 0.09, 0.11, 0.17 (2), 0.21, 0.22, 0.26, 0.30, 0.53, 0.84(2) and 0.95 mg/kg.

The Meeting estimated a maximum residue level of 2 mg/kg and an STMR of 0.19 mg/kg for broflanilide in cabbage and Chinese cabbage.

For animal feed, the Meeting estimated a highest residue of 0.95 mg/kg and median residue of 0.19 mg/kg for broflanilide in cabbage.

Tomato (including cherry tomato)

The critical GAP for tomato in the Republic of Korea allows two foliar applications of broflanilide at 2.5 g ai/hL with a RTI of 7 days and a PHI of 2 days. Information on the spray volume was not provided.

A total of 20 field trials conducted with tomato in the United States were performed with 2× 25 g ai/ha (translating into a spray concentration of 8.8–13 g ai/hL) with a RTI of 7 days and harvest after 1 DALA.

The Meeting noted that the proportionality principle could not be applied to trials as the resultant scaling factors are outside the acceptable range (not lower than 0.3).

Hence, the Meeting concluded that no maximum residue level could be estimated for broflanilide in tomato.

Radish, Japanese

The critical GAP for Japanese radish in Japan allows three foliar applications of broflanilide at 2.5 g ai/hL with a PHI of 1 day.

Field trials with Japanese radish in Japan were performed according to the GAP (±25 percent). The ranked order of broflanilide residues in radish roots were (n=6): < 0.01(6) mg/kg.

The Meeting estimated a maximum residue level of 0.01(*) mg/kg and an STMR of 0.01 mg/kg for broflanilide in radish, Japanese.

Tuberous and corm vegetables, Subgroup of

The critical GAP for subgroup of tuberous and corm vegetables in the United States allows one in-furrow soil application of broflanilide at 50 g ai/ha and the PHI covered by conditions of use.

Field trials conducted with potato from Canada and the United States were performed according to GAP (±25 percent). The ranked order of broflanilide residues was (n=20): < 0.001(5), 0.0012(2), 0.0015(2), 0.0017, 0.0018, 0.0021, 0.0023, 0.0026, 0.0029, 0.0046. 0.0049(2), 0.015, 0.034 mg/kg.

The Meeting estimated a maximum residue level of 0.04 mg/kg and an STMR of 0.00175 mg/kg for broflanilide in the subgroup of tuberous and corm vegetables.

For animal feed, the Meeting estimated a highest residue of 0.034 mg/kg and median residue of 0.00175 mg/kg for broflanilide in potato culls.

Cereal grains, Group of (except rice)

The critical GAP for cereals (barley, oat, wheat, triticale, rye, millet, sorghum, amaranth, buckwheat, cañihua, chia, cram-cram, huauzontle, quinoa, spelt) in the United States allows for seed treatment with broflanilide at a concentration of 50 g ai/t seeds. The critical GAP for maize, including sweet corn in the United States allows one in-furrow soil application of broflanilide at 50 g ai/ha and the PHI covered by conditions of use.

The Meeting considered that both treatments are similar, as they are both soil treatments. In addition, the results of a seed treatment metabolism study performed with wheat at 100 g ai/ton seeds demonstrated that uptake of radioactivity through the roots into the plant is very limited (TRR maximum of 0.011 mg ai/kg). Therefore, the Meeting decided to consider all data sets for wheat, barley and maize to explore a potential group recommendation.

Field trials with wheat were conducted in Canada and the United States at an exaggerated rate of 100 g ai/ton of seed, giving broflanilide residues of < 0.001 (25) mg/kg.

Field trials with barley were conducted in Canada and the United States at an exaggerated rate of 100 g ai/ton of seed, giving broflanilide residues of < 0.001 (16) mg/kg.

In field trials with maize conducted in Canada and the United States according to the GAP, broflanilide residues were < 0.001 (20) mg/kg.

In field trials with sweet corn conducted in the United States following GAP treatment (±25 percent), broflanilide residues were < 0.001 (12), mg/kg.

The Meeting noted that for the overdosed seed treatment trials in wheat and barley, as well as for the in-furrow treatment of maize all residues were <LOQ.

Hence, the Meeting estimated a maximum residue level of 0.001(*) mg/kg for broflanilide for the group of cereals grains, except rice.

The Meeting also estimated an STMR of 0 mg/kg for the group of cereals grains, except rice and sweet corns, and an STMR of 0.001 mg/kg for sweet corns.

Coffee beans, green

The critical GAP for coffee in Colombia allows two foliar applications of broflanilide at 18 g ai/ha with a RTI of 30 days and a PHI of 45 days.

In field trials conducted with coffee in Brazil and Colombia following GAP (±25 percent), the ranked order of broflanilide residues was (n=9): < 0.001(2), 0.0015, 0.0016, 0.0023, 0.0034, 0.0037, 0.0039, 0.005 mg/kg.

The Meeting estimated a maximum residue level of 0.01 mg/kg, and a STMR of 0.0023 mg/kg for broflanilide in coffee beans, green.

Residues in animal feeds

Wheat forage

The critical GAP for wheat in Canada and the United States allows for seed treatment with broflanilide at a concentration of 50 g ai/t seeds with no livestock feeding restrictions.

Field trials were conducted with wheat in Canada and the United States at an exaggerated rate of 100 g ai/ton of seed. The ranked order of residues in wheat forage was (n=25): < 0.001(24), 0.0011 mg/kg.

The Meeting noted that trials were overdosed and decided to set 0.001 mg/kg (as received) as highest and median residue for broflanilide in wheat forage.

Maize forage

The critical GAP for maize in the United States allows one in-furrow soil application of broflanilide at 50 g ai/ha and the PHI covered by conditions of use.

In field trials conducted with maize in Canada and the United States, broflanilide residues in maize forage following GAP (± 25) were < 0.001(25) mg/kg, as received.

The Meeting estimated a highest and median residue of 0.001 mg/kg (as received) for broflanilide in maize forage.

Cereal grains (including pseudocereals) feed products with low water (<20 percent) content (hay, straw), Subgroup of (except rice)

The critical GAP for wheat and barley in the United States allows for seed treatment with broflanilide at 50 g ai/t seeds with no livestock feeding restrictions. The critical GAP for maize in the United States allows one in-furrow soil application of broflanilide at 50 g ai/ha and the PHI covered by conditions of use. As discussed previously, the Meeting considered that both treatments are similar.

Field trials were conducted with wheat and barley in Canada and the United States at an exaggerated rate of 100 g ai/ton of seed. The ranked order of residues for wheat hay was (n=25): < 0.001(24), 0.0012 mg/kg and for barley hay was (n=16): < 0.001(14), 0.0018, 0.0032 mg/kg, as received.

The Meeting decided to combine the data sets for wheat and barley hay as they were considered similar and apply proportionality principle to the residues from the overdosed trials. Therefore, a scaling factor of 0.5 was applied to residues >LOQ, resulting in a total residue population of (n=41): 0.0006, 0.0009, < 0.001(38), 0.0016 mg/kg, as received.

The ranked order of residues for wheat straw was (n=25): < 0.001(23), 0.001(2) mg/kg and for barley straw was (n=16): < 0.001(16) mg/kg, as received.

The Meeting decided to combine the data sets for wheat and barley straw and apply the scaling factor of 0.5, resulting in a total residue population of (n=41): 0.0005(2), < 0.001(39), mg/kg, as received.

The ranked order of residues in maize stover following GAP treatment (±25) was (n=25): < 0.001(25) mg/kg as received.

Based on the more critical hay data, the Meeting estimated a highest residue of 0.0016 mg/kg (as received), a median residue of 0.001 mg/kg (as received) and a maximum residue level of 0.01 mg/kg (dw, based on 88 percent DM content) for the subgroup of cereal grains (including pseudocereals) feed products with low water (<20 percent) content (hay, straw), except rice feed products.

Fate of residues during processing

The Meeting received information on the hydrolysis of [B-ring-U-^{14}C]- and [C-ring-U-^{14}C]-labelled broflanilide, simulating typical processing conditions (90 °C, pH 4, 20 minutes to simulate pasteurization, 100 °C, pH 5, 60 minutes to simulate boiling, baking and brewing and 120 °C, pH 6, 20 minutes to simulate sterilization). No significant hydrolysis of broflanilide was observed at the conditions studied.

The Meeting concluded that broflanilide is stable under the conditions of pasteurization, boiling, baking and brewing, as well as sterilization.

The fate of broflanilide residues has been examined simulating household and commercial processing of potato, maize, wheat and coffee, and the results are shown in Table 133.

Table 133 Estimated processing factors for maximum residue and dietary exposure of processed commodities according to the residue definition broflanilide

Crop	Residue (mg/kg) in RAC		Processed commodity	Individual PF	Median or best estimate PF	Residue (mg/kg) in processed commodity

Residues in animal commodities

Farm animal feeding studies

The Meeting received feeding studies with broflanilide on lactating cows and laying hens.

The study with lactating cows was conducted at treatment rates of 0.015, 0.15, 1.5 and 10 ppm. Residues of parent broflanilide were only detected in milk from the 10 ppm group at up to 0.0018 mg/kg and in cream from the 1.5 and 10 ppm groups at up to 0.016 mg/kg.

Residues of metabolite DM-8007 above LOQ were detected in milk from the 0.15 ppm, 1.5 ppm and 10 ppm groups at up to 0.12 mg/kg and in cream from in all groups at up to 1.3 mg/kg. Metabolite DM-8007 was also detected above LOQ in fats from all groups at up to 0.79 mg/kg, in liver from the 1.5 and 10 ppm groups at up to 0.078 mg/kg and in muscle and kidney from the 10 ppm group at up to 0.08 mg/kg.

The study with laying hens was conducted at treatment rates of 0.02, 0.10 and 0.50 ppm. In eggs and tissues, residues of broflanilide and metabolite DC-DM-8007 were consistently below LOQ for all dose levels.

Residues of metabolite DM-8007 above LOQ were only found in eggs and liver from the 0.5 ppm group at up to 0.023 and 0.021 mg/kg, respectively, as well as in fat from all groups at up to 0.15 mg/kg.

Estimated maximum and mean dietary burdens of livestock and animal commodities maximum residue levels

Dietary burden calculations for beef cattle, dairy cattle, broilers and laying poultry are presented in Annex 6. The calculations were made according to the livestock diets from the United States-Canada, European Union, Australia and Japan in the OECD Table (Annex 6 of the 2006 JMPR Report). The summary results are shown in Table 134.

Table 134 Estimated maximum and mean dietary burdens of farm animals

	Animal dietary burden for broflanilide, ppm of dry matter diet							
	United States-Canada		European Union		Australia		Japan	
	Max.	Mean	Max.	Mean	Max.	Mean	Max.	Mean
Beef cattle	0.052	0.004	1.3	0.26	0.021	0.004	-	-
Dairy cattle	0.019	0.0026	1.3❶	0.26❷	0.02	0.004	0.001	0.001

Animal dietary burden for broflanilide, ppm of dry matter diet								
	United States-Canada		European Union		Australia		Japan	
	Max.	Mean	Max.	Mean	Max.	Mean	Max.	Mean
Poultry – broiler	-	-	0.018	0.001	-	-	-	-
Poultry – layer	-	-	0.33❸	0.065❹	-	-	-	-

Notes:

❶ Highest maximum beef or dairy cattle burden suitable for MRL estimates for mammalian meat and milk.

❷ Highest mean beef or dairy cattle burden suitable for STMR estimates for mammalian meat and milk.

❸ Highest maximum broiler or laying hen burden suitable for MRL estimates for poultry products and eggs.

❹ Highest mean broiler or laying hen burden suitable for STMR estimates for poultry products and eggs.

Animal commodities maximum residue levels

For beef and dairy cattle, a maximum and mean dietary burden of 1.3 ppm and 0.26 ppm were estimated, respectively.

For maximum residue level estimation, the maximum dietary burden of 1.3 ppm was evaluated by interpolating between the 0.15 and 1.5 ppm dosing levels of the lactating cow feeding study (Table 135).

Table 135 Maximum residue level estimation of broflanilide in cattle commodities

Maximum residue level beef or dairy cattle	Feed level (ppm)	Sum of broflanilide + DM-8007 in milk (mg/kg)	Sum of broflanilide + DM-8007 in cream (mg/kg)	Sum of broflanilide + DM-8007 (mg/kg)			
				Liver	Kidney	Muscle	Fat
Feeding study	0.15	0.003[a]	0.021[a]	< 0.02	< 0.02	< 0.02	0.026
	1.5	0.012[a]	0.153[a]	0.023	0.02	< 0.02	0.17
Dietary burden and highest residue	1.3	0.011	0.13	0.023	0.02	< 0.02	0.15

Notes:

[a] Mean at plateau level.

For the STMR estimation, the mean dietary burden of 0.26 ppm was evaluated by interpolating between the 0.15 and 1.5 ppm dosing levels of the lactating cow feeding study (Table 136).

Table 136 STMR estimation of broflanilide in cattle commodities

STMR beef or dairy cattle	Feed level (ppm)	Sum of broflanilide + DM-8007 in milk (mg/kg)	Sum of broflanilide + DM-8007 in cream (mg/kg)	Sum of broflanilide + DM-8007 (mg/kg)			
				Liver	Kidney	Muscle	Fat
Feeding study	0.15	0.003 [a]	0.021 [a]	< 0.02	< 0.02	< 0.02	0.024
	1.5	0.012 [a]	0.153 [a]	0.02	< 0.02	< 0.02	0.13
Dietary burden and mean residue	0.26	0.004	0.032	0.02	< 0.02	< 0.02	0.033

Notes:

[a] Mean at plateau level.

The Meeting estimated a maximum residue level for milks at 0.015 mg/kg, milk (fat) at 0.4 mg/kg (assuming 40 percent fat content in cream), edible offal (mammalian) at 0.03 mg/kg and 0.15 mg/kg for meat from mammals (fat) and mammalian fats.

The Meeting estimated STMR values of 0.004 mg/kg in milks, 0.08 mg/kg in milk (fat) (assuming 40 percent fat content in cream), 0.02 mg/kg in edible offal (mammalian), 0.02 mg/kg in muscle from mammals and 0.033 mg/kg in mammalian fats.

For broiler and laying poultry, a maximum and mean dietary burden of 0.33 ppm and 0.065 ppm were estimated, respectively. For maximum residue level estimation, the maximum dietary burden of 0.33 ppm was evaluated by interpolating between the 0.1 and 0.5 ppm dosing levels of the laying hen feeding study (Table 137).

Table 137 Maximum residue level estimation of broflanilide in poultry commodities

Maximum residue level broiler or layer poultry	Feed level (ppm)	Sum of broflanilide + DM-8007 in eggs (mg/kg)	Sum of broflanilide + DM-8007 (mg/kg)		
			Liver	Muscle	Fat
Feeding study	0.1	< 0.02	< 0.02	< 0.02	0.049
	0.5	0.033	0.031	< 0.02	0.16
Dietary burden and highest residues	0.33	0.027	0.026	< 0.02	0.113

For the STMR estimation, the mean dietary burden of 0.065 ppm was evaluated by interpolating between the 0.02 and 0.1 ppm dosing levels of the laying hen feeding study (Table 138).

Table 138 STMR estimation of broflanilide in poultry commodities

STMR broiler or layer poultry	Feed level (ppm)	Sum of broflanilide + DM-8007 in eggs (mg/kg)	Sum of broflanilide + DM-8007 (mg/kg)		
			Liver	Muscle	Fat
Feeding study	0.02	< 0.02	< 0.02	< 0.02	0.020
	0.1	< 0.02	< 0.02	< 0.02	0.044
Dietary burden and mean residues	0.065	< 0.02	< 0.02	< 0.02	0.034

The Meeting recommended a maximum residue level of 0.03 mg/kg for eggs, 0.03 mg/kg for poultry edible offal, 0.02(*) mg/kg for poultry meat and 0.15 mg/kg for poultry fats.

The Meeting estimated an STMR value of 0.02 mg/kg in eggs, poultry edible offal and poultry muscle as well as 0.034 mg/kg for poultry fats.

RECOMMENDATIONS

On the basis of the data obtained from supervised trials, the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI.

Definition of the residue for compliance with the MRL and dietary risk assessment for plant commodities: *Broflanilide*

Definition of the residue for compliance with the MRL and dietary risk assessment for animal commodities: *Sum of broflanilide plus 3-benzamido-N-[2-bromo-4-(perfluoropropan-2-yl)-6-(trifluoromethyl)phenyl]-2-fluorobenzamide (DM-8007), expressed as broflanilide*

The residue is fat-soluble.

Table 139 Recommendations for residues of broflanilide from the 2022 JMPR

CCN	Commodity	Recommended Maximum residue level (mg/kg)	STMR or STMR-P mg/kg	HR or HR-P mg/kg

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The ADI for broflanilide is 0–0.02 mg/kg bw. The International Estimated Daily Intakes (IEDIs) for broflanilide were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the JMPR. The results are shown in Annex 3 of the 2019 JMPR Report.

The IEDIs ranged from 0–1 percent of the maximum ADI. The Meeting concluded that long-term dietary exposure to residues of broflanilide from uses considered by the JMPR is unlikely to present a public health concern.

Acute dietary exposure

The Meeting determined that establishment of an acute reference dose is unnecessary for broflanilide and concluded that the acute exposure of residues of broflanilide from uses considered by the Meeting is unlikely to present a public health concern.

CHLORANTRANILIPROLE (230)

First draft prepared by Dr H Kobayashi, Agricultural Chemicals Office, Ministry of Agriculture, Forestry and Fisheries, Japan

EXPLANATION

Chlorantraniliprole was first evaluated for residues and toxicological aspects by the 2008 JMPR. The 2008 JMPR established an ADI for chlorantraniliprole of 0–2 mg/kg bw and concluded that an ARfD was not necessary.

Definition of the residue for both compliance with MRL and estimation of dietary intake (for plant and animal commodities): chlorantraniliprole.

The residue is fat soluble.

It was evaluated for additional maximum residue levels in 2010, 2013, 2014, 2016, and 2019 (extra). At the Fifty-second CCPR (2021), chlorantraniliprole was listed for consideration of further additional maximum residue levels by the 2022 JMPR.

The current Meeting received new information on use patterns, supervised residue trials and storage studies on avocado and tea.

RESIDUE ANALYSIS

Analytical methods

The Meeting received a new method of analysis for tea (Woodward and Tsuchizawa (2010)).

For tea leaves, powdered dried tea leaves (5 g) was soaked in 20 mL of water for 2 hours, and then added to acetonitrile-water (8:2, v/v) and shaken for 30 minutes. After filtration, the extract was loaded onto an SPE cartridge (conditioned with acetonitrile (5 mL) and water (5 mL)), washed with 5 mL of acetonitrile-water (2:8, v/v) and eluted with 10 mL of acetonitrile-water (8:2, v/v).

For tea infusion, 9 g of dried tea leaves was extracted with 540 mL of boiling water for 5 minutes. The filtered extract was cleaned up by SPE cartridge with the same procedure as that for tea leaves.

Both samples after clean-up were introduced to LC-MS/MS using ESI (C18 column, 5 mmol/L ammonium acetate (aq) – 5 mmol ammonium acetate in methanol, 50:50->5:95, v/v). Ion monitored was 484.0 -> 285.8 for chlorantraniliprole. Calibration curve was linear (R^2 > 0.999) between 0.001 and 0.04 mg/kg. LOD and LOQ for chlorantraniliprole were 0.003 and 0.01 mg/kg, respectively.

The validation data were shown in Table 1.

Table 1 Method validation data for tea

Analyte	Matrix	Fortification mg/kg	n	Recovery range % (mean)	RSD percent
Chlorantraniliprole	Tea leaves	0.01	5	100-114 (107)	4.8
		0.5	5	96-101 (99)	1.9
		50	5	96-102 (99)	2.7
	Tea infusion	0.01	5	84-101 (95)	7.4
		0.5	5	94-103 (98)	3.8
		20	5	100-104 (102)	1.8

Avocados were analysed using Method 13294, evaluated by the 2008 JMPR.

In summary, 5 g of avocado with 10 mL of water was mixed with 40 mL of acetonitrile, blended (approximately 2 minutes) and centrifuged. Acetonitrile (50 mL) was added to the supernatant and centrifuged again. An aliquot (5 mL) of supernatant was added to 20 mL of water and cleaned up by SPE (SAX, HLB) cartridge column eluted with acetonitrile-ethyl acetate (4:1, v/v). After filtration, the sample was introduced to LC-MS/MS using ESI (C18 column, 0.01 mol/L formic acid (aq) – 0.01 mol/L formic acid in methanol). Ions monitored were 484 -> 453 and 484 -> 286 for chlorantraniliprole. Calibration curve was linear (R^2 > 0.99) between 0.004 and 0.2 mg/kg. LOD and LOQ for chlorantraniliprole were 0.003 and 0.01 mg/kg, respectively.

Stability of pesticide residues in stored analytical samples

The Meeting received storage stability studies for tea (Woodward and Tsuchizawa (2010), Kawano (2021a) and Kawano (2021b)). Tea leaves fortified with chlorantraniliprole at 0.5 or 0.1 mg/kg were stored frozen at approximately -20 °C for 39–131 days and analysed in duplicate (Table 2). Samples at day 0 was not analysed; however, concurrent recovery in the analysis of field trial samples were between 79–111 percent at the fortification levels of 0.01–30 mg/kg (Table 3).

Table 2 Storage stability of chlorantraniliprole in tea leaves

Analyte	Matrix	Fortification mg/kg	Storage period (days)	Mean recovery (%)
Chlorantraniliprole	Tea leaves [a]	0.5	66	102
	Tea leaves [a]	0.5	39	99
	Tea leaves [b]	0.1	131	95
	Tea leaves [c]	0.1	53	93

Notes:

[a] Woodward and Tsuchizawa (2010).

[b] Kawano (2021a).

[c] Kawano (2021b).

Table 3 Concurrent recovery of chlorantraniliprole in tea leaves

Analyte	Matrix	Fortification mg/kg	n	Recovery range % (mean)	RSD percent
Chlorantraniliprole	Tea leaves [a]	0.01	3	102-116 (111)	7.0
	Tea leaves [a]	0.01	3	73-83 (79)	6.9

[b] Kawano (2021a).

[c] Kawano (2021b).

USE PATTERN

The Meeting received the GAP for avocado and tea as shown in Table 4. The labels provided cover broader spectrum of uses.

Table 4 Use pattern of chlorantraniliprole

Crop	Country	Concentration g ai/kg Formulation	Application							
			Type	kg ai/ha	g ai/L	Application volume (L/ha)	Growth stage	No	minimum RTI (days)	PHI (days)
Avocado	United States	350 g ai/kg, WG	Foliar spray	0.112/a	-	-	NA	2 [a]	10	1
Tea	Japan	100 g ai/kg, FL	Foliar spray	-	0.05	4000 [b]	NA	1 [c]	NA	3

[a] According to the US label, the application rate for each application (0.074–0.112 kg ai/ha) and the maximum seasonal rate (0.224 kg ai/ha) indicates that cGAP can be 3 × 0.074 kg ai/ha or 2 × 0.112 kg ai/ha. As the PHI is the same for these GAPs (1 day), the latter is considered more critical.

[b] Recommended maximum application volume.

[c] Maximum 1 application before first pick and maximum 1 application between picks (e.g. maximum 1 application before first pick, up to a total of 2 (1+1) before second pick, 3 (1+1+1) before third pick etc.).

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

Residue levels were reported as measured. When residue concentrations were less than LOQ, they are shown as below the LOQ, e.g., < 0.01 mg/kg. Residue values from the trials conducted according to the maximum GAP were used for the estimation of maximum residue levels, STMR and HR. These results are underlined.

Laboratory reports included method validation including batch recoveries with spiking at residue levels similar to those occurring in samples from the supervised trials. Dates of analyses or duration of residue sample storage were also provided. Field reports provided data on the sprayers used and their calibration, plot size, residue sample size and sampling date. The results of field trials are shown in tables indicated in Table 5.

Table 5 Results of supervised field trials for chlorantraniliprole

Commodity	Result
Avocado	Table 6
Tea	Table 7

Avocado (Shepard (2021))

The Meeting received five supervised trials conducted in 2020 and 2021 on avocado in the United States of America. In these trials, avocados received two foliar applications of chlorantraniliprole (350 g/kg WG) at 0.111–0.114 kg ai/ha with intervals of 9–10 days. In two trials, plants were harvested at 1 day after the last application (DALA) and other three trials were decline study (harvested at 0–7 DALA). Two trials were conducted at the same venue in the same year.

Samples harvested were stored at -20 °C for up to 6.5 months before analysis. Since the storage stability data from the 2008 JMPR had covered a diverse range of crops and demonstrated stability of chlorantraniliprole for at least 24 months, it was considered that the data should be sufficient to cover the storage stability of chlorantraniliprole in avocados in this submission.

The residues of chlorantraniliprole in avocado, with stone removed, were analysed by Method 13294 (LOQ=0.01 mg/kg). Two samples for each trial were duplicatedly analysed and the averages were shown as residue data. Procedural recoveries of chlorantraniliprole in avocado were 92–100 percent.

The residues of chlorantraniliprole in avocado when harvested around 1 DALA were 0.063–0.16 mg/kg (Table 6).

Table 6 Residues of chlorantraniliprole in avocado after foliar application of chlorantraniliprole 350 g/kg WG

Location, year (variety)	No	RTI (day)	kg ai/ha	DALA	Residue (mg/kg) Chlorantraniliprole	Note

Notes:

[a] The higher individual analytical value in duplicate samples: 0.064 mg/kg.

[b] The higher individual analytical value in duplicate samples: 0.12 mg/kg.

[c] The higher individual analytical value in duplicate samples: 0.11 mg/kg.

[d] The higher individual analytical value in duplicate samples: 0.20 mg/kg.

[e] Trials were conducted in the same year and the same place. The difference of application dates was 39 days.

Tea (Woodward and Tsuchizawa (2010), Kawano (2021a) and Kawano (2021b))

The Meeting received 10 supervised trials conducted in 2006-2021 on tea in Japan. In these trials, tea received one foliar application of chlorantraniliprole (0.05 g ai/L, dilution of formulation at 100 g/kg FL) and harvested 3–21 days after treatment (DAT). Samples after harvest were stored at <-20 °C for up to 3.5 months before analysis.

Dried tea leaves were prepared from fresh tea leaves harvested to be steamed twice at 100 °C for 1 minute, and then dried three times in an oven at 80 °C for 120 minutes with intervals of 30 minutes.

The residues of chlorantraniliprole in tea leaves were analysed by LC-MS/MS method (LOQ=0.01 mg/kg). Procedural recoveries of chlorantraniliprole in dried tea leaves were 73–116 percent.

The residues of chlorantraniliprole in dried tea leaves when harvested 3 DAT were 19–32 mg/kg (Table 7).

Table 7 Residues of chlorantraniliprole in tea, green after foliar application of chlorantraniliprole 100g/kg FL

FATE OF RESIDUES IN STORAGE AND PROCESSING

Tea (Kawano (2021a) and Kawano (2021b))

Tea infusion was prepared from dried tea leaves (stored at -20 °C for up to 3.5 months) as follows: 9 g of dried tea leaves were soaked in 540 mL of boiling water for 5 minutes and filtered. Tea infusion was analysed with LC-MS/MS method with LOQ of 0.01 mg/kg. The procedural recoveries for tea infusion were 88–101 percent.

The processing factors from 32 trials ranged from 0.0053 to 0.011 with a best estimate (median) of 0.0081 (Table 8, Table 9).

Table 9 Processing factor from tea leaves to tea infusion (Summary)

RAC	Processed commodity	Calculated processing factors [a]	PF (mean or best estimate)
Tea leaves	Tea infusion	0.0053, 0.0062, 0.0064, 0.0071 (3), 0.0072, 0.0073, 0.0074, 0.0076, 0.0077 (2), 0.0078 (2), 0.0079, 0.0080, 0.0082 (2), 0.0083 (3), 0.0084, 0.0085 (2), 0.0086 (3), 0.0090, 0.0091, 0.0094 (2), 0.011	0.0081

Notes:

[a] Each value represents a separate trial. The factor is the ratio of the residue in processed commodity divided by the residue in the RAC.

APPRAISAL

Chlorantraniliprole was first evaluated for residues and toxicological aspects by the 2008 JMPR. The 2008 JMPR established an ADI for chlorantraniliprole of 0–2 mg/kg bw and concluded that an ARfD was not necessary.

The 2008 JMPR also established the definition of residue as follows:

Definition of the residue for both compliance with MRL and estimation of dietary intake for plant and animal commodities: *chlorantraniliprole*

The residue is fat soluble.

It was evaluated for additional uses by JMPR in 2010, 2013, 2014 and 2016. At the Fifty-second Session of the CCPR (2021), chlorantraniliprole was listed for consideration of additional uses by the 2022 JMPR.

The current Meeting received new information on method of analysis, storage studies, use patterns, supervised residue trials and processing studies on avocado and tea.

Methods of analysis

The Meeting noted that the analytical method for avocado had been evaluated by the 2008 JMPR.

The Meeting received information on a new analytical method for chlorantraniliprole in tea.

Chlorantraniliprole was extracted from tea leaves (dry) with acetonitrile/water (8:2, v/v), cleaned-up and analysed with LC-MS/MS. Tea infusion, prepared by soaking tea leaves in boiling water and filtered, was cleaned-up and then analysed with the same method. Recovery data supported an LOQ of 0.01 mg/kg. The Meeting agreed that the method is suitable for analysing chlorantraniliprole in dried tea leaves and tea infusion.

Stability of pesticides in stored analytical samples

Stability studies of chlorantraniliprole in tea leaves (dry) were available. The Meeting concluded that chlorantraniliprole in tea leaves stored at ≤-20 °C was stable for at least 4 months. All the residue samples were analysed within this period. Concurrent recoveries for tea leaves in the field trial samples were 73–116 percent.

Results of supervised residue trials on crops

Avocado

The critical GAP for avocado in the United States is two foliar applications at 0.112 kg ai/ha with a minimum interval of 10 days and PHI of 1 day.

In trials matching the GAP, residues of chlorantraniliprole in avocados were (n=5): 0.043, 0.063, 0.083, 0.094 and 0.16 mg/kg.

The Meeting estimated a maximum residue level of 0.3 mg/kg and an STMR value of 0.083 mg/kg for avocado.

Tea, green, black (black, fermented and dried)

The critical GAP for tea in Japan is one foliar application of chlorantraniliprole (5 g ai/hL) before each pick with a PHI of 3 days.

The Meeting noted that the typical interval between picks is 30 days. According to the decline study, 0.3–9.6 percent of the DAT3 residue remained 18 days. The Meeting considered that the residue carry-over from previous treatments would be insignificant and agreed that the trials approximated the cGAP in Japan.

In trials approximating the GAP, residues of chlorantraniliprole in tea leaves (dry) were (n=10): 19 (2), 22, 23, 24, 25, 28 (2), 29 and 32 mg/kg.

The Meeting estimated a maximum residue level of 80 mg/kg and an STMR of 24.5 mg/kg.

Fate of residues during processing

Tea infusion

The Meeting received residue data for chlorantraniliprole in tea infusions.

Residues of chlorantraniliprole in tea infusion, prepared from the tea leaves in trials conducted in 2020 and 2021, were (n=8): 0.14, 0.16, 0.18, 0.20 (2), 0.22 (2) and 0.23 mg/kg.

The Meeting estimated an STMR value of 0.20 mg/kg in tea infusion.

RECOMMENDATIONS

On the basis of the data from supervised trials the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessment.

Definition of the residue for compliance with MRL and for estimation of dietary risk assessment for plant and animal commodities: *chlorantraniliprole*.

The residue is fat-soluble.

Table 10 Maximum residue level Recommendations for chlorantraniliprole

CCN	Commodity	Recommended Maximum residue level (mg/kg)		STMR or STMR-P mg/kg	HR or HR-P mg/kg
		New	Previous		
FI0326	Avocado	0.3		0.083	
DT1114	Tea, green, black (black, fermented and dried)	80		24.5	

CCN	Commodity	Recommended Maximum residue level (mg/kg)		STMR or STMR-P mg/kg	HR or HR-P mg/kg
		New	Previous

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The ADI for chlorantraniliprole is 0–2 mg/kg bw. The International Estimated Daily Intakes (IEDIs) for chlorantraniliprole were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the current and earlier JMPR. The results are shown in Annex 3 of the 2022 JMPR Report.

The IEDIs ranged from 0–1 percent of the maximum ADI for chlorantraniliprole. The Meeting concluded that long-term dietary exposure to residues of chlorantraniliprole from uses considered by the JMPR is unlikely to present a public health concern.

Acute dietary exposure

The ARfD for chlorantraniliprole is not necessary. The Meeting concluded that acute dietary exposure to residues of chlorantraniliprole from uses considered by the present Meeting is unlikely to present a public health concern.

CHLORMEQUAT (015)

First draft prepared by Dr Yukiko Yamada, International Food Safety Consultant and National Institute of Health Sciences, MHLW, Japan

EXPLANATION

Chlormequat (usually formulated as the chloride salt) is a plant growth regulator registered for use on cereals and grapes. It acts primarily by reducing cell elongation, as well as by lowering the rate of cell division and by inhibiting the synthesis of gibberellins. Chlormequat was evaluated by the Meeting in 1970, 1972, 1994 (T, R), 1997 (R), 1999 (T, for ARfD), 2000 (R) and 2017 (T, R, periodic re-evaluation).

The 2017 Meeting reaffirmed the ADI of 0–0.05 mg/kg bw (established in 1997) and ARfD of 0.05 mg/kg bw (established in 1999). The 2017 Meeting confirmed residue definitions as follows:

The residue definition (for compliance with the MRL and dietary risk assessment) in plant and animal commodities: *chlormequat cation*.

The residue is not fat soluble.

For chlormequat chloride technical concentrate and soluble concentrate, specifications were established by the Joint Meeting on Pesticides Specifications in 2005.

The Forty-third Session of the Codex Alimentarius Commission (2020) approved the new work proposals including the priority list of pesticides for evaluation by the current Meeting. The priority list included chlormequat for evaluation of uses on barley and wheat.

The current Meeting received new information on: GAP in Australia, Canada and the United Kingdom of Great Britain and Northern Ireland, analytical method, supervised residue trials conducted in Canada and the United States, and processing studies, for wheat and barley.

RESIDUE ANALYTICAL METHODS

Analytical methods

The 2017 Meeting evaluated analytical methods for determining chlormequat chloride in plant and animal matrices and their validation data.

The current Meeting received information on an LC-MS/MS method (M01-011) for determining chlormequat chloride in the supervised residue trials and processing studies. This method was similar to the LC-MS/MS method (CEN/TC 275/WG 4N) provided to the 2017 JMPR. In M01-011 method, a homogenized sample of each of wheat or barley matrices (grain, leafy parts and processed commodities) was fortified with a known concentration of chlormequat-D4 chloride as internal standard. Residues of chlormequat/internal standard were extracted from the fortified sample with methanol/water (2:1, v/v) using a high-speed homogenizer. An aliquot of extract was then filtered for determination of chlormequat by LC-MS/MS.

For validation of the method for determining chlormequat chloride in wheat and barley matrices, recovery tests were performed at the fortification levels of 0.01 mg/kg and 0.1 mg/kg, each in five replicates. In these recovery tests, two mass transitions were monitored: m/z 122 → 58 for quantification; and m/z m/z 122 → 59 or m/z 122 → 63 for confirmation as shown in the following table.

At the fortification levels of 0.01 and 0.1 mg/kg in all the wheat and barley matrices tested, the recoveries and RSD values were within the acceptable range and the validated LOQs were 0.01 mg/kg.

Table 1 Summary of recoveries of the LC-MS/MS method for the determination of chlormequat chloride in wheat, barley and their processed commodities

Notes:

[a] Aspirated grain fractions.

Stability of pesticide residues in stored analytical samples

The 2017 Meeting evaluated the storage stability data on cereal matrices (grain, straw and processed matrices). Chlormequat chloride in wheat grain and straw samples fortified at 0.10 and 0.50 mg/kg were

demonstrated to be stable for at least 24 months when stored frozen at approximately -18 or -20 °C. Wheat bran and wholemeal bread, and barley malt and beer from a processing study were re-analysed for chlormequat chloride after about 11–13 months of further frozen storage. Residues of chlormequat chloride were stable for at least 13 months in wheat bran and whole wheat bread, 12 months in barley malt and 11 months in beer, when stored frozen at approximately -18 °C.

The proved stable periods cover the sample storage intervals in the residue trials.

USE PATTERN

Chlormequat has been registered as a plant growth regulator for uses on a number of crops. The 2017 Meeting received labels from many countries and the use patterns (foliar applications) related to the supervised trials submitted to the Meeting were summarized.

The current Meeting received a new label from Australia, Canada and the United Kingdom. As the supervised trial data were submitted to the current Meeting on wheat and barley, the uses on wheat and, barley are summarized below. The labels of Canada and the United Kingdom do not restrict grazing or harvesting forage while that of Australia contains "grazing and cutting for stock feed are not allowed before 21 days after the application".

Table 2 Registered uses of chlormequat chloride on cereals relevant to the current evaluation of supervised trials on wheat and barley

Crop	Country	Conc. g ai/L Form	Application					Min. PHI days
			Method	Growth stage/timing	Rate kg ai/ha	Min Water Volume, L/ha	No	
Barley, spring & winter	Canada	620 SL	Foliar	GS 30–32 [a]	1.426	100	1	NA
				GS 14–32 GS 32–39	0.713 + 0.713		1 + 1	NA

Notes:

[a] If applications are not possible at Zadoks GS 30 to 32 due to environmental or field conditions, apply up to GS 39.

[b] If applications are not possible at Zadoks GS 31 to 32 due to environmental or field conditions, do not apply later than GS 39.

[c] A maximum dose of 1.33 L/ha (0.9975 kg ai/ha) must not be exceeded when applied before stem elongation (GS 30).

Growth stages for comparison

Zadoks GS	Stage	BBCH	Stage
12	2-leaf	21	beginning of tillering: 1st tiller detectable
14	4-leaf	25	mid-tillering
21	main stem and one tiller	30	beginning of stem elongation
23	main stem and three tillers	31	1st node at least 1 cm above tillering node
29	Main stem and nine or more tillers	32	Node 2 at least 2 cm above node 1
30	beginning of stem elongation	33	Node 3 at least 2 cm above node 2
31	1-node	37	Flag leaf just visible, still rolled
32	2-node	39	Flag leaf stage: flag leaf fully unrolled, ligule just visible
39	flag leaf collar visible		

RESULTS OF SUPERVISED TRIALS ON CROPS

The current Meeting received information on supervised trials using chlormequat chloride on wheat and barley. The results of these supervised trials are summarized in the following table:

Group	Subgroup	Commodity	Table No.
Cereal grains	Wheat, similar grains and pseudocereals without husks	Wheat	Table 3
			Table 4
	Barley, similar grains and pseudocereals with husks	Barley	Table 5
			Table 6
Cereal grains (including pseudocereals) and grass feed products	Cereal grains feed products with high water (≥20%) content (forage and silage) and cereal grains feed products with low water content (<20%) content (hay, straw)	Barley, forage Barley, hay and/or straw	Table 7
		Barley forage	Table 8
		Barley straw	Table 9
		Wheat, forage Wheat, hay and/or straw	Table 10
		Wheat forage	Table 11
		Wheat straw	Table 12

In addition to the descriptions and details of the field trials, each study report includes a summary of the analytical methods, together with the corresponding procedural recoveries, LOQ, LOD, and information on storage of samples. Duration of freezer storage between sampling and analysis were reported for all trials and were covered by the conditions of the freezer storage stability studies.

All appropriate trials are summarized and used. In the trials, where multiple analyses were conducted on a single sample, the mean value is reported. Where multiple samples were taken from a single plot, the individual and mean values are reported. Where results from separate plots with distinguishing characteristics such as different varieties or treatment schedules were reports, results are listed for each plot.

When residues were not quantifiable, they are shown as below the LOQ of the relevant analytical method (e.g., < 0.01 mg/kg). Residues and application rate have generally been rounded to two or three significant figures.

Although control plots were included in the trials, control data are not reported in the following tables unless residues in control samples exceeded the LOQ. Results have not been corrected for concurrent method recoveries.

Residue values from the trials conducted according to the critical GAP were used for the estimation of maximum residue levels, STMR and HR (if applicable). Those results included in the tables are underlined.

Cereal Grains

Wheat, similar grains and pseudocereals without husks–Trials in Canada in 2015

A total of six field trials were conducted on locally grown commercial wheat varieties (one winter wheat and five spring wheat varieties) in Canada during 2015 growing season (AA150722; Norris, F.A., 2016). The wheat was grown under normal agronomic practices for the region and grew and developed normally.

Each trial consisted of three plots: a control plot, and two treated plots. The treated plots for the winter wheat site received either a single foliar application of chlormequat chloride (620 SL) at a growth stage of Zadoks GS 12–30 (target rate of 0.62 kg ai/ha, for forage and grain sample collection) or at a growth stage of Zadoks GS 31–39 target rate of 1.12 kg ai/ha, for hay, grain and straw sample collection. The treated plots for spring wheat sites received single foliar application of chlormequat chloride (620 SL) at a rate of either at a growth stage of Zadoks GS 12–30 (target rate of 0.50 kg ai/ha, for forage-sample collection) or at a growth stage of Zadoks GS 31–32 (target rate of 1.12 kg ai/ha, for hay, grain and straw sample collection).

In the trials, except in two decline trials, one untreated sample and two treated samples were taken at the following growth stages: forage at 15–20 cm stage prior to stem elongation (jointing); hay at early flower (boot) to soft dough stage; and grain and straw at commercial maturity (grains = kernel with hull removed). In the two decline trials, forage, hay, grain and straw samples were collected 7 days before commercial harvest stage, at commercial harvest, and at 7 and 14 days after the commercial harvest stage.

Samples were frozen immediately after collection and shipped frozen at -33 to -10 °C to the analytical laboratory. Upon receipt, the samples were transported at <-5 °C to the laboratory and maintained frozen at <-18 ºC until extraction for a maximum of ca. 4 months (136 days). Extracts were analysed within 7 days. Separate storage stability studies evaluated by the 2017 JMPR demonstrated that chlormequat chloride is stable for at least 24 months in wheat grain and straw when stored frozen.

Residues of chlormequat chloride were determined by LC-MS/MS (method M01-011) with an LOQ of 0.01 mg/kg. Concurrent recoveries (fortification levels: 0.01–2.6 mg/kg) were within the acceptable range with relative standard deviation <20 percent.

Trials in the United States in 2016

A total of 17 supervised trials were conducted on locally grown commercial wheat varieties (winter wheat in 8 sites and spring wheat in nine sites) in the United States during 2016 (AA 160702, Hoi, S.W., 2017a). The wheat was grown under normal agronomic practices for the regions and grew and developed normally.

Each trial consisted of three plots: a control plot, and two treated plots. The treated plot for winter wheat received a single foliar application of chlormequat (620 SL) either at a growth stage of Zadoks GS 20 (target rate of 0.25 kg ai/ha, for forage sample collection) or at a growth stage of Zadoks GS 39 (target rate of 0.45 kg ai/ha, for hay, grain and straw sample collection). The treated plot for spring wheat received a single foliar application of chlormequat chloride (620 SL) either at a growth stage of Zadoks GS 20 (target rate of 0.20 kg ai/ha, for forage sample collection) or at a growth stage of Zadoks GS 32 (target rate of 0.45 kg ai/ha, for hay grain and straw sample collection). In two trials, an additional treated plot received a chlormequat chloride application at a nominal rate of 2.20 kg ai/ha at GS 39 for obtaining raw agricultural commodity (RAC) for a processing study (See the section on processing). These trials, other than those for obtaining the RAC for processing study, were conducted according to the GAP in Canada, which allows one application of chlormequat chloride (620 SL) at a rate of 1.12 kg ai/ha up to and not later than GS 39.

In the trials, except in two decline trials, one untreated sample and two treated samples of wheat grain and straw were collected at the following growth stages (based on > 40 percent of plants within the population): forage, cut between tillering and stem elongation (GS 25–30); hay, early flower (boot) to soft dough stage (GS 45–85) and grain/straw, commercial maturity (GS 92)(grain=kernel with hull intact). In the two decline trials, forage, hay, grain and straw samples were collected 10 days and 5 days before commercial harvest stage, at commercial harvest, and 5 days and 10 days after the commercial harvest stage.

Samples were frozen immediately after collection and shipped at approximately -29 to-6 ºC to the analytical laboratory. Upon receipt, they were maintained frozen at <-18 °C until extraction for a maximum of approximately 10 months (310 days). Extracts were analysed within 5 days. Separate storage stability studies evaluated by the 2017 JMPR demonstrated that chlormequat chloride is stable for at least 24 months in wheat grain and straw when stored frozen.

Residues of chlormequat chloride were determined by LC-MS/MS (method M01-011) with an LOQ of 0.01 mg/kg. Concurrent recoveries (fortification levels: 0.01–5.2 mg/kg) were 89–101 percent, with relative standard deviation < 20 percent.

In the following tables, either chlormequat chloride or chlormequat cation was reported in the "Chloride (Individual)" or "Cation (individual)". As the residue definition is chlormequat cation for both compliance and dietary exposure assessment, the mean concentrations of chlormequat cation were reported in the "Cation (Mean)" column.

Notes:

Except where indicated, no residues above the LOQ were found in any of the untreated control samples.

*Trial accidentally oversprayed with an additional application of 1.6 kg ai/ha chlormequat chloride 18 days prior to the trial application.

#Trial flagged by applicant as having abnormally high residues due to extremely low rainfall during the trial, contributing to lowered yields, and use of a durum wheat variety. Noting that this result differs significantly from the rest of the data, it is considered not representative of the residues expected after treatment in accordance with GAP, and has not been included the consideration for MRL estimation.

Barley, similar grains and pseudocereals with husks

A total of 20 supervised trials were conducted on locally grown commercial varieties of barley in Canada (10) and the United States (10) during 2016 (AA160703, Hoi S.W., 2017b). In all of the sites, spring barley were grown under normal agronomic practices for the regions and developed normally. Each trial consisted of two plots: a control plot and a treated plot. Each treated plot received a single foliar application of chlormequat chloride (620 SL) at a growth stage of Zadoks GS 32 at either lower target rate (target rate of 0.58 kg ai/ha in the Canadian trials or 0.71 kg ai/ha in the United States trials) or higher rate (target rate of 1.43 kg ai/ha in the United States trials or 1.15 kg ai/ha in Canadian trials).

In these trials, except the decline studies, the barley matrices were sampled at the following growth stages (based on >50 percent of plants within the population): hay, early flower (boot) to soft dough stage (GS 45–85); and grain/straw, commercial maturity (GS 92)(grain=kernel with hull intact). In the residue decline trials, hay, grain and straw samples were taken at 10 days and 5 days before the normal commercial harvest stage, at commercial harvest, and at 5 and 10 days after the normal commercial harvest stage.

Samples were frozen immediately after sampling and shipped frozen to the analytical laboratory. Samples were maintained frozen at <-18 ºC until extraction for a maximum of 316 days (*ca.* 11 months). Extracts were analysed within 6 days. Separate storage stability studies concluded that chlormequat chloride is stable for at least 24 months under frozen storage conditions in cereal grain and straw.

Residues of chlormequat chloride were determined by LC-MS/MS, using method M01-011. The method was validated with an LOQ of 0.01 mg/kg. Concurrent procedural recoveries were within the acceptable range of 70–110 percent, with relative standard deviation <20 percent.

Table 5 Residues of chlormequat in barley grain (spring barley) from supervised trials conducted with single foliar application of chlormequat chloride (620 SL formulation) in Canada and the United States in 2016

Notes:

No residues above the LOQ were found in any of the untreated control samples.

Animal Feeds

Cereal grains feed products with high water (≥20%) content (forage and silage) and

cereal grains feed products with low water content (<20%) content (hay, straw)

Barley forage; and Barley, hay and/or straw

In a total of 20 supervised trials conducted on barley in Canada (10) and the United States (10) during 2016 (AA160703, Hoi S.W., 2017b), hay samples were taken at earlier growth stages (GS 45–85) and straw samples were taken at the same time as grains (GS 92).

In the following tables, individual analytical results of duplicate samples were reported as “Cation (individual)” followed by the mean analytical results in the “Cation (Mean)” column.

Table 7 Residues of chlormequat in barley hay (H) or straw (S) from supervised trials conducted with foliar application of chlormequat chloride (620 SL formulation) in Canada and the United States in 2016 (residue concentrations expressed on an as-received basis)

Wheat forage; and Wheat, hay and/or straw

Trials in Canada in 2015

In a total of six field trials conducted on wheat (one on winter wheat and the other five on spring wheat) in Canada during 2015 growing season (AA150722; Norris, F.A., 2016), samples of forage and hay were taken at earlier growth stages (forage, GS 25–30; and hay, GS 45–85). Straw samples were taken at the same time as grains (GS 92). Details of sampling and analysis are described earlier.

Trials in the United States in 2016

In a total of 17 supervised trials conducted on wheat in the United States during 2016 (AA 160702, Hoi, S.W., 2017a), samples of forage and hay were taken at earlier growth stages (forage, GS 25–30; and hay, GS 45–85). Straw samples were taken at the same time as grains (GS 92).

In the following tables, either chlormequat chloride or chlormequat cation was reported in the "Chloride (Individual)" or "Cation (individual)". As the residue definition is chlormequat cation for both compliance and dietary exposure assessment, the mean concentrations of chlormequat cation were reported in the "Cation (Mean)" column.

Table 10 Residues of chlormequat in wheat forage (F), hay (H) or straw (S) from supervised trials conducted with foliar application of chlormequat chloride (620 SL formulation) in Canada in 2015 and in the United States in 2016 (residue concentrations expressed on an as-received basis)

Notes:

Except where indicated, no residues above the LOQ were found in any of the untreated control samples.

*Trial accidentally oversprayed with an additional application of 1.6 kg ai/ha chlormequat chloride 18 days prior to the trial application.

#Trial flagged by applicant as having abnormally high residues due to extremely low rainfall during the trial, contributing to lowered yields, and use of a durum wheat variety.

Notes:

Except where indicated, no residues above the LOQ were found in any of the untreated control samples. Values in italics have been proportionally adjusted for application rate in order to match the Argentine GAP for wheat.

*Trial accidentally oversprayed with an additional application of 1.6 kg ai/ha chlormequat chloride 18 days prior to the trial application.

#Trial flagged by applicant as having abnormally high residues due to extremely low rainfall during the trial, contributing to lowered yields, and use of a durum wheat variety.

FATE OF RESIDUES IN STORAGE AND IN PROCESSING

Effect of processing on the nature of residue

The 2017 JMPR evaluated the high-temperature hydrolysis study simulating processing procedures, and processing studies on barley, oat, rye and wheat. Chlormequat was not hydrolysed during simulated hydrolysis. The 2017 Meeting estimated processing factors for processed commodities of barley and wheat from harvested grains.

The current Meeting received the results of new processing studies on barley and wheat as follows. Processing factors are estimated in the same way as in 2017 Meeting.

Barley

The 2017 JMPR calculated processing factors for processing of barley: cleaned grain (pot barley), offal (pot barley), pearling dust, pot barley, cleaned grain (malting), offal (malting), steeping water, malt sprouts, malt, spent grain, condensate, flocs, wort, yeast, green beer and beer, for which no data were provided to the current Meeting. The current Meeting received information on processing of barley to bran, pearled barley and flour.

Two trials were conducted in Canada and the United States in 2016 for collecting bulk samples for processing studies (AA 160703, Hoi, S.W., 2017b). Chlormequat chloride (620 SL) was applied once as a foliar spray at a rate of 1.41 kg ai/ha (Canadian trial) or at an exaggerated rate of 2.92 kg ai/ha (United State trial) at GS 32. Barley grain was harvested in duplicate at normal commercial harvest (GS 92) and kept in the processing laboratory at ≤ -12 ºC until processing. Before weighing and cleaning, some grain samples were collected and kept in frozen storage. Grains were processed using laboratory-scale equipment representative of commercial practices to pearled barley, flour and bran, but samples were processed by batch rather than continuous, as in commercial operation. Each grain sample was processed independently.

Barley grain samples were weighed, and their moisture contents were adjusted to 11.0–13.5 percent with drying as necessary. Sampled were cleaned by aspiration to remove grain dust, and screening to separate large and small foreign particles from the barley grain. Cleaned barley was hulled and separated in a laboratory huller into blocked barley and husk (hulls). The resulting husk were discarded.

For production of pearled barley, blocked barley was processed in an abrasive testing mill. After milling, the material was separated with a sifter equipped with a 24-mesh sieve. Material on top of the sieve was pearled barley. Fine material (pearlings) passed through the sieve and was weighed and the discarded. Pearled barley fractions were collected and placed in frozen storage.

For production of flour and bran, the moisture content of the blocked barley was adjusted to 14.5 percent. The sample was mixed for a minimum of 15 minutes and allowed to equilibrate for a minimum of 12 hours before milling. Conditioned blocked barley was fed through the break side of a mill with three break rolls. After passing through the break rolls, the material was fed onto the break sifter

screens (140 and 800 µm). Material passing through the 140 µm screen was break flour. Material not passing through 140 µm screen but passing through the 800 µm screen was middlings. Material exiting the end of sifter was coarse bran. Middlings were then fed into the reduction side of the mill with to reduction rolls. After passing through the reduction rolls, the material was passed over a 160 µm screen. Material passing through the screen was reduction flour. Material remaining on top of the screen was shorts. Shorts were passed through the reduction roll two additional times. Break and reduction flours were combined and mixed for 13–17 minutes. Resulting barley flour fractions were collected and placed into frozen storage.

Coarse bran exiting the break sieve was placed into the reduction side of the mill and conveyed by beater bars over a 128 µm screen. Material passing though the screen was shorts and was added to shorts from the reduction mill. Material passing over the screen and exiting the end was bran. After weighing, shorts were discarded. Resulting bran fractions were collected and placed into frozen storage.

Samples were maintained frozen at <-18 ºC until extraction for a maximum of 316 days. Extracts were analysed within 6 days. Residues of chlormequat chloride were determined by LC-MS/MS method M01-011 with an LOQ of 0.01 mg/kg. Concurrent procedural recoveries were within the acceptable range of 70–110 percent, with relative standard deviation < 20 percent.

The residues in the RAC and processed commodities are shown in Table 13.

Table 13 Residues of chormequat in barley grains and their processed commodities

Trial No. (Variety)	Application		Sample	Chlormequat cation, mg/kg [a]	Processing factor
	kg ai/ha	No			
AA160703-CAN-10 (Spring barley, Newdale)	1.41	1	Grain [b]	1.35, 1.58	-
			Pre-processing grain	1.59, 1.42	1.18, 0.899
			Bran	1.38, 1.48	1.02, 0.937
			Pearled barley	0.425, 0.337	0.315, 0.213
			Flour	0.309, 0.298	0.229, 0.189
AA160703-ND-3 (Spring barley, Tradition)	2.92	1	Grain [b]	1.90, 1.87	-
			Pre-processing grain	1.76, 1.87	0.926, 1.00
			Bran	1.68, 1.71	0.884, 0.914
			Pearled barley	0.425, 0.337	0.224, 0.180
			Flour	0.309, 0.298	0.163, 0.159

Notes:

[a] Chlormequat chloride was analysed and expressed in chlormequat cation equivalents. Each sample was analysed in duplicate, and the mean analytical result is included in the above table.

[b] At harvest (same values as in Table 3)

Wheat

The 2017 JMPR calculated processing factors for wheat offal, epidermis coarse bran, fine bran, straight flour, low grade meal, flour (type 550), total bran (whole meal flour), straight flour (whole meal flour), whole meal flour, Dough and wholegrain bread. The current Meeting received information on processing of wheat grain to aspirated grain fraction, middlings, shorts, flour, germ and bran.

Two trials were conducted in the United States in 2016 for collecting bulk samples for processing studies (AA 160702, Hoi, S.W., 2017a). Chlormequat chloride (620 SL) was applied once as a foliar spray at a rate of 1.13–1.14 kg ai/ha or at an exaggerated rate of 2.23 kg ai/ha at GS 32. Wheat grain was harvested in duplicate at normal commercial harvest (GS 92) and kept frozen in the processing laboratory

at < -1 ºC until processing. Before weighing, cleaning and processing, some grain samples were collected and kept in frozen storage. Grains were processed using laboratory-scale equipment representative of commercial practices. Grain samples were processed to the aspirated grain fraction (AGF), middlings, shorts, flour and bran, germ and bran. Each grain sample was processed independently.

Generation of AGF simulated industrial practices used in terminal elevators to remove grain dust. Samples were processed in batch rather than continuous, as in commercial operation. The bulk grain samples from AA 160702 OK-2 trial with the application at 1.1 kg ai/ha were weighed and their moisture content was determined to be below 13.0 percent. Therefore, no additional drying was carried out. Each sample was placed in a dust generation room containing a holding bin, two bucket conveyors, and a screw conveyor. As the sample moved in the system (120 minutes), the sample was aspirated to remove grain dust. The grain dust moving through the 2360 µm (8 mesh) sieve was combined to produce one AGF sample and the sample was frozen for storage.

Bulk wheat grain samples from AA 160702 OK-2 trial and IA-2 for processing were taken from frozen storage and weighed. The moisture content was determined for each sample. The samples from IA-2 trial showed moisture content above 13.5 percent, they were dried in a tray oven at 54–71 ºC until their moisture content became 11.0–13.5 percent. Then samples were cleaned by aspiration to remove grain dust and screening to separate large and small foreign particles from the cleaned wheat samples.

Cleaned wheat, after adjusting to moisture content of 16 percent for 1–1.5 hours (tempering), was passed through a disc mill and sifted. The germ fraction remained on top of the 30-mesh sieve was aspirated to remove bran. The germ (with endosperm) was passed through a reduction mill. The germ and reduced endosperm were sifted with sieves to separate the germ from the endosperm. The germ fraction was also aspirated again to remove additional bran and milled/sieved to remove additional endosperm. Resulting germ fractions were collected and placed in frozen storage.

The wheat varieties used for processing studies were determined to be intermediate structure (between floury and vitreous)(OK-2) or floury (IA-2) and were tempered accordingly for flour production. Tempered wheat was fed through the spout on the break side of a mill equipped with three break rolls, and then fed onto the break sifter screens (140 µm and 800 µm). Materials passing through the 800 µm screen is middlings. Material not passing though was conveyed to the end of the sifter. Material exiting the end of the sifter is bran (coarse). After sampling, the remaining middlings were poured into the feed hopper of the reduction system (to mill middlings into flour and by-products) with two reduction rolls. After passing through the reduction rolls, the material was fed to the reduction sifter screen of 160 µm. Material passing through the screen is reduction flour. Material not passing through and conveyed to the end of the sifter is shorts (low-grade mill product, containing principally germ and fine bran particles). The break and reduction flours were mixed using a mixer to produce standard mill run flour. Flour fractions were collected and placed into frozen storage.

Bran exiting the break sieve is placed in the reduction side of the mill, but not reduced with the rollers. The coarse bran is conveyed by beater bars over a 128 µm screen. Material passing through the screen is shorts and is added to shorts from the reduction mill. Material passing over the screen and exiting the end is bran. Shorts and bran fractions were collected and placed into frozen storage.

Samples of processed commodities were maintained frozen at < -18 ºC until extraction for a maximum of 310 days. Exacts were analysed within 5 days of extraction. Residues of chlormequat chloride were determined by LC-MS/MS method M01-011. The method was validated with an LOQ of 0.01 mg/kg. Concurrent procedural recoveries were within the acceptable range of 70–110 percent with relative standard deviation below 20 percent.

The residues in the RAC and processed commodities are shown in Table 14.

Table 14 Residues of chormequat in wheat grains and their processed commodities

Trial No. (Variety)	Application		Sample	Chlormequat cation, mg/kg [a]	Processing factor
	kg ai/ha	No			
AA160702-OK-2 (Winter Wheat, Endurance)	1.13	1	Grain [b]	1.58, 1.50	-

Germ	4	4.34, 4.81, 5.36, 6.21	5.1
AGF	2	7.67, 8.48	8.1

APPRAISAL

Chlormequat is a plant growth regulator and usually formulated as the chloride salt. It acts primarily by reducing cell elongation, as well as by lowering the rate of cell division and by inhibiting the synthesis of gibberellins. Chlormequat was evaluated by the Meeting in 1970, 1972, 1994 (T, R), 1997 (R), 1999 (T, for ARfD), 2000 (R) and 2017 (T, R, periodic re-evaluation).

The 2017 Meeting reaffirmed the ADI of 0–0.05 mg/kg bw (established in 1997) and ARfD of 0.05 mg/kg bw (established in 1999). The 2017 Meeting confirmed residue definitions as follows:

The residue definition (for compliance with the MRL and dietary risk assessment) in plant and animal commodities: chlormequat cation.

The residue is not fat soluble.

The Forty-third Session of the Codex Alimentarius Commission (2020) approved the new work proposals including the priority list of pesticides for evaluation by the current Meeting. The priority list included chlormequat for evaluation of uses on barley and wheat.

The current Meeting received new information on: GAP in Canada, analytical methods, supervised residue trials and processing studies, for wheat and barley.

Analytical methods

The 2017 Meeting evaluated two LC-MS/MS methods and one GC method for plant commodities, and a LC-MS/MS method and an ion chromatography method for animal commodities for determining chlormequat chloride.

The current Meeting received information on a new LC-MS/MS method (M01-011), which was similar to the LC-MS/MS method (CEN/TC 275/WG 4N) provided to the 2017 JMPR, for determining chlormequat chloride in the supervised residue trials and processing studies. In this method, a homogenized samples of wheat or barley matrices (grain, leafy parts and processed commodities) were fortified with a known concentration of chlormequat-D4 chloride as internal standard. Residues of chlormequat/internal standard were extracted from the fortified sample with methanol/water (2:1, v/v). An aliquot of extract was then filtered for determination of chlormequat chloride by LC-MS/MS.

At the fortification levels of 0.01 and 0.1 mg/kg in grain, straw, hay, forage and processed commodities of wheat and barley, the mean recoveries were 90–110 percent and the RSD values were < 13 percent. The validated LOQ was 0.01 mg/kg for chlormequat chloride in these matrices.

Stability of pesticide residues in stored analytical samples

The 2017 Meeting evaluated the stability data on chlormequat chloride in cereal matrices (grain, straw and processed matrices) stored at approximately -18 or -20 °C. The proved stable periods cover the sample storage intervals in the residue trials.

Results of supervised residue trials on crops

The Meeting received supervised trial data for chlormequat on wheat and barley conducted in Canada and the United States in 2015–2016.

Cereal grains

Wheat

The 2017 JMPR evaluated supervised trials conducted in France, Germany and Italy on winter, spring and durum wheat against the critical GAP in Argentina (one foliar application at the maximum rate of 2.025 kg ai/ha during BBCH 21–31) and estimated the maximum residue level of 2 mg/kg and STMR of 0.58 mg/kg for wheat.

The GAP of Argentina as shown above is valid at the time of this evaluation and is more critical than GAP of Canada for wheat (one foliar application at a maximum rate of 1.12 kg ai/ha, up to GS 39).

The current Meeting received information on supervised residue trials conducted in Canada (5) and the United States (17) on spring and winter wheat. In the United State trials, grains were harvested with hulls intact while the definition of the subgroup covering wheat states "without husks". The processing study using the wheat grains obtained in the trials conducted in the United States showed that the residues in pre-processing grain and in the grains at harvest were similar with the best estimate of processing factor of 1.0. Therefore, the Meeting decided to use the data on residues in grains with husk from these United State trials for evaluation.

As in each trial in Canada and the United States, a single application made at GS 32 or 39 at rates of 1.0–1.1 kg ai/ha while the GAP in Argentina allows a maximum rate of 2.025 kg ai/ha, the Meeting decided to use the proportionality principle for estimating a maximum residue level and an STMR. Scaled residues were calculated using the formula below.

Scaled residue (mg/kg) = (residue in the trial, mg/kg) × 2.025 (kg ai/ha) / (rate used in the trial, *kg ai/ha*).

After each scaled residue value, the residue found in each trial and respective application rate are indicated in a pair of parentheses, e.g., (residue value in mg/kg, application rate in kg ai/ha).

Residues of chlormequat cation in spring wheat grain in the trials in Canada and the United States with the application at GS 32 approximating the GAP in Argentina with scaling were in rank order (n=14): 0.52 (0.29, 1.119), 0.60 (0.31, 1.050), 0.92 (0.50, 1.105), 0.93 (0.53, 1.090), 1.2 (0.65, 1.102), 1.5 (0.86, 1.132), 1.8 (1.0, 1.110), 1.9 (1.01, 1.092), 2.2 (1.2, 1.090), 2.5 (1.4, 1.130), 2.6 (1.44, 1.124), 3.4 (1.85, 1.102), 3.4 (1.94, 1.149) and 5.3 (1.44, 1.124) mg/kg.

Residues of chlormequat cation in winter wheat grain in the trials in Canada and the United States with the application at GS 39 approximating the GAP in Argentina with scaling were in rank order were in rank order (n=9): 0.47 (0.26, 1.114), 0.77 (0.43, 1.127), 0.94 (0.52, 1.119), 0.99 (0.54, 0.102), 0.99 (0.54, 0.102), 1.4 (0.78, 1.140), 1.5 (0.85, 1.142), 2.3 (1.26, 1.102) and 2.8 (1.54, 1.132) mg/kg.

As the application timing in the trials on spring wheat was GS 32 and on winter wheat was GS 39 while the GAP in Argentina specifies BBCH 31, influence of the application timing (GS 32 vs GS 39) on the residues were tested by Mann-Whitney test, which indicates that there is no significant difference between the two residue populations. The Meeting decided to combine the data from the two different application timing to derive a maximum residue level and STMR.

Combined residue populations of chloride cation from the independent trials (one trial used for comparison above was not independent) in Canada and the United States on spring and winter wheat were in rank order (n=22): 0.47, 0.52, 0.59, 0.77, 0.91, 0.92, 0.94, 0.99, 0.99, 1.2, 1.5, 1.5, 1.8, 1.9, 2.2, 2.3, 2.5, 2.6, 2.8, 3.4, 3.4 and 5.3 mg/kg.

The residue population from the trials in Canada and the United States would lead to a higher estimates of maximum residue level and STMR. Based on the residue population from the Canadian and United States trials, the Meeting estimated a maximum residue level of 7 mg/kg and an STMR of 1.5 mg/kg for wheat.

IESTI calculation for wheat grain and its processed products resulted in a maximum of 110 percent of ARfD for children (consumption of wheat flakes; the processing factor of 0.8 estimated by the 2017 JMPR for the processing of oat its flakes was used). The Meeting therefore used an alternative GAP approach for estimating maximum residue level and STMR, and decided to evaluate the trial data against the GAP of Canada for wheat.

The combined residues of chlormequat cation in wheat grain from the trials in Canadian and United States, matching the GAP in Canada, were in rank order (n=22): 0.26, 0.29, 0.31, 0.43, 0.50, 0.50, 0.52, 0.54, 0.54, 0.65, 0.85, 0.86, 1.0, 1.0, 1.2, 1.3, 1.4, 1.4, 1.5, 1.9, 1.9 and 2.9 mg/kg.

The Meeting estimated a maximum residue level of 4 mg/kg for wheat to replace the previous recommendation of 2 mg/kg. The Meeting estimated an STMR of 0.855 mg/kg.

Barley

The 2017 JMPR evaluated supervised trials conducted in France, Germany and Spain on barley with the application timing at BBCH 32–37 against the critical GAP in the United Kingdom (one foliar application at the maximum rate of 1.65 kg ai/ha during BBCH 25–30) and estimated a maximum residue level of 2 mg/kg and STMR of 0.37 mg/kg for barley.

The current critical GAP was from the United Kingdom for barley which allows one foliar application at the maximum rate of 1.50 kg ai/ha up to and including GS 32. This GAP is similar to GAP in Canada (one foliar application at the maximum rate of 1.43 kg ai/kg up to GS 39).

The current Meeting received information on supervised residue trials conducted in Canada (10) and the United States (10) on barley in 2016 with a single application at GS 32 at rates 1.36–1.50 kg ai/ha.

Residues of chlormequat cation in barley grains in the independent trials conducted in Canada and the United States approximating GAP in the United Kingdom were in rank order (n=10): 0.12, 0.54, 1.0, 1.0, 1.5, 1.5, 1.6, 2.6, 3.3 and 3.9 mg/kg.

The Meeting estimated a maximum residue level of 7 mg/kg and an STMR of 1.5 mg/kg for barley.

IESTI calculation for barley grain and its processed products resulted in a maximum of 110 percent of ARfD for children (consumption of barley flakes; the processing factor of 0.8 estimated by the 2017 JMPR for the processing of oat its flakes was used). The Meeting looked for an alternative GAP that would lead to a smaller estimate of maximum residue level and STMR. GAP of Canada for wheat is similar to GAP of the United Kingdom and it would lead to the same maximum residue level. There was insufficient information available on the validity of GAP contained in the use pattern table of the Evaluation of the 2017 JMPR, the Meeting decided to maintain the previous recommendation of 2 mg/kg (STMR 0.37 mg/kg) until information becomes available on valid GAPs for barley in countries which allow lower application rates than the GAP used by this Meeting to enable the alternative GAP approach.

Residues in animal feeds

Barley forage

The 2017 JMPR received data on barley forage taken after one application of chlormequat at BBCH 32 or 37 in the trials conducted in Europe. However, as feeding cereal grain forage was not common in Europe unless specified on the label, the data were not evaluated.

The critical GAP is in the United Kingdom for barley allows one foliar application up to and including GS 32 at the maximum rate of 1.50 kg ai/ha. Neither the United Kingdom label nor the Canadian label contains restrictions regarding grazing or cutting for feed. Generally, forage can be used for grazing or cutting for feed 2 to 3 weeks after the application of pesticides.

In the trials conducted on barley in Canada and the United States and provided to the current Meeting, barley forage samples were not taken or analysed. The Meeting therefore evaluated the European trials against the critical GAP in the United Kingdom.

Residues of chlormequat cation in forage taken 14 to 21 days after the application in the European trials approximating GAP in Canada were in rank order:

Application at BBCH 37 (n=3):2.9, 3.6 and 12 mg/kg; and

Application at BBCH 32 (n=4): 1.9, 3.3, 3.7 and 6.7 mg/kg.

Mann-Whitney U-test indicates that these two populations were not significantly different. The Meeting combined the residue populations to estimate a median residue and highest residue.

The combined residues of chlormequat cation in barley forage were in rank order (n=7): 1.9, 2.9, 3.3, 3.6, 3.7, 6.7 and 12 mg/kg.

The Meeting estimated a median residue of 3.6 mg/kg (as received) and highest residue of 12 mg/kg (as received) for barley forage.

Wheat forage

The 2017 JMPR evaluated supervised trials conducted in France, Germany and Italy against the critical GAP in Argentina (one foliar application at the maximum rate of 2.025 kg ai/ha during BBCH 21–31) and estimated a median residue of 8.7 mg/kg and highest residue of 25 mg/kg for wheat forage (as received).

The current Meeting received information on residues of chlormequat cation in wheat forage, samples of which were taken at around GS 30 after one application at GS 12–30 at rates of 0.48–0.64 kg ai/ha, much lower rates than in the critical GAP in Argentina. As residues of chlormequat cation at 14–21 DAT were in a range of 0.85–12 mg/kg, the Meeting concluded that the median and highest residues recommended by the 2017 JMPR cover the residues found in wheat forage from the trials in Canada and the United States.

Barley, hay and/or straw

The 2017 JMPR evaluated supervised trials conducted in Europe on barley against the critical GAP in the United Kingdom (one foliar application at the maximum rate of 1.65 kg ai/ha during BBCH 25–30; since expired) and estimated a maximum residue level of 50 mg/kg (dw), and a median residue of 4.15 mg/kg (as received) and highest residue of 30 mg/kg for barley straw and fodder, dry.

Residues of chlormequat cation in barley hay in the trials conducted in the United States approximating the GAP in the United Kingdom were in rank order (n=10):5.4, 14, 18, 19, 33, 36, 39, 46, 48 and 60 mg/kg (as received), or 6.1, 15, 20, 22, 38, 41, 53, 54, and 68 mg/kg (dw).

Residues of chlormequat cation in barley straw in the trials conducted in the United States approximating the GAP in the United Kingdom were in rank order (n=10): 2.4, 3.8, 4.5, 5.9, 6.7, 9.8, 14, 16, 17, and 30 mg/kg (as received) or 2.8, 4.3, 5.1, 6.7, 7.6, 11, 15, 18, 19 and 34 mg/kg (dw).

The residue population of hay from the United States trials would lead to a higher maximum residue level, and median and highest residue than the residue population of straw and those estimated by the 2017 JMPR based on the European trials. Using the residue population of hay from the United States trials, the Meeting estimated a maximum residue level of 150 mg/kg (dw) for barley hay and/or straw and withdrew the previous recommendation for barley straw and fodder, dry of 50 mg/kg, dw. The Meeting also estimated a median residue and highest residue of 34.5 mg/kg and 73 mg/kg (as received) for barley hay and 8.25 mg/kg and 32 mg/kg (as received) for barley straw.

Wheat hay and/or straw

The 2017 JMPR evaluated residue trials on wheat conducted in Europe against the critical GAP in Argentina and estimated a maximum residue level of 80 mg/kg (dw), median residue of 13 mg/kg (as received) and highest residue of 55 mg/kg for wheat straw and fodder, dry.

Residues of chlormequat cation in wheat hay from the trials in Canada and the United States approximating the GAP in Argentina after scaling were in rank order (including one pair of not-independent trials for comparison of application timing):

Application at GS 39 (n=9): 28 (15.6, 1.114), 28 (15.6, 1.114), 34 (18.3, 1.102), 34 (18.6, 1.119), 42 (23.5, 1.127), 67 (36.5, 1.102), 70 (39.5, 1.142), 74 (41.6, 1.132) and 80 (43.4, 1.102) mg/kg; and

Application at GS 32 (n=14): 0.64 (0.36, 1.13), 6.9 (3.73, 1.105), 7.4 (4, 1.090), 21 (11.2, 1.119), 30 (16.7, 1.132), 37 (20, 1.102), 41(21, 1.050), 43 (23.9, 1.119), 55 (29.5, 1.092), 59 (32.7, 1.124), 62 (33.6, 1.102), 63 (36, 1.149), 64 (35, 1.111) and 111 (0, 1.090) mg/kg.

Mann-Whitney U-test indicates that these two data populations are not significantly different.

The combined data set from independent trials in Canada and the United States were in rank order (n=22): 0.64, 6.9, 7.4, 21, 28, 30, 34, 34, 37, 41, 42, 43, 55, 59, 62, 63, 64, 67, 70, 74, 80 and 111mg/kg (as received) or 0.73, 7.8, 8.4, 23, 32, 34, 38, 38, 42, 46, 48, 49, 62, 67, 70, 73, 72, 76, 80, 85, 91 and 127 mg/kg (dw).

Residues of chlormequat cation in wheat straw from the trials in Canada and the United States approximating GAP in Argentina after scaling were:

Application at GS 39 (n=9): 3.8 (2.09, 1.127), 14 (7.44, 1.114), 16 (9.07, 1.119), 17 (9.42, 1.142), 20 (11.0, 1.132), 21 (11.3, 1.102), 22 (11.9, 1.102), 32 (18, 1.140) and 40 (21.5, 1.102) mg/kg

Application at GS 32 (n=14):7.4 (4.0, 1.090), 10 (5.4, 1.050), 15 (7.93, 1.105), 17 (9.46, 1.132), 18 (9.76, 1.119), 20 (11, 1.130), 23 (12.6, 1.102), 23 (12.6, 1.102), 24 (13.7, 1.149), 35 (19.6, 1.124), 36 (19.9, 1.119), 37 (20.1, 1.102), 45 (24, 1.109) and 55 (30, 1.110) mg/kg,

Mann-Whitney U-test indicates that these two populations are not significantly different. The Meeting decided to combine these datasets.

The combined data set from independent trials in Canada and the United States were in rank order (n=22): 3.8, 7.4, 10, 14, 15, 16, 17, 17, 18, 20, 20, 21, 22, 23, 23, 24, 35, 36, 37, 40, 45 and 55 mg/kg

(as received) or 4.3, 8.4, 11, 16, 17, 18, 19, 19, 20, 23, 23, 24, 25, 26, 26, 27, 40, 41, 42, 45, 51 and 62 mg/kg. (dw).

The residue population of hay from trials conducted in Canada and the United States would lead to a higher maximum residue level than that from the residue population in straw from the Canadian and United States trials and the previous recommendation made in 2017 based on straw. Using the data population of residues in hay, the Meeting estimated a maximum residue level of 200 mg/kg (dw) for wheat hay and/or straw. The previous recommendation on wheat straw or fodder, dry (80 mg/kg, dw) was withdrawn. The Meeting estimated a median residue and highest residue of 42.5 and 117 mg/kg (as received) for wheat hay and 20.5 and 55 mg/kg (as received) for wheat straw.

Since barley hay/straw and wheat hay/straw are not distinguishable in trade, the Meeting agreed that the higher maximum residue level of wheat of 200 mg/kg should also apply to barley hay and/or straw.

Fate of residues during processing

Processing

The Meeting received information on processing of wheat to bran, flour, middlings, shorts, Germ and aspirated grain fractions; and of barley to bran, pearled barley and flour. For the processing studies, samples of wheat and barley grains were obtained from the supervised trials with the applications at the critical GAP rate and its 2-fold rate, and chlormequat cation was analysed. Processing factors of wheat to its processed commodities and barley to its processed commodities are summarized below together with the processing factors derived by the 2017 JMPR for additional processed commodities. Using the best estimates of processing factors and the STMR values for wheat and barley, the STMR-P values were calculated for processed commodities of wheat and barley. For estimation of acute dietary exposure from flakes of wheat and barley, the Meeting used the processing factor of 0.80 for the processing of oat to its flakes estimated by the 2017 JMPR.

Processing factors of chlormequat for wheat to its processed commodities and barley to its processed commodities are shown below.

Table 16 Calculated STMR-Ps for processed food and feed commodities

Commodity (Food/feed)	N	Processing factor		STMR/ STMR-P/ Median
		Individual	Best estimate	
Wheat grain at harvest	4	-	-	0.855
Bran	4+6	1.15, 1.16, 2.22, 2.38 2.5, 2.8, 2.9, 3.1, 3.4, 4.6	2.65	2.3
Flour	4+5	0.086, 0.089, 0.113, 0.115 0.19, 0.28, 0.29, 0.30, 0.41	0.19	0.16
Germ	4	4.34, 4.81, 5.36, 6.21	5.1	4.3
Wholemeal [a]	6	0.86, 0.91, 1.0, 1.0, 1.1, 1.4	1.0	0.855
Wholemeal bread	6	0.49, 0.51, 0.53, 0.55, 0.63, 0.79	0.54	0.46
Barley grain at harvest	4	-	-	0.37
Bran	4	0.884, 0.914, 0.937, 1.02	0.93	0.34
Pearled barley	4+5	0.180, 0.213, 0.224, 0.315 0.06, 0.8, 0.9, 1.0, 1.0	0.32	0.12
Flour	4	0.159, 0.163, 0.189, 0.229	0.18	0.066
Malt	5	0.69, 0.9, 0.9, 0.9, 1.0	0.9	0.33
Beer	5	0.015, 0.1, 0.2, 0.2, 0.2	0.2	0.074
Wheat grain at harvest	4	-	-	0.855

Commodity (Food/feed)	N	Processing factor		STMR/ STMR-P/ Median
		Individual	Best estimate	
Middlings	4	0.33, 0.34, 0.73, 0.84	0.54	0.46
Shorts	4	0.47, 0.48, 1.6, 1.8	1.0	0.89
AGF	2	7.67, 8.48	8.1	6.9
Barley grain at harvest	4	-	-	0.37
Spent grain	4	0.01, 0.02, 0.02, 0.03	0.02	0.007

Notes:

NB: Values in italics were from the 2017 JMPR.

[a] The processing factors calculated separately for wheat wholemeal flour and wholemeal in the 2017 JMPR Report were combined under wheat "wholemeal".

Based on the processing factors and maximum residue level of wheat grain of 4 mg/kg, the Meeting estimated maximum residue levels for wheat bran (unprocessed) at 10 mg/kg, replacing the previous recommendation of 7 mg/kg, and for wheat germ at 20 mg/kg.

Residues in animal commodities

Livestock dietary burden

Dietary burden calculations for cattle and poultry are provided below. The dietary burdens were estimated using the OECD diets listed in Appendix IX of the 2016 edition of the FAO Manual.

Table 17 Estimated maximum and mean dietary burdens of farm animals

	Animal dietary burden: chlormequat, ppm of dry matter diet							
	United States-Canada		European Union		Australia		Japan	
	max	Mean	max	Mean	max	Mean	Max	Mean
Beef cattle	22.4	9.72	32.6	12.9	133.0	48.3	3.22	3.22
Dairy cattle	28.5	11.5	32.6	12.9	99.8	38.8	3.05	2.78
Poultry broiler	3.17	3.17	2.00	2.00	1.92	1.92	0.34	0.34
Poultry layer	3.17	3.17	15.3	6.83	1.88	1.88	1.47	1.47

The calculated highest maximum dietary burden was 133.0 ppm (chlormequat cation) based on the Australian diet, which is more than 30 percent higher than the highest dose rate in the cattle feeding study. Therefore, it was not possible to estimate residues in mammalian commodities at the highest maximum burden.

Chlormequat was registered in Australia and, according to the current product labels, approved for use on wheat with one application at a maximum rate of 0.758 kg ai/ha from Z 25 to Z 31, but not for other cereal grains. Grazing and cutting for stock feed are not allowed before 21 days after the application. Most of forage and hay data and all of straw data used for estimating median and highest residue were from the samples taken at 20 days or later after application in the trials. Taking into consideration the registration of chlormequat for wheat in Australia, no importation of hay or straw into Australia, and that the application timing in the GAP in Australia is comparable to the GAP of Argentina, the Meeting decided to apply the proportionality principle to the median and highest residue values of wheat feed items for re-calculating the maximum and mean dietary burden based on the Australian diet.

Based on the maximum rate of 2.025 kg ai/ha in Argentinian GAP for wheat and that of 0.758 kg ai/ha in the Australian GAP for wheat, the median and highest residue in wheat derived feed were scaled for the purpose of calculating dietary burdens based on the Australian diet. The scaled

median and highest residue were: 15.9 and 28.8 mg/kg in wheat hay, 7.67 and 20.6 mg/kg for wheat straw, and 3.26 and 9.36 mg/kg for wheat forage.

After recalculation using adjusted median and highest residue for wheat and removing forage, hay and straw derived from other cereal grains, animal dietary burdens based on the Australian diet, together with other diets, were as follows.

Table 18 Recalculated maximum and mean dietary burdens of chlormequat (for adjustment for the Australian diet)

	United States-Canada		European Union		Australia		Japan	
	Max	Mean	max	Mean	max	Mean	Max	Mean
Beef cattle	22.4	9.72	32.6	12.9	37.4❶	18.1❷	3.22	3.22
Dairy cattle	28.5	11.5	32.6❸	12.9❹	26.0	12.3	3.05	2.78
Poultry broiler	3.17	3.17	2.00	2.00	3.10	3.10	0.34	0.34
Poultry layer	3.17	3.17	15.3❺	6.83❻	2.99	2.99	1.47	1.47

Notes:

❶Highest maximum dietary burden for beef cattle suitable for estimation of maximum residue levels for mammalian meat, fat and offal.

❷Highest mean dietary burden for beef cattle suitable for estimation of STMRs for mammalian meat, fat and offal.

❸Highest maximum dietary burden for dairy cattle suitable for estimation of maximum residue level for milks.

❹Highest mean dietary burden for dairy cattle suitable for estimation of STMRs for milks.

❺Highest maximum dietary burden for broiler and layer suitable for estimation of maximum residue levels for poultry meat, fat, offal, and eggs.

❻Highest mean dietary burden for broiler and layer suitable for estimation of STMRs for poultry meat, fat, offal and eggs.

Animal commodity maximum residue levels.

Mammals

The highest maximum dietary burden of chlormequat cation for dairy cattle was 32.6 ppm and the highest mean dietary burden was 12.9 ppm.

	Feed level (ppm, cation)	Residue in milk (mg/kg as the cation)
MRL		
Feeding study	28	0.15
	93	0.26
Dietary burden (max) & highest residue	32.6	0.16
STMR		
Feeding study	28	0.15
Dietary burden (mean)	12.9	0.069

The Meeting estimated a maximum residue level of 0.2 mg/kg for milks to replace the previous recommendation of 0.3 mg/kg, and an STMR of 0.069 mg/kg for milks.

The highest maximum dietary burden of chlormequat cation for beef cattle was 37.4 ppm and the highest mean dietary burden was 18.1 ppm.

Table 19 Residues in tissues from cattle dosed with chlormequat in the diet

	Feed level (ppm, cation)	Residues (mg/kg, as chlormequat cation) Meat	Fat	Liver	Kidney
MRL					
Feeding study	28	0.085	0.040	0.078	0.36
	93	0.085 [a]	0.078	0.39	0.82
Dietary burden, HR	37.4	0.085	0.043	0.11	0.40
STMR					
Feeding study	28	< 0.04	< 0.04	0.062	0.31
Dietary burden, STMR	18.1	< 0.04	< 0.04	0.036	0.20

Notes:

[a] This value is from the dose level of 28 ppm as the cation. A higher highest residue was observed among the cows fed at this level than those fed 93 ppm as the cation.

The Meeting estimated maximum residues level of 0.2 mg/kg for meat from mammals other than marine mammals, confirming the previous recommendation, and an STMR and an HR of 0.04 and 0.085 mg/kg. respectively.

The Meeting estimated a maximum residue level of 0.1 mg/kg for mammalian fat, confirming the previous recommendation, and an STMR and an HR of 0.04 and 0.043 mg/kg, respectively.

Based on the residue data for kidney, higher than those for liver, the Meeting estimated a maximum residue level of 0.5 mg/kg for edible offal, mammalian, replacing the previous recommendation of 1 mg/kg. The Meeting estimated an STMR and an HR of 0.036 and 0.11 mg/kg for liver, and 0.20 and 0.40 mg/kg for kidney, respectively.

Poultry

The highest maximum dietary burden of chlormequat cation for poultry was 15.3 ppm and the highest mean dietary burden was 6.83 ppm. No residues of chlormequat cation above the LOQ (0.05 mg/kg as chlormequat chloride) were found at the highest feeding level of 46.5 ppm (as the cation) in meat or fat. Therefore, the Meeting estimated maximum residue levels of 0.04(*) mg/kg for poultry meat and fat confirming the previous recommendations. The Meeting estimated STMR and HR for meat and fat of 0.04 mg/kg.

Table 20 Residues in eggs and tissues from poultry dosed with chlormequat in the diet

	Feed level (ppm, cation)	Residues in liver (mg/kg, cation)	Residues in eggs (mg/kg, cation)
MRL			
Feeding study	14.0	0.078	0.093
	46.5	0.26	0.12
Dietary burden, HR	15.3	0.085	0.094
STMR			
Feeding study	4.65	0.04	< 0.04
	14	0.054	0.078
Dietary burden, STMR	6.83	0.043	0.049

The Meeting estimated a maximum residue level of 0.2 mg/kg for poultry edible offal, replacing the previous recommendation, and an STMR and an HR of 0.043 and 0.085 mg/kg respectively. The

Meeting also estimated a maximum residue level of 0.2 mg.kg for eggs, replacing the previous recommendation, and an STMR and an HR of 0.049 and 0.094 mg/kg respectively.

RECOMMENDATIONS

On the basis of the data from supervised trials, the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessments.

Definition of the residue (for compliance with the MRL and dietary exposure assessment) in plant and animal commodities: *chlormequat cation*.

The residue is not fat soluble.

Table 21 Maximum residue level recommendations for chlormequat

CCN	Commodity	Recommended Maximum residue level (mg/kg)		STMR or STMR-P mg/kg	HR or HR-P mg/kg
		New	Previous		
GC 0640	Barley	2	2	0.37	-

CM 0640	Barley, pearled (pot barley)			0.12	
CF 3511	Barley, flour			0.066	
	Barley malt			0.33	
	Barley beer			0.074	

Notes:

(ar) – as received; (dw) – dry weight.

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The International Estimated Daily Intakes (IEDIs) of chlormequat cation were calculated for the 17 GEMS/Food cluster diets using STMRs/STMR-Ps estimated by the current Meeting. The results are shown in Annex 3 of the 2022 Report.

The ADI for chlormequat chloride is 0–0.05 mg/kg bw/day (or 0–0.0388 mg/kg bw/day expressed as chlormequat cation). The calculated IEDIs for chlormequat cation were 1–20 percent of the maximum ADI for chlormequat expressed as cation. The Meeting concluded that the long-term dietary exposure to residues of chlormequat cation, when chlormequat chloride is used in accordance with GAPs that have been considered by JMPR, are unlikely to pose a public health concern.

Acute dietary exposure

The International Estimated Short-Term Intakes (IESTIs) of chlormequat cation were calculated for food commodities using HRs/HR-Ps or STMRs/STMR-Ps estimated by the current Meeting. The results are shown in Annex 4 to the 2022 Report.

The ARfD for chlormequat chloride is 0.05 mg/kg bw (or 0.0388 mg/kg bw expressed as chlormequat cation).

The calculated IESTIs for chlormequat ranged from 0–60 percent of the ARfD for children, and 0–30 percent for the general population. The Meeting concluded that the acute dietary exposure to residues of chlormequat cation, when chlormequat chloride is used in accordance with GAPs that have been considered by JMPR, are unlikely

DIAZINON (022)

First draft prepared by Dr J Cudmore, Chemicals Regulation Division of the Health and Safety Executive, United Kingdom

EXPLANATION

Diazinon is a contact organophosphorus insecticide with a wide range of insecticidal activity. It is effective against sucking, chewing and boring insects, including soil-living insects. Diazinon has been evaluated on numerous occasions by the JMPR commencing in 1963. The most recent periodic review was in 1993. Following public health concerns identified by the International Agency for Research on Cancer (IARC), the JMPR in 2016 evaluated all previously considered toxicological data in addition to new studies. The 2016 JMPR recommended an ADI of 0–0.003 mg/kg bw and an ARfD of 0.03 mg/kg bw. Diazinon was scheduled at the Fifty-first Session of the CCPR (2019) for Periodic Review for residues by the 2020 JMPR and re-scheduled for the 2022 JMPR.

The Meeting received information from the manufacturer on physical and chemical properties, animal and plant metabolism, rotational crop studies, environmental fate in soil, analytical methods, storage stability, use patterns, supervised residue trials, processing studies and livestock feeding studies.

IDENTITY

ISO Common Name	Diazinon	
Chemical name	IUPAC:	*O,O*-diethyl-*O*-(2-isopropyl-6-methylpyrimidin-4-yl)phosphorothioate
	CAS:	*O,O*-diethyl-*O*-[6-methyl-2-(1-methylethyl)-4-pyrimidinyl]phosphorothioate
CIPAC No.	15	
CAS No	333-41-5	
Structural formula		
Molecular formula	$C_{12}H_{21}N_2O_3PS$	
Molecular mass	304.34 g/mol	

PHYSICAL AND CHEMICAL PROPERTIES

The physical and chemical properties of diazinon are summarised in Table 1.

Table 1 Physical and chemical properties of the pure and technical grade diazinon

Property	Results	Test material purity and specification	Reference
Appearance and odour	Pale yellow liquid at 20 °C Faint organophosphate odour	Pure (99.3%)	R-14219
	Yellow liquid at 20 °C	Technical (96%)	R-14213
Freezing point	<-25 °C	Pure (99.3%)	R-14219
Vapour pressure	1.197×10^{-2} Pa at 25 °C	Pure (99.4%)	R-2093
Volatility	Henry's Law constant = 6.1×10^{-2} Pa m^3 mol^{-1}	Not specified	R-2251
Octanol/water partition coefficient	Log P_{ow} = 3.30 at 25 °C	Pure, radiolabelled (99% radiochemical purity)	R-2095
	Log P_{ow} = 3.81 at 25 °C, pH 6.58	Pure (97.8%)	R-4599
	Log P_{ow} = 3.69 at 24 °C	Technical (96.3%)	R-6502
Solubility in water	0.0655 g/L in water at 25 °C	Technical (purity not stated)	R-6500
	0.060 g/L at pH 7 and 22 °C	Pure (99.4%)	R-2094
	0.0595 g/L in pure water and 25 °C. Solubility in water is not pH-dependent at pH 5, 7 and 9.	Pure (97.8%)	R-4597
Surface tension	49.5 mN/m (90 percent saturated solution)	Pure (99.3%)	R-14219
Solubility in organic solvents	>9000 g/L in acetonitrile, acetone, methanol, carbon tetrachloride, heptane, toluene and n-octanol at 25 °C	Technical (93%)	R-4628
	>2000 g/L in methanol and hexane at 25 °C	Technical	R-6500
Explosive properties	No thermal or mechanical (shock) sensitivity exhibited. Not explosive.	Technical (96%)	R-14213
Hydrolysis in water	pH / Temp. (° C) / K_{obs} ($days^{-1}$) / DT_{50} (days)	Not specified	R-228

Formulation

Formulations of diazinon are available as wettable powders, emulsion, oil in water and emulsion concentrates.

Formulation type	Active substance content	Application type
WP (Wettable Powder)	400 g/kg	Foliar applications
EW (Emulsion, oil in water)	500 g/L	Foliar applications
EC (Emulsion concentrate)	600 g/L	Foliar applications

METABOLISM AND ENVIRONMENTAL FATE

Radiolabel Position

The fate and behaviour of diazinon in animals, plants and the environment were investigated using ^{14}C - diazinon labelled in the pyrimidine ring as shown in Figure 1.

^{14}C-labelled diazinon

A conjugate of GS-31144§ (postulated to be a malonyl glucose conjugate)	2-(2-hydroxyisopropyl)-6-methyl-4-pyrimidinol malonyl glucose conjugate		Beans Potatoes Lettuce

Notes:

† The structure of the two metabolites G and H were not fully elucidated. The mass spectral analysis did not confirm the positions of the hydroxyl groups. The metabolites were susceptible to hydrolysis with β-glucosidase but no identification work was undertaken on the aglycone.

§ The identity of the conjugates were not established. The aglycones released from enzymatic or acid hydrolysis were confirmed.

Plant metabolism

The meeting received information on metabolism of diazinon in apples, green beans, sweet corn, lettuce and potatoes.

Apples (Study ABR-89058)

Apple trees (variety Empire hybrid) grown outdoors in a loam soil were treated with [^{14}C]-pyrimidine-diazinon (specific activity = 9.8 µCi/mg, radiochemical purity 98 percent).

The test material was formulated as a WG formulation and applied three times. The first application was made when the buds were in the early tight cluster stage (approximately BBCH 55) at a rate of 3.36 kg ai/ha. This application was split between a soil application (3.024 kg ai/ha) and a foliar application to a single branch (0.336 kg ai/ha). The second and third applications were foliar applications to the same branch made when the apples were 5 and 7.5 cm in diameter at a rate of 10.09 kg ai/ha. The second application was made 104 days after the first application and the third application was made 29 days later.

Mature apples were harvested 14 days after the last treatment. Foliage samples were also collected. All samples were stored frozen at ≤ -15 °C for up to 15 months prior to analysis. The total radioactivity in the samples was determined by combustion with LSC. Leaves, peel and pulp were extracted twice with methanol: Water (9:1,v/v) and the extracts were then partitioned with ethyl acetate. Characterisation and identification of the organosoluble and aqueous extracts was performed using 2D-TLC and/or HPLC analysis with mass spectral identification on specific metabolites. Extracts were also treated with ß-glucosidase for 12 hours at 37 °C to support the identification of the glucose conjugates.

The total radioactive residues and the distribution of radioactivity in apples are shown in Table 3. The TRR ranged from 0.126 mg eq/kg (apple pulp) to 51.1 mg eq/kg (apple leaves). The TRR was higher in apple peel (3.44 mg eq/kg) compared to apple pulp (0.126 mg eq/kg).

Solvent extractabilities with methanol: water (9: 1, v/v) ranged from 89.7 percent TRR for peel to 91.9 percentTRR for leaves. The majority of the extracted residue was found to be organosoluble.

Table 3 TRR and distribution of radioactivity in apple treated with ^{14}C-diazinon

Fraction	Apple leaves		Whole apple		Apple peel		Apple pulp

Notes:

† The values for whole apples were estimated by multiplying the mg/kg values in the peel by 0.351 and mg/kg values in the flesh by 0.649 and summing the two values. The percent TRR values have been calculated from these mg/kg estimates.

§ B2 is an unidentified metabolite.

No information is given in the study on the number of individual metabolites found in this fraction.

**Includes metabolites that have been quantified together. It does not include fractions that contain identified and unidentified metabolites.

Beans with pods (study ABR-90040)

Beans with pods (variety provider) grown outdoor in a loam soil were treated with [^{14}C]-pyrimidine-diazinon (specific activity = 9.8 µCi/mg, radiochemical purity 98 percent).

The test material was formulated as an EC formulation and applied three times. The first application was made at a rate of 4.48 kg ai/ha applied pre-emergence 1 day after sowing. A further two foliar applications were made at a rate of 1.4 kg ai/ha. The first foliar application was made 34 days after the pre-emergence use and the second foliar application was made 15 days later.

A sample of vines was taken 31 days after the pre-emergence application (i.e. 3 days before the first foliar application). A sample of vines with beans was taken 7 days after the first foliar application. Samples of beans with pods and vines were taken 14 days after the last application, which is stated to represent crop maturity. The growth stages are not stated.

Samples were stored frozen at ≤ -15 °C for up to 21 months prior to analysis.

The total radioactivity in the samples was determined by combustion with LSC. Vines and beans were extracted twice with methanol: Water (9:1, v/v) and the extracts were then partitioned with ethyl acetate. Characterization and identification of the organosoluble and aqueous extracts was performed using 2D-TLC and/or HPLC analysis with mass spectral identification on specific metabolites. Proton NMR was used to assist in the structural elucidation of metabolite E_2. Extracts were also treated with ß-glucosidase for 12 hours at 37 °C to support the identification of the glucose conjugates.

The total radioactive residues and the distribution of radioactivity in beans are shown in Table 5.

The TRR ranged from 0.425 mg eq/kg (vines harvested 32 DAFT) to 3.53 mg eq/kg (vines harvested 14 DALA). The solvent extractabilities with methanol: water (9:1, v/v) ranged from 54.3 percent TRR for vines harvested 32 DAFT to 89.2 percent TRR for vines with beans. The majority of the extracted radioactivity was found to be aqueous soluble.

Table 5 TRR and distribution of radioactivity in beans treated with ^{14}C-diazinon

Fraction	Vines harvested 32 DAFT		Vines and beans harvested 41 DAFT		Beans with pods harvested 14 DALA		Vines harvested 14 DALA

Notes:

DAFT: Days after first treatment.

DALA: Days after last treatment.

The identification/characterization of residues in the crop fractions are outlined in Table 6.

The identification of metabolites in the vines and beans harvested 41 days after sowing was not reported. It is stated that the identification/characterization was unsuccessful, and this was attributed to co-extraction of sugars and multiple overlapping of components in the HPLC analysis.

Diazinon was not found in the vine samples. In beans, harvested 14 DALA, diazinon was found at 2.1 percent TRR (0.01 mg/kg). In a number of cases the individual levels of the metabolites were not determined.

For vines, harvested 32 DAFT, the highest TRR was 17.3 percent TRR (0.07 mg eq/kg) which was a mixture of two glucose conjugates and an unknown metabolite. The metabolites CL-XIX-29 and a glucose conjugate of GS-31144 occurred at 15.5 percent TRR (0.07 mg eq/kg). All other metabolites identified occurred at levels below 10 percent TRR.

In vines, harvested 14 DALA, the metabolites CL-XIX-29 and a glucose conjugate of GS-31144 were found at a level of 27.5 percent TRR (0.97 mg eq/kg), an unknown metabolite occurred at 19.5 percent TRR (0.69 mg eq/kg) and two glucose conjugates were found at a level of 12.5 percent TRR (0.44 mg eq/kg). All other metabolites identified were < 10 percent TRR.

In beans, harvested 14 DALA, the major metabolites/fractions were G-27550 (26.7 percent TRR, 0.12 mg eq/kg) and a mixture of two glucose conjugates of the trihydroxy pyrimidinyl moiety and an unknown metabolite (19.5 percent TRR, 0.09 mg eq/kg). All other metabolites identified were < 10 percent of the TRR.

Number of individual metabolites not reported.

** Includes metabolites that have been quantified together.

In a supplementary study, retained crop fractions of beans with pods (14 DALA) and vines (14 DALA) were subject to analysis after 69 months of freezer storage. The total radioactivity in the samples was determined by combustion with LSC. The samples were extracted with methanol: water (9: 1, v/v) and partitioned with ethyl acetate.

The HPLC profiles of a mature bean sample and a mature vine sample, extracted after 19 months of storage, were compared to the HPLC profiles of a mature bean sample and mature vine sample extracted after 69 months of storage. The HPLC profiles of the extracts from 19 months of storage compared to 69 months of storage were qualitatively similar. For the vine samples, the percent TRR of the main fractions were quantitatively similar. For the bean samples, the percent TRR of the main fractions were quantitatively similar, except the region containing the glucose conjugates of CL-XIX-29 and JAK-111-57 was no longer present.

The TRR determined by combustion and the solvent extractabilities for the bean samples extracted after 69 months of storage are shown in Table 7.

Table 7 TRR and distribution of radioactivity in beans treated with ^{14}C-diazinon

Fraction	Beans with pods harvested 14 DALA		Vines harvested 14 DALA	
	Percent TRR	mg eq/kg	Percent TRR	mg eq/kg
TRR	100	0.509	100	3.755
Methanol: water (9:1, v/v)	74.9	0.381	78.2	2.94
Aqueous phase	50.1	0.255	68.4	2.57
Organic phase	24.8	0.126	9.78	0.367
Non-extracted	25.1	0.128	21.8	0.819

Notes:

DALA: Days after last treatment.

After extraction with methanol: water and partitioning with ethyl acetate, the aqueous fractions were subject to sample clean-up, derivatization and enzyme hydrolysis steps in order to aid the identification of residues. Separate fractions were treated with cellulase (12 hours at 37 °C), ß-glucosidase (12 hours at 37 °C), HCl (6 M HCl for 1 hour at 95 °C), acetic anhydride: pyridine (90: 10 v/v, room temperature for 12 hours) and 3 M HCl in butanol (1 hour at 95 °C). Metabolites were identified using TLC, HPLC, MS and H-NMR.

The metabolites in mature beans and vines were identified as G-27550, which co-chromatographed with an unknown metabolite (B_2), GS-31144, JAK-III-57, CL-XIX-29 and various conjugates. The results are summarized in Table 8.

In mature beans, the main fraction represented 20.3 percent TRR. This fraction contained conjugates of JAK-IV-23, JAK-III-57, G-27550 and GS-31144 as well as JAK-IV-23 and two unknown metabolites. The individual levels were not stated. Treatment with cellulase released JAK-IV-23 and the

acid hydrolysis treatment released GS-31144 and G-27550. Based on the characterization (derivatization via acetylation) and a comparison to descriptions in the literature, it was postulated that the conjugates of JAK-IV-23, GS-31144 and G-27550 were malonyl glucose conjugates. No further details were provided.

All other fractions in mature beans were present at levels not exceeding 9.3 percent TRR (0.047 mg eq/kg).

In vines, the main fraction represented 27 percent TRR. The two metabolites identified in this fraction were CL-XIX-29 and a conjugate of GS-31144. Two further fractions accounted for over 10 percent of the TRR. A fraction of 17.4 percent TRR, that contained conjugates of JAK-IV-23, JAK-III-57, G-27550 and GS-31144 as well as two unknowns, and a fraction of 10.9 percent TRR that contained a conjugate of CL-XIX-29 and a conjugate of JAK-III-57.

All other fractions for the vines were present at levels not exceeding 6.4 percent TRR (0.239 mg eq/kg).

1 percent NaCl	3.0	0.015
Organic	0.5	0.003
Aqueous	1.8	0.009
Cellulase hydrolysis	8.5	0.044
Organic	0.1	0.000
Aqueous	6.7	0.034
Protease hydrolysis	2.9	0.015
Final PES	6.4	0.033

Notes:

†The characterization and identification work was undertaken on an additional subsample of green beans.

The extraction procedures individually released 2.1–8.5 percent TRR (0.011–0.044 mg eq/kg), leaving 6.4 percent TRR (0.033 mg eq/kg) in the final post-extraction solids.

The methanol/water and NaCl organosoluble fractions were analysed by 2D-TLC. In the methanol/water organosoluble fraction, parent diazinon and G-27550 were present as the major metabolites, whilst the aqueous fraction comprised of polar metabolites. The NaCl organosoluble fraction was found to contain G-27550 and GS-31144 as the major components. The individual metabolite levels were not quantified and the solubilised radioactivity following enzyme hydrolysis was too viscous for chromatographic profiling.

Sweet corn (Study ABR-89057)

Sweet corn (variety not stated) grown in a greenhouse was treated with [^{14}C]-pyrimidine-diazinon (specific activity = 9.8 µCi/mg, radiochemical purity 98 percent).

The test material was formulated as an EC formulation and applied three times. The first application was made pre-emergence at a rate of 4.48 kg ai/ha applied the day of sowing. The second and third applications were foliar applications at a rate of 3.5 kg ai/ha. The second application was made 50 days after the pre-emergence application and the third application was made 24 days later.

Samples of crop fractions were taken 72 DAFT (days after first treatment) i.e. 2 days before the second foliar application. Further crop fractions were taken 14 days after the last application. The growth stages are not stated.

The samples were stored frozen for up to 18 months prior to analysis.

The total radioactivity in the samples was determined by combustion with LSC. Samples were extracted twice with methanol: Water (9:1, v/v) and the extracts were then partitioned with ethyl acetate. Extracts from the mature forage samples were also treated with ß-glucosidase for 12 hours at 37 °C to support the identification of the glucose conjugates extracted. PES were also subjected to enzymatic hydrolysis; a sample was incubated at 37 °C with sodium acetate buffer with amyloglucosidase.

Characterization and identification was performed using 2D-TLC and/or HPLC analysis with mass spectral identification on specific metabolites. The total radioactive residues and the distribution of radioactivity in sweet corn fractions are shown in Table 10.

The TRR ranged from 0.087 mg eq/kg for the ears harvested 72 DAFT to 3.89 mg eq/kg for forage harvested 14 DALA. The solvent extractabilities with methanol: water (9:1, v/v) ranged from 20.3 percent TRR for stalks harvested 72 DAFT to 74.5 percent TRR for forage harvested 14 DALA. The majority of the radioactivity was shown to be aqueous soluble.

Notes:

DALA: Days after last application.

Diazinon was identified in forage harvested 72 DAFT at a level of 0.5 percent TRR (0.01 mg/kg) and in forage harvested 14 DALA at 1.8 percent TRR (0.07 mg/kg). In both forage and stalks harvested 72 DAFT, all identified metabolites were < 10 percent TRR. The highest TRR was identified as G-27550 which occurred at a level of 7 percent and 7.7 percent TRR in forage and stalks respectively. For forage harvested 22 DAFT only 9.5 percent TRR was identified and 30.9 percent of the TRR remained

unextracted. For stalks harvested 22 DAFT, only 10.1 percent TRR was identified and 79.7 percent of the TRR remained unextracted.

For forage harvested 14 DALA, G-27550 was identified as a major metabolite (10.8 percent TRR, 0.42 mg eq/kg).

For cob and grain, of the metabolites identified none exceeded 10 percent TRR. The non-extracted residue was 52.5 percent and 73.6 percent TRR for mature cob and mature grain respectively.

Treatment of the PES from grain with amyloglucosidase solubilized around 60 percent of the TRR. The majority of this radioactivity was highly polar in nature, based on its retention time in HPLC analysis, comprising of a number of analytes. Following a series of clean-up steps, the residue separated into two peaks by HPLC. Attempts were made to precipitate sugars that may be present in the fraction, but these were unsuccessful. Therefore, the isolated peaks were acetylated, and TLC analysis indicated the presence of a complex mixture of sugar conjugates.

For the aqueous fractions, only the extraction from the sweet corn forage harvested 14 DALA were subject to further identification work. The identification/characterization of both aqueous and organic metabolites in mature sweet corn forage is shown in Table 12.

In a number of cases, the individual levels of the metabolites was not determined. The major fractions identified in mature forage were G-27550 (14.5 percent TRR, 0.56 mg eq/kg), a mixture of 4 glucose conjugates (12.4 percent TRR, 0.48 mg eq/kg) and an unknown (11.8 percent TRR, 0.46 mg eq/kg).

Lettuce (ABR-90039)

Lettuce (variety Simpson) grown outdoor was treated with [^{14}C]-pyrimidine-diazinon (specific activity = 9.8 µCi/mg, radiochemical purity 98 percent).

The test material was formulated as an EC formulation and applied three times. The first application was made pre-emergence at a rate of 4.48 kg ai/ha, one day after sowing. The second and third applications were foliar applications at a rate of 1.4 kg ai/ha. The second application was made 34 days after the pre-emergence application with the third application being made 7 days later.

Immature leaves were harvested just before the third application was made. Mature leaves were harvested 14 days after the last application. Samples were stored frozen for up to 19 months prior to analysis.

Samples were extracted twice with methanol: Water (9:1, v/v) and the extracts were then partitioned with ethyl acetate. Characterization and identification was performed using 2D-TLC and/or HPLC analysis with mass spectral identification on specific metabolites. Extracts were also treated with ß-glucosidase for 12 hours at 37 °C to support the identification of the glucose conjugates extracted.

The total radioactive residues and the distribution of radioactivity in lettuce are shown in Table 13.

The TRR was 1.885 mg eq/kg and 0.656 mg eq/kg in immature lettuce and mature lettuce respectively. For immature lettuce, the solvent extractability using methanol: water (9: 1, v/v) was 87.2 percent TRR. The extracted residue was found to consist of approximately equal amounts of aqueous and organosoluble residue. For mature lettuce, the solvent extractability using methanol: water (9:1, v/v) was 78.4 percent TRR. The majority of the extracted residue was found to be aqueous soluble.

Table 13 TRR and distribution of radioactivity in lettuce treated with ^{14}C-diazinon

Fraction	Immature lettuce leaves		Mature lettuce leaves	
	Percent TRR	mg eq/kg	Percent TRR	mg eq/kg

Unknown metabolites	0.4	< 0.01	0.1	< 0.01
Total identified	39.8	0.75	23.4	0.16

In the organic fraction, G-27550 was the highest metabolite identified (18.9 percent TRR in immature lettuce and 10.2 percent TRR in mature lettuce).

Table 15 summarizes the characterization and identification of residues in the organo and aqueous fractions for mature lettuce leaves.

Diazinon was identified at a level of 11.8 percent TRR (0.08 mg eq/kg). In a number of cases the individual levels of the metabolites were not determined. The major metabolites/ identified were G-27550 (17.5 percent TRR, 0.12 mg eq/kg), an unknown metabolite (12.7 percent TRR, 0.08 mg eq/kg) and GS-31144 (11.7 percent TRR, 0.08 mg eq/kg).

For mature lettuce leaves, 63.5 percent TRR (0.42 mg eq/kg) was identified and 21.6 percent TRR (0.142 mg eq/kg) remained unextracted.

Notes:

** Includes metabolites that have been quantified together.

In a supplementary study, retained crop fractions of lettuce were subject to analysis after 69 months of freezer storage. The total radioactivity in the samples was determined by combustion with LSC. The samples were extracted with methanol: water (9: 1, v/v) and partitioned with ethyl acetate.

The HPLC profile of the extracts of lettuce from 19 months of storage and from 69 months of storage were compared. The HPLC profiles were qualitatively similar and the percent TRR of the main fractions were quantitatively similar.

The TRR determined by combustion and the solvent extractabilities for lettuce samples extracted after 69 months of storage are shown in Table 16.

Table 16 TRR and distribution of radioactivity in lettuce treated with ^{14}C-diazinon

Fraction	Immature lettuce leaves		Mature lettuce leaves	
	Percent TRR	mg eq/kg	Percent TRR	mg eq/kg
TRR	100	2.178	100	0.751
Methanol: water (9:1, v/v)	81.5	1.78	72.2	0.542
Aqueous phase	33.2	0.723	48	0.36
Organic phase	48.3	1.05	24	0.18
Non-extracted	18.5	0.403	27.8	0.209

After extraction with methanol: water (9: 1 v/v) the aqueous fractions were subject to sample clean-up, derivatization and enzyme hydrolysis steps in order to aid the identification of residues. Separate fractions were treated with cellulase (12 hours at 37 °C), ß-glucosidase (12 hours at 37 °C), HCl (6 M HCl for 1 hour at 95 °C), acetic anhydride: pyridine (90: 10 v/v, room temperature for 12 hours) and 3 M HCl in butanol (1 hour at 95 °C). Metabolites were identified using TLC and HPLC.

Diazinon was not identified. In a number of cases the individual levels of the metabolites were not determined. For immature lettuce, the major metabolite/fraction identified was a mixture of G-27550 and unknown metabolite B_2 (11.7 percent TRR, 0.255 mg eq/kg). A total of 24.4 percent TRR (0.522 mg eq/kg) was identified.

For mature lettuce, the major metabolites/fractions identified were mixture of conjugates along with 3 unknown metabolites (16.7 percent TRR, 0.125 mg eq/kg) and a mixture of two conjugates (10.1 percent TRR, 0.076 mg eq/kg). The aglycones of the conjugates were identified as G-27550 and GS-31144. The study postulates that the conjugates are malonyl glucose conjugates based on the successfully derivatization, via acetylation, and information from the literature. No further details are provided.

The results are summarized in Table 17.

† The characterization and identification work was undertaken on an additional subsample of lettuce.

§ Aglycones confirmed but the identity of the conjugate only postulated to be malonyl glucose conjugate.

In addition, the PES from mature lettuce was subject to further extraction procedures (methanol/water reflux, NaCl reflux, enzyme hydrolysis). The results are summarized in Table 18.

Table 18 Summary of the radioactivity following treatment of the PES of mature lettuce

Fraction	Percent TRR	mg eq/kg
Initial PES	27.8	0.209
9/1 v/v MeOH/H_2O	9.1	0.068
Organic	2.3	0.017
Aqueous	2.6	0.019
1 percent NaCl	6.7	0.050
Organic	1.3	0.010
Aqueous	4.1	0.030
Cellulase hydrolysis	2.5	0.018
Organic	0.2	0.001
Aqueous	1.7	0.013
Protease hydrolysis	2.6	0.020
Final PES	6.4	0.040

The extraction procedures individually released 2.5–9.1 percent TRR (0.018–0.068 mg eq/kg), leaving 6.4 percent of the TRR (0.040 mg eq/kg) in the post-extraction solids.

The methanol/water and NaCl organosoluble fractions were analysed by HPLC and 2D-TLC. In the methanol/water organosoluble fraction, parent diazinon (1 percent TRR), G-27550 (< 0.5 percent TRR) and an unknown metabolite (0.6 percent TRR) were identified.

The NaCl organosoluble and aqueous fractions were found to contain G-27550 (1 percent TRR in each fraction), GS-31144 (< 0.1 percent TRR) and an unknown (0.2 percent TRR).

Following cellulase hydrolysis, G-27550 (0.1 percent TRR) was identified in the organic phase and the aqueous phase fraction was found to contain polar metabolites, the number and levels were not stated.

The protease hydrolysis fractions were too viscous for chromatographic profiling.

Potatoes (study ABR-89059)

Potatoes (variety Katahdim) grown outdoor were treated with [^{14}C]-pyrimidine-diazinon (specific activity = 9.8 µCi/mg, radiochemical purity 98 percent).

The test material was formulated as an EC formulation and applied three times. The first application was made pre-emergence at a rate of 4.48 kg ai/ha and applied three days after planting of seed potatoes. The second and third applications were foliar applications at a rate of 1.4 kg ai/ha. The second application was made 75 days after the pre-emergence application with the third application being made 7 days later.

Foliage and tuber samples were harvested 74 days after the pre-emergence use (i.e. 1 day before the first foliar application). Further samples of foliage and tubers were harvested 15 DALA. Samples were stored frozen for up to 16 months prior to analysis.

The total radioactivity in the samples was determined by combustion with LSC. Samples were extracted twice with methanol: water (9:1, v/v) and the extracts were then partitioned with ethyl acetate. Extracts were also treated with ß-glucosidase for 12 hours at 37 °C to support the identification of the glucose conjugates extracted. PES were also subjected to enzymatic hydrolysis; a sample was incubated at 37 °C with sodium acetate buffer with amyloglucosidase. In addition, the PES were subject to acid hydrolysis; samples were refluxed with 3 M HCl for 2 hours (temperature not stated).

Characterization and identification was performed using 2D-TLC and/or HPLC analysis with mass spectral identification on specific metabolites. The total radioactive residues and the distribution of radioactivity in lettuce are shown in Table 19.

The TRR ranged from 0.059 mg eq/kg for immature foliage to 1.93 mg eq/kg for mature foliage. The solvent extractabilities using methanol: water (9:1, v/v) ranged from 15.8 percent TRR for mature tubers to 81.5 percent TRR for mature foliage. The majority of the extracted residue was found to be aqueous soluble.

3M HCl	-	-	-	-	-	-	71.6	0.197

Notes:

DALA: Days after last application

Treatment of the PES from potato tubers with amyloglucosidase solubilized around 33 percent TRR. The majority of this radioactivity was polar, based on its retention time in HPLC analysis and possibly contained various sugar conjugates. Acid hydrolysis released around 72 percent of the TRR with 11.5 percent of the TRR identified as G-27550.

The identification/characterization of residues was only determined in mature potato foliage samples with the summary outlined in Table 20. Diazinon was found at 14.2 percent TRR (0.27 mg/kg). In a number of cases the individual levels of the metabolites were not determined. The major metabolites/fractions identified in potato foliage were a mixture of two glucose conjugates (20.8 percent TRR, 0.4 mg eq/kg), a trihydroxy glucose conjugate (14.1 percent TRR, 0.27 mg eq/kg) and CL-XIX and a glucose conjugate of GS-31144 (11.5 percent TRR, 0.22 mg eq/kg). The structure of the trihydroxy glucose conjugate was not fully elucidated.

Notes:

†B_2 is an unidentified metabolite.

**Includes metabolites that have been quantified together. It does not include fractions that contain identified and unidentified metabolites.

A literature paper from 1972 outlining the metabolism in rice and peas was also provided to the Meeting. This has not been evaluated as the paper did not include sufficient details to contribute to the metabolic pathway and residue definitions for plants.

In Figure 2 an overall proposal for the metabolic pathway of diazinon in plants is outlined.

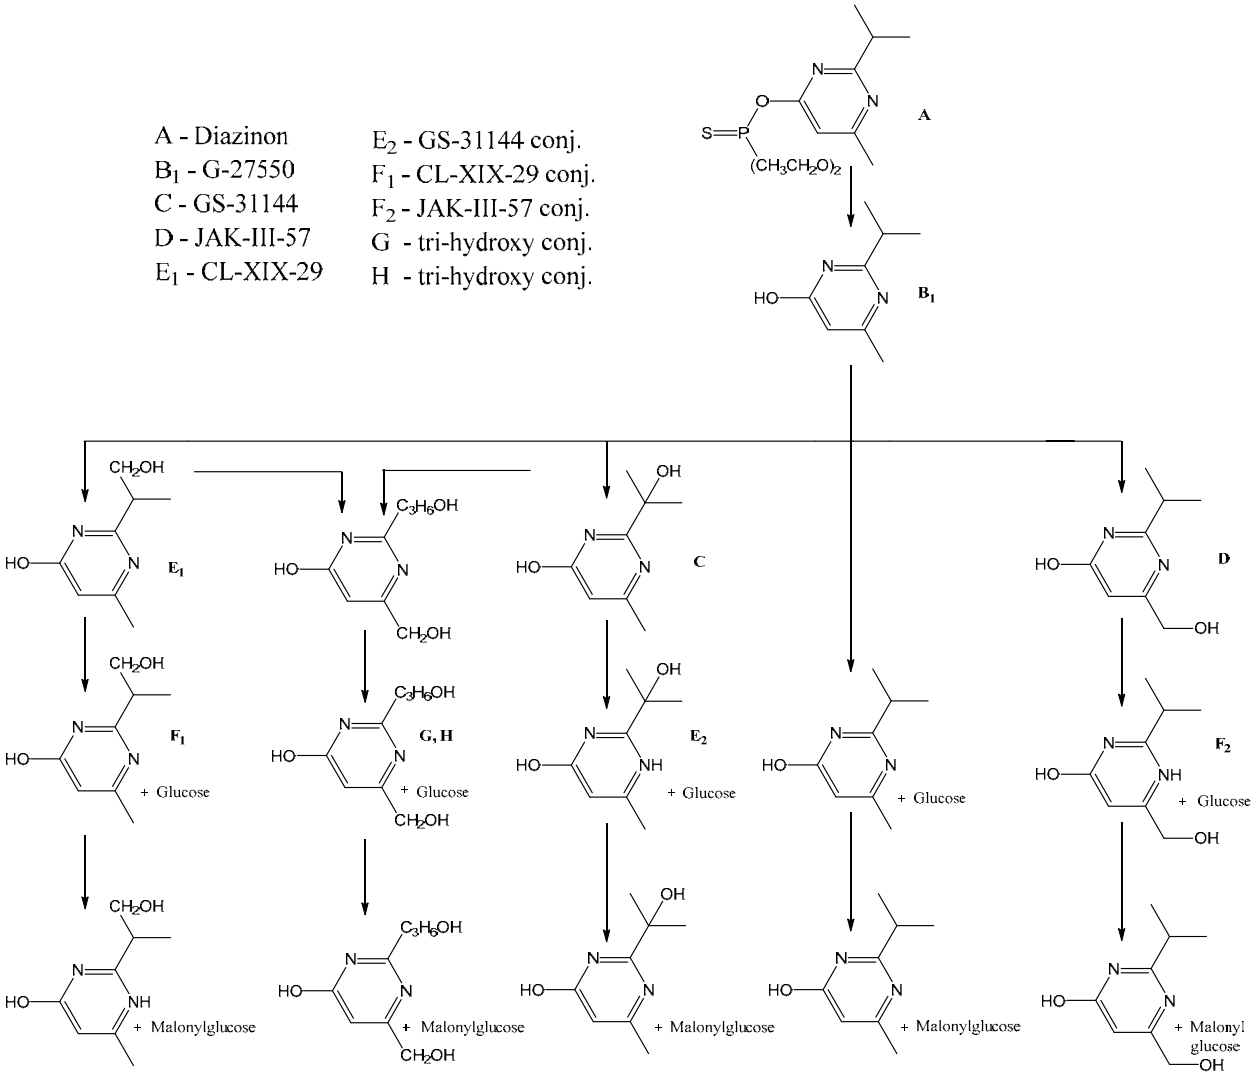

Figure 2 Proposed Metabolic pathway in plants

Environmental fate in soil

The meeting received information on aerobic degradation in soil, photolysis in soil, hydrolytic degradation, anaerobic degradation and soil leaching. Only the data on aerobic degradation in soil, photolysis in soil and the hydrolytic degradation, which are relevant to MRL setting, are reported here.

Aqueous hydrolysis

The aqueous hydrolysis of diazinon was investigated in two studies.

In the first study (R-228) aqueous hydrolysis was investigated for a concentration of 10 mg/L diazinon, at pH 5, 7 and 9 and temperatures of 30, 50 and 70 °C. Quantification was performed by GC-FID. The percentage of diazinon at each time interval is outlined in Table 21.

The study showed that diazinon degraded in aqueous media, assuming first order kinetics, with the rate constants and half-lives outlined in Table 22.

Table 22 Rate constants and DT_{50} values for diazinon degradation in aqueous media

pH	Temp. (°C)	Kobs (days-1)	DT_{50} (days)
5.0	20 (extrapolated)	2.03 × 10-6	3.8
7.0		1.03 × 10-7	78
9.0		2.03 × 10-7	40
5.0	30	4.56 × 10-6	1.8

5.0	70	5.52 × 10-5	0.15
7.0		1.88 × 10-5	0.4
9.0		3.75 × 10-5	0.2

Notes:

The degradation products were not determined.

In a second study (R-231) the rate of hydrolysis of [^{14}C]-pyrimidine-diazinon was investigated at 23-25°C and at a pH of 5, 7 and 9. The concentration of diazinon was approximately 11 µg/ml. Total radioactive residues were determined by combustion and LSC. Quantification was performed at intervals between 0 and 32 days by HPLC and TLC.

[^{14}C]-pyrimidine-diazinon degraded over time at pH 5, 7 and 9. HPLC analysis identified the presence of three components: diazinon, G-27550 and an unknown component. Levels of G-27550

reached a maximum of 67.4 percent AR at pH 5 (day 21), 6.9 percent AR at pH 7 (day 32) and 18.8 percent AR at pH 9 (day 32). The unknown component accounted for no more than 7.5 percent AR in all samples. The levels of the degradation products of diazinon at the varying pH values over time are summarized in Table 23.

Table 23 Distribution of the radioactivity applied to buffer samples

pH buffer	Time interval (days)	percent of applied radioactivity

Notes:

ND Not detected.

The calculated rate constants and degradation half-lives (DT_{50}) are summarized in Table 24.

Table 24 Rate constants and DT_{50} values for diazinon degradation in aqueous media

pH	Temp. (°C)	K_{obs} ($days^{-1}$)	DT_{50} (days)
5	25	5.6×10^{-2}	12
7		5.0×10^{-3}	138
9		9×10^{-3}	77

Aqueous photolysis

The photolysis of diazinon in aqueous solutions was investigated in two studies.

In the first study (G24480/2088), non-radio-labelled diazinon at a concentration of 50 µg/mL in deionised water was exposed to artificial light (1000 W mercury lamp) for a period of 12 days at 20–25 °C. The concentration of diazinon was determined by HPLC-UV at the start and end of the exposure and remained at 50 µg/mL.

In a second study (G24480/0239), ^{14}C-diazinon at a concentration of 6 mg/L in phosphate buffer at pH 7 was exposed to 360 hours of natural sunlight over 30 days. On average the daily sunlight was 12 hours and the temperatures ranged from 12–49 °C. Aliquots of the buffer solution were sampled at intervals from 0–360 hours. The TRR were determined directly by LSC and are summarized in Table 25.

Table 25 Total radioactivity recovered on exposure of diazinon to sunlight

Time (hours)	Total radioactivity recovered (percent)		
	Dark control	Replicate 1	Replicate 2
5	100	100	100
12	111	106	106
24	107	106	102
48	109	102	103
72	96	90	100
146	90	87	93
240	85	82	84
360	72	74	82

Aliquots were directly placed on TLC plates and separated using two solvent systems. In addition, the test vessels from the 360 hour samples were extracted with hexane to account for any residues that had bound to the walls of the test vessels. The results are summarized in Tables 26 and 27.

Half-lives of diazinon were calculated as 23.3 days for solvent system 1 and 25.8 days for solvent system 2.

Soil photolysis

The photodegradation of diazinon in soil was investigated in two studies.

In the first study (R-236) [^{14}C]-pyrimidine-diazinon was applied to a sandy loam soil. The characteristic of the soil are outlined below:

Soil	percent sand	percent silt	percent clay	percent organic matter	pH	Cation exchange capacity (meq/100g)
Sandy loam	54.8	29.4	15.8	2	5.4	15

A water/soil slurry was applied to TLC plates which were dried and duplicate aliquots (4.6 µg ai/10 µL) of diazinon was applied to each soil band. Plates were irradiated using an artificial light source (10 hours) or using natural sunlight (32.6 hours) at 25 ° C. Control samples were stored in the dark. At each sampling interval duplicate TLC plates were developed and analysed by LSC and UV.

Mass balances of the radioactivity applied were 93.7–101 percent AR. Significant degradation of diazinon (approximately 62 percent AR) occurred within 24 hours of sunlight exposure; a similar amount of degradation of diazinon (approximately 65 percent) occurred after 9 days following exposure to artificial light. In the dark control samples, diazinon degradation was approximately 34 percent AR after 10 days.

G-27550 represented an average of 41 percent, 24 percent and 16 percent AR in artificially irradiated, natural sunlight and dark control samples, respectively after the exposure period. GS-31144 accounted for up to 3.6 percent AR after 32.6 hours of natural sunlight but was not found in the dark or artificial sunlight samples.

During the course of the experiments no attempt was made to collect volatiles.

The distribution of the radioactivity after the application of diazinon in soil is summarized in Tables 29 to 31.

Notes:

ND = Not detected.

[a] = No information available.

Half-lives of diazinon were calculated as 17.3 hours (natural sunlight), 5.5 days (artificial light) and 14.7 days (dark control).

In a second study (6015-208) [^{14}C]-pyrimidine-diazinon was applied to a sandy loam soil.

Soil samples were either exposed to continuous artificial light for 210 hours or natural sun light for 58.5 hours at 25 °C.

A water/soil slurry was applied to TLC plates which were dried and duplicate aliquots of 7–51 mg/kg diazinon was applied to each soil band. Plates were irradiated using an artificial light source or using natural sunlight. Control samples were stored in the dark. At each sampling interval TLC plates were developed and analysed by LSC and UV.

During the course of the experiments, volatiles were only collected from the samples irradiated with artificial light.

The distribution of the radioactivity after the application of diazinon in soil is summarized in Tables 32–34.

Table 32 Distribution of radioactivity (percent AR) after application of diazinon in soil and photolysis by artificial light

* Sum of all radioactive regions.

Average recoveries were 92.3 percent, 87.7 percent and 96.0 percent AR for the artificial light, sunlight and dark control samples, respectively and remained consistent throughout the study, indicating minimal evolution of volatile radioactive components. Radioactivity in the traps accounted for no more than 0.2 percent AR after 210 hours of artificial light exposure. After 210 hours of artificial light exposure, the radioactivity profile was qualitatively similar to the profile of the samples exposed to 58.5 hours of natural sunlight.

Only one major degradation product was identified, G-27550. Two minor unknown metabolites were also determined.

DT_{50} values were determined by linear regression analysis of the data. Diazinon was found to degrade under natural sunlight with a half-life of 37.4 hours. However, the DT_{50} for samples exposed to artificial light could not be calculated due to limited degradation occurring. The DT_{50} for diazinon in the dark control samples was 926 hours.

Aerobic degradation in soil

Three studies have investigated the aerobic degradation of diazinon.

In the first study (R-259) diazinon, [14C]-pyrimidine-diazinon was applied at a rate of 10 mg ai/kg dry weight of soil to a sandy loam soil. The soil characteristics are outlined below:

Soil Characteristic	Sandy loam
Sand	47 percent
Silt	49.1 percent
Clay	3.9 percent
Organic carbon	1.1 percent
Cation exchange capacity	7.3 meq/100 g soil
pH	7.5

The degradation in the laboratory under aerobic conditions was investigated. The soil was maintained at a 75 percent moisture holding capacity and maintained in the dark at 25 °C. Volatiles were collected in trapping solutions. Samples of soil were removed for analysis from day 0 to 166 days after treatment. The TRR were determined by combustion with LSC.

Samples were extracted five times with methanol: water (8: 2, v/v). The combined methanol: water extracts were partitioned with dichloromethane. The remaining sediment was further extracted by refluxing for 6 hours with methanol. Extracts were analysed by TLC, GC-FID and GC-MS.

Total recoveries ranged from 74–105 percent AR. Diazinon decreased from 100 percent AR to 0.3 percent AR after 166 days. The volatile radioactivity was almost entirely attributed to CO_2. The levels of

CO_2 increased to 55.6 percent AR after 166 days. The major metabolite, G-27550 reached a maximum level of 72.9 percent AR after 14 days and then decreased to 4.7 percent AR after 166 days. Non-extracted radioactivity levels increased during the study, reaching 15.1 percent AR after 166 days

The distribution of radioactivity in soil is outlined in Table 35.

Table 35 Distribution of radioactivity (percent of AR)

Metabolite	Days after treatment					
	0	14	28	56	84	166
Diazinon	101.6	12.3	5.3	3.2	2.0	0.3

Total extracted	104.7	85.2	61.2	72.8	51.0	11.3
Total recovery	105.1	92.4	74.0	98.0	81.4	82.8

Notes:

ND = not detected.

The degradation rate of diazinon was investigated in a second study (R014085) in which [^{14}C]-pyrimidine-diazinon was applied at a rate of 1.2 mg ai/kg dry weight of soil to three different soils types. The soil characteristics are outlined below:

Soil Characteristic	Soil 1	Soil 2	Soil 3
Particle size distribution (percent) 63 µm – 2mm (sand) 2 µm – 63 µm (silt) < 2 µm (clay)	 64.54 23.20 12.27	 83.13 7.83 9.04	 47.30 25.28 27.43
Texture class	Sandy loam	Loamy sand	Clay loam
Organic carbon (percent)	1.9	0.8	2.8
pH	6.4	6.2	6.5
Cation exchange capacity (meq/100 g)	16.5	7.0	25.6
Water holding capacity (percent)	55.8	38.8	59.2

The soil samples were incubated in the dark at 20 °C for 76 days. Volatiles were collected in trapping solutions. The TRR were determined by combustion with LSC. Samples were extracted with acetonitrile and acetonitrile: water (4:1, v/v). The extraction procedure was repeated three times. The TRR in extracts were determined by LSC. Extracts were analysed by HPLC-UV and TLC. The TRR in non-extracted material was not determined.

The total recoveries ranged from 76.7 to 98.7 percent. The distribution of radioactivity is outlined in Table 36.

Extractability from all samples declined with time, with 62.2–73 percent AR extracted at day 76.

The metabolite G-27550 accounted for a maximum of 67.6 percent and 75.2 percent AR in the clay loam and sandy loam soils, respectively at day 30 and 49.1 percent AR in loamy sand soil at day 55. Another identified degradate, GS-31144, was present at 4.2–4.7 percent AR at day 76. Volatile radioactivity accounted for a maximum of 10.2 percent AR at day 76, with $^{14}CO_2$ accounting for up to 9.9 percent AR. No other degradates of diazinon detected exceeded 2.5 percent AR.

The half-time (DT_{50}) and DT_{90} values were determined using single first order kinetics (SFO) and are outlined in Table 37.

Table 37 Summary of DT_{50} and DT_{90} values for diazinon

Test Soil	DT_{50} Diazinon (days)	DT_{90} Diazinon (days)
Sandy loam	8.0	26
Loamy sand	23	75
Clay loam	9.9	33

In a third study (R-14086) the degradation rate of the metabolite G-27550 was investigated. The same soils as outlined in the second study above (sandy loam, loamy sand and clay loam) were used. G-27550, labelled in the pyrimidine ring, was applied at a rate of 0.6 mg/kg dw of soil. The soil samples were incubated in the dark at 20 °C for 76 days. Samples were extracted with acetonitrile and acetonitrile: water (4:1, v/v). The extraction procedure was repeated three times. The TRR were determined in the extracts by combustion with LSC. Extracts were analysed by HPLC-UV and TLC. The amount of radioactivity in non-extracted material was not determined in the study.

The distribution of radioactivity is outlined in Table 38.

The amount of G-27550 declined from 101–104.4 percent AR to 71.2–74.5 percent AR after 59 days and 51.6-54.0 percent after 120 days. A minor metabolite, GS-31144, represented a maximum of 6.2 percent AR after 120 days. No other radioactive components exceeded 2.7 percent AR at 120 days.

Degradation was slow in all three soils. The calculated DT_{50} and DT_{90} values (assuming first-order kinetics) are presented in Table 39.

Table 39 Summary of DT_{50} and DT_{90} values for G-27550

Residues in Succeeding or Rotational crops

Confined rotational crop studies

The nature of the residue in rotational crops has been investigated two studies.

Study 1 (ABR-90064)

Rotational crops of spring wheat, lettuce, sugar beet and soya beans were planted following the harvest of greenhouse grown maize treated with diazinon.

The primary crop of maize was treated with [^{14}C]-pyrimidine-diazinon (specific activity 9.7 µCi/mg, radiochemical purity of 98.8 percent) at a rate of 4.48 kg ai/ha, applied pre-emergence, followed by two foliar applications, at a rate of 3.5 kg ai/ha, made at growth stage of BBCH 30–39. The two foliar applications were made 50 and 74 days after sowing of the primary crop. The rotational crops were planted 98 days after the last foliar application to maize.

Rotational crop plant samples were harvested 156 days (lettuce), 206 days (spring wheat), 226 days (soya beans) and 288 days (sugar beets) after the last application. These crop samples are reported as representing crop maturity. Crops were also harvested at 25 percent and/or 50 percent maturity. The growth stages were not reported. Wheat samples were separated into tops, stalks, hulls and grain, sugar beet samples were separated into leaves and roots and soya bean plants were separated into stalks, pods and beans.

Total radioactive residues were determined by combustion with LSC. All samples were extracted two times with methanol: water (9:1, v/v). For spring wheat stalks and mature soya bean stalks the extracts were partitioned with hexane followed by ethyl acetate. Aqueous extracts from these samples were also subject to enzyme hydrolysis using ß-glucosidase (no experimental conditions were given).

Characterisation and identification was performed using 2D-TLC and/or HPLC analysis with mass spectral identification on specific metabolites. Samples were stored frozen prior to analysis. The length of storage is not stated.

The total radioactive residues and the distribution of radioactivity in the rotational crops is shown in Table 40.

The TRR ranged from 0.016 mg eq/kg for both mature sugar beet roots and tops to 0.624 mg eq/kg for mature wheat stalks. The solvent extractabilities with methanol: water (9:1, v/v) ranged from 11.6 percent TRR for mature wheat grain to 90.7 percent TRR for 50 percent mature sugar beet leaves.

The results of the partitioning were not presented in the report.

Table 40 Distribution of radioactive residues in rotational crops

Commodity	TRR (mg eq /kg)	Extracted (Methanol: water, 9: 1, v/v)		Non-extracted

The identification of metabolites was only undertaken for wheat samples. Table 41 shows the identification of diazinon and its metabolites in wheat. Diazinon was only identified in mature stalks (7.21 percent TRR, 0.045 mg/kg). In a number of cases the individual levels of the metabolites were not determined.

In 25 percent mature foliage, the major metabolites/fractions identified were an unknown plus G-27550 (22 percent TRR, 0.03 mg eq/kg) and an unknown metabolite (10.3 percent TRR, 0.014 mg eq/kg).

In mature stalks, the major metabolites/fractions identified were an unknown plus G-27550 (21 percent TRR, 0.131 mg eq/kg) and an unknown metabolite (14.3 percent TRR, 0.089 mg eq/kg).

In mature hulls, the major metabolites/fractions identified were an unknown plus G-27550 (17 percent TRR, 0.085 mg eq/kg) and CL-XIX-29 plus three conjugates (11 percent TRR, 0.055 mg eq/kg).

In mature grain, none of the metabolites/fractions identified exceeded 3 percent TRR.

Study 2 (ABR-90065)

Rotational crops of winter wheat, soya bean and sugar beet were planted outdoors following the harvest of primary crops treated with diazinon.

Primary crops of lettuce, beans with pods and potatoes were all treated with [^{14}C]-pyrimidine-diazinon (specific activity 9.8 µCi/mg, radiochemical purity of 98 percent) at a rate of 4.48 kg ai/ha, applied pre-emergence, followed by two foliar applications at a rate of 1.4 kg ai/ha. In all cases the pre-emergence application was made 1 day after sowing of the primary crop. For lettuce, the first foliar application was made 34 days after the pre-emergence application with the second foliar application being made 7 days later. For beans with pods, the the first foliar application was made 34 days after the pre-emergence application with the second foliar application being made 15 days later. For potatoes the first foliar application was made 75 days after the pre-emergence application with the second foliar application being made 7 days later.

The foliar applications to the primary crops occurred when there was approximately 25 percent crop interception for lettuce and beans with pods and 60 percent crop interception for potatoes.

Following the harvest of the primary crop of treated lettuce, rotational crops of winter wheat and lettuce were planted 90 DALA and 308 DALA respectively. Following harvest of the primary crop of treated beans with pods, a rotational crop of soya bean was planted 327 DALA and following the harvest of the primary crop of treated potatoes, a rotational crop of sugar beet was planted 294 DALA.

Plant samples of the rotational crops were taken at various time points following planting as outlined in Table 42. The growth stages of the crop are not reported. Wheat samples were separated into

tops, stalks, hulls and grain, sugar beet samples were separated into tops and roots and soya bean plants were separated into stalks, pods and beans.

Table 42 Time periods for harvesting of rotational crops

Crop fraction	Days after planting the rotational crops	Days after soil treatment
Wheat – planted 90 DALA		
Forage	48	379
25 percent mature stalks	233	364
50 percent mature stalks	260	391
Mature stalks	296	427
Mature hulls	296	427
Mature grain	296	427
Lettuce – planted 308 DALA		
50 percent maturity	42	391
Mature	56	405
Soya beans – planted 327 DALA		
25 percent mature stalks	39	415
50 percent mature stalks	70	446
Mature stalks	135	511
Mature pods	135	511
Mature beans	135	511
Sugar beets – planted 294 DALA		
25 percent mature tops	44	420
50 percent mature tops	70	446
50 percent mature beets	70	446
Mature tops	135	511
Mature beets	135	511

Total radioactive residues were determined by combustion with LSC. All rotational crop samples were extracted two times with methanol: water (9:1, v/v). Samples were stored at ≤ -12 °C for 15 months.

The total radioactive residues and the distribution of radioactivity in the rotational crops is shown in Table 43. The lowest TRR was 0.003 mg eq/kg for 25 percent and 50 percent mature stalks of winter wheat and for mature sugar beet tops. The highest TRR was 0.027 mg eq/kg for mature soya bean stalks.

The solvent extractabilities using methanol: water (9:1, v/v) ranged from 10.1 percent TRR for mature soya bean pods to 61.4 percent TRR for 50 percent mature soybean stalks. Owing to the TRR in sugar beet leaves and tops being low (0.003–0.007 mg eq/kg) no extraction was undertaken.

Table 43 Distribution of radioactive residues in rotational crops

Primary crop	Commodity	Total (mg eq/kg)	Percent Extracted (Methanol: water, 9: 1, v/v)		Percent Non-extracted	
			Percent TRR	mg eq/kg	Percent TRR	mg eq/kg
Lettuce	Winter wheat – 90 DALA

Notes:

No identification work was undertaken.

Field Rotational Crop Studies (G24880-2514)

Eight rotational crop field trials were conducted in the United States. Rotational crops of lettuce, turnips and wheat were planted 30, 60 and 180 days after the last application to primary crops of lettuce, squash (variety not stated), melon and tomato.

The primary crops were all treated with one application at 4.48 kg ai/ha, applied pre-emergence using a granular formulation, followed by five foliar applications at a rate of 0.56 kg ai/ha using an EC formulation. Table 44 summarises the application timings for the foliar applications to the primary crops.

Table 44 Application timings for the foliar applications to the primary crop

Trial number	Primary crop	Application No	Growth stage	Days after planting
1	Lettuce	1	Seedling	14
		2	Seeding	21
		3	Vegetative	28
		4	Vegetative	35
		5	Vegetative	42
2	Tomato	1	Immature flowering	59
		2	Immature flowering	66
		3	Immature flowering	73
		4	Immature flowering	80

Trial number	Primary crop	Application No	Growth stage	Days after planting
		5	Immature fruit	87
3	Lettuce	1	Seedling	43
		2	Seedling	51
		3	Seedling	57
		4	Immature plant	64
		5	Mature plant	71
4	Squash	1	Pre-bloom	20
		2	Bud set, pre-bloom	27
		3	Blooming fruit set	34

		4	Blooming	37
		5	Limited fruit and blooms	42
6, 7 and 8	Lettuce	1	Vegetative	14
		2	Vegetative	21
		3	Vegetative	28
		4	Vegetative	35
		5	Vegetative	42

Rotational crop samples were taken and stored frozen for a maximum period of 15 months prior to analysis.

Samples were analysed for diazinon, G-24576 and CGA-14128 using method AG-550A. Procedural recoveries were conducted at fortification levels of 0.01–1 mg/kg. Recoveries ranged from 80–131 percent for diazinon, 75–137 percent for G-24576 and 75–120 percent for CGA-14128.

The residues determined in rotational crops are outlined in Table 45. All residues of diazinon, G-24576 and CGA-14128 were less than 0.01 mg /kg in all rotational crops at all plant back intervals.

Table 45 Residues in rotational crops from trials conducted in the United States following an application of 1 × 4.48 kg ai/ha (applied pre-emergence) plus 5 × 0.56 kg ai/ha (applied as a foliar application post emergence) to the primary crops

Duplicate results represent two independent representative treated samples taken at the trial site with the mean residue level given in brackets

Animal metabolism

The meeting received information on metabolism of diazinon in ruminants (lactating goat) and poultry (laying hens).

Lactating goat (studies ABR-88117, ABR-8818, ABR-88135)

Two lactating goats (unstated breed) were orally dosed by capsule with [^{14}C]-pyrimidine-diazinon (specific activity 9.7 µCi/mg, radiochemical purity 98.8 percent). The goats were dosed daily for four consecutive days at a nominal rate of 4.1 mg/kg bw/day (109–114 ppm feed). The biological phase and the initial analytical phase were reported in one study with subsequent analytical work performed in a further two studies.

Milk, urine and faeces were collected daily. The animals were sacrificed approximately 24 hours after administration of the last dose and samples of liver, kidney, fat and muscle were taken. Samples were homogenised and the total radioactivity in the samples was determined by combustion with LSC.

Milk samples were extracted with acetonitrile: water (1:1, v/v) and partitioned with hexane. The aqueous phase was then partitioned with butanol followed by ethyl acetate. Tissue samples were extracted three times with methanol: water (9:1, v/v) and partitioned with hexane. The aqueous phase was then partitioned with butanol followed by ethyl acetate.

Characterisation and identification was performed using 2D-TLC and/or HPLC analysis with mass spectral identification on specific metabolites. Samples were stored frozen for up to 5 months prior to analysis.

The TRR in mg eq/kg and as a percentage of the total dose applied are shown in Tables 46, 47 and 48 for urine and faeces, milk and tissues respectively.

Table 46 Radioactive residues in ruminant urine and faeces from lactating goats administered with [^{14}C]-pyrimidine-diazinon

Sampling day	percent of dose			
	Urine		Faeces

The distribution of the radioactivity in tissues is shown in Table 49.

The TRR ranged from 0.112 mg eq/kg for perirenal fat to 3.019 mg eq/kg in kidney. The solvent extractability for milk (acetonitrile: water, 1:1, v/v) was 91.5 percent TRR. The majority of the extracted residue was found to be organosoluble. The solvent extractabilities for tissues (methanol: water, 9:1, v/v) ranged from 79 percent TRR for kidney to 99 percent TRR for muscle (leg). The majority of the extracted residue was found to be organosoluble.

Table 49 Distribution of radioactivity in samples from lactating goats administered with [^{14}C] pyrimidine-diazinon (animal 1)

Notes:

Consists of 1-5 discrete peaks, with maximum individual TRR ≤ 15 percent.

** Includes metabolites that have been quantified together.

Tissue samples, from the initial extraction with methanol: water (9: 1, v/v), were also subjected to acid hydrolysis (6 M HCl at 85 °C, left overnight). The results are summarised in Table 51. In a number of cases the individual levels of the metabolites were not determined.

Table 51 Identification of diazinon and its metabolites following acid hydrolysis of selected tissue extracts

Liver and kidney organosoluble extracts and kidney aqueous soluble extracts were also treated with β-glucuronidase (incubated at 37 °C, left overnight). No detailed results are reported; but it is stated that increased levels of GS-31144 and G-27550 were observed indicating the potential presence of glucuronic conjugates of these metabolites.

Poultry (studies ABR-88116, ABR-119, ABR-88135 and ABR-89040)

Four laying hens (leghorn) were orally dosed by capsule with [^{14}C]-pyrimidine-diazinon (specific activity 30.3 µCi/mg, radiochemical purity of 99.1 percent) once daily for seven consecutive days at a nominal rate of 1.6 mg/kg bw/day (25 ppm feed). There was one control animal. The biological phase and initial analytical phase was undertaken in one study. The additional three studies undertook further analytical work.

Samples of excreta and eggs (separated into whites and yolk) were collected daily. At sacrifice, approximately 24 hours after the last dose, samples of liver, kidney, muscle , skin with attached fat and peritoneal fat. The samples were homogenised, combusted and analysed by LSC. Samples were stored frozen for up to 12 months prior to analysis.

Egg and tissue samples were extracted three times with methanol: water (9:1, v/v) and where then partitioned with hexane followed by butanol. Characterisation and identification was performed using 2D-TLC and/or HPLC analysis with mass spectral identification on specific metabolites.

The TRR in mg eq/kg and as a percentage of the total radioactivity applied are shown in Table 52 for excreta and eggs and in table 53 for tissue samples.

Skin with attached fat	0.018	0.01
Peritoneal fat pad	0.010	< 0.01
Total	0.311	0.09

The distribution of the radioactivity in tissues is shown in Table 54.

The TRR ranged from 0.01 mg eq/kg for perirenal fat to 0.148 mg eq/kg for kidney. The solvent extractability for egg yolk (methanol: water, 9:1, v/v) was 67 percent TRR. The extracted residue was found to be mostly organosoluble. For egg whites the solvent extractability (methanol: water, 9:1, v/v) was 98 percent TRR. The majority of the extracted residue was found to be organosoluble. The solvent extractabilities for tissues (methanol: water, 9:1, v/v) ranged from 31 percent TRR for peritoneal fat to 76 percent TRR for kidney.

In a follow up study, the aqueous extracts were partitioned with hexane, then butanol followed by ethyl acetate. The resulting organic and aqueous fractions were treated with β-glucuronidase (incubated at 37 °C, left overnight). The metabolites GS-31144, G-27550 and CL-XIX-29 were identified following treatment with β-glucuronidase.

The overall identification and characterization of metabolites is shown in Table 57.

Notes:

† G-27550, GS-31144, CL-XIX-29 identified following treatment with β-glucuronidase.

Includes metabolites that have been quantified together.

In a further follow up study, the PES from egg yolk and tissues were subjected to enzymatic hydrolysis (incubated with protease at 37 °C and left overnight). The post-enzyme (protease) extraction radioactivity distributions are summarized in Table 58.

Table 58 Distribution of radioactivity released from the PES of egg and tissue samples following treatment with protease

Matrix	Percent TRR released by enzymatic treatment [mg eq/kg]	Percent TRR remaining in solids [mg eq/kg]
Egg yolk (day 7) - PES	N/A	33 [0.021]
Protease	21 [0.014]	12 [0.008]
Liver - PES	N/A	37 [0.041]
Protease	19 [0.021]	18 [0.02]

Protease	56 [0.01]	0
Peritoneal fat	N/A	69 [0.007]
Protease	69	0

Notes:

N/A Not applicable.

Further analysis of the radioactivity released following protease treatment was only undertaken for the liver samples. It is reported that residues of diazinon, CGA-14128, G-24576, G-27550, GS-31144 and CL-XIX-29 were found. No further detailed are available.

In Figure 3 an overall proposal for the metabolic pathway of diazinon in goat and hens is outlined.

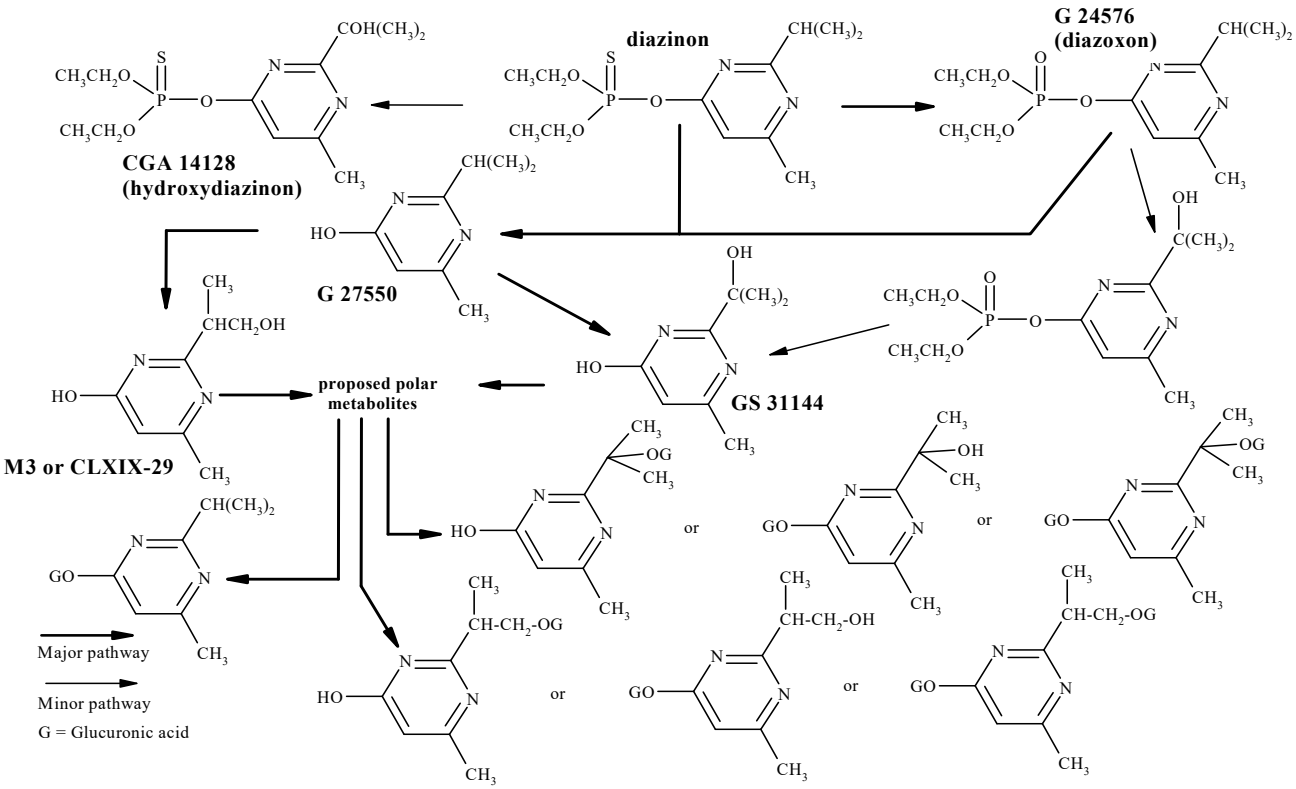

Figure 3 Proposed metabolic pathway in goats and hens

RESIDUE ANALYSIS

Analytical methods

Method MAK 824/042610

Residues of diazinon were extracted from pineapple pulp and peel using acetonitrile: water (9: 1, v/v) followed by centrifugation. The supernatant was concentrated under vacuum and 5 percent w/v sodium chloride solution and hexane was added. The upper hexane layer was partitioned twice with acetonitrile. The two acetonitrile phases were combined and the solvent removed under vacuum. The residue was redissolved in 5 ml of methanol: water (1:1, v/v). Final determination was by LC-MS/MS using a C8 column, gradient elution and using the ion transition m/z 305.4 → 169.2. An ILV of the method was also undertaken.

A summary of the recovery data are outlined in table 59. The method was linear over the range 1–50 ng/mL.

AG-550 and AG-550 A

AG-550 and AG-550 A are the same method, with AG-550 A representing an update to include additional validation data.

Diazinon, G-24576 and CGA-14128 were extracted from animal tissues (excluding fat), milk, eggs, and crops, including processed fractions, using acetone: water (9:1, v/v) followed by extraction with petroleum ether: dichloromethane: water (5: 5: 1, v/v/v). The residues were then partitioned with dichloromethane. The dichloromethane layer was evaporated to dryness and reconstituted in acetone.

Residues of diazinon, G-24576 and CGA-14128 present in fat were extracted using acetonitrile and partitioned into hexane. The solvent was concentrated to dryness and reconstituted in acetone: water (9:1, v/v).

Sample clean-up was achieved by solid-phase extraction using a florisil Sep-Pak cartridge prior to analysis. Final determination was achieved by GC-FPD

Additional validation for the determination of diazinon in products of animal origin was undertaken using the same extraction procedures outlined above but with final determination achieved using GC-NPD.

A summary of the recovery data are outlined in Tables 60, 61 and 62 for diazinon, G-2465 and CGA-14128 respectively. For the GC-FPD method, the individual recoveries were not reported. The method was linear over the range 5–100 ng/mL for the GC-FPD method and 10–200 ng/mL for the GC-NPD method.

Method REM 4/81

This method was used in the storage stability study for animal matrices.

Samples of muscle, liver and kidney were macerated with methanol. The extracts were diluted with water and partitioned with dichloromethane. The solvent was evaporated and the residue cleaned up via SPE prior to chromatographic analysis.

Samples of fat were ground with anhydrous sodium sulphate and refluxed in hexane. The hexane extract was cleaned up following partitioning with acetonitrile followed by SPE.

Extracts were analysed by gas chromatography using nitrogen-phosphorus or flame ionisation detection. The limit of determination of the method is stated to be 0.01 mg/kg for all matrices. No validation data were provided.

Stability of residues in stored analytical samples

The meeting received freezer storage stability data for diazinon, G-24576, CGA-14128 and G-27550 in a variety of plant and animal matrices.

Plant commodities

Corn, tomato, potato, apple, strawberry, lettuce, processed commodities

Samples of corn, tomato, apple, strawberry, lettuce and processed fractions were homogenised and then separate samples were fortified at 1 mg/kg with diazinon or G-24576 or CGA-1412. The samples were stored frozen at ≤ -12 °C. At each time point two stored samples, two freshly prepared procedural recoveries samples and an unfortified control sample were analysed.

Samples were analysed using method AG-550. The results are presented in Tables 63 to 65 for diazinon, G-24576 and CGA-14128.

Table 63 Storage stability data for diazinon residues in frozen plant matrices

			114		120, 137 (129)	106	82
			281		47, 51 (49)	46	94
			470		121, 135 (128)	128	111

Notes:

† In the report where recoveries were < 100 percent they were corrected on the basis of the procedural recovery. The uncorrected recoveries were not reported. The mean uncorrected recovery has been calculated on the basis of the mean procedural recovery. The mean recoveries which did not require correction have also been included in this column for completeness.

Strawberry

Samples of strawberry were homogenised, fortified at 10 mg/kg and stored frozen at ≤ -20 °C. The following samples were prepared:

- 20 samples fortified with 10 mg/kg diazinon
- 20 samples fortified with 10 mg/kg G-24576
- 20 samples fortified with 10 mg/kg CGA-14128 and fortified with 10 mg/kg G-27550

At each time point two stored samples and two procedural recoveries were analysed along with an untreated control sample. Samples were analysed using method AG-550. The stored samples fortified with G-24576 were also analysed for G-27550. The results are shown in Tables 66 to 69.

			3		101, 103 (102)	
			7		87, 90 (89)	
			13		105, 144 (125)	
			28		92, 92 (92)	
			56		102, 96 (99)	

Notes:

† The procedural recoveries at each time point are not stated.

Residues of diazinon, CGA-14128 and G-27550 were found to be stable in strawberry for the 56 days of frozen storage. Residues of G-24576 were not stable over the 56 days of frozen storage. Recoveries of only 20 percent were obtained in day zero samples, which were analysed approximately 4 hours after fortification, in contrast to procedural recoveries which were prepared and analysed within a shorter time interval. It has been postulated that G-24576 degrades to G-27550 and therefore G-27550 was determined in the strawberry samples fortified with G-24576. The results are shown in Table 70.

Table 70 Analysis for G-27550 residues in samples of strawberry fortified with G-24576

Commodity category	Crop/commodity	Analyte	Storage period (days)	Fortification level of G-24576 (mg/kg)	Concentration, mg/kg, of G-27550 (mean)	Procedural recovery (%)†	G-24576 equivalent recoveries, percent §
High acid content	Strawberry	G-27550	0	10	4.3 , 4.3 (4.3)	Mean = 120 at 0.1 mg/kg (n=6)	81, 81 (81)
			1		5.5, 5.9 (5.7)		104, 112 (108
			3		5.3, 58 (5.6)		100, 110 (106)
			7		4.4, 4.5 (4.5)	Mean = 105 at 0.5 mg/kg (n=4)	83, 85 (85)
			13		6.4, 5.7 (6.1)		121, 108 (115)
			28		4.5, 4.6 (4.6)	Mean =94 at 10 mg/kg (n=4)	85, 87 (87)
			56		5.6, 52 (5.4)		106, 98 (103)

Notes:

† The procedural recoveries at each time point are not stated.

§ MW of G-24576 = 288 g/mol.

MW G-27550 = 152 g/mol.

G-24576 equivalent levels = 1.89 × G-27550 levels.

Pineapple

Samples of pineapple pulp and peel were homogenised and fortified with 0.1 mg/kg diazinon. Samples were stored at ≤ - 18 °C. At each time point two stored samples, one freshly prepared procedural recovery sample and an unfortified control sample were analysed. The samples were analysed using method MAK 824/042610. The results are summarised in Table 71.

Table 71 Storage stability data for diazinon residues in pineapple

Commodity category	Crop/commodity	Analyte	Storage period (months)	Fortification level (mg/kg)	Analysed concentration (mean, mg/kg)	Recovery (mean,%)	Procedural recovery (percent)
High acid content	Pineapple peel	Diazinon	0	0.1	0.085, 0.080 (0.083)	85, 80 (83)	-
			1		0.073, 0.073 (0.073)	73, 73 (73)	86
			3		0.069, 0.070 (0.070)	69, 70 (70)	85
	Pineapple pulp		0	0.1	0.089, 0.083 (0.086)	89, 83 (86)	-

			3		0.067, 0.068 (0.068)	67, 68 (68)	85

Diazinon residues were found to be stable in pineapple pulp and peel for the three-month storage period when stored at ≤ -18 °C.

Animal commodities

Study SPR 19-81

The storage stability of diazinon was investigated in the tissue samples from sheep. Three sheep were plunge dipped once in a dip containing a nominal concentration of 500 mg diazinon/L. The animals were slaughtered the day after treatment and samples were homogenised before being frozen at -20 °C. Samples of muscle, liver, kidney and fat were analysed on the day of storage and after 8 months for freezer storage. Samples were analysed using method REM 4/81. The results are summarised in Table 72.

Table 72 Storage stability of diazinon residues in sheep tissues

Commodity category	Crop/commodity	Analyte	Storage period (months)	Analysed concentration (mg/kg)			Percentage recovery, relative to day 0 (percent)			Mean procedural recovery (percent)

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

Pome fruits

Apple and pear

Six trials on apple and seven trials on pear were conducted in the United States in 1991. Two of the apple trials and two of the pear trials (conducted Yakima Country, Washington) are regarded as replicate trials and therefore there are five independent apple trials and six independent pear trials.

At each trial site different application rates were investigated.

Three foliar applications were made using a WP formulation at application rates between 0.053–0.96 kg ai/hL. The retreatment intervals were between 13 and 17 days and samples were collected for analysis between 21 and 28 days after the last application.

Samples were stored frozen at -20 °C for up to 160 days.

Residues of diazinon, G-24576 and CGA-14128 were determined using the analytical method AG-550A. Procedural recoveries were undertaken for each analyte at fortification levels of 0.01–1 mg/kg. For diazinon recoveries ranged from 79–99 percent, for G-24576 recoveries ranged from 66–91 percent and for CGA-14128 recoveries ranged from 80–107 percent.

A summary of the residue trials in apples and pears are shown in Tables 74 and 75 respectively.

Duplicate results represent two independent representative treated samples taken at the trial site with the mean residue level given in brackets.

Assorted tropical and sub-tropical fruits – inedible peel

Pineapples

Four trials on pineapple were conducted in Costa Rica in 2004. The trials were conducted in two separate locations at the same time and therefore there are only two independent trials.

Six foliar applications were made using an EC formulation at application rates between 0.997–1.13 kg ai/ha. The retreatment intervals were between 9–11 days and samples were collected for analysis 7 days after the last application.

Samples were stored frozen at ≤ - 18 °C for up to 21 days.

Residues of diazinon were determined in pulp and peel using the analytical method MAK/824. Procedural recoveries were undertaken at fortification levels of 0.1 and 0.5 mg/kg. Recoveries ranged from 72–91 percent for peel and recoveries of 91 percent were obtained for pulp.

Residues in the whole fruit were calculated based on the weights and residues present in the pulp and peel samples. A summary of the residue trials are shown in Table 76.

Brassica vegetables

Cabbage

Seven trials on cabbage were conducted in the United States in 1991. At each trial site two replicate trials were conducted, in some of the trials the replicates were undertaken at a different application rate. In each trial one application of 4.5 kg ai/ha was made using a granular formulation followed by 5 foliar applications at 0.56 kg ai/ha using a WP formulation. The interval between the granular application and the first foliar application ranged from 34–283 days. The retreatment interval for the foliar applications was 7 days.

Samples were stored frozen at ≤ -18 °C for up to 12 months.

Residues of diazinon, G-24576 and CGA-14128 were determined using the analytical method AG-550A. Procedural recoveries were undertaken for each analyte at fortification levels of 0.1, 0.5, 1 and 5 mg/kg. For diazinon recoveries ranged from 74–144 percent, for G-24576 recoveries ranged from 74–140 percent and for CGA-14128 recoveries ranged from 77–151 percent.

A summary of the residue trials in cabbage are shown in Table 77.

Duplicate results represent two independent representative treated samples taken at the trial site with the mean residue level given in brackets.

Cereal grains

Wheat

One trial on wheat was conducted in the Russian Federation in 1996. The trial was conducted with one application of 1.08 kg ai/ha using an EC formulation. Residues were determined 278 days after the application.

Only a brief translation of the Russian report has been provided and full details of the field phase and analytical phase were not provided. Samples were stored for up to 4 months prior to analysis. The conditions of storage are not stated. Residues of diazinon were determined in wheat grain and straw using a GC-NPD method. Validation data and procedural recoveries were not available.

A summary of the residue trials in wheat are shown in Table 78.

FATE OF RESIDUES IN STORAGE AND PROCESSING

Nature of the residue on processing

No information was received by the Meeting on the nature of the residue on processing.

Magnitude of the residue on processing

The meeting received information on the fate of diazinon residues during processing of apples and pears.

In the first study apples and pears were treated with diazinon at a rate of 3 × 2.2 kg ai/ha or a rate of 4 × 4.5 kg ai/ha. The fruits were harvested 21 days after the last application and residues of diazinon, G-24576 and CGA-14128 were determined in unwashed fruits, the wash water and washed fruits. Washed fruits were then peeled and baked. The conditions employed for processing were not stated.

Processed fractions were stored for up to 7 months at ≤ -18 °C prior to analysis. Samples were analysed using method AG-550.

Residues of diazinon, G-24576 and CGA-14128 on processing are summarised in Tables 80 and 81 for apples and pears respectively.

Table 80 Residues in apple and processed fractions

Crop/processed commodity	Diazinon residue (mg/kg)	Pf for diazinon	G-24576 residue (mg/kg)	CGA-14128 residue (mg/kg)
Trial 1: 3 × 2.2 kg ai/ha				
Whole fruit, unwashed	0.04	-	< 0.01	< 0.01
Wash water	< 0.01	-	< 0.01	< 0.01

Whole fruit, peeled and baked	< 0.01	< 0.01	< 0.01

Notes:

† No explanation for the positive residue in the washed fruit was provided.

In a second study two processing trials on apples were undertaken. Residues of diazinon, G-24576 and CGA-14128 were determined in apple on processing into culls, pomace, juice, sauce and canned apple. The conditions employed for processing were not stated.

Apples were treated at a rate of 6 × 3.4 kg ai/ha or 6 × 6.7 kg ai/ha and harvested immediately after the last application. Samples were stored frozen for up to 9 months prior to analysis. Residues were determined using method AG-550.

Residues of diazinon, G-24576 and CGA-14128 on processing are summarised in Table 82.

Table 82 Residues in apple and processed fractions

Crop/processed commodity	Diazinon residue (mg/kg)	Pf diazinon	G-24576 residues (mg/kg)	CGA-14128 residues (mg/kg)
Trial 1: 6 × 3.4 kg ai/ha

Notes:

Pf = Residue level in processed commodity (mg/kg) ÷ residue level in RAC (mg/kg)

RESIDUES IN ANIMAL COMMODITIES

Farm animal feeding studies

Dairy cattle

Nine dairy cows (Holstein, 3–10 years old, 411–678 kg bw) were divided into three dose groups, each containing three cows, with a further one cow serving as a control for all dose groups. Animals were dosed with diazinon once daily for 28- 30 consecutive days by means of a gelatine capsule administered with a balling gun.

The doses administered to the three dose groups were 41, 124 and 414 ppm. During the study, daily feed consumption and milk production were constant and were on average 21.2 kg/day and 17.0 kg/day respectively.

Milk samples were taken twice daily with the morning sample being kept refrigerated and then combined with the evening sample for each cow. Tissue samples were collected at sacrifice which occurred within 24 hours of the last dose. Milk and tissue samples were stored frozen and analysed within 5 months.

Samples were analysed for diazinon, G-24576 and CGA-14128 using method AG-550A (GC-FPD). Procedural recoveries were undertaken at fortification levels of 0.01–0.5 mg/kg and were acceptable for all commodity/ analyte combinations except milk/ CGA-14128 for which the recoveries were 105–137 percent.

Residues of diazinon were < 0.01 mg/kg in milk from the lowest dose study. Residues of G-24576 and CGA-14128 were < 0.01 mg/kg at all dose rates. The residues of diazinon from the two higher feeding rates are shown in Table 83.

Table 83 Residues of diazinon in whole milk following administration of diazinon to dairy cows once daily at a rate of 124 ppm and 414 ppm

Day	Residue level (mg/kg)

In tissues residues of G-24576 and CGA-14128 were < 0.01 mg/kg at each dose rate. Residues of diazinon were found in muscle, fat, liver and kidney. A summary of the residues found in tissues is outlined in Table 84.

Laying hen

Forty five laying hens (leghorn, 1.4–1.6 kg bw) were divided into three dose groups. For each dose group there were 15 hens that were divided into three replicates (i.e. five hens per replicate, 15 hens per dose group). For each dose group a further five hens were maintained as controls.

Animals were dosed with diazinon once daily for 28 consecutive days by means of a gelatine capsule administered with a balling gun. The doses administered to the three dose groups were 0.5, 1.5 and 5 ppm. During the study, daily feed consumption and egg production were constant. The average feed consumption was 0.11 kg/day.

Egg samples were taken daily, with eggs within each replicate, for each dose group, being pooled to form one composite sample. Tissue samples were collected at sacrifice which occurred 19–23 hours after the last dose. Egg and tissue samples (muscle, skin plus attached fat, peritoneal fat and liver) were stored frozen and analysed within 5 months.

Samples were analysed for diazinon, G-24576 and CGA-14128 using method AG-550A. Procedural recoveries were undertaken at fortification levels of 0.01–0.5 mg/kg and were acceptable for all commodity/ analyte combinations except for one set for recoveries performed at 0.2 mg/kg for tissue samples. The recoveries for tissues at 0.2 mg/kg were 141 percent for diazinon, 150 percent for G-24576 and 172 percent for CGA-14128. The identity of the specific tissue used foe the procedural recoveries is not stated.

Residues of diazinon, G-24576 and CGA-14128 were < 0.01 mg/kg in eggs and all tissue samples for all dose levels.

APPRAISAL

Diazinon is a contact organophosphorus insecticide with a wide range of insecticidal activity. It is effective against sucking, chewing and boring insects, including soil-living insects. Diazinon has been evaluated on numerous occasions by the JMPR commencing in 1963. The Most recent periodic review

was in 1993. Following public health concerns identified by the International Agency for Research on Cancer (IARC), the JMPR in 2016 evaluated all previously considered toxicological data in addition to new studies. The 2016 JMPR recommended an ADI of 0–0.003 mg/kg bw and an ARfD of 0.03 mg/kg bw. Diazinon was scheduled at the Fifty-first Session of the CCPR (2019) for Periodic Review for residues by the 2020 JMPR and re-scheduled for the 2022 JMPR.

The Meeting received information from the manufacturer on physical and chemical properties, animal and plant metabolism, rotational crop studies, environmental fate in soil, analytical methods, storage stability, use patterns, supervised residue trials, processing studies and livestock feeding studies.

In this document, the common names, chemical structures and chemical names of the metabolites are shown below.

Table 85 Summary information on compounds referred to in the appraisal

Name/Code	Chemical name	Chemical structure	Occurrence in metabolism studies
Diazinon	*O,O*-diethyl-*O*-(2-isopropyl-6-methyl-4-pyrimidinyl)-phosphorothioate		Apple Beans Sweet corn Lettuce Potatoes Goat Hen Rotated spring wheat
G-24576 (diazoxon)	*O,O*-diethyl-*O*-(2-isopropyl-6-methyl-4-pyrimidinyl) phosphorate		Goat Hen
CGA-14128 (hydroxydiazinon)	*O,O*-diethyl-*O*-(2-[2-hydroxy-2-isopropyl]-6-methyl-4-pyrimidinyl)phosphorothioate		Goat Hen
G-27550 B_1	6-methyl-2-(1-methyl-ethyl)-4-pyrimidinol		Apple Beans Sweet corn Lettuce Potatoes Goat Hen Rotated Spring wheat

Name/Code	Chemical name	Chemical structure	Occurrence in metabolism studies
Glucose conjugate of G-27550	6-methyl-2-(1-methyl-ethyl)-4-pyrimidinol glucose conjugate		Bean, vines only
GS-31144 C	2-(2-hydroxyisopropyl)-6-methyl-4-pyrimidinol		Apple Beans Sweet corn Lettuce Potatoes Goat Hen Rotated spring wheat
Glucose conjugate of GS-31144 E_2	2-(2-hydroxyisopropyl)-6-methyl-4- pyrimidinol glucose conjugate		Apple Beans Sweet corn Lettuce Potatoes
Two glucose conjugates of trihydroxy pyrimidinyl moiety† G and H	2-(2-hydroxyisopropyl)-6-hydroxymethyl-4-pyrimidinol glucose conjugate		Apple Beans Sweet corn Lettuce Potatoes Rotated spring wheat
JAK-III-57 D	2-(1-methylethyl)-6-hydroxymethyl-4- pyrimidinol		Apple Beans Sweet corn Lettuce Potatoes Rotated spring wheat
Glucose conjugate of JAK-III-57 F_2	2-(1-methylethyl)-6-hydroxymethyl-4- pyrimidinol glucose conjugate		Apple Beans Sweet corn Lettuce Potatoes Rotated spring wheat
CL-XIX-29 E_1 (also referred to as M3 in some studies)	2-(1-hydroxypropan-2-yl)-6-methyl-4-pyrimidinol		Apple Beans Sweet corn Lettuce Potatoes Hen Rotated spring wheat

Name/Code	Chemical name	Chemical structure	Occurrence in metabolism studies
Glucose conjugate of CL-XIX-29 F1	2-(1-hydroxypropan-2-yl)-6-methyl-4-pyrimidinol glucose conjugate		Apple Beans Sweet corn Lettuce Potatoes Rotated spring wheat
JAK-IV-23	2-isopropyl-6-oxo-1,6-dihydropyrimidine-4-carboxylic acid		Beans
Glucose conjugate of JAK-IV-23	2-isopropyl-6-oxo-1,6-dihydropyrimidine-4-carboxylic acid glucose conjugate		Beans
Glucuronic acid conjugates of G-27550	6-methyl-2-(1-methyl-ethyl)-4-pyrimidinol glucuronic acid conjugate		Hen
Glucuronic acid conjugates of GS-31144	2-(2-hydroxyisopropyl)-6-methyl-4- pyrimidinol glucuronic acid conjugate		Hen
Glucuronic acid conjugates of CL-XIX-29	2-(1-hydroxypropan-2-yl)-6-methyl-4-pyrimidinol malonyl glucuronic acid conjugate		Hen
A conjugate of G-27550 [§] (postulated to be a malonyl glucose conjugate)	6-methyl-2-(1-methyl-ethyl)-4-pyrimidinol malonyl glucose conjugate		Beans Lettuce

Name/Code	Chemical name	Chemical structure	Occurrence in metabolism studies
A conjugate of JAK-III-57 § (postulated to be a malonyl glucose conjugate)	2-(1-methylethyl)-6-hydroxymethyl-4- pyrimidinol malonyl glucose conjugate		Beans Lettuce
A conjugate of GS-31144 § (postulated to be a malonyl glucose conjugate)	2-(2-hydroxyisopropyl)-6-methyl-4- pyrimidinol malonyl glucose conjugate		Beans Lettuce

Notes:

† The structure of the two metabolites G and H were not fully elucidated. The mass spectral analysis did not confirm the positions of the hydroxyl groups. The metabolites were susceptible to hydrolysis with β-glucosidase but no identification work was undertaken on the aglycone.

§ The identity of the conjugates were not established. The aglcones released from enzymatic or acid hydrolysis were confirmed.

With respect to the physical and chemical properties that may impact residues in crops, diazinon is regarded as moderately volatile, it has a higher solubility in organic solvents, compared to its solubility in water, and the partition coefficient (3.3–3.8) indicates its potential to sequester in fat.

Plant metabolism

Plant metabolism data, conducted via pre-emergence/soil directed applications followed by foliar applications, were provided for apple, beans with pods, sweet corn, lettuce and potatoes. In all the studies, the extraction procedure resulted in fractions that contained identified metabolites that were not individually quantified.

Apple

Apples, grown outdoors, were treated with [^{14}C]-pyrimidine-diazinon three times. The first application was at a rate of 3.36 kg ai/ha applied in the early tight cluster stage (approximately BBCH 55); this application was split between a soil application (3.024 kg ai/ha) and a foliar application to a single branch (0.336 kg ai/ha). The second and third applications were foliar applications at a rate of 10.09 kg ai/ha, made to the same branch when the apples were present, 104 days and 133 days after the first application.

Mature apples were harvested 14 days after the last treatment. Foliage samples were also collected. The foliage, pulp and peel were analysed. The TRR in leaves, peel, pulp and whole apple were 51.1 mg eq/kg, 3.44 mg eq/kg, 0.126 mg eq/kg and 1.29 mg eq/kg respectively. Solvent extractabilities, methanol: water (9: 1), ranged from 89.7 percent of the TRR for peel to 91.9 percent of the TRR for leaves.

The major residue identified in leaves, peel and whole apple was diazinon (22.3 mg/kg, 43.7 percent TRR for leaves, 2.5 mg/kg, 73.3 percent TRR for peel and 0.89 mg/kg, 69 percent TRR for whole apple). Metabolite G-27550 was found at 11.9 percent TRR (0.4 mg eq/kg) in peel, at 5.9 percent TRR (3 mg eq/kg) in leaves and at 14.7 percent TRR (0.19 mg/kg) in whole apple.

In the pulp the major residue was G-27550 (60.7 percent TRR, 0.08 mg eq/kg). Diazinon was found at a level of 16.1 percent TRR (0.02 mg/kg).

Glucose conjugates of GS-31144, CL-XIX-29, JAK-111-57 and of the trihydroxy pyrimidyl moiety were identified. For peel, pulp and whole apple the individual levels of these metabolites were not reported.

The PES accounted for 8.1 percent TRR (4.1 mg eq/kg) in leaves, 10.4 percent TRR (0.4 mg eq/kg) in peel, 9 percent TRR (0.01 mg eq/kg) in pulp and 11.6 percent TRR (0.15 mg eq/kg) in whole apple. The TRR identified was 72 percent TRR for leaves, 89 percent TRR for peel, 86 percent TRR for pulp and 87 percent TRR for whole apple.

Beans with pods

Beans with pods, grown outdoors, were treated with [^{14}C]-pyrimidine-diazinon three times. A pre-emergence application was made at a rate of 4.48 kg ai/ha applied 1 day after sowing. Two foliar applications were made at a rate of 1.4 kg ai/ha. The first foliar application was made 34 days after the pre-emergence application and the 2nd foliar application was made 15 days later.

Samples of beans with pods and vines were taken 14 days after the last application, which was stated to represent crop maturity. Immature crop fractions were also sampled: vines were taken 3 days before the first foliar application, 31 days after first treatment (DAFT), and vines with beans were taken 7 days after the first foliar application (41 DAFT). The growth stages of the various crop fractions sampled and analysed were not stated.

The TRR in beans with pods harvested 14 DALA, was 0.456 mg eq/kg. The solvent extractability, methanol: water (9:1), was 76 percent TRR. Diazinon was found at a level of 2.1 percent TRR (0.01 mg/kg). The predominant residue was G-27550 at 26.7 percent TRR (0.12 mg eq/kg). The metabolite JAK-111-57 (4.4 percent TRR, 0.02 mg eq/kg) was also identified. The metabolite CL-XIX-29 and glucose conjugates of GS-31144, CL-XIX-29, JAK-111-57 and of the trihydroxy pyrimidinyl moiety were also identified. However, the individual levels were not reported. The TRR identified in beans with pods was 53 percent TRR. The PES accounted for 24 percent TRR (0.109 mg eq/kg).

The TRR in the vines with beans, harvested 41 DAFT, was 4.45 mg eq/kg. The identification and characterisation of the TRR was unsuccessful.

The TRR in vines was 0.425 mg eq/kg and 3.53 mg eq/kg for vines harvested 32 DAFT and 14 DALA respectively. Solvent extraction was undertaken with methanol: water (9:1) and was 54 percent TRR for the vines harvested 32 DAFT. The solvent extractability was higher for the vines harvested 14 DALA at 82 percent TRR. Diazinon was not identified in either of the vine samples. In vines, harvested 32 DAFT, the highest contribution to the TRR was 17.3 percent TRR (0.07 mg eq/kg) which was attributed to a mixture of two glucose conjugates of the trihydroxy pyrimidinyl moiety and an unknown metabolite. The metabolites CL-XIX-29 and a glucose conjugate of GS-31144 accounted for 15.5 percent TRR (0.07 mg eq/kg), with the individual levels not reported. In the vines harvested 14 DALA, the highest contribution to the TRR (27.5 percent TRR, 0.97 mg eq/kg) was attributed to a mixture of CL-XIX-29 and a glucose conjugate of GS-31144. An unknown metabolite occurred at a level of 19.5 percent TRR (0.69 mg eq/kg). Glucose conjugates of GS-31144 and CL-XIX-29 were identified and together accounted

for 12.5 percent TRR (0.44 mg eq/kg), with the individual levels not stated. The TRR identified in the vines was 58 percent TRR. The PES accounted for 18 percent TRR (0.639 mg eq/kg).

In a supplementary study, retained samples of beans with pods and vines harvested 14 DALA were re-extracted after 69 months of storage. The TRR and solvent extractability (methanol: water (9:1)) for the beans with pods was 0.509 mg eq/kg and 75 percent TRR. This was comparable to the earlier extractions for which the TRR was 0.456 mg eq/kg and the solvent extractability was 76 percent TRR. For the vines the TRR and the solvent extractability was 3.76 mg eq/kg and 78 percent TRR respectively which was comparable to the earlier extraction for which the TRR was 3.53 mg eq/kg and the solvent extractability was 82 percent TRR.

For both beans with pods and vines the extracted residue was partitioned with ethyl acetate and only the aqueous fraction was subjected to further analysis. In beans with pods, the highest contribution to the TRR was 20.3 percent TRR (0.103 mg eq/kg) which was found to contain JAK-IV-23, glucose conjugates of the trihydroxy pyrimidinyl moiety and unidentified conjugates of G-27550, JAK-III-57 and GS-31144. In vines, this fraction accounted for 17.4 percent TRR (0.652 mg eq/kg). The individual levels of the metabolites were not reported for either beans with pods or vines. In vines the highest contribution to the TRR was 27 percent TRR (1.013 mg eq/kg) which was found to contain CL-XIX-29 and a glucose conjugate of GS-31133, with the individual levels not being specified. Free G-27550, GS-31144 and JAK-III-59 were also identified in both beans with pods and vines.

The PES, from the beans with pods, from the supplementary study were subject to further extraction with methanol: water (9:1), 1 percent NaCl, cellulase hydrolysis and protease hydrolysis. The extraction procedures individually released 2.1–8.5 percent TRR (0.011–0.044 mg eq/kg), leaving 6.4 percent TRR (0.033 mg eq/kg) in the final post-extraction solids. In the released radioactivity, diazinon, G-27550 and GS-31144 were identified along with a number of unidentified polar fractions, with the individual levels of the analytes not specified

Sweetcorn

Sweetcorn, grown in a greenhouse, was treated with [^{14}C]-pyrimidine-diazinon three times. The first application was made pre-emergence, on the day of sowing, at a rate of 4.48 kg ai/ha. The second and third applications were foliar applications at a rate of 3.5 kg ai/ha applied 50 and 74 DAFT. Samples of various sweet corn fractions were taken 2 days prior to the last application (72 DAFT) and 14 DALA.

The TRR in the crop fractions sampled 72 DAFT were 2.070 mg eq/kg, 0.087 mg eq/kg and 0.810 mg eq/kg for forage, ears and stalks respectively. The solvent extractabilities (methanol: water (9:1) were 69 percent TRR for forage, 59 percent TRR for ears and 20 percent TRR for stalks.

The TRR in cob and grain harvested 14 DALA were 0.250 mg eq/kg and 0.453 mg eq/kg respectively. Solvent extraction was undertaken with methanol: water (9:1) and was 47.5 percent TRR, for the cob, and 26.4 percent TRR for the grain.

Following solvent extraction, the residue was partitioned with ethyl acetate. Although the majority of the TRR was shown to be aqueous soluble, only the organo-soluble fractions of forage (72 DAFT), stalks (72 DAFT), cobs and grain were subject to further analysis. For forage (14 DALA) both the organo-soluble and aqueous fractions were analysed.

In grain, diazinon was not identified. The metabolites G-27550, GS-31144 and JAK-111-57 were identified at levels of < 1 percent TRR (< 0.004 mg eq/kg). Two unknown metabolites at 0.1 percent TRR (0.0005 mg eq/kg) were also found in the grain. A total of 1.1 percent TRR (0.005 mg eq/kg) was identified in grain. The PES accounted for 74 percent TRR (0.33 mg eq/kg). Subsequent treatment of the

PES with amyloglucosidase released around 60 percent TRR (0.28 mg eq/kg) which was found to be highly polar in nature and likely to comprise of a complex mixture of sugar conjugates. The identities of the aglycone were not established.

In the stalks, harvested 72 DAFT, the predominant residue identified was G-27550 (7.7 percent TRR, 0.0624 mg eq/kg). The metabolites GS-31144 (1.3 percent TRR, 0.01 mg eq/kg) and JAK-111-57 (1.1 percent TRR, 0.009 mg eq/kg) were also identified. Two unknown metabolites were found at levels of 0.6 percent TRR (0.005 mg eq/kg) and 1.5 percent TRR (0.0122 mg eq/kg). Diazinon was not identified. A total of 10 percent TRR (0.0819 mg eq/kg) was identified. The PES accounted for 80 percent TRR (0.646 mg eq/kg).

In the forage samples harvested 72 DAFT, diazinon was identified at a level of 0.5 percent TRR (0.01 mg/kg). The predominant residue was G-27550 (7 percent TRR, 0.145 mg eq/kg). The metabolites GS-31144 (0.7 percent TRR, 0.0145 mg eq/kg) and JAK-111-57 (1.3 percent TRR, 0.0269 mg eq/kg) were also identified. Two unknown metabolites occurred at levels of < 1 percent TRR (< 0.026 mg eq/kg). The TRR identified was 9.5 percent TRR (0.2 mg eq/kg). The PES accounted for 31 percent TRR (0.64 mg eq/kg).

In sweet corn forage (14 DALA), the predominant residue was G27550 (14.5 percent TRR, 0.56 mg eq/kg). Conjugates of CL-XIX-29, JAK-111-57 and of the trihydroxy pyrimidinyl moiety accounted for 12.4 percent TRR (0.48 mg eq/kg), with the individual levels not specified. Unknown metabolite was found at 11.8 percent TRR (0.46 mg eq/kg). Approximately 41 percent TRR (1.6 mg eq/kg) was identified. The PES accounted for 25.5 percent TRR (0.992 mg eq/kg).

Lettuce

Lettuce, grown outdoors, was treated with [^{14}C]-pyrimidine-diazinon three times. The first application was made pre-emergence at a rate of 4.48 kg ai/ha. The second and third applications were foliar applications at a rate of 1.4 kg ai/ha applied at 7 days intervals. Immature leaves were harvested prior to the last application (0 DALA). Mature leaves were harvested 14 DALA.

The TRR were 1.885 mg eq/kg and 0.656 mg eq/kg for immature and mature lettuce respectively. Solvent extraction was undertaken using methanol: water (9:1, v/v). The solvent extractabilities were 87.2 percent of the TRR and 78.4 percent of the TRR for immature and mature lettuce respectively.

For immature lettuce, 47 percent TRR was found to be aqueous soluble and 40 percent TRR was found to be organosoluble. Only the organosoluble residue was subjected to further analysis. The main components identified in the organosoluble fraction from immature lettuce were G-27550 (18.9 percent TRR, 0.36 mg eq/kg) and diazinon (18.6 percent TRR, 0.35 mg/kg). The PES, remaining after solvent extraction, was 12.8 percent TRR (0.241 mg eq/kg).

For mature lettuce both the organosoluble and aqueous soluble extracts were subject to further identification/characterization. The extracts were also treated with ß-glucosidase to confirm the presence of the conjugates identified. The main metabolites identified were G-27550 (17.5 percent TRR, 0.12 mg eq/kg), diazinon (11.8 percent TRR, 0.08 mg/kg) and GS-31144 (11.7 percent TRR, 0.08 mg eq/kg). An unknown metabolite accounted for 12.7 percent TRR (0.08 mg eq/kg). Glucose conjugates of GS-31144, CL-XIX-29, JAK-111-57 as well as free CL-XIX-29 were also identified, with the individual levels not being specified. Two glucose conjugates of the trihydroxy pyrimidinyl moiety were also identified. In total 63.5 percent of the TRR was identified. Following solvent extraction, the PES for mature lettuce accounted for 21.6 percent TRR (0.142 mg eq/kg).

In a supplementary study, retained samples of immature and mature lettuce, after 69 months of storage, were re-extracted with methanol: water (9: 1) followed by partitioning with ethyl acetate. The resulting aqueous phase was subjected to further analysis.

For immature lettuce the TRR and the solvent extractability were 2.2 mg eq/kg and 82 percent TRR. This compared to the original extraction for which the TRR was 1.9 mg eq/kg and 87 percent TRR. For mature lettuce the TRR was 0.75 mg eq/kg and the solvent extractability was 72 percent TRR. This was also comparable to the original extraction for which the TRR and solvent extractability was 0.66 mg eq/kg and 78 percent TRR respectively.

For immature lettuce, the main fraction accounted for 11.7 percent TRR (0.255 mg eq/kg). This fraction contained G-27550 and an unknown metabolite, with the individual levels not stated. The metabolite G-27550 was also identified separately at a level of 8 percent TRR (0.175 mg eq/kg). The metabolites GS-31144 (5.7 percent TRR, 0.124 mg eq/kg) and glucose conjugates of GS-31144 (1.2 percent TRR, 0.027 mg eq/kg), CL-XIX-29/ JAK-III-57 (3.6 percent TRR, 0.079 mg eq/kg) and of the trihydroxy pyrimidinyl moiety (2.5 percent TRR, 0.054 mg eq/kg). Enzymatic and acid hydrolysis released G-27550 and GS-31144 as well as three unidentified metabolites. These accounted for 8.5 percent TRR (0.185 mg eq/kg) with the individual levels not specified. A further conjugate of G-27550 accounted for 3 percent TRR (0.064 mg eq/kg).

In mature lettuce, the main fraction accounted for 16.7 percent TRR (0.125 mg eq/kg). This fraction contained conjugates of G-27550, GS-31144 and three unknown metabolites. The individual levels were not specified. The metabolites G-27550/unknown (4.7 percent TRR, 0.035 mg/ eq/kg), G-27550 (3.2 percent TRR, 0.024 mg/eq/kg), GS-31144 (7.8 percent TRR, 0.059 mg eq/kg) and JAK-III-57 (1.3 percent TRR, 0.01 mg eq/kg). Glucose conjugates of GS-31144 (3.6 percent TRR, 0.027 mg eq/kg), CL-XIX-29/ JAK-III-57 (10.1 percent TRR, 0.076 mg eq/kg) and of the trihydroxy pyrimidinyl moeity (4 percent TRR, 0.03 mg eq/kg) were also identified.

The PES, from the mature lettuce from the supplementary study were subject to further extraction with methanol: water (9:1), 1 percent NaCl, cellulase hydrolysis and protease hydrolysis. In the released radioactivity, low levels of diazinon, G-27550 and GS-31144 were identified along with a number of unidentified polar fractions, for which the number and levels of metabolites was not stated.

The PES accounted for approximately 80 percent TRR for tubers harvested -1 and 15 DALA (0.057 mg eq/kg for -1 DALA and 0.23 mg eq/kg for 15 DALA). Treatment of the PES from the tubers harvested 15 DALA with amyloglucosidase solubilized around 33 percent TRR. The identity of the solubilized radioactivity was not confirmed. Acid hydrolysis of the PES released around 72 percent TRR with 11.5 percent TRR identified as G-27550.

The TRR for foliage were 0.059 mg eq/kg and 1.930 mg eq/kg at -1 and 15 DALA respectively. The solvent extractabilities using methanol: water (9:1) were 32 percent TRR and 81.5 percent TRR for foliage harvested -1 DALA and 15 DALA respectively. Further characterization and identification was only undertaken on the foliage samples from 15 DALA. Diazinon was found in the potato foliage at 14.2 percent TRR (0.27 mg/kg). The highest contribution to the radioactivity, accounting for 20.8 percent TRR (0.4 mg eq/kg) was a glucose conjugate of JAK-111-57 and CL-XIX-29, with the individual levels not specified. A glucose conjugate of the trihydroxy pyrimidinyl moiety accounted for 14.1 percent TRR (0.27 mg eq/kg). Free CL-XIX-29 and a glucose conjugate of GS-31144 accounted for 11.5 percent TRR (0.22 mg eq/kg), with the individual levels not stated. The Total radioactivity identified was 68 percent TRR (1.31 mg eq/kg). The PES were 18.5 percent TRR (0.357 mg eq/kg).

Summary and conclusion of metabolism in crops

The metabolism of diazinon has been investigated in apples, beans with pods, sweet corn, lettuce and potatoes. All studies were undertaken with the application of [^{14}C]-pyrimidine-diazinon three times. The first application was either a pre-emergence application or a soil directed application followed by two foliar applications.

The Meeting noted that the time period over which the studies were conducted (15 months for apple, 21 and 68 months for beans with pods, 18 months for sweetcorn, 19 months and 69 months for lettuce and 16 months for potatoes) was longer than would be standard. HPLC profiles of crop fractions of lettuce and beans with pods extracted after 19 months of storage and extracted after 69 months of storage were comparable. The Meeting noted that stability data from fortified samples showed that G-24576 was unstable in a range of plant commodities and therefore the Meeting concluded that in the absence of data to support the storage interval from harvest to extraction, the plant metabolism data could not be relied on for an assessment of the residue definitions for risk assessment.

The data indicate that the metabolism in all 5 crops is qualitatively similar and proceeds with cleavage of the ester bond of diazinon leading to the loss of the diethylthiophosphate moiety and the formation of G-27550. Oxidation of the isopropyl moiety of G-27550 leads to the formation of GS-31144 and CL-XIX-29 while oxidation of the methyl moiety on the pyrimidine ring of G-27550 leads to the formation of JAK-III-57. Glucose conjugates of G-27550 and of the hydroxypyrimidine metabolites were identified.

However, the lower solvent extractability for beans with pods, sweet corn, lettuce and potatoes compared to apples indicates potential qualitative and quantitative differences in the metabolism. The radioactivity remaining in the PES, after solvent extraction, was high for beans with pods, sweet corns, lettuce and potatoes and subsequent analysis did not fully establish the identity of the released radioactivity but toxicological relevant metabolites were released such as diazinon, G-27550 and GS-31144.

The level of identification in beans with pods, sweet corn, lettuce and potatoes was low. For the crop fractions relevant to human consumption the level of identification was 24 percent TRR (0.109 mg eq/kg) for beans with pods, 1.1 percent TRR (0.005 mg eq/kg) for grain, 40 percent TRR (0.75 mg eq/kg) for immature lettuce leaves, 63.5 percent TRR (0.42 mg eq/kg) for mature lettuce leaves and 11.5 percent TRR (0.03 mg eq/kg) for potato tubers.

For apples, the radioactivity identified was 86 percent TRR (0.112 mg eq/kg) for pulp, 87 percent TRR (1.12 mg eq/kg) for whole apples and 89 percent TRR (3.01 mg eq/kg) for peel. The PES, following methanol: water extraction (9:1) accounted for 12 percent TRR (0.15 mg eq/kg) in whole apple.

For the plant metabolites identified, G-27550, GS-31144 and CL-XIX-29 were also identified in the rat.

Environmental fate

The Meeting received information on the environmental fate and behaviour of diazinon, including hydrolytic stability, aqueous photolysis, photochemical degradation in soil, and aerobic soil degradation studies.

Aqueous hydrolysis

Hydrolysis of diazinon was rapid at pH 5 (DT_{50} of 0.15 days at 70 °C and 12 days at 25 °C) and significantly slower under neutral conditions (DT_{50} of 0.4 days at 70 °C and 138 days at 25 °C) and basic conditions (0.2 days at 70 °C and 77 days at 25 °C).

Hydrolysis of diazinon also increased with temperature. The main degradation product identified was G-27550. At pH 5 and 25 °C, after 21 days diazinon accounted for 29 percent AR and G-27550 accounted for 67 percent AR.

The Meeting concluded that hydrolysis could be a significant degradation pathway under environmental conditions.

Aqueous photolysis

The photolysis of diazinon in aqueous solutions was investigated in two studies. Diazinon was found to be stable in deionised water at 20–25 °C when exposed to artificial light for 12 days. In a buffer solution at pH 7, temperatures 12–49 °C, diazinon was found to degrade when exposed to natural sunlight over 30 days. Only metabolite G-27550 was identified. The DT50 values calculated from the second study were 23 and 26 days.

The Meeting concluded that the degradation of diazinon, as a result of aqueous photolysis, was slow and was therefore unlikely to be a significant pathway under environmental conditions.

Soil photolysis

The photodegradation of diazinon in soil was investigated in two studies.

The DT50 for diazinon ranged from 17.3 to 37.4 hours under sunlight, while the DT_{50} values for diazinon in the dark control samples ranged from 15–39 days. The DT_{50}, calculated from study 1 only, for artificial light was 5.5 days.

The only degradation products identified were G-27550 and GS-31144. G-27550 accounted for up to 43 percent, 24 percent and 18 percent AR in artificially irradiated, natural sunlight and dark control samples, respectively after the exposure period. GS-31144 accounted for up to 3 percent AR after 21 hours of natural sunlight but was not found in the dark or artificial sunlight samples.

There were four unknown compounds which individually exceeded 10 percent of the AR at several time points.

The Meeting concluded that soil photolysis is a route of degradation for diazinon.

Aerobic soil degradation

Soil degradation studies were conducted in three soil types at application rates ranging from 1.2 to 10 mg ai/kg dry weight (dw) of soil. After 76 days of incubation at 20 °C in the dark, diazinon ranged from 1.8–9.1 percent AR. The main degradation products identified were GS-31144 and G-27550. G-27550 accounted for 48.1–65.8 percent AR after 76 days of incubation.

The mineralization of diazinon into CO2 accounted for up to a maximum 9.9 percent AR. Extractability from all samples declined with time, with 62.2–73 percent AR extracted at day 76.

The DT_{50} values calculated for diazinon were 8 days, 23 days and 9.9 days for sandy loam, loamy sand and clay loam soils respectively. The DT_{50} values calculated for G-27550 were 124 days, 131 days and 124 days for sandy loam, loamy sand and clay loam soils respectively

The Meeting concluded that under aerobic conditions diazinon was non-persistent in soil and that G-27550 was persistent in soil.

Residues in Succeeding or Rotational crops

Confined rotational crop studies

The Meeting received two confined rotational crop studies.

In the first confined rotational crop study a primary crop of maize was treated with [^{14}C]-pyrimidine-diazinon three times. The first application was made at a rate of 4.48 kg ai/ha (pre-emergence) followed by two foliar applications at a rate of 3.5 kg ai/ha (BBCH 30–39). The two foliar applications were made 50 and 74 days after sowing of the primary crop

Rotational crops of wheat, lettuce, sugar beet and soya bean were planted after harvest of the primary maize crop, which was 98 days after the last foliar application.

The TRR in immature lettuce and mature lettuce were 0.072 mg eq/kg and 0.039 mg eq/kg respectively. The solvent extractability for the mature lettuce using methanol: water (9:1, v/v) was 72 percent TRR. No further characterization/ identification of the residue was undertaken for the lettuce samples.

For sugar beet roots the TRR were 0.048 mg eq/kg and 0.016 mg eq/kg for immature roots and mature roots respectively. The TRR in the leaves were 0.061 mg eq/kg, 0.040 mg eq/kg and 0.16 mg eq/kg for 25 percent mature leaves, immature leaves and mature leaves respectively. Solvent extraction was only undertaken for the 50 percent mature leaves with 91 percent TRR extracted with methanol: water (9:1, v/v). No further characterization/ identification of the residue was undertaken for the sugar beet samples.

In the mature soya beans, the TRR was 0.19 mg eq/kg. The solvent extractability with methanol: water (9:1, v/v) was 16 percent TRR. For the mature pods, the TRR was 0.23 mg eq/kg and the solvent extractability with methanol: water (9:1, v/v) was 43 percent TRR. The TRR determined in the stalks were 0.12 mg eq/kg, 0.16 mg eq/kg and 0.19 mg eq/kg for 25 percent mature stalks, 50 percent mature stalks and 50 percent mature stalks respectively. The solvent extractability with methanol: water (9:1, v/v) ranged from 63–72 percent TRR. No further characterization/ identification of the extracted residue and unextracted residue was undertaken for the soya bean samples.

In wheat grain, the TRR was 0.24 mg eq/kg and the solvent extractability with methanol: water (9:1, v/v) was 11.6 percent TRR. In the extracted residue, a glucose conjugate of the trihydroxy pyrimidinyl moiety (0.8 percent TRR, 0.002 mg eq/kg), GS-31144 (0.4 percent TRR, < 0.001 mg eq/kg) and an unknown metabolite with G-27750 (0.8 percent TRR, 0.002 mg eq/kg) were identified.

For wheat hulls, stalks and foliage the TRR range from 0.14 mg eq/kg (foliage) to 0.62 mg eq/kg (wheat hulls). Solvent extractabilities with methanol water (9:1, v/v) ranged from 58 percent TRR (wheat hulls) to 70 percent TRR (stalks). In the extracted residue from these crop fractions a glucose conjugate of the trihydroxy pyrimidinyl moiety (0.012–0.055 mg eq/kg), CL-XIX-29 (0.004–0.023 mg eq/kg), JAK-111-57 (0.004–0.08 mg eq/kg), CL-XIX-29 with a glucose conjugate of JAK-III-57 (0.008 mg eq/kg) and GS-31144 (0.008–0.029 mg eq/kg) were identified at various levels. An unknown metabolite quantified with G-27750 was also identified (0.03–0.085 mg eq/kg. Diazinon was only found in the stalks at 0.045 mg/kg.

The TRR identified was 1.2 percent TRR (0.002 mg eq/kg) for wheat grain, 19 percent TRR (0.094 mg eq/kg) for wheat hulls, 21 percent TRR (0.133 mg eq/kg) for mature stalks and 24 percent TRR

(0.033 mg eq/kg) for 25 percent mature foliage. No further analysis of the unextracted residue was undertaken.

A second study focused on the uptake of residues in rotational crops with no identification of the radioactive residues undertaken. Primary crops of lettuce, beans with pods and potatoes were all treated with [^{14}C]-pyrimidine-diazinon at a rate of 4.48 kg ai/ha, applied pre-emergence, one day after sowing of the primary crop, followed by two foliar applications at 1.4 kg ai/ha. The foliar applications were made at intervals of 34 days and 41 days for lettuce, 34 days and 49 days for beans with pods, and 75 days and 82 days for potatoes, after the pre-emergence application. Rotational crops of wheat, lettuce, soya beans and sugar beet were planted 90 to 327 DALA after harvest of the primary crop.

The TRR in wheat grain, immature wheat stalks, immature and mature lettuce, and sugar beet roots and leaves were < 0.01 mg eq/kg. Residues above 0.01 mg/kg were obtained in mature wheat stalks (0.012 mg eq/kg), wheat hulls (0.011 mg eq/kg) and wheat full grazing leaves (0.014 mg eq/kg). Residues above 0.01 mg eq/kg were also obtained in various soya bean fractions; mature beans (0.015 mg eq/kg), mature pods (0.012 mg eq/kg), 0.011 mg eq/kg (50 percent mature stalks) and 0.027 mg eq/kg (mature stalks).

Solvent extraction was undertaken for a limited number of crop fractions using methanol: water (9:1, v/v). The solvent extractabilities were low and ranged from 16 percent TRR (mature soya beans) to 61 percent TRR (50 percent mature soya bean stalks).

Summary and conclusion of metabolism in rotational crops

The Meeting noted that the rotational crops did not investigate shorter PBI of 30 days and the rotational crops were planted after the harvest of treated primary crops, rather than being planted after applications to the bare soil. Although significant crop interception will have occurred for the foliar applications and the intervals (34–75 days) between the pre-emergence and first foliar application may have further reduced the total amount of residue available in the soil, residues above 0.01 mg/kg were identified in rotational crops. Based on the use patterns provided to the current Meeting residues above 0.01 mg/kg are expected in rotational crops. However, the identity of the residues in rotational crops has not been confirmed.

Owing to the limited information on the identity of the metabolites in rotated crops, the Meeting decided a comparison of the primary and rotational crop metabolism was not possible. The data available for wheat, indicates that the metabolite G-27550 is likely to be significant in rotational crops.

Field rotational crop study

A field rotational crop study was conducted using lettuce, turnips and wheat planted 30, 60 and 180 days after the last application to a primary crop. Primary crops of lettuce, squash, melons and tomatoes were treated with one pre-emergence application at 4.48 kg ai/ha followed by five foliar applications at 0.56 kg ai/ha and then harvested before planting of the rotational crops. The foliar applications to the primary crop were made at various growth stages and therefore the intervals between the applications and the amount of crop interception varied.

Residues of diazinon, G-24576 and CGA-14128 were < 0.01 mg/kg in all rotational crop samples from all plant back periods. The Meeting decided that a conclusion on the residue levels in rotational crops could not be drawn as the relevant residues for rotational crops could not be confirmed from the metabolism studies, noting that metabolite G-27550, which based on the available information may be significant in rotational crops, had not been included in the trials. The storage stability data on fortified samples showed that G-24576 rapidly degraded in a range of plant commodities and therefore the

reported results of < 0.01 mg/kg for this metabolite in rotational crops could not be relied on as the samples were stored for up to 15 months prior to analysis.

Animal metabolism

The meeting received information on metabolism of diazinon in ruminants (lactating goat) and poultry (laying hens).

Rat

Metabolism studies on laboratory animals including rats were reviewed in the framework of the toxicological evaluation by the WHO core Assessment Group of the 2016 JMPR.

Lactating goat

Two goats were orally dosed, by capsule, with [^{14}C]-pyrimidine-diazinon at a rate of 109–114 ppm for four consecutive days. Goats were slaughtered 24 hours after the last dose. The majority (72–77 percent) of the administered dose was excreted in urine (64 percent) and faeces (9–12 percent). The total radioactivity excreted in milk was 0.31 percent AD.

The TRR in milk over the 4 days ranged from 0.45–0.469 mg eq/kg, for animal 1 and 0.33 mg eq/kg–0.46 mg eq/kg for animal 2. A plateau was reached after 2-3 days. The solvent extractability for milk, using acetonitrile: water (1:1, v/v), was 91 percent TRR (0.627 mg eq/kg). The predominant residues were GS-31144 (37.3 percent TRR, 0.256 mg eq/kg) and G-27550 (39.3 percent TRR, 0.270 mg eq/kg). A total of 77 percent TRR was identified and 9 percent TRR (0.06 mg eq/kg) remained in the PES.

For liver the TRR was 1.57 mg eq/kg. The solvent extractability with methanol: water (9:1, v/v) was 79 percent TRR (1.24 mg eq/kg). The predominant metabolites identified were GS-31144 (19 percent TRR, 0.298 mg eq/kg) and G-27550 (19.2 percent TRR, 0.301 mg eq/kg). A total of 39 percent TRR was identified. The PES accounted for 21 percent TRR (0.33 mg eq/kg) and was not subject to any further analysis.

In kidney the TRR was 3.0 mg eq/kg. Solvent extraction with methanol: water (9:1 v/v) released 94 percent TRR (2.84 mg eq/kg). The predominant metabolites identified were GS-31144 (31 percent TRR, 0.92 mg eq/kg) and G-27550 (19.8 percent TRR, 0.60 mg eq/kg). A total of 52 percent TRR was identified. The PES accounted for 6 percent TRR (0.18 mg eq/kg).

The TRR determined in fat was around 0.36 mg eq/kg. Around 95 percent TRR was extracted with methanol: water (9:1, v/v). The predominant residue was diazinon (maximum 68 percent TRR, 0.25 mg/kg). The metabolite CGA-14128 accounted for around 12.8 percent TRR (0.047 mg eq/kg). The metabolites GS-31144, G-27550 and G-24576 were also identified. The total radioactivity identified exceeded 95 percent TRR for fat.

The TRR determined in muscle was around 0.40 mg eq/kg. Methanol: water (9:1, v/v) extracted ≥ 95 percent TRR The predominant residues were GS-31144 (maximum 40 percent TRR, 0.18 mg eq/kg) and G-27550 (maximum 35 percent TRR, 0.16 mg eq/kg). Over 76 percent TRR was identified in muscle and the PES was ≤ 5 percent TRR (0.02 mg eq/kg).

The solvent extracts from the tissue samples were subject to acid hydrolysis (6 M HCl at 85°C, left overnight). Increased levels of GS-31144, G27550, G-24576 and CGA-14128 indicate the potential presence of conjugates of these metabolites. The liver and kidney solvent extracts were also treated with b-glucuronidase (incubated at 37°C, left overnight). No details were reported but increased levels of the

metabolites GS-31144 and G-27550 were observed indicating the potential presence of glucuronic conjugates of these metabolites.

Laying hens

Laying hens were orally dosed, by capsule, with [^{14}C]-pyrimidine-diazinon at a rate of 25 ppm for seven consecutive days. Hens were slaughtered 24 hours after the last dose. The majority (79 percent) of the administered dose was excreted. The total radioactivity found in eggs was 0.3 percent of the administered dose. For tissues the total radioactivity, taken 24 hours after the last dose, accounted for 0.09 percent of the administered dose.

The TRR in egg yolk and egg white were 0.065 mg eq/kg and 0.066 mg eq/kg respectively. Solvent extractability with methanol: water (9,1, v/v) was 67 percent TRR (0.043 mg eq/kg) for egg yolk and 98 percent TRR (0.065 mg eq/kg) for egg white. The predominant residues identified were a mixture of glucuronic conjugates of G-27550, GS-31144 and CL-XIX-29 and CL-XIX-29 (25 percent TRR, 0.016 mg eq/kg in yolk and 41 percent TRR, 0.027 mg eq/kg in egg white). The metabolite G-31144 accounted for 19 percent TRR (0.012 mg eq/kg) in yolk and 33 percent TRR (0.022 mg eq/kg in egg white) and G-27550 accounted for 11 percent TRR (0.007 mg eq/kg) in yolk and 9.4 percent TRR (0.006 mg eq/kg) in egg white. For egg yolks 33 percent TRR (0.022 mg eq/kg) remained in the PES and a total of 63 percent TRR (0.04 mg eq/kg) was identified. For egg whites, 2 percent TRR (0.001 mg eq/kg) remained in the PES and 98 percent TRR (0.065 mg eq/kg) was identified.

In liver, the TRR was 0.11 mg eq/kg and 63 percent of the TRR was extracted with methanol: water (9:1, v/v). The predominant residue, accounting for 47 percent TRR (0.052 mg eq/kg) was a mixture of glucuronic acid conjugates of G-27550, GS-31144 and CL-XIX-29. The levels of the individual metabolites were not determined. The PES, following solvent extraction, accounted for 37 percent TRR (0.041 mg eq/kg). Following treatment with protease diazinon, CGA-14128, G-24576, G-27550, GS-31144 and CL-XIX-29 were identified. For liver, 63 percent TRR (0.69 mg eq/kg) was identified.

For kidney, the TRR was 0.15 mg eq/kg. The solvent extractability using methanol: water (9:1,v/v) was 76 percent TRR (0.11 mg eq/kg). The predominant residue (56 percent TRR, 0.083 mg eq/kg) was a mixture of glucuronic conjugates of G-27550, GS-31144, CL-XIX-29 with the individual levels not being reported. The PES accounted for 24 percent TRR and 76 percent TRR (0.11 mg eq/kg) was identified.

In muscle, the TRR was 0.025 mg eq/kg and 64 percent TRR (0.016 mg eq/kg) was extracted with methanol: water (9: 1, v/v). Glucuronic acid conjugates of G-27550, GS-31144, CL-XIX-29 and CL-XIX-29 accounted for 22 percent TRR (0.006 mg eq/kg) in the organosoluble fraction. Glucuronic acid conjugates of G-27550, GS-31144, G-27550, GS-31144 and CL-XIX-29 also accounted for a further 31 percent TRR (0.008 mg eq/kg) in the aqueous soluble fraction. In all cases, the individual levels of the metabolites were not reported. After solvent extraction, 36 percent TRR (0.009 mg eq/kg) remained in the PES. For muscle, 64 percent of the TRR (0.016 mg eq/kg) was identified.

The TRR in skin with fat and peritoneal fat were low at 0.018 mg eq/kg and 0.01 mg eq/kg respectively. The solvent extractability with methanol water (9:1, v/v) was 46 percent TRR (0.008 mg eq/kg) and 31 percent TRR (0.003 mg eq/kg) for skin with fat and peritoneal fat respectively. The PES were ≤ 0.01 mg eq/kg. No metabolites > 10 percent TRR or > 0.01 mg eq/kg were identified.

Treatment of the PES from eggs and tissues with protease released between 21 percent TRR (egg yolk) and 69 percent TRR (Peritoneal fat). Further analysis was only undertaken for the liver samples. It was reported that residues of diazinon, CGA-14128, G-24576, G-27550, GS-31144 and CL-XIX-29 were found, with the individual levels not specified.

Summary and conclusion of metabolism in livestock

The Meeting concluded that, in all species investigated (goats, hens and rats), the total administered radioactivity was predominantly eliminated in excreta. The data indicate that the metabolic profile was qualitatively similar in all three species and proceeds with cleavage of the ester bond of diazinon leading to the loss of the diethyl thiophosphate moiety and the formation of G-27550. Oxidation of the isopropyl moiety of diazinon leads to the formation of CGA-14128 while replacement of sulphur in the diethyl thiophosphate group of diazinon with oxygen leads to the formation of G-24576. Oxidation of the isopropyl moiety of G-27550 leads to the formation of GS-31144. Oxidation of the isopropyl moiety also leads to the formation of CL-XIX-29 (hens and rats only).

For poultry, based on the low levels of radioactivity observed in eggs and tissues, the Meeting decided the extractability and level of identification was sufficient. However, the predominant residues in eggs, liver, kidney and muscle were glucuronic acid conjugates of various aglycones for which the individual levels were not specified. In goat liver the PES was high and the level of identification in both liver and kidney was low (< 52 percent TRR). Owing to these deficiencies a quantitative consideration of the data for the assessment of the residue definitions for livestock was not possible.

The metabolite G-24576 (diazoxon) was identified in all tissues, milk and eggs. The Meeting noted that the storage stability data conducted with fortified samples, evaluated by the 1999 JMPR, demonstrated that G-24576 rapidly degrades in milk and tissues (except fat) within 0–4 months. As samples were stored for up to 5 months in the lactating goat study and up to 12 months in the poultry study the levels reported for this metabolite in the various animal matrices cannot be relied on. The Meeting considered that this metabolite is more toxic than diazinon.

Methods of analysis

The Meeting received information on analytical methods for diazinon in plant and animal matrices.

The Meeting received the description and validation data for the analysis of diazinon in pineapple. Residues were extracted with acetonitrile: water (9:1, v/v) with final determination by LC-MS/MS. The method was successfully validated with an LOQ of 0.01 mg/kg. This method was also successfully validated by an independent laboratory, demonstrating good reproducibility.

The Meeting also received the description and validation data for the analysis of diazinon, G-24576 and CGA-14128 in a range of plant commodities. Residues were extracted with acetone: water (9:1, v/v) followed by extraction with petroleum ether: dichloromethane: water (5:5:1, v/v/v) with final determination by GC-FPD. The Meeting noted that the individual recoveries were not available for each fortification level and for some commodities the mean recoveries were (up to 128 percent. However, the Meeting decided the method was suitable for the determination of diazinon, G-24576 and CGA-14128 in crops of a high water content, crops of a high acid content, crops of a high oil content, crops of a high starch content, crude and refined corn oil. The LOQ validated was 0.01 mg/kg for all three analytes. For hops the method was validated with an LOQ of 0.01 mg/kg for diazinon and CGA-14128. The Meeting decided that the method was not validated for the determination of G-24576 in hops owing to the low mean recovery of 54 percent.

For animal matrices, the Meeting received the description and validation data for the determination of diazinon in muscle, fat, liver, milks and egg. Residues were extracted from animal matrices, except fat, with acetone: water (9:1, v/v) followed by extraction with petroleum ether: dichloromethane: water (5:5:1, v/v/v). For fat, residues were extracted with acetonitrile. Final determination was by GC-FPD or GC-NPD (diazinon only). The Meeting noted that the individual recoveries were not available and the mean

recoveries for some commodities ranged from 68–125 percent. However, the Meeting decided the method was suitable for the determination of diazinon, G-24576 and CGA-14128 in animal commodities (muscle, fat, liver, milk and eggs) with an LOQ of 0.01 mg/kg for the GC-FPD method. Diazinon could also be determined in muscle, fat, liver, milk and eggs with an LOQ of 0.005 mg/kg for the GC-NPD method.

The Meeting was unable to conclude on the acceptability of method REM 4/81, used in the storage stability studies for animal matrices, as no validation data were provided.

The extraction efficiency was not investigated for any of the analytical methods, The meeting noted that the plant and animal metabolism data involved extraction with methanol: water (except milk which used acetonitrile: water) whereas the analytical methods used acetonitrile: water or acetone: water followed by petroleum ether: dichloromethane: water. Based on the high solubility of diazinon in a range of organic solvents the Meeting concluded that the methods are acceptable for the extraction of incurred residues of diazinon in plants and animals.

Stability of pesticide residues in stored analytical samples

The Meeting received freezer storage stability data for diazinon, CGA-14128, G-27550 and G-24576 in various homogenised plant matrices.

Diazinon was stable in pineapple pulp (high acid) and peel at ≤ -18 °C for at least 3 months of storage. Diazinon, CGA-14128 and G-27550 were stable in strawberries (high acid) at ≤ -20 °C for at least 56 days of storage. G-24576 was found to rapidly decline in strawberries, when stored at ≤ -20 °C, with a recovery of < 9 percent at the first time point of 1 month of storage. The strawberry samples, fortified with G-24576 only, were found to contain residues of G-27550, indicating that G-24576 may degrade to G-27550.

The Meeting also received storage stability data for diazinon, G-24576 and CGA-1412 in maize (high starch), tomato (high water), potato (high starch), apple (high water), strawberry (high acid), lettuce (high water) and various processed fractions.

The Meeting concluded that G-24576 was stable in refined corn oil for at least 26 month of storage at ≤ -12 °C. Significant degradation was observed in all other commodities.

For diazinon and CGA-14128 the data showed different rates of decline in the various commodities. The Meeting concluded on the following storage stability intervals, see Table 2 below.

Table 86 Storage stability of diazinon and CGA-14128 in different plant matrices

Matrices	Crop	Storage interval demonstrated (months) at ≤ -12 °C	
		Diazinon	CGA-14128
High water	Tomato	26	Up to 6
	Apple	Up to 26	Not stable
	Lettuce	26	26
High acid	Strawberries	2	2
	Pineapples	3	No data
High starch	Maize	26	26
	Potato	26	26
High oil	Soya beans	27	27
Processed commodities	Refined corn oil	27	27
	Tomato paste	16	4
	Sugar beet molasses	16	4

The Meeting agreed that the demonstrated storage stability covered the storage intervals for diazinon in the field trials for apple and pineapple.The Meeting also agreed that the data were sufficient to support the storage interval for the rotational crop field trial samples (lettuce, wheat and turnips).

For animal commodities, the Meeting decided that the data indicated that diazinon is stable in muscle, liver, kidney and fat for at least 8 months of freezer storage. However, the Meeting was unable to conclude on the acceptability of the data as no validation data were provided for the analytical method used to quantify residues.

The Meeting noted that the 1999 JMPR evaluated storage stability data for diazinon, CGA-14128 and G-24576 for milk and tissues in an iterim study. This study was not provided to the current Meeting. Diazinon and CGA-14128 were stable in milk and tissues for 9 months of storage when stored at ≤ -18 °C. G-24576 was stable in fat for 9 months of storage at ≤ -18 °C. However, in milk and muscle degradation of G-24576 was observed at the first time point of 4 months. For liver, G-24576 was found to have degraded in the time zero sample.

The Meeting concluded that the demonstrated storage stability for diazinon and CGA-14128 in animal commodities covered the storage interval in the feeding studies. The data do not support the storage interval in the feeding studies for G-24576.

Definition of the residue

Plant commodities

The nature of the diazinon residue was investigated in apple, bean with pods, sweet corn, lettuce and potatoes following one pre-emergence or soil directed application and two foliar applications. In the metabolism studies, the storage intervals between harvest and extraction were not supported, the individual levels of the metabolites were not always quantified in the extracted residues, the level of identification was low and the residue remaining in the PES was high and therefore the data is of limited value for a comparison of the metabolism for the assessment of the residue definition for risk assessment for plants.

The Meeting noted that diazinon was identified in various crop fractions in the metabolism studies and was found at levels above 0.01 mg/kg in the residue trials provided to the Meeting for apples, pears, pineapples and cabbage. The Meeting considered that diazinon was a suitable marker for the enforcement of MRLs. Suitable analytical methods are available to analyse diazinon in plants.

The nature of the residue on processing has not been investigated. The environmental hydrolysis studies included information on the effects of pH and temperature and indicate that diazinon is susceptible to hydrolysis and this is likely to be more prominent at higher temperatures. The potential for degradation products to be formed in processed commodities, particularly G-27550 cannot be excluded. Therefore, the Meeting could not confirm if diazinon would be a suitable marker for the enforcement of MRLs for processed commodities.

As a result of concerns relating to the lack of suitable quantitative information on the individual levels of metabolites in plants, a conclusion was unable to be reached on a residue definition for dietary risk assessment.

Animal commodities

The nature of the diazinon residue was investigated in lactating goats and laying hens following oral administration of the test substance. Owing to the low level of identification in some tissues, the lack of

suitable quantitative information on the individual levels of metabolites and the storage stability, the Meeting decided not to use the animal metabolism studies to establish residue definitions for livestock.

The Meeting recommended the following residue definitions for diazinon:

Definition of the residue for compliance with MRLs for plants: *Diazinon*

As for risk assessment, the Meeting was unable to reach a conclusion on a residue definition for plant commodities.

The Meeting was unable to conclude on the residue definition for compliance with MRLs and for risk assessment for animal commodities.

Results of supervised residue trials on crops

Supervised trials were available for apple, pears, pineapple, cabbage and wheat.

As a conclusion could not be reached on the residue definition for risk assessment, the Meeting withdrew all previous recommendations for maximum residue levels for diazinon, including the spice MRLs.

Pome fruits

The critical GAP for apples, pears and quince is for Chile which is 3 applications of 0.07 kg ai/hL applied at 15 day intervals with a PHI of 21 days.

Apple

A total of three independent trials conducted in the United States at 0.053 kg ai/hl–0.087 kg ai/hl, with a RTI of 14-15 days and a PHI of 21 days matched the GAP. Where replicate trials at different application rates were conducted at the trial site and both application regimes matched the GAP, the trial giving the highest residue was selected.

Residues of diazinon in independent trials approximating the critical GAP were (n= 3): 0.02, <u>0.04</u> (2) mg/kg.

Pears

A total of two independent trials conducted in the United States at 0.078 kg ai/hl, with a RTI of 14-15 days and a PHI of 21 days matched the GAP.

The Meeting agreed to apply the proportionality principle to two trials conducted at 0.18 kg ai/hl, noting that as residues were < 0.01 mg/kg a scaling factor was not required.

Residues of diazinon in independent trials approximating the critical GAP were (n= 4): < 0.01 (3) and 0.06 mg/kg.

As the median residues of diazinon for apples and pears are within a 5-fold range, the Meeting decided to make a recommendation for apples, pears and quince on the basis of the combined data sets for apples and pears.

Residues of diazinon on the basis of the combined data set were (n= 7): < 0.01 (3), 0.02, 0.04 (2) and 0.06 mg/kg

The Meeting estimated a maximum residue level of 0.15 mg/kg for apples, pears and quince.

Assorted tropical and sub-tropical fruits–inedible peel

Pineapples

The critical GAP is for the United States which is 2 applications of 1.12 kg ai/ha with retreatment intervals of 28 days and a PHI of 7 days.

As no trials matched the GAP the Meeting did not estimate a maximum residue level.

Brassica vegetables

Cabbag, Head

The critical GAP is for Costa Rica which is 3 applications of 0.75 kg ai/ha with a retreatment interval of 8 days and a PHI of 10 days.

As no trials matched the GAP the Meeting did not estimate a maximum residue level.

Cereals grains

Wheat

The critical GAP is for Russia which is 1 application of 1.08 kg ai/ha and a PHI of 60 days.

As no trials matched the GAP the Meeting did not estimate a maximum residue level.

Residues in animal feeds

Wheat straw

The critical GAP is for Russia which is 1 application of 1.08 kg ai/ha and a PHI of 60 days.

As no trials matched the GAP the Meeting did not estimate residue levels for use in the estimation of livestock dietary burdens.

Fate of residues during processing

High temperature hydrolysis

No information on the nature of the residue on processing was received by the Meeting. Based on the environmental hydrolysis study, that included the effects of temperature and pH, the Meeting concluded that diazinon is likely to be susceptible to hydrolysis and this is likely to be more prominent at higher temperatures. The formation of hydrolysis products such as G-27550 could not be excluded in processed foods.

Processing

The Meeting received information on the processing of apples and pears. Residues of diazinon, G-24576 and CGA-14128 were determined in the RAC and processed fractions. No details on the processing conditions employed were available.

Residues of G-24576 and CGA-14128 were all < 0.01 mg/kg. Residues of diazinon were also < 0.01 mg/kg in the RAC for pears. The Meeting decided that the storage interval of 9 months was supported for diazinon and CGA-14128. However, G-24576 would not be stable over the storage interval. No information about the level of the metabolite G-27550 was available.

The Meeting did not estimate processing factors, STMR-P and HR-P as a conclusion could not be reached on the residue definitions for processed commodities.

Residues in animal commodities

Farm animal feeding studies

Farm animal feeding studies in lactating cattle and laying hens were provided to the Meeting.

Lactating cattle

Groups of three lactating cows were fed diazinon in the diet once daily at a dose rate of 41, 124 and 414 ppm for 28–30 consecutive days. One animal served as a control.

Milk samples were taken twice daily and combined for each individual animal. Residues of CGA 14128 and G-24576 were < 0.01 mg/kg in all milk samples. At a feeding rate of 124 ppm, diazon in milk was ≤ 0.01 mg/kg. At a feeding rate of 414 ppm, the highest residue of diazinon was 0.08 mg/kg at 7 days. A plateau was reached in milk after 3 days and the mean residue over the plateau period was 0.03 mg/kg.

Tissue samples were collected at sacrifice which occurred within 24 hours of the last dose. The metabolite G-24576 was not found in any tissue samples. However, the storage stability data demonstrated that G-24576 would be unstable in all tissue samples, apart from fat, and therefore no conclusions can be drawn from the levels reported. The storage data evaluated by the 1999 JMPR indicated that diazinon and GCA 14128 would be stable over the 5 months of storage, but this study was not available to the current Meeting. The mean and highest residues in tissue samples are summarised below.

Table 87 Mean and highest residues of diazinon and GCA 14128 found in animal tissues

Tissue	Residue level at day 28, day 29 and day 30 (mg/kg)								
	41 ppm			121 ppm			414 ppm		
	Diazinon	G-24576	CGA-14128	Diazinon	G-24576	CGA-14128	Diazinon	G-24576†	CGA-14128
Liver									
HR	< 0.01	< 0.01	< 0.01	0.02	< 0.01	< 0.01	0.06	< 0.01	< 0.01

† G-24576 was found to be unstable in all animal commodities except fat

Laying hens

Three groups of 15 hens were fed diazinon in the diet once daily at a dose rate of 0.5, 1.5 and 5 ppm for 28 consecutive days. A further 15 hens served as control animals.

Egg samples were taken daily. Tissue samples were taken at sacrifice which ocurred 19–23 hours after the last dose.

Residues of diazinon, G-24576 and GCA 14128 were < 0.01 mg/kg in all samples. However, the Meeting noted that G-24576 would not be stable in the samples over the storage interval prior to analysis.

Farm animal dietary burden

As the Meeting was unable to estimate STMRs and HRs for plants, the dietary burdens of livestock could not be estimated.

Animal commodity maximum residue levels

As the dietary burdens of livestock could not be estimated, the Meeting was unable to estimate maximum residue levels for animal commodities.

RECOMMENDATIONS

The residue definition for compliance with the MRL for plant is: *diazinon*.

The Meeting was unable to conclude on a residue definition for risk assessment for plants.

The Meeting was unable to conclude on a residue definition for compliance with MRLs and for risk assessment for animal commodities.

DIETARY RISK ASSESSMENT

As the Meeting was unable to recommend residue definitions for risk assessment for plants and animal commodities, long-term and acute dietary exposure assessments could not be conducted.

DIFENOCONAZOLE (224)

First draft prepared by A Leahigh the Environmental Protection Agency, United States of America

EXPLANATION

Difenoconazole was evaluated by the JMPR for the first time in 2007 when an ADI of 0–0.01 mg/kg bw and an ARfD of 0.3 mg/kg bw were established. In 2007, 2010, 2013, 2015, 2017, and 2021 the JMPR evaluated for residues and recommended numerous maximum residue levels.

The physical and chemical properties, animal and plant metabolism, environmental fate, analytical methods, storage stability, national registered use patterns, supervised residue trials, and processing in several plant commodities and residue of animal commodities were evaluated in previous JMPR evaluations.

The definition of the residue for compliance with MRL and for dietary intake for plant commodities is parent difenoconazole, while for animal commodities it is defined as sum of difenoconazole and 1-[2-chloro-4-(4-chloro-phenoxy)-phenyl]-2-(1,2,4-triazol)-1-yl-ethanol (CGA205375), expressed as difenoconazole. The residue is fat-soluble.

Difenoconazole was scheduled at the Fifty-second Session of the CCPR for the evaluation of additional MRLs in 2022 JMPR. The current Meeting received additional information on analytical methods, storage stability, use pattern, and residue data of supervised trials in China on Goji Berry, Dried Goji Berry, Pencil Yam, Dried Pencil Yam, Ginger, Dried Ginger, Fresh Tea Leaves, Green Tea and Black Tea.

METHODS OF RESIDUE ANALYSIS

Goji berry (fresh and dried)

The analytical method (Study report number: R20002A, Yanmei Yang, 2021) for determining residues of difenoconazole in fresh and dried goji berry is as follows.

Goji berry samples were analysed for the residues of difenoconazole using UPLC-MS/MS. The validated limit of quantitation (LOQ) for residues of difenoconazole in goji berries (fresh and dried) is 0.01 mg/kg.

Briefly, 10 grams of fresh goji berry sample is mixed with 10 mL of acetonitrile and homogenized by a vortexer for 10 minutes at 2500 rpm. For dried goji berries, five grams was mixed with 8 mL of distilled water and 10 mL of acetonitrile and homogenized by a vortexer for 10 minutes at 2500 rpmn. Five grams of NaCl was added to the homogenized sample, which was then shaken by a vortexer for 5 minutes at 2500 rpm. Finally, the acetonitrile and water phases were completely separated by centrifugation for 5 minutes at 8000 rpm. A 1.5 mL aliquot was taken from the acetonitrile phase and transferred to a 2 mL centrifuge tube with 50 mg of primary secondary amine (PSA), 50 mg of octadecyl silica (C18), and 8 mg of Graphitised Carbon Black (GCB). After being homogenized by a vortexer for 5 minutes at 2500 rpm, the tube was centrifuged for 2 minutes at 5000 rpm. The upper layer was filtered through a 0.22 µm nylon syringe filter. Then 0.5 mL of the filtrate was diluted with 0.5 mL of water for analysis by UPLC-MS/MS. The quantitative and confirmation ions of difenoconazole were m/z 406.1/251.1 and 406.1/337.1, respectively. The residue levels were calculated with single point by direct comparison of the sample peak responses to those of external matrix-matched standards.

The method validation was performed by analysing fresh and dried goji berry for difenoconazole for each of 2 blank control specimens, 5 replicate specimens fortified at LOQ (0.01 mg/kg), 5 replicate

specimens fortified at 10× LOQ (0.1 mg/kg), and 5 replicate specimens fortified at 500× LOQ (5.0 mg/kg). Recoveries of difenoconazole in goji berry ranged from 86 to 105 percent (mean: 92–102 percent, n=6) and calculations of the relative standard deviation (RSD%) of the recoveries obtained in each spiking level presents RSDs ≤ 6 percent. The validated LOQ for residues of difenoconazole in both fresh and dried goji berry were 0.01 mg/kg. Table 1 lists all recoveries obtained during method validation.

Pencil yam (fresh and dried)

The analytical method (Study report number: HZ2020N001A, Xueyan Zhang, 2021) for determining residues of difenoconazole in fresh and dried pencil yam is as follows.

Briefly, 5.0 g of homogenized fresh pencil yam sample was weighed into a 50-mL PTFE centrifuge tube, to which 5-mL distilled water and 25-mL acetonitrile was added. For dried pencil yams 5.0 g of the pulverized dried pencil yam sample was weighed into a 50-mL PTFE centrifuge tube, to which 10-mL distilled water was added to soak for 10 minutes. After the 10 minute soaking period, 25 mL of acetonitrile was added. Then, the sample was homogenized thoroughly with the Multi-Tube Vortexer for 10 minutes, and shaken vigorously for 1 minute after the addition of 8 g NaCl. After being centrifuged for 5 minutes at 3000 rpm, 10-mL of the supernatant acetonitrile phase was transferred into a 150-mL round-bottomed flask. The extract was evaporated to near dryness by rotary evaporation at 40 °C, blow-dried and re-dissolved with 2.5 mL of acetonitrile/toluene (3:l, v/v) for the subsequent clean-up procedure. The extract was loaded onto a Sep-Pak Vac NH_2 SPE column (1 g, 6 mL) that had been preconditioned with 5-mL acetonitrile/toluene (3:l, v/v). Then, each of the three 2.5 mL portions of acetonitrile/toluene (3:l, v/v) was used to rinse the vessel and were successively loaded onto the column (the elution is approximately 10-mL in total). The effluent was collected into a 150-mL round bottomed flask, and concentrated to about 0.5 mL by rotary evaporators at 40 °C. Then it was blow dried and re-dissolved with acetonitrile. One mililitre of the extract was transferred into an HPLC sample vial after being filtered through 0.22-m syringe filter for UPLC/ESI-MS/MS analysis. The quantitative and confirmation ions of difenoconazole were *m/z* 406.1/251.0 and *m/z* 406.1/337.0, respectively. The residue levels were calculated with single point by direct comparison of the sample peak responses to those of external matrix-matched standards.

The method validation was performed by analysing fresh and dried pencil yam for difenoconazole for each of 2 blank control specimen, 5 replicate specimens fortified at LOQ (0.01 mg/kg), 5 replicate specimens fortified at 50× LOQ (0.5 mg/kg) and 5 replicate specimens fortified at 200× LOQ (2 mg/kg). Recoveries of difenoconazole in pencil yam ranged from 71 to 109 percent (mean: 85–103 percent, n=6) and calculations of the RSD of the recoveries obtained in each spiking level presents RSD ≤ 10 percent. Table 1 lists all recoveries obtained during method validation. The validated limit of quantitation (LOQ) for residual of difenoconazole in pencil yams (fresh and dried) is 0.01 mg/kg.

Ginger (fresh and dried)

The analytical method (Study report number: AR-2020PR20, Yizhi Feng, 2020) for difenoconazole in fresh ginger and dried ginger was submitted as follows.

Briefly, 10 mL of acetonitrile was mixed with 5 grams of fresh ginger or 2 grams of dried ginger. For dried ginger samples, 10 mL of water was added and the samples were shaken prior to adding the 10 mL of acetonitrile. Samples were shaken in a mechanical shaker for 5 minutes at approximately 2500 rpm. Approximately 5 g NaCl was added into the sample tubes. The samples were shaken in a mechanical shaker for 5 minutes at approximately 2500 rpm, and centrifuged for 5 minutes at 5000 rpm. A 1.0 mL aliquot of the acetonitrile phase (upper phase) was transferred into a centrifuge tube with, approximately, the following proportion of salts: Cl8 (100 mg) and PSA (100 mg). The centrifuge tube was shaken at approximately 2500 rpm shake for 30 seconds, followed by centrifugation at 5000 rpm for

1 minute. The extract was filtered with 0.22 µm organic filter membrane and submitted for analysis by LC-MS/MS. The quantitative and confirmation ions of difenoconazole were *m/z* 406.1/251.1 and *m/z* 406.1/336.9, respectively. The residue levels were calculated with single point by direct comparison of the sample peak responses to those of external matrix-matched standards.

The method was validated for analysis of ginger, hot-dried ginger, and freeze-dried ginger by adding known concentrations to control samples and analysing for difenoconazole. Fortification levels were LOQ (0.01 mg/kg), 10× LOQ (0.1 mg/kg), and 100× LOQ (1.0 mg/kg). Recoveries of difenoconazole in ginger, hot-dried ginger, and freeze-dried ginger were between 90 percent and 119 percent (mean: 93–115 percent, n=9), and the RSDs of the recoveries obtained in each spiking level present ≤ 5 percent. The validated LOQ for residues of difenoconazole in fresh and dried ginger were 0.01 mg/kg. The analytical method was considered to be suitable for the analysis of difenoconazole residues in the fresh ginger, hot-dried ginger, and freeze-dried ginger samples. Table 1 lists all recoveries obtained during method validation.

Fresh tea leaves, green tea, and black tea

The analytical method (Study report number: RM20004G20001, Yanjie Li, 2021) for difenoconazole in fresh green tea, green tea and black tea was submitted as follows.

Briefly, 20 mL of acetonitrile was mixed with 5 grams of fresh tea leaves or 2 grams of black and green tea. For black and green tea, 4 mL of water was added and the samples were shaken prior to adding the 20 mL of acetonitrile. Samples were shaken in a mechanical shaker for 10 minutes. Approximately 3 g NaCl was added to the sample tubes. The samples were shaken in a mechanical shaker for 5 minutes and centrifuged for 5 minutes at 4000 rpm. A 1.0 mL aliquot of the acetonitrile phase (upper phase) was transferred into round bottom flask and evaporated using a rotary evaporator at a bath temperature of 40 °C to near dryness. The samples were reconstituted to a final volume of 3 mL with acetonitrile/toluene (3:1, v/v). An SPE cartridge was conditioned with 5 mL of acetonitrile/toluene (3:1, v/v) and extracts were transferred into the SPE cartridges. The round bottom flask was rinsed twice with 2 mL portions of acetonitrile/toluene (3:1, v/v) and the rinsate was added to the SPE cartridge. The eluents were collected into clean round bottom flasks and evaporated using a rotary evaporator at a bath temperature of 40 °C to near dryness. The samples were reconstituted to a final volume of 2.5 mL with acetonitrile/toluene (3:1, v/v). The samples were transferred into an HPLC sample vial after being filtered through 0.22-m syringe filter for UPLC-MS/MS analysis. The quantitative and confirmation ions of difenoconazole were *m/z* 406.1/251.1 and *m/z* 406.1/337.05, respectively. The residue levels were calculated with single point by direct comparison of the sample peak responses to those of external matrix-matched standards.

For validation, untreated fresh tea leaves, green tea, and black tea were fortified with difenoconazole and analysed. The validation for each matrix typically consisted of at least , two untreated samples (control sample), five samples fortified at the LOQ (0.01 mg/kg), five samples fortified at 100× LOQ (1.0 mg/kg), and five samples fortified at 1000× LOQ (10 mg/kg). Fresh tea leaves were additionally fortified (n=5) at 2000× LOQ (20 mg/kg). Recoveries of difenoconazole in tea leaves, green tea, and black tea were between 71 percent and 105 percent (mean: 76–96 percent, n=10), and the RSDs of the recoveries obtained in each spiking level present ≤ 5 percent. The validated LOQ for residues of difenoconazole in tea leaves, green tea, and black tea were 0.01 mg/kg. The analytical method was considered to be suitable for the analysis of difenoconazole residues in fresh tea, green tea, and black tea. Table 1 lists all recoveries obtained during method validation.

Overall, the Meeting concluded that the presented methods were sufficiently validated and are suitable to measure difenoconazole in plant commodities. The demonstrated LOQ for all commodities evaluated was 0.01 mg/kg.

Table1 Summary of the method validation recovery data.

Matrix	Fortification (mg/kg)	n	Recovery (percent)	Mean recovery (percent)	RSD (percent)
Goji Berry[1]	0.01	5	94, 95(2), 97, 105	97	5
	0.1	5	93, 94, 96(2), 101	96	3

STABILITY OF PESTICIDES IN STORED ANALYTICAL SAMPLES

The freezer storage stability of difenoconazole has been assessed previously by the JMPR.

The current Meeting received additional information on storage stability of difenoconazole in goji berry, dried goji berry, pencil yam, dried pencil yam, ginger, dried ginger, fresh tea leaves, green tea, and black tea.

Goji berry (fresh and dried)

The Meeting received a study (study report number: R20002B, Yanli Qi, 2021) evaluating the stability of difenoconazole in goji berry and dried goji berry.

Briefly, the untreated control goji berry and dried goji berry samples were fortified separately with standard solutions containing difenoconazole at a level of 1.0 mg/kg and stored frozen (≤-18 °C) for durations of approximately 0, 1, 3, 6, and 12 months. Samples were analysed according to the method described in study report number R20002A.

Storage stability results of difenoconazole in goji berry and dried goji berry are summarised in Table 2. The mean concentrations of difenoconazole in fresh goji berry and dried goji berry were 81–99 percent and 85–111 percent, respectively. Therefore, the Meeting concluded that residues of difenoconazole were stable for at least 12 months in whole fresh goji berry and dried goji berry stored frozen at ≤-18 °C. Corresponding magnitude of the residue samples were stored frozen up to approximately 6 months prior to analysis for fresh and dried goji berry

Pencil yam (fresh and dried)

The Meeting received a study (study report number: HZ2020N001B, Xueyan Zhang, 2021) evaluating the stability of difenoconazole in fresh pencil yam and dried pencil yam.

Briefly, the untreated control fresh pencil yam and dried pencil yam samples were fortified separately with standard solutions containing difenoconazole at a level of 0.5 mg/kg and then stored at (≤-18 °C) for durations of approximately 0, 1, 3, 6, 9, and 14 months. Samples were analysed according to the method described in study report number HZ2020N001A.

Storage stability results of difenoconazole in fresh pencil yam and dried pencil yam are summarised in Table 2. Mean concentrations of difenoconazole from stored fortified fresh pencil yam and dried pencil yam were 80–97 percent and 80–100 percent for of at least 14 months of frozen storage. Therefore, the Meeting concluded that residues of difenoconazole were stable for at least 14 months in fresh pencil yam and dried pencil yam stored frozen at ≤-18 °C. Corresponding magnitude of the residue samples were stored frozen up to approximately 10 months for pencil yam and approximately 9 months for dried pencil yam.

Ginger (fresh and dried)

The Meeting received a study (Study report number: SR-2020SS01, Yizhi Feng, 2020) evaluating the stability of difenoconazole in fresh ginger, hot-dried ginger, and freeze-dried ginger under frozen storage.

Briefly, the untreated control fresh ginger, hot-dried ginger, and freeze-dried ginger were fortified separately with difenoconazole at 1.0 mg/kg and stored frozen (≤-18 °C) for approximately 0, 1, 3, 6, 9, and 12 months. Samples were analysed according to the method described in study report number AR-2020PR20.

Storage stability results of difenoconazole in fresh ginger, hot-dried ginger, and freeze-dried ginger are summarised in Table 2. Mean concentrations of difenoconazole from stored fortified fresh ginger, hot-dried ginger, and freeze-dried ginger samples were 86–89 percent after approximately 12 months of frozen storage. Corresponding magnitude of the residue samples were stored frozen up to approximately 3 months for fresh ginger and approximately 4 months hot- and freeze-dried ginger.

Fresh tea leaves, green tea, and black tea

The Meeting received a study (Study report number: RB20004G20001, Yanjie Li, 2021) evaluating the stability of difenoconazole in fresh tea leaves, green tea, and black tea under frozen storage.

Briefly, untreated samples of fresh tea leaves, green tea, and black tea were fortified separately with difenoconazole at 1.0 mg/kg and stored frozen (-27.1 °C to -19.0 °C) for durations of approximately 0, 1, 3, 7, 9, and 12 months. Samples were analysed according to the method described in study report number RM20004G20001.

Storage stability results of difenoconazole in fresh tea leaves, green tea, and black tea are summarised in Table 2. Mean concentrations of difenoconazole from stored fortified samples of fresh tea leaves, green tea, and black tea were 95–112 percent after approximately 12 months of frozen storage. Corresponding magnitude of the residue samples were stored frozen up to approximately 11 months for fresh tea leaves and black tea and approximately 12 months for green tea.

USE PATTERN

Difenoconazole is a systemic triazole fungicide globally registered in many countries for the control of a broad-spectrum of foliar, seed and soil-borne diseases caused by Ascomycetes, Basidiomycetes, and Deuteromycetes. In the following table, GAP information on all crops supported with residue trial data are summarised in Table 3.

Table 3 Approved uses of difenoconazole on goji berry, pencil yam, ginger, and tea in China.

Crop	Formulation percent	Method	Rate (kg ai/ha)	Spray Concentration (kg ai/hL)	Number of Applications	PHI (Days)
Goji berry	WG, 10 percent	Foliar spray		0.0050-0.0067	1	7
	EW, 4 percent	Foliar spray		0.0027-0.0040	3	3
	SC, 10 percent	Foliar spray		0.0050-0.010	3*	5
	WG, 37 percent	Foliar spray		0.0050-0.0067	1	7
Pencil yam	WG, 10 percent	Foliar spray	0.057-0.0795		3*	60
	WG, 10 percent	Foliar spray	0.045-0.0675		3*	60

	WP, 10 percent	Foliar spray	0.045-0.09		2	14
	WP, 60 percent	Foliar spray	0.0444-0.0888		2	14
	WP, 37 percent	Foliar spray	0.045-0.09		2	14
	WP, 30 percent	Foliar spray	0.045-0.09		2	14
Tea	WG, 10 percent	Foliar spray		0.0067-0.01	3*	14

Notes:

*RTI = Re-treatment interval of 7 days.

RESULTS OF SUPERVISED RESIDUE TRIALS ON CROPS

The Meeting received data on supervised field trials following foliar application of difenoconazole to goji berry (Study report Number: R20002, Weirong Wang, 2021), pencil yam (Study report Number: HZ2020N001, Wenxi Li, 2021), ginger (Study report Number: PR-2020PR20, Yizhi Feng, 2020) and tea (Study report Number: RA20004G20001, Yanjie Li, 2022).

The field trial reports included method validation data, as recoveries from spiked samples at levels reflecting those observed in the field trial samples; dates from critical events during the study, including application, harvest, storage, and analysis; as well as detailed information on the field site and

treatment parameters. Analytical reports were sufficiently detailed and included example chromatograms and example calculations.

Residues from the trials conducted according to Critical GAP have been used for the estimation of maximum residue levels and they are underlined. The higher mean result of replicate plots in each trial site is used for estimation of maximum residue levels and supervised trial median residues (STMRs). However, the highest result of all individual samples is used for highest Residues (HRs).

Goji berry

Four residue trials on goji berry conducted in China are presented below. Two replicate treated plots were set in each trial site and duplicate fresh goji berry samples were taken from each treated plot.

Fresh goji berry samples were collected immediately prior to the last application then 2 hours, 1, 3, 5, 7, and 10 days after the last application at all trials. Samples in untreated control plot were collected at the first sampling and the last sampling at each test site. Sampling started in the untreated control plot, followed by the treated plot. Two independent samples were collected at each plot. A minimum of 1kg fresh goji berry (minimum of 12 plants) was collected per sample. No diseased or damaged fruit was collected.

Samples were analysed according to the method described in study report number R20002A.

Pencil Yam

Four residue trials on pencil yam conducted in China are presented below. Two replicate treated plots were set in each trial site and duplicate fresh pencil yam samples were taken from a single plot.

Fresh pencil yam samples were taken from each field site. At least 500 g of samples of pencil yam roots with normal growth and no disease were collected from 12 random points in each plot. Fresh pencil yam samples were homogenized. All samples were stored in a freezer at -20 °C until analysis.

Samples were analysed according to the method described in study report number HZ2020N001A.

Ginger

Eight residue trials on ginger conducted in China are presented below. Three replicate treated plots were set at each trial site and duplicate fresh ginger root were taken from each plot. Ginger samples were randomly collected from at least 12 sites in one plot for each sample, and mature ginger samples with normal growth and no disease were collected with a sampling amount of no less than 10 kg.

Samples were analysed according to the method described in study report number AR-2020PR20.

Tea

Eight residue trials on tea conducted in China are presented below. Two replicate treated plots were set in each trial site and duplicate fresh tea leaves samples were taken from a single plot

Fresh tea leaves sample were taken from each field site. A minimum of 1kg fresh tea leaves were collected from at least 12 separate points of the plot.

Samples were analysed according to the method described in study report number RM20004G20001.

NS = Not specified.

FATE OF RESIDUES IN PROCESSING

The Meeting received new information on the fate of difenoconazole residues during the processing in goji berry, pencil yam, ginger, and tea.

If residues in the RAC were below the LOQ, no processing factor could be derived. In case of residues below the LOQ, but above the LOD in the processed product, the numeric value of the LOQ was used for the calculation. If residues in the processed product were below the LOD, the numeric value of the LOQ was used for the calculation but the PF was expressed as "less than" (e.g. < 0.5).

Dried goji berry

Goji berry samples were processed by two drying methods (sun drying and hot-air drying) with the fresh goji berry samples collected 3 days and 5 days after the last application in all trials. The processing simulated industrial practice as closely as possible. The water content of dried Goji berry was less than 13 percent. Two kinds of processing procedures are presented as follows:

Sun drying: Fresh Goji berry were impregnated with 2 percent food-grade sodium carbonate solution for 5–10 seconds to break the epidermal waxy layer of fruits, and then spread on fruit stacks and dried naturally outside for 5-11 days.

Hot-air drying: Fresh Goji berry were impregnated with 2 percent food-grade sodium carbonate solution for 5–10 seconds to break the epidermal waxy layer of fruits, and then spread on fruit stacks and baked at 50 °C in an electric blast drying oven for 2–3 days.

Samples were analysed according to the method described in study report number R20002A.

Dried pencil Yam

Fresh pencil yam samples were taken from each field site described above for the RAC and a portion was processed into dried pencil yam using simulated commercial practices: Yam tap roots were washed in cool water and dried, lateral roots were removed by scissors, the tap root was then cut into thin slices and baked under infrared light (50–60 °C, 2–3 days) until the moisture content was <13 percent.

Samples were analysed according to the method described in study report number HZ2020N001A.

Dried ginger

Fresh ginger samples were taken from each field site described above for the RAC and a portion was processed into dried ginger using hot-air and freeze-drying processes that simulate typical commercial processes. For both processes, samples of fresh ginger were washed under cold water to remove skin impurities, cut into small (approximately 1 mm) sections, and the sections quartered. For the hot-air process, the quarters were dried in a drying oven (90 °C, 12 hours). For the freeze-drying process, samples were placed in a vacuum freeze dryer for 24 hours. After drying samples were brought to room temperature and crushed with a grinder.

Samples were analysed according to the method described in study report number AR-2020PR20.

Tea

Fresh tea leaves sample were taken from each field site and a portion of which were processed into green tea and black tea with simulation of industrial practices as closely as possible. The processing procedure is presented as follows:

Green tea: fresh tea leaves were heated to inactivate the enzymes at 220 °C for 5 minutes (fixing), rolled at 25 °C for 30 minutess (rolling), and dried at 120 °C for 60 minutess (drying).

Black tea: fresh tea leaves were withered for 6 hours (withering), rolled at 25 °C for 30 minutes (rolling), fermented at 38 °C for 6 to 8 hours (fermentation), and dried at 120 °C for 60 minutes (drying).

Samples were analysed according to the method described in study report number RM20004G20001.

APPRAISAL

Difenoconazole was evaluated for the first time by the JMPR 2007 when an acceptable daily intake (ADI) of 0–0.01 mg/kg bw and an acute reference dose (ARfD) of 0.3 mg/kg bw were established. In 2007, 2010, 2013, 2015, and 2017 the JMPR evaluated the compound for residues and recommended a number of maximum residue levels.

The definition of the residue for compliance with MRL and for dietary risk assessment for plant commodities is parent *difenoconazole*, while for animal commodities it is defined as *sum of difenoconazole*

and 1-[2-chloro-4-(4-chloro-phenoxy)-phenyl]-2-(1,2,4-triazol)-1-yl-ethanol (CGA205375), expressed as difenoconazole. The residue is fat-soluble.

Difenoconazole was scheduled at the Fifty-second Session of the CCPR for the evaluation of additional MRLs in 2022 JMPR. The current Meeting received additional analytical methods, storage stability data, GAP information and residue trial data from uses on goji berries, pencil yams, ginger, and tea as well as their processed commodities.

Methods of analysis

The Meeting received additional information on analytical methods for difenoconazole in goji berry, pencil yam, ginger, and tea commodities.

For all provided analytical methods, residues of difenoconazole were extracted with acetonitrile/water (1/1, v/v), cleaned up by SPE, and analysed by HPLC-MS/MS.

Recoveries and percentRSDs were within the acceptable range. The LOQ was 0.01 mg/kg for all commodities tested.

The Meeting concluded that the presented methods were sufficiently validated and are suitable to measure difenoconazole in plant commodities.

Stability of pesticides residues in stored analytical samples

The current Meeting received additional information on freezer storage stability of difenoconazole in goji berry, dried goji berry, pencil yam, dried pencil yam, ginger, dried ginger, fresh tea leaves, green tea, and black tea.

Residues of difenoconazole were stable for at least 12 months in fresh and dried goji berry, 14 months in fresh and dried pencil yam, 12 months in fresh ginger, hot-dried ginger, and freeze-dried ginger, and 12 months in fresh tea leaves, green tea, and black tea when stored frozen at ≤-18 °C.

The Meeting concluded that the storage stability data were sufficiently validated and are adequate to support the storage durations in the studies provided to the current Meeting.

Results of supervised residue trials on crops

Goji berry

The use of difenoconazole on goji berry is registered in the People's Republic of China for foliar spray applications. The Meeting determined that the Critical GAP consists of three treatments with a re-treatment interval (RTI) of 7 days at a target application concentration of 0.010 kg ai/hL with a PHI of 5 days.

In independent trials matching the cGAP, residues of difenoconazole in goji berries were (n=4): 0.24, 0.59, 0.70, and 2.2 mg/kg.

The Meeting estimated a maximum residue level of 5 mg/kg, an STMR of 0.65 mg/kg, and an HR of 2.4 mg/kg (from a single sample) for difenoconazole in goji berry.

Meeting withdrew its previous recommendation of 0.6 mg/kg for difenoconazole in fruiting vegetables other than cucurbits except dried chili pepper and recommended a new maximum residue level of 0.6 mg/kg in fruiting vegetables other than cucurbits except dried chili pepper and goji berry.

Pencil Yam

The use of difenoconazole on pencil yam is registered in the People's Republic of China for foliar spray applications. The Meeting determined that the Critical GAP consists of three treatments (RTI=7 days) at a target application rate of 0.080 kg ai/ha with a PHI of 60 days.

In independent trials matching the cGAP, residues of difenoconazole in pencil yams were (n=4): < 0.01 (3) and 0.010 mg/kg.

The Meeting estimated a maximum residue level of 0.02 mg/kg, an STMR of 0.010 mg/kg, and an HR of 0.010 mg/kg for difenoconazole in pencil yam.

Ginger

The use of difenoconazole on ginger is registered in the People's Republic of China for foliar spray applications. The Meeting determined that the Critical GAP consists of three treatments (RTI=7 days) at a target application rate of 0.11 kg ai/ha with a PHI of 14 days.

In independent trials matching the cGAP, residues of difenoconazole in ginger were (n=8): < 0.01 (4), 0.033, 0.038, 0.062, and 0.10 mg/kg.

The Meeting estimated a maximum residue level of 0.2 mg/kg, an STMR of 0.022 mg/kg, and an HR of 0.10 mg/kg for difenoconazole in fresh ginger.

Tea

The Meeting received a GAP for tea from the People's Republic of China consisting of three treatments (RTI=7 days) at a target application concentration of 0.010 kg ai/hL with a PHI of 14 days.

In independent trials matching the GAP, residues of difenoconazole in green tea (dry) were (n=8): 0.019, 0.060, 0.20, 0.35, 0.62, 0.77, 2.4, and 4.2 mg/kg.

Residues in black tea (fermented and dry) derived from the green tea (dry) samples were (n=8): 0.023, 0.061, 0.22, 0.26, 0.32, 0.39, 1.7, and 4.5 mg/kg.

The 2021 Extra Meeting recommended a maximum residue level of 20 mg/kg and an STMR of 4.85 mg/kg for residues of difenoconazole in tea, green, black (black fermented and dried). The current Meeting confirmed its previous recommendation, which accommodates the residues listed above.

Fate of residues during processing

The Meeting received new information on the fate of difenoconazole residues during processing in goji berry, pencil yam, and ginger.

Table 12 Estimated processing factors for the commodities considered at this Meeting

RAC	Processed Commodity	Processing Factor	Median Processing Factor	STMR RAC (mg/kg)	HR RAC (mg/kg)	STMR-P (mg/kg)	HR-P (mg/kg)
Goji berry	Dried goji berry	1.3, 1.5, 1.6, 1.7, 1.8, 1.9, 2.0, 2.5(2), 2.6, 3.1, 4.2, 5.0, 11, 26, 28	2.5	0.65	2.4	1.6	5.5
Pencil Yam	Dried Pencil Yam	2.3, 3.4	2.9	0.010	0.010	0.029	0.029
Ginger	Hot Dried [a]	3.2, 3.4, 4.6, 5.1(2), 5.7, 6.7, 7.0, 7.5, 7.6, 7.8, 8.0	6.0	0.022	-	0.13	-

Notes:

[a] Hot dried ginger processing factors are higher than freeze dried ginger processing factors. Dried ginger was grinded to a powder prior to analysis.

Using the estimated maximum residue level of 5 mg/kg for goji berry and applying the processing factor of 2.5, the Meeting estimated a maximum residue level of 15 mg/kg for difenoconazole in goji berry, dried.

Using the estimated maximum residue level of 0.02 mg/kg for pencil yam and applying the processing factor of 2.9, the Meeting estimated a maximum residue level of 0.07 mg/kg for difenoconazole in pencil yam, dried.

Using the estimated maximum residue level of 0.2 mg/kg for ginger and applying the processing factor of 6.0, the Meeting estimated a maximum residue level of 1.5 mg/kg for difenoconazole in ginger, dried.

Residues in animal commodities

Estimated maximum and mean dietary burdens of livestock and animal commodities maximum residue levels

No animal feeds are associated with the uses considered by the current Meeting. The Meeting confirmed its previous recommendations.

RECOMMENDATIONS

On the basis of the data from supervised trials, the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessment.

Definition of the residue for compliance with the MRL and for dietary risk assessment for plant commodities: *difenoconazole*.

Definition of the residue for compliance with the MRL and for dietary risk assessment for animal commodities: *sum of difenoconazole and 1-[2-chloro-4-(4-chloro-phenoxy)-phenyl]-2-(1,2,4-triazol)-1-yl-ethanol), expressed as difenoconazole*.

The residue is fat-soluble.

Table 13 Residue levels suitable for establishing maximum residue limits and for IEDI and IESTI estimations

Commodity		Recommended Maximum Residue Level (mg/kg)		STMR or STMR-P (mg/kg)	HR or HR-P (mg/kg)
CCN	Name	New	Previous		
VO 2704	Goji berry	5	-	0.65	2.4
DV 2704	Goji berry, dried	15	-	1.6	5.5
VO 0050	Group of fruiting vegetables other than cucurbits (except peppers, chili)	W	0.6	0.14	0.39
VO 0050	Group of fruiting vegetables other than cucurbits (except goji berry and pepper, chili)	0.6	-	0.14	0.39
VR 2950	Pencil yam	0.02	-	0.010	0.010
	Pencil yam, dried	0.07	-	0.029	0.029

Commodity		Recommended Maximum Residue Level (mg/kg)		STMR or STMR-P (mg/kg)	HR or HR-P (mg/kg)
CCN	Name	New	Previous		
HS 0784	Ginger, rhizome	0.2	-	0.022	0.10
DV 0784	Ginger rhizome, dried	1.5	-	0.13	-

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The ADI for difenoconazole is 0–0.01 mg/kg bw. The International Estimated Daily Intakes (IEDIs) for difenoconazole were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the previous and present JMPR. The results are shown in Annex 3 of the 2022 JMPR Report. The IEDIs ranged 10–80 percent of the maximum ADI.

The Meeting concluded that the long-term dietary exposure to residues of difenoconazole from uses considered by the JMPR is unlikely to present a public health concern.

Acute dietary exposure

The 2007 JMPR established an ARfD of 0.3 mg/kg bw. The International Estimate of Short-Term Intakes (IESTIs) for difenoconazole were calculated for the food commodities for which STMRs or HRs were estimated by the present Meeting and for which consumption data were available. The results are shown in Annex 4 of the 2022 JMPR Report. The IESTIs varied from 0–3 percent of the ARfD for children and 0 percent for the general population.

The Meeting concluded that the acute dietary exposure to residues of difenoconazole from other uses that have been considered by the present Meeting is unlikely to present a public health concern.

DIMETHOATE (027)/OMETHOATE (055)

First draft prepared by D.W. Lunn, Ministry for Primary Industries, New Zealand

APPRAISAL

Dimethoate is an organophosphate insecticide which acts through acetylcholinesterase inhibition. It has been evaluated on numerous occasions by the JMPR since 1963, with the last periodic review conducted in 1996 (toxicology) and 1998 (residues), a subsequent evaluation for toxicology and residues in 2003 to establish an acute reference dose and further evaluations for additional uses in 2006 and 2008.

Dimethoate was scheduled by the Fiftieth Session of the CCPR (2018) for periodic review and the 2019 JMPR considered information supplied by the sponsor on identity, physicochemical properties, metabolism and environmental fate, methods of residue analysis, freezer storage stability, registered use patterns, supervised residue trials, fate of residues in processing, and animal feeding studies, together with additional supervised residue trial data supplied by Australia for mandarin, oranges, avocados, mangoes, capsicum and pulses, and by Thailand for yard-long bean.

The 2019 JMPR established a revised ADI of 0–0.001 mg/kg bw and reaffirmed the ARfD of 0.02 mg/kg bw for dimethoate, but was unable to complete the assessment of omethoate, a metabolite of dimethoate and also used as a pesticide, with respect to its mutagenic potential.

The 2019 JMPR also recommended a residue definition of dimethoate and omethoate (measured and reported seperately) for MRL-compliance in plant and animal commodities and concluded that the residue is not fat-soluble.

However, the Meeting was unable to recommend residue definitions for dietary risk assessment because of concerns relating to the genotoxicity of omethoate and other related metabolites.

Evaluation of the metabolism studies in rats was carried out by the WHO Core Assessment Group in 2019 and a further assessment of omethoate and its metabolites was conducted by the current Meeting. Residue components observed in the dimethoate rat metabolism study were dimethoate, omethoate, dimethoate carboxylic acid, dimethyl dithiophosphate, dimethyl thiophosphate, and dimethyl phosphate.

The previously-submitted residue information evaluated by the 2019 JMPR was re-evaluated in light of this new toxicological information and new information on current dimethoate GAP.

Table 1 Major metabolites discussed in this Appraisal

Component name	Structure	Origin
Dimethoate		Parent compound
Omethoate (XI)		Potato, olives, wheat, rat, goat, hen

Component name	Structure	Origin
Dimethoate carboxylic acid (III)		Potato, olives, wheat, rat, goat, hen
O-desmethyl omethoate carboxylic acid (XX)		Potato, wheat
O-desmethyl isodimethoate (XII)		Potato, olives, wheat
O-desmethyl omethoate (XI)		Potato, olives, wheat
Desmethyl dimethoate (X)		Potato, hydrolysis, soil (minor component)
O-desmethyl N-desmethyl omethoate (XXIII)		Potato, olives, wheat

Residue definition

Plant commodities

For MRL-compliance, based on the metabolism studies and field trials, the 2019 JMPR concluded that dimethoate and omethoate were good marker compounds particularly for shorter pre-harvest intervals, and in directly treated commodities such as leafy vegetables and fruits and noted that suitable validated methods were available for dimethoate and omethoate in an extensive range of plant commodities.

The 2019 JMPR further noted that in residue trials for some commodities, for example cherries and olives, omethoate was present at higher levels than dimethoate, particularly around harvest. Therefore,

inclusion of both dimethoate and omethoate in the definition for compliance with MRLs was warranted and since omethoate is itself a pesticide, it should therefore be measured separately from dimethoate.

The 2019 JMPR considered that a suitable residue definition for compliance with MRLs in plant commodities was *dimethoate and omethoate, measured and reported separately*.

The 2019 JMPR also considered that dimethoate and omethoate were expected to have similar bioavailability to livestock, and determined that the *sum of dimethoate and omethoate* would be used to estimate median and highest residues in feed commodities for estimation of livestock dietary burden.

For dietary risk assessment, the 2019 JMPR reviewed metabolism studies in olives, potatoes and wheat, supervised field trials where a number of these metabolites were analysed and a number of older studies containing summarized metabolism data on lemons, sugar beet, maize, cotton, peas, potatoes and beans.

The 2019 JMPR concluded that in the olive, wheat and potato studies, the major components of the residue in matrices treated directly with dimethoate at shorter sampling intervals (0–14 days) were dimethoate and omethoate.

In matrices to which residues are translocated, and at longer intervals after application, the metabolite pattern is different and dimethoate and omethoate are present at lower levels and the major residues are metabolites O-desmethyl N-desmethyl omethoate (XXIII), O-desmethyl isodimethoate (XII), O-desmethyl omethoate carboxylic acid (XX) and O-desmethyl omethoate (XI).

In a number of residue trials in wheat, olives and sugar beet, dimethoate, omethoate and six metabolites were analysed. No residues of any of the components were found above 0.01 mg/kg in wheat grain, and in sugar beet roots all components other than desmethyl dimethoate (X) were also below the LOQ. In olives, dimethoate and omethoate were the most significant residue components, with dimethoate carboxylic acid (III) found in olive flesh (0.02 mg/kg) and desmethyl dimethoate (X) found in sugar beet roots (0.03 mg/kg).

The current Meeting, in deciding which metabolites should be included in the residue definition for plant commodities, considered the likely occurrence and toxicological relevance of the compounds present at more than 10 percent of total identified residues in the metabolism studies.

Compounds considered were omethoate, O-desmethyl-N-desmethyl omethoate, O-desmethyl-isodimethoate, desmethyl dimethoate, O-desmethyl omethoate carboxylic acid, O-desmethyl-omethoate and O,O-dimethyl phosphonic acid.

The Meeting noted that O-desmethyl-N-desmethyl omethoate, O-desmethyl-isodimethoate, desmethyl dimethoate, O-desmethyl omethoate carboxylic acid, O-desmethyl-omethoate and O,O-dimethyl phosphonic acid were of no toxicological relevance and these metabolites were not discussed further.

Omethoate was a significant residue in most directly treated plant matrices, both in the plant metabolism studies and supervised field trials, and present in some processed olive and orange commodities. It was also found in the rat metabolism study, has a lower ADI (0.0004 mg/kg bw/day) and a lower ARfD (0.002 mg/kg bw) than dimethoate. The Meeting considered that omethoate should be included in the residue definition.

Based on the above, the current Meeting considered that for dietary intake risk assessment for plant commodities, the residue definition should be: *Dimethoate plus 2.5× omethoate, expressed as dimethoate for long-term dietary exposure and dimethoate plus 10× omethoate for acute dietary exposure*.

Animal commodities

Based on the goat and laying hen metabolism studies, the 2019 JMPR concluded that the major component of the residue was incorporated into phosphorylated natural products. Dimethoate residues were not detected in any matrix, indicating rapid metabolism.

Omethoate residues were found in cattle liver (0.12 mg eq/kg), poultry liver (0.081 mg eq/kg) and egg white (0.004 mg eq/kg).

Residues of dimethoate carboxylic acid (III) made up 16 percent TRR (0.13 mg eq/kg) in poultry liver, 2.5 percent TRR (0.031 mg eq/kg) in goat liver, 8.3 percent TRR (0.019 mg eq/kg) in goats milk and 3.9 percent TRR (0.005 mg eq/kg) in egg white.

In the lactating cattle feeding study, no residues of dimethoate were found above the LOQ in milk, muscle, liver, or kidney, while low levels of omethoate were detected in milk, kidney, and muscle for the highest dose group, in liver for the highest and second highest dose groups, while low levels of dimethoate were detected in fat at all doses, without any clear correlation between dose and residue level. Omethoate was detected in fat at higher dose levels.

In the laying hen feeding study, no residues of dimethoate or omethoate were detected in tissues or eggs at any dose level.

The 2019 JMPR considered that a suitable residue definition for compliance with MRLs in animal commodities was *dimethoate and omethoate, measured and reported separately* and that residues of dimethoate and omethoate are not fat-soluble.

For dietary risk assessment, in deciding which metabolites should be included in the residue definition for animal commodities, the current Meeting noted that the only metabolites found in animal commodities were considered omethoate and dimethoate carboxylic acid. The Meeting noted that dimethoate carboxylic acid was of no toxicological relevance and decided it need not be included in the residue definition.

Omethoate was found in at low levels in cattle milk (< 0.02 mg/kg) and most cattle tissues (< 0.005 mg/kg) but in the goat and poultry metabolism studies, was only found in goat liver (9.8 percent TRR, 0.12 mg eq/kg), poultry liver (16 percent TRR, 0.081 mg eq/kg) and egg white (3.9 percent TRR, 0.005 mg eq/kg).

It was also found in the rat metabolism study and is more toxic than dimethoate. The Meeting considered that omethoate should be included in the residue definition for risk assessment.

Based on the above, the current Meeting considered that for dietary intake risk assessment for animal commodities, the residue definition should be: *Dimethoate plus 2.5× omethoate, expressed as dimethoate for long-term dietary exposure and dimethoate plus 10× omethoate for acute dietary exposure*.

Results of supervised residue trials on crops

The 2019 JMPR evaluated supervised trials on the use of dimethoate on mandarins, oranges, cherries, olives, avocados, mangoes, bulb onions, brassica vegetables, melons, sweet peppers, tomatoes, leaf lettuce, legume vegetables, pulses, root and tuber vegetables, barley, wheat and rape seed.

Product labels provided to the 2019 Meeting were from Australia, Brazil, Thailand, the United States and a number of European Union member states. The current Meeting noted that since 2019, all European Union dimethoate authorisations have been withdrawn and that of the proposed MRLs recommended by the 2019 JMPR, only those for citrus, avocados, tomatoes, dried beans, rape seed

(Australian GAPs) and yard-long beans (Thailand GAP) were still valid. New GAP information was provided for Brussels sprouts (Canada) and a new GAP was identified for wheat.

For acute dietary exposure estimation, the highest individual total residue values from the trials have been used to derive the highest residues.

The residue trial tables include values for the sum of dimethoate and omethoate for use in the livestock dietary burden calculation where applicable.

Where residues were reported below the LOQ, the following conventions were adopted for summing residues (using an LOQ of 0.01 mg/kg as an example):

Table 2 Convention adopted for summing of residues

Dimethoate (mg/kg)	Omethoate (mg/kg)	Sum of dimethoate and omethoate (mg/kg)
0.30	0.04	0.34
0.30	< 0.01	0.31
< 0.01	< 0.01	< 0.02

For dietary intake estimation it is necessary to account for the residues of both dimethoate and omethoate. In order to estimate STMR and HR values for use in the dietary intake calculations, the relative toxicity of the two compounds must be taken into account. Since dimethoate and omethoate share a common toxicological mode of action, in line with the approach taken by previous Meetings, the toxicologically significant residues were estimated by adding the dimethoate and omethoate residues after scaling the omethoate residues to dimethoate toxicity equivalents - based on the ratio of the dimethoate to omethoate maximum ADIs for STMR estimation and acute RfDs for HR estimation.

For long-term dietary exposure estimation, toxic equivalent residues (mg teq/kg) = dimethoate + 2.5×omethoate.

For short-term dietary exposure estimation, toxic equivalent residues (mg teq/kg) = dimethoate + 10×omethoate.

Where residues were reported as < 0.01 mg/kg, a value of 0.01 mg/kg was used when calculating total residues for dietary exposure estimation.

Citrus fruits

The 2019 JMPR concluded that the critical GAP for citrus fruit was in Australia, a post-harvest dip or flood application of 0.04 kg ai/100 L (40 ppm), with no withholding period required.

In mandarin trials supporting this GAP, dimethoate residues in whole fruit were: 0.58, 0.70, 0.71 and 0.82 mg/kg (n=4) and omethoate residues were: < 0.01 (4) mg/kg (n=4).

In orange trials supporting this GAP, dimethoate residues in whole fruit were: 0.51, 0.59, 0.60, 0.63, 0.66 and 0.67 mg/kg (n=6) and omethoate residues were: 0.003 (3), 0.004 (2) and 0.005 mg/kg (n=6).

The 2019 Meeting also agreed to combine the residue data sets for oranges and mandarins to estimate maximum residue levels for the subgroups of mandarins and oranges and noted that these levels would accommodate the foliar application GAPs in Australia and Brazil.

The combined mandarin and orange (whole fruit) dataset for dimethoate was: 0.51, 0.58, 0.59, 0.60, 0.63, 0.65, 0.67, 0.70, 0.71, and 0.82 mg/kg (n=10).

The combined mandarin and orange (whole fruit) dataset for omethoate was: 0.003 (3), 0.004 (2), 0.005, and < 0.01 (4) mg/kg (n=10).

The Meeting confirmed the 2019 JMPR estimated maximum residue levels of 2 mg/kg for dimethoate and 0.02 mg/kg for omethoate in the subgroup of mandarins and the subgroup of oranges.

Residues for livestock dietary burden estimation (sum of dimethoate and omethoate) in citrus (whole fruit) were: 0.51, 0.59 (2), 0.6, 0.63, 0.66, 0.675, 0.71, 0.72 and 0.83 mg/kg (n=10). The median residue was 0.645 mg/kg.

Mandarin

For dietary exposure estimation, in the Australian trials matching the critical GAP, dimethoate residues in mandarin flesh were: 0.014, 0.056, 0.0.056 and 0.076 mg/kg (n=4) with a highest value of 0.089 mg/kg and omethoate residues were: < 0.01 (4) mg/kg (n=4).

For assessing long-term dietary exposure, the toxic equivalent residues in mandarin flesh (dimethoate + 2.5× omethoate residues) were: 0.039, 0.081 0.081 and 0.1 mg teq/kg.

For assessing short-term dietary exposure, the toxic equivalent residues in mandarin flesh were: 0.11, 0.16, 0.16 and 0.18 mg teq/kg and the highest individual value was 0.19 mg teq/kg.

The Meeting estimated an $STMR_{chronic}$ of 0.081 mg teq/kg, an HR of 0.19 mg teq/kg and a $STMR_{(acute)}$ residue of 0.16 mg teq/kg for dimethoate in the subgroup of mandarins.

Orange

For dietary exposure estimation, in the Australian trials matching the critical GAP, dimethoate residues in orange flesh were: 0.19, 0.26, 0.275, 0.34, 0.37 and 0.38 mg/kg (n=6) and omethoate residues were: 0.001 (2), 0.002 (3) and 0.003 mg/kg (n=6).

For assessing long-term dietary exposure, the toxic equivalent residues in orange flesh were: 0.19, 0.265, 0.28, 0.345, 0.38 and 0.385 mg teq/kg.

For assessing short-term dietary exposure from residues in oranges, the toxic equivalent residues in flesh were: 0.2, 0.28, 0.285, 0.36, 0.4 and 0.4 mg teq/kg.

The Meeting estimated an $STMR_{chronic}$ of 0.31 mg teq/kg, an HR of 0.4 mg teq/kg and a $STMR_{(acute)}$ residue of 0.32 mg teq/kg for dimethoate in the subgroup of oranges.

The Meeting noted that an acute dietary exposure assessment showed that residues in the *subgroup of oranges exceed the ARfD of 0.02 mg/kg bw, at 120 percent for peeled oranges for Australian children.* No alternative GAP was available.

Avocados

The 2019 JMPR concluded that the critical GAP for avocados was in Australia, for dilute foliar applications of 0.03 kg ai/100 L as required (with a 7-day PHI) followed by a 1-minute post-harvest dip using 0.04 kg ai/100 L, with no withholding period.

In avocado trials supporting this GAP, dimethoate residues in (whole fruit) were: 0.41, 0.44, 0.71, and 0.75 mg/kg (n=4) and omethoate residues were: 0.016, 0.025, 0.042, and 0.067 mg/kg (n=4).

The Meeting confirmed the 2019 JMPR estimated maximum residue level of 2 mg/kg for dimethoate and 0.15 mg/kg for omethoate in avocado.

For dietary exposure estimation, in the Australian trials matching the critical GAP, dimethoate residues in flesh were: 0.062, 0.062, 0.11 and 0.17 mg/kg (n=4) and omethoate residues were: < 0.01, < 0.01, 0.01 and 0.032 mg/kg (n=4).

For assessing long-term dietary exposure from residues in avocados, the toxic equivalent residues in flesh were: 0.087, 0.087, 0.135 and 0.25 mg teq/kg.

For assessing short-term dietary exposure from residues in avocados, the toxic equivalent residues in flesh were: 0.16, 0.16, 0.21 and 0.49 mg teq/kg.

The Meeting estimated an $STMR_{chronic}$ of 0.11 mg teq/kg, an HR of 0.49 mg teq/kg and a $STMR_{(acute)}$ residue of 0.37 mg teq/kg for dimethoate in avocados.

Brussels sprouts

The 2019 JMPR estimated a maximum residue level for Brussels sprouts based on the GAP in the Czech Republic. As this GAP no longer exists, the current Meeting re-evaluated the available data based on a newly provided Canadian GAP.

The critical GAP in Canada for brussels sprouts is for 2 foliar applications of 0.48 kg ai/ha, with a 7-day minimum retreatment interval and a PHI of 21 days.

In trials matching this GAP, but with a lower application rate (0.24–0.25 kg ai/ha) dimethoate residues in Brussels sprouts were: < 0.01 (3), 0.01, 0.02,(3) and 0.03 (2) mg/kg (n=9) and omethoate residues were: < 0.01 (8) and 0.01 mg/kg (n=9).

When proportionally adjusted to the Canadian application rate (scaling factor of 1.9), dimethoate residues were: < 0.019 (3), 0.019, 0.038 (3) and 0.058 (2) mg/kg (n=9) and omethoate residues were: < 0.019 (8) and 0.019 mg/kg (n=9).

The current Meeting estimated a maximum residue level of 0.1 mg/kg for dimethoate and 0.03 mg/kg for for omethoate in Brussels sprouts, to replace the 2019 JMPR estimations.

For assessing long-term dietary exposure from residues in Brussels sprouts, the toxic equivalent residues were: < 0.067 (3), 0.067, 0.086 (3) and 0.11 (2) mg teq/kg (n=9).

For assessing short-term dietary exposure from residues in Brussels sprouts, the toxic equivalent residues were: < 0.21 (3), 0.21, 0.23 (3) and 0.25 (2) mg teq/kg (n=9).

The Meeting estimated an $STMR_{chronic}$ of 0.086 mg teq/kg, an HR of 0.25 mg teq/kg and a $STMR_{(acute)}$ residue of 0.23 mg teq/kg for dimethoate in Brussels sprouts.

Tomato

The 2019 JMPR concluded that the critical GAP for tomatoes was in Australia, for 2 × 0.3 kg ai/ha foliar applications with a minimum 14-day retreatment interval and a 21-day PHI. Scaled dimethoate residues in trials from Europe supporting this GAP were: < 0.005 mg/kg (n=8) and omethoate residues were: < 0.005 (6), 0.005 and 0.005 mg/kg (n=8).

The Meeting confirmed the 2019 JMPR estimated maximum residue level of 0.01(*) mg/kg for dimethoate and 0.01 mg/kg for for omethoate in tomato.

Residues for livestock dietary burden estimation (sum of dimethoate and omethoate) in tomato were: < 0.01 (6) and 0.01 (2) mg/kg (n=8). The median residue was 0.01 mg/kg.

For assessing long-term dietary exposure from residues in tomatoes, the toxic equivalent residues were: < 0.0175 (6) and 0.0175 (2) mg teq/kg.

For assessing short-term dietary exposure from residues in tomatoes, the toxic equivalent residues were: < 0.055 (6) and 0.055 (2) mg teq/kg.

The Meeting estimated an $STMR_{chronic}$ of 0.0175 mg teq/kg, an HR of 0.055 mg teq/kg and a $STMR_{(acute)}$ residue of 0.055 mg teq/kg for dimethoate in tomatoes.

Yard-long bean (pods)

The 2019 JMPR concluded that the critical GAP for yard-long beans was in Thailand, for 4 × 0.6 kg ai/ha foliar applications with a 7-day PHI.

Dimethoate residues in trials in supporting this GAP were: < 0.05 (5) and 0.05 mg/kg (n=6) and omethoate residues were: < 0.05 (6) mg/kg (n=6).

The Meeting confirmed the 2019 JMPR estimated maximum residue level of 0.07 mg/kg for dimethoate and 0.05 mg/kg for for omethoate in yard long bean.

For assessing long-term dietary exposure from residues in yard-long bean, the toxic equivalent residues were: < 0.175 (5) and 0.175 mg teq/kg.

For assessing short-term dietary exposure from residues in yard-long bean, the toxic equivalent residues were: < 0.55 (5) and 0.55 mg teq/kg.

The Meeting estimated an $STMR_{chronic}$ of 0.175 mg teq/kg, an HR of 0.55 mg teq/kg and a $STMR_{(acute)}$ residue of 0.55 mg teq/kg for dimethoate in yard-long bean.

Beans (dry)

The 2019 JMPR concluded that the critical GAP for dry beans (except soya beans) was in Australia, for foliar applications of 0.32 kg ai/ha, with a minimum 14-day retreatment interval and a 14 day PHI for both grazing and harvest.

Dimethoate residues in dry beans from trials supporting this GAP were: < 0.05 (4), 0.066, and 0.4 mg/kg (n=6) and omethoate residues were: < 0.05 (5), and 0.064 mg/kg (n=6).

Residues for livestock dietary burden estimation (sum of dimethoate and omethoate) in dry beans were: < 0.10 (4), 0.12, and 0.46 mg/kg (n=6). The median residue was 0.1 mg/kg.

The Meeting estimated a maximum residue level of 0.7 mg/kg for dimethoate and 0.08 mg/kg for omethoate in the subgroup of dry beans (except soya bean) to replace the previous estimation for the subgroup of dry beans.

For assessing long-term dietary exposure from residues in dry beans, the toxic equivalent residues were: < 0.175 (4), 0.19 and 0.56 mg teq/kg.

For assessing short-term dietary exposure from residues in dry beans, the toxic equivalent residues were: < 0.55 (4), 0.57 and 1.0 mg teq/kg.

The Meeting estimated an $STMR_{chronic}$ of 0.175 mg teq/kg and a $STMR_{(acute)}$ residue of 0.38 mg/kg for dimethoate in dry beans (subgroup) except soya bean.

Wheat

The 2019 JMPR estimated a maximum residue level for wheat based on the GAP in the Czech Republic. As this GAP no longer exists, the current Meeting re-evaluated the available data based on the current GAP in the United States.

The critical GAP in the United States for wheat is for a single foliar application of 0.56 kg ai/ha, with a 35-day PHI and a 14-day grazing interval.

In trials matching this GAP, but at a lower application rate of 0.2–0.21 kg ai/ha, dimethoate residues in wheat grain were: < 0.001 (9), 0.002 (2), 0.005, < 0.01 (5) and 0.01 mg/kg (n=18) and omethoate residues were: < 0.0012 (12) and < 0.01 (6) mg/kg (n=18).

When proportionally adjusted to the United States application rate (scaling factor of 2.66), dimethoate residues were: < 0.0027 (9), 0.0053 (2), 0.013, < 0.027 (5) and 0.027 mg/kg (n=18) and omethoate residues were: < 0.0027 (12) and < 0.027 (6) mg/kg (n=18).

Scaled residues for livestock dietary burden estimation (sum of dimethoate and omethoate) in wheat were: < 0.0053 (9), < 0.008 (2), < 0.016 and < 0.053 (6) mg/kg (n=18). The median residue was 0.008 mg/kg.

The Meeting estimated a maximum residue level of 0.06 mg/kg for dimethoate and 0.03 mg/kg for omethoate in wheat to replace the 2019 JMPR estimations.

For assessing long-term dietary exposure from wheat, the toxic equivalent residues were: < 0.0093 (9), 0.012 (2), 0.02, < 0.093 (5) and 0.09 mg teq/kg (n=18).

For assessing short-term dietary exposure from wheat, the toxic equivalent residues were: < 0.029 (9), 0.032 (2), 0.04, < 0.29 (5) and 0.29 mg teq/kg (n=18).

The Meeting estimated an $STMR_{chronic}$ of 0.011 mg teq/kg and a $STMR_{(acute)}$ residue of 0.032 mg/kg for dimethoate in wheat.

Rape seed (canola)

The 2019 JMPR concluded that the critical GAP for rape seed (canola) was in Australia, for a single foliar application of 0.14 kg ai/ha, with a 7 day PHI for both grazing and harvest.

In rape seed trials supporting this GAP, dimethoate residues were: < 0.02, 0.02, 0.026, 0.027, 0.028, 0.051, 0.066 and 0.084 mg/kg (n=8) and omethoate residues were: < 0.02 (7) and 0.02 mg/kg (n=8).

The Meeting confirmed the 2019 JMPR estimated maximum residue level of 0.15 mg/kg for dimethoate and 0.03 mg/kg for omethoate in rape seed.

For assessing long-term dietary exposure from rape seed, the toxic equivalent residues were: < 0.07 0.07, 0.076, 0.077, 0.078, 0.1, 0.12 and 0.13 mg teq/kg (n=8).

For assessing short-term dietary exposure from rape seed, the toxic equivalent residues were: < 0.22, 0.22, 0.23 (3), 0.25, 0.27 and 0.28 mg teq/kg.

The Meeting estimated an $STMR_{chronic}$ of 0.0775 mg teq/kg and a $STMR_{(acute)}$ residue of 0.23 mg/kg for dimethoate in rape seed.

Residues in animal feeds

Bean forage

The 2019 JMPR concluded that in the Australian residue trials on dry beans, the data for forage did not match GAP, as samples were only collected at intervals of 0 and 7 days after application and no median or highest residues could be estimated for bean forage.

Wheat forage

The current Meeting reviewed the available data on wheat forage (whole plants) in light of the US GAP and the 14-day pre-grazing interval. In trials matching this GAP, but at a lower application rate of 0.2–0.21 kg ai/ha, total residues (sum of dimethoate and omethoate) were: < 0.02, 0.03, 0.03, 0.05, 0.08, 0.28, 0.29, 0.44, 0.61, 0.75, 1.5 and 1.65 mg/kg as received (n=12).

When proportionally adjusted to the United States application rate (scaling factor of 2.66), total residues in wheat forage (for livestock dietary burden estimation) were: < 0.053, 0.08, 0.08, 0.13, 0.21, 0.75, 0.77, 1.2, 1.6, 2.0, 4.0 and 4.4 mg/kg as received (n=12).

The Meeting estimated a median total residue of 0.76 mg/kg fw and a highest total residue of 4.4 mg/kg fw for the sum of omethoate and dimethoate in wheat forage (for livestock dietary burden estimation).

Wheat straw

The 2019 JMPR estimated a maximum residue level for wheat straw and fodder, dry based on the GAP in the Czech Republic. As this GAP no longer exists, the current Meeting re-evaluated the available data based on the GAP in the United States.

The critical GAP in United States for wheat is for a single foliar application of 0.56 kg ai/ha, with a 35-day PHI and a 14-day grazing interval.

In trials matching this GAP, but at a lower application rate of 0.2–0.21 kg ai/ha, residues of dimethoate in wheat straw were: < 0.01 (8), 0.01 (2), 0.05 (3), 0.08, 0.19, 0.68, 0.76 and 0.83 mg/kg as received (n=18).

When proportionally adjusted to the United States application rate (scaling factor of 2.66), dimethoate residues in straw were: < 0.027 (8), 0.027 (2), 0.13 (3), 0.21, 0.51, 1.8, 2.0 and 2.2 mg/kg as received (n=18).

After adjustment for dry weight using the default dry matter content of 88 percent from the OECD livestock feed table, dry weight residues in straw were: < 0.03 (8), 0.03 (2), 0.15 (3), 0.24, 0.58, 2.1, 2.3 and 2.5 mg/kg dry weight.

In these trials, residues of omethoate were: < 0.01 (13), 0.01, 0.02, 0.05 (2) and 0.074 mg/kg as received (n=18).

When proportionally adjusted to the United States application rate (scaling factor of 2.66), omethoate residues in straw were: < 0.027 (13), 0.027, 0.053, 0.13 (2) and 0.2 mg/kg as received (n=18).

After adjustment for dry weight using the default dry matter content of 88 percent from the OECD livestock feed table, dry weight residues in straw were: < 0.03 (13), 0.03, 0.06, 0.15 (2) and 0.22 mg/kg dry weight.

The Meeting estimated a maximum residue level of 4 mg/kg (dw) for dimethoate and 0.3 mg/kg (dw) for omethoate in wheat straw and/or hay to replace the 2019 JMPR estimations.

For estimation of the livestock dietary burden, total (sum of dimethoate and omethoate) residues in straw were: < 0.02 (8), 0.02 (2), 0.06 (3), 0.09, 0.24, 0.7, 0.81 and 0.9 mg/kg (as received) (n=18).

When proportionally adjusted to the United States application rate (scaling factor of 2.66), total residues in straw were: < 0.053 (8), 0.053 (2), 0.16 (3), 0.24, 0.64, 1.9, 2.2 and 2.4 mg/kg as received (n=18). The median total residue was 0.053 mg/kg (0.06 mg/kg dry weight) and the highest total residue was 2.4 mg/kg (2.7 mg/kg dry weight).

Fate of residues during processing

The 2019 JMPR evaluated an hydrolysis study (simulating high temperature processing conditions) and concluded that both dimethoate and omethoate were hydrolysed to their desmethyl metabolites under simulated baking/boiling/brewing conditions (28/36 percent AR) and after sterilization (60/63 percent) respectively and that no conversion from dimethoate to omethoate was observed under any of the conditions.

Residues in processed commodities

Processing factors were calculated by the 2019 JMPR for dimethoate and omethoate (for maximum residue level estimation, for calculating livestock dietary burdens and for risk assessment.

Table 3 Processing factors for citrus and cereal commodities

Processed commodity	Dimethoate	Omethoate
ORANGE		
Juice	0.14	0.20
Dry pulp	2.1	1.6
Molasses	5.8	5.9
Orange oil	0.20	< 0.07
WHEAT		
Wholemeal flour	0.66	0.5
White flour	0.21	0.5
Bran	4.4	3.5
Wheat germ	2.9	2.0

Maximum residue levels in processed commodities

Where residues concentrated in the processed food commodities, maximum residue levels were estimated using the estimated maximum residue levels for the raw commodities and applying the calculated mean processing factors.

Table 4 Estimated dimethoate and omethoate maximum residue levels for processed commodities.

Commodity	Processing factors [a]		Maximum Residue Level (mg/kg)	
	Dimethoate	Omethoate	Dimethoate	Omethoate
Orange			MRL=2.0	0.02
Orange dried pulp	2.1	1.6	4.2	0.032
Wheat			MRL=0.06	0.03
Wheat bran	4.4	3.5	0.26	0.105
Wheat germ	2.9	2.0	0.17	0.06

Notes:

[a] The ratio of the residues in the processed item divided by the residue in the Raw Agricultural Commodity.

The Meeting estimated a maximum residue level of 5 mg/kg for dimethoate and 0.04 mg/kg for omethoate in citrus pulp, dry to replace the previous estimations.

The Meeting estimated a maximum residue level of 0.3 mg/kg for dimethoate and 0.15 mg/kg for omethoate in wheat bran to replace the previous estimations.

The Meeting estimated a maximum residue level of 0.2 mg/kg for dimethoate and 0.06 mg/kg for omethoate in wheat germ to replace the previous estimations.

Residues in processed food commodities

For estimating dietary exposure from toxic equivalent residues in processed food commodities, the Meeting applied the processing factors for dimethoate and omethoate to the levels of dimethoate and omethoate in the individual trials then scaled the individual omethoate residues for "potency" (based on the ratio of the dimethoate to omethoate HBGVs) and summed the resulting values from each trial to obtain a data set of toxic equivalent residues for estimating STMR-P and HR-P values.

Table 5 Calculated dimethoate toxic equivalent residue STMR-Ps. $STMR_{acute}$ and HR-Ps for processed food commodities

RAC	Processing factors [a]		Residues (mg/kg) [b]		Toxic equivalent residues [c] (mg teq/kg)	
	Dimethoate	Omethoate	Dimethoate Median-P	Omethoate Median-P	$STMR\text{-}P_{chronic}$	$STMR\text{-}P_{acute}$
Orange	median=0.615	median=0.0035				
Juice	0.14	0.2	0.086	0.0007	0.088	0.093
Oil	0.2	0.07	0.12	0.000245	0.12	0.13
Molasses	5.8	5.9	3.6	0.021	3.6	3.8

Wheat bran	4.4	3.5	0.018	0.009	0.041	0.11
Wheat germ	2.9	2.0	0.012	0.0053	0.025	0.065
Wholemeal flour	0.66	0.5	0.0026	0.0013	0.006	0.016
White flour	0.21	0.5	0.00084	0.0013	0.0042	0.014

Notes:

[a] The ratios of the residue in the processed item divided by the residue in the Raw Agricultural Commodity.

[b] Sum of calculated [dimethoate+10×omethoate] residues in the processed commodity.

[c] Sum of calculated [dimethoate+2.5×omethoate] residues in the processed commodity.

Residues in processed feed commodities

For estimating residues in processed feed commodities, the Meeting applied the processing factors for dimethoate and omethoate to the levels of dimethoate and omethoate in the individual trials and summed the resulting values to obtain a data set of total residues for estimating median-P and highest-P values.

Table 6 Calculated median-Ps for total residues (dimethoate+omethoate) in processed feed commodities

RAC	Processing factors [a]		Total residues (mg/kg)		
	Dimethoate	Omethoate	Dimethoate [b]	Omethoate [b]	Median-P
Orange + mandarin (whole fruit)	0.645	0.0045			
Citrus pulp, dry	2.1	1.6	1.35	0.0072	1.36

Notes:

[a] The ratios of the residue in the processed item divided by the residue in the Raw Agricultural Commodity.

[b] Each value is the sum of calculated [dimethoate+omethoate] residues in the processed commodity.

Residues in animal commodities

Farm animal dietary burden

Farm animal feeding studies in lactating cattle and laying hens were evaluated by the 2019 JMPR. In the lactating cow study, no residues of dimethoate were found above the LOQ (0.001 mg/kg) in milk, muscle, liver or kidney from any dose group ((1, 3.4, 10 and 33 ppm in the diet).

Low levels of omethoate were measured in milk and cattle tissues from the 33 ppm dose group and in cattle liver from the 10 ppm dose group. No residues of omethoate were found above the LOQ (0.001 mg/kg) in any of the egg or tissue samples from any dose group.

For fat, there were some low level residues of dimethoate and to a lesser extent of omethoate, without a consistent relationship between dose and residue level. The depuration data showed that clearance was rapid, with no detections above the LOQ.

Table 7 Residues of dimethoate and omethoate in milk and tissues from lactating cows dosed with the equivalent of 1, 3.4, 10.1 or 33.2 ppm dimethoate daily for 28 days

Matrix	Dose (ppm)	Dimethoate residues (mg/kg)			Omethoate residues (mg/kg)		
		Values [a]	mean	Max [b]	Values [a]	mean	Max [b]

Notes:

P = perirenal, S = subcutaneous, O = omental.

[a] Mean values from duplicate analyses.

[b] Highest individual result.

In the laying hen study, the 2019 JMPR reported that no residues of dimethoate or omethoate were found above the LOQ in any of the egg or tissue samples from animals in any dose group (0.15, 0.4, 1.2 and 4 ppm in the diet).

Livestock dietary burden

Dietary burden calculations for cattle and poultry are provided below. The dietary burdens were estimated using the 2018 OECD Feed diets listed in Appendix XIV Electronic attachments to the 2016 edition of the FAO manual.

Table 8 Summary of livestock dietary burden (ppm dimethoate+omethoate)

	United States-Canada		European Unions		Australia		Japan	
	Max	Mean	Max	Mean	Max	Mean	Max	Mean
Beef cattle	0.42	0.16	3.6	0.71	17.6❶	3.0❷	0.0022	0.0022
Dairy cattle	3.7	0.76	3.8	0.93	11.0❸	2.3❹	0.0009	0.0009
Broiler hens	0.007	0.01	0.029	0.029	0.082	0.082	0.0009	0.0009
Laying hens	0.007	0.0067	1.8❺	0.33❻	0.082	0.082	-	-

❶ Highest maximum dietary burden for beef cattle suitable for estimation of MRLs for mammalian meat and offal.

❷ Highest mean dietary burden for beef cattle suitable for estimation of STMRs for mammalian meat and offal.

❸ Highest maximum dietary burden for dairy cattle suitable for estimation of MRLs for milk.

❹Highest mean dietary burden for dairy cattle suitable for estimation of STMRs for milk.

❺ Highest maximum dietary burden for broiler and layer poultry suitable for estimation of MRLs for poultry meat, offal and eggs.

❻ Highest mean dietary burden for broiler and layer poultry suitable for estimation of STMRs for poultry meat, offal and eggs.

Animal commodity maximum residue levels

Cattle

For estimating maximum residue levels in mammalian commodities, the maximum dietary burden for beef cattle was 17.6 ppm and for dairy cattle was 11 ppm. Mean dietary burdens were 3.0 ppm for beef cattle and 2.3 ppm for dairy cattle.

For dimethoate, the Meeting noted that in the cattle feeding study, residues of dimethoate were all < 0.001 mg/kg in milk, muscle, liver and kidney from animals in all dose groups (up to 33 ppm, about 2–3 times the maximum dietary burdens), and the Meeting estimated maximum residue levels of 0.001(*) mg/kg for dimethoate in mammalian meat, edible offal mammalian and milks.

For mammalian fat, there was no clear relationship between the administered dose and measured residues of dimethoate in fat. As a conservative estimate, the Meeting agreed to use the highest residue found in the feeding study (0.027 mg/kg) and the overall mean residue (0.003 mg/kg) to estimate a maximum residue level and assess dietary exposure.

The Meeting estimated a maximum residue level of 0.03 mg/kg for dimethoate in mammalian fat

Since dimethoate residues in muscle, liver, kidney and milk were all < 0.001 mg/kg in all dose groups (up to 33 ppm, about 2–3 times the maximum dietary burdens), the Meeting estimated dimethoate STMRs and HRs of 0 mg/kg for mammalian meat, liver, kidney and milk and for mammalian fat, the Meeting estimated an HR of 0.027 mg/kg and an STMR of 0.003 mg/kg.

For omethoate, the Meeting agreed to interpolate the results from the 10.1 ppm and 33.2 ppm feed levels to estimate maximum residue levels and HRs in tissues (at a maximum dietary burden of 17.6 ppm) and in milk (at a maximum dietary burden of 11 ppm) and median residues were extrapolated from the 3.4 ppm feed level.

Table 9 Omethoate highest and median residues in mammalian commodities

	Feed level (ppm) for milk	Residues (m/kg) in milk	Feed level (ppm) for tissues	Residues (mg/kg) in			
				Muscle	Liver	Kidney	Fat
HR and MRL (beef or dairy cattle)							
Feeding study	10.1 33.2	< 0.001 0.011	10.1 33.2	< 0.001 [a] 0.0051	< 0.001 0.0059	< 0.001 0.0047	- -
Dietary burden and highest residue	11	0.0014	17.6	0.003	0.0031	0.0022	0.027 [b]
Median residue (beef or dairy cattle)							
Feeding study	3.4	< 0.001	3.4	< 0.001	< 0.001	< 0.001	-
Dietary burden and highest residue	2.3	< 0.001	3.0	< 0.001	< 0.001	< 0.001	0.003 [b]

Notes:

[a] Residue is in muscle from animals in the 3.4 ppm dose group.

[b] The highest and overall mean values from all dose groups in the feeding study.

Highest residues of omethoate were 0.0014 mg/kg in milk, 0.0031 mg/kg in liver, 0.0022 mg/kg in kidney, 0.003 mg/kg in muscle and 0.002 mg/kg in fat.

The Meeting estimated maximum residue levels of 0.0015 mg/kg for omethoate in milk, 0.005 mg/kg in mammalian meat and edible offal (based on residues in liver) and 0.003 mg/kg in mammalian fat.

The Meeting estimated median omethoate residues of 0 mg/kg in kidney and fat (based on residues < 0.001 mg/kg in dose groups 3-fold higher than the mean dietary burden) and 0.001 mg/kg in milk, muscle and liver.

For assessing long-term dietary exposure from animal commodities, the toxic equivalent $median_{chronic}$ residues were 0.0025 mg teq/kg for milk, liver and mammalian meat, 0.003 mg teq/kg for mammalian fat and 0 mg teq/kg for kidney.

For assessing short-term dietary exposure from animal commodities, the toxic equivalent highest residues were 0.03 mg teq/kg for mammalian meat, 0.031 mg teq/kg for liver, 0.022 mg teq/kg for kidney and 0.047 mg teq/kg for mammalian fat and the toxic equivalent median residue for milk is 0.01 mg/kg.

Poultry

The maximum dietary burden for poultry for both meat and egg production was 1.8 ppm, while the highest mean dietary burden was 0.33 ppm.

In a poultry feeding study, when hens were fed dimethoate daily for 28 days at 0.15, 0.4, 1.2 or 4 ppm in the diet, the JMPR 2019 reported that no residues of dimethoate or omethoate were found above the LOQ (0.001 mg/kg) in any of the egg or tissue samples from any dose group.

The Meeting therefore estimated maximum residue levels of 0.001(*) mg/kg, HRs and STMRs of 0 mg/kg for both dimethoate and omethoate in poulty meat, poultry fats, poultry, edible offal of, and eggs

RECOMMENDATIONS

On the basis of the data obtained from supervised trials, the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessments.

Definition of the residue for compliance with the MRL for plant and animal commodities: *Dimethoate and omethoate (measured and reported separately)*

Definition of the residue for dietary risk assessment for plant and animal commodities: Sum of dimethoate plus 2.5× omethoate for long-term dietary exposure and the sum of dimethoate plus 10× omethoate for acute dietary exposure.

The residue is not fat-soluble.

Table 10 Maximum residue levels and dietary intake–Dimethoate (see also omethoate)

DIETARY RISK ASSESSMENT

The Meeting considered how to best approach the dietary risk assessment of mixed residues of dimethoate and omethoate and decided that an appropriately conservative approach would be to sum the dimethoate and omethoate residues after first scaling the omethoate residues to account for the differences in toxicity. The relevant factors for chronic and short-term intake were derived from the ratios of the dimethoate and omethoate maximum ADI and acute RfD values and are 2.5 and 10 respectively. Dietary intake estimates for the combined adjusted residues were compared with the dimethoate maximum ADI and ARfD.

Long-term dietary exposure

The ADI for dimethoate is 0–0.001 mg/kg bw. The International Estimated Daily Intakes (IEDIs) for dimethoate (including omethoate) were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the JMPR. The results are shown in Annex 3 of the 2022 JMPR Report.

The IEDIs ranged from 10–100 percent of the maximum ADI. The Meeting concluded that long-term dietary exposure to residues of dimethoate (including omethoate) from uses considered by the JMPR is unlikely to present a public health concern.

Acute dietary exposure

The ARfD for dimethoate is 0.02 mg/kg bw. The International Estimate of Short Term Intakes (IESTIs) for dimethoate (including omethoate) were calculated for the food commodities and their processed commodities for which HRs/HR-Ps or STMRs/STMR-Ps were estimated by the present Meeting and for which consumption data were available. The results are shown in Annex 4 of the 2022 JMPR Report.

The IESTIs varied from 0–120 percent of the ARfD for children and 0–70 percent of the ARfD for the general population. The Meeting concluded that acute dietary exposure to residues of dimethoate (including omethoate) from uses considered by the present Meeting is unlikely to present a public health concern except oranges (120 percent for Australian children).

EMAMECTIN BENZOATE (247)

First draft prepared by D Poflotski, Australian Pesticides and Veterinary Medicines Authority, Armidale, Australia

EXPLANATION

Emamectin benzoate is a foliar insecticide derivative of abamectin, which is isolated from fermentation of Streptomyces avermitilis, a naturally occurring soil actinomycete. It acts by stimulating the release of γ-aminobutyric acid, an inhibitory neurotransmitter, thus causing insect paralysis within hours of ingestion, and subsequent insect death 2–4 days later. It is also registered for use as a veterinary drug in the treatment of sea lice (Siphonostomatoida) infestations in salmon and trout in several countries.

Emamectin benzoate was considered for the first time for toxicology and residues by the 2011 JMPR. An ADI of 0–0.0005 mg/kg bw and ARfD of 0.02 mg/kg bw have been established.

The residue definition for emamectin benzoate is:

Definition of the residue for compliance with the MRL or for estimation of the dietary intake for plant and animal commodities: emamectin B1a benzoate.

The residue not fat soluble.

Emamectin benzoate was scheduled at the Fifty-second Session of the CCPR for the evaluation of additional MRLs in the 2022 JMPR.

The current Meeting received information on analytical methodology, storage stability and additional supervised residues trials on basil, chives, coffee, flowerhead brassica vegetables, leafy vegetables (including brassica leafy vegetables), soya bean and tea.

RESIDUE ANALYSIS

Analytical methods

The Meeting received details of analytical methods including validation data for the determination of emamectin B1a benzoate (B1a, NOA426007), emamectin B1b benzoate (B1b, NOA422390) and the isomers/metabolites; 8,9-ZMa (8,9-ZMa, NOA438376), L'649 (AB1a, NOA438309), L'599 (MFB1a, NOA415692) and L'831 (FAB1a, NOA415693)) in foodstuffs of plant and animal origin. In addition, the Meeting received information on analytical methods for the determination of emamectin B1a benzoate, emamectin B1b benzoate and its avermectin-like metabolites in foodstuffs of plant and animal origin as used in the various study reports (supervised residue trials and storage stability). The analytical methods are summarised below.

Table 1 Summary of the analytical methods for emamectin B1a benzoate, emamectin B1b benzoate and the avermectin-like metabolites

Author, Year, Report ID *(Method ID)*	Matrix	Analytes	Extraction	Clean-up	Separation Analysis/LOQ [a)]

Notes:

[a] Defined by the lowest limit of method validation.

Method RAM 465/01

The analytical method is suitable for the determination of emamectin benzoate and its avermectin-like residues in apples, beans with pods and bean vines (fresh), broccoli, cauliflower, cabbage, cucumbers, lettuce leaves, melons, oil seed rape seeds, peaches/nectarines, pears, potatoes, sugar snap peas with pods (fresh), sweet peppers, tomatoes, winter wheat grain, and wheat straw. A modification also allows for analysis in almond and pecan nutmeat and almond hulls. Description and validation of RAM 465/01 and its modifications was previously considered by the JMPR 2011 evaluation.

The method involves extraction of residues of emamectin benzoate from crops by homogenisation with methanol. Extracts are centrifuged and aliquots diluted with ultra-pure water. Sample clean-up for FAB1a is by solid phase extraction (SPE) using OasisTM HLB cartridges. Final determination of all analytes is by high performance liquid chromatography (HPLC) using a two-column switching method with triple quadrupole mass spectrometric detection (LC-LC-MS/MS, positive ion spray). The LOQ is 0.001 mg/kg for each analyte.

Additional validation results were available from the 2008 supervised trials in basil and chives (Samoil, 2017, IR-4 PR No. 07137) demonstrating that RAM 465/01 is suitable for the determination of residues of emamectin benzoate (B1a and B1b) and the metabolites 8,9-ZMa, AB1a, MFB1a and FAB1a in basil and chives fresh and dried samples.

The working method was validated in fresh basil at 0.001 mg/kg for B1a, B1b, 8,9-ZMa, AB1a and MFB1a and at 0.002 mg/kg for FAB1a (lowest level of method validation, LLMV). In dry chive samples the working method was validated at 0.001 mg/kg residue level for B1a, B1b, 8,9-ZMa, AB1a and MFB1a and at 0.010 mg/kg for FAB1a (lowest level of method validation, LLMV). Additional higher validation levels for fresh and dry samples ranged from 0.005 mg/kg to 0.300 mg/kg, depending on the analyte.

Table 2 Validation recoveries of emamectin benzoate and its metabolites in basil (fresh) and chives (dry)

Matrix	Analyte	No. of tests	Spiking level (mg/kg)	Range [percent]	Mean	RSD [percent]

		3	0.050	71-89	79	12
		3	0.150	91-98	95	4

Overall validation recoveries fortified at levels between 0.001 to 0.300 mg/kg averaged; 104 percent (n=12) for B1a, 107 percent (n=9) for B1b, 103 percent (n=9) for 8,9-ZMa, 93 percent (n=9) for AB1a, 83 percent (n=9) for FAB1a 102 percent (n=10) for MFB1a, from control fresh basil and 93 percent (n=9) for B1a, 89 percent (n=9) for B1b, 89 percent (n=9) for 8,9-ZMa, 84 percent (n=9) for AB1a, and 82 percent (n=9) for FAB1a and 84 percent (n=9) for MFB1a from control dry chives samples with relative standard deviations <20 percent for both matrices.

Method 465/01 is considered suitable for determination of emamectin benzoate (B1a and B1b) and its metabolites in fresh and dried basil and chives.

The supervised trials on tea (Ogiyama, 2019a, JP2018C324, Ogiyama, 2019b, JP2018C081 and Morita, 2020, JP2019C109) were analysed with a method similar to RAM 465/01. For dried tea leaves, the method involved extraction with methanol, clean-up with C_{18}, NH_2, PRS, florisil and graphite mini columns. Tea infusion samples were directly purified using C18 and PRS mini columns. Quantification was by LC-MS/MS with the LOQs at 0.001 mg/kg for each analyte.

Matrix effects were not significant (< 20 percent) for emamectin B1a benzoate in both dried green tea leaf samples and tea infusion samples, therefore matrix matched standards were not used.

For studies JP2018C324 and JP2018C081, method linearity was validated over the range of 0.125 to 5 pg/mL for B1a, B1b and 8,9-ZMa, 0.115 to 4.6 pg/mL for AB1a, 0.222 to 8.88 pg/mL for FAB1a and 0.225 to 9 pg/mL for MFB1a. Correlation coefficients (r) were >0.99 for all analytes and transitions. For study JP2019C109, method linearity was validated over the range of 0.0625 to 5 pg/mL for B1a, B1b and 8,9-ZMa, 0.0575 to 4.61 pg/mL for AB1a, 0.111 to 8.88 pg/mL for FAB1a and 0.1125 to 9 pg/mL for MFB1a. Correlation coefficients (r) were > 0.99 for all analytes and transitions.

The accuracy of the method was assessed based on the determined recovery rates. Samples were fortified at concentrations of 0.0009–0.001 (LOQ), 0.009–0.01, 0.02 and 0.09–0.1 mg/kg. Mean recoveries per concentration level were in a range of 79–108 percent, with acceptable RSD values within the range of 0.4–11 percent.

Additional validation recoveries from the supervised trials in tea demonstrated that the method is suitable for the determination of residues of emamectin benzoate (B1a and B1b) and the metabolites 8,9-ZMa, AB1a, MFB1a and FAB1a in dried tea leaves and tea infusion samples.

Notes:

[1] Tea leaves were sampled and steamed at the conditions of 1 m/45 seconds and 60 kg/h for about 45 seconds using a conveyor belt steaming machine and dried at 80°C for 120 minutes to produce dried green tea leaves.

[2] Commercial tea sample

The method is considered suitable for determination of emamectin benzoate (B1a and B1b) and its metabolites in tea.

Method RAM 465/02

The method is suitable for determination of emamectin benzoate (B1a and B1b) in grape (fruits), potato (tubers) and tomato (fruits) and emamectin benzoate (B1a and B1b) and its avermectin-like metabolites in coffee (bean).

The analytical method involves extraction of emamectin benzoate from crops by homogenisation with methanol. Extracts are centrifuged and filtered via PTFE filter. The method was modified to include sample clean-up for FAB1a by SPE using OasisTM HLB cartridges prior to analysis. Final determination of all analytes is by HPLC with triple quadrupole mass spectrometric detection (LC-MS/MS, positive ion spray).

Table 4 Ion transitions for emamectin benzoate and its metabolites for method RAM 465/02

Analyte	Ion Transition (***m/z***)	
	Primary	Confirmatory
Emamectin B1a benzoate (B1a, NOA426007)	886.4 → 158.2	886.4 → 82.1
Emamectin B1b benzoate (B1b, NOA422390)	872.4 → 158.1	872.4 → 144.1
Emamectin isomer 8, 9-Z (8,9-ZMa, NOA438376)	886.4 → 158.1	886.4 → 82.1
Emamectin metabolite L'649 (AB1a, NOA438309)	872.4 → 158.2	872.4 → 144.1
Emamectin metabolite L'599 (MFB1a, NOA415692)	914.4 → 186.1	914.4 → 113.0
Emamectin metabolite L'831 (FAB1a, NOA415693)	900.4 → 172.1	900.4 → 140.1

Method RAM 465/02 was validated for determination of B1a and B1b in grape, tomato and potato and for B1a, B1b, 8,9-ZMa, AB1a, MFB1a and FAB1a in coffee bean (Alves, 2020b, S19-23176).

Matrix effects were evaluated during the validation. Calibration standards with matrix effect were used for the quantification of B1a and B1b in grape and tomato fruits, and potato tubers and for emamectin benzoate (B1a and B1b), 8,9-ZMa and AB1a in coffee beans. For MFB1a and FAB1a in coffee beans, standards without a matrix effect were used for quantification.

The final injection extracts showed stability at a range of 1 °C to 10 °C for a period of 10 days for tomato, 14 days for coffee bean and 9 days for grape and potato.

Method linearity was validated over the range of 0.05 to 10 ng/mL (matrix-matched calibration solutions). Correlation coefficients (r) were >0.99 for each transition.

The accuracy of the method was assessed based on the determined recovery rates. Samples were fortified at concentrations of 0.001 mg/kg (LOQ) and 0.10 mg/kg (100× LOQ). Mean recoveries per concentration level were in a range of 74–106 percent, with acceptable RSD values within the range of 2–16 percent.

The limit of quantification (LOQ) for each analyte was demonstrated to be 0.001 mg/kg in each matrix. The limit of detection (LOD) was calculated for B1a and B1b in grape (fruit), tomato (fruit), and potato (tuber) and for all analytes in coffee beans for both the primary and confirmatory transitions were found to be 0.0002 mg/kg (<30 percent of the LOQ).

Table 5 RAM 465/02: Validation recoveries of emamectin B1a benzoate and emamectin B1b benzoate in coffee, grape, potato and tomato and their metabolites in coffee

Method RAM 465/02 was also validated for the determination of B1a, B1b, 8,9-ZMa, AB1a, MFB1a and FAB1a in coffee beans, roasted coffee and instant coffee (Melquiades, 2021, S21-06372).

The magnitude of matrix effects was considered significant (≥20 percent suppression or enhancement) for all analytes in coffee beans, roasted coffee and instant coffee.

Final matrix extracts stored in vials at a temperature of approximately 1 °C and 10 °C showed stability for the analysis of residues of B1a, B1b, 8,9-ZMa, AB1a, MFB1a and FAB1a for a storage period of 7 days for coffee beans, 9 or 10 days for roasted coffee and 9 days for instant coffee.

Method linearity was validated over the range of 0.05 to 10 ng/mL. Correlation coefficients were >0.99 for each transition.

The accuracy of the method was assessed based on the determined recovery rates. Samples were fortified at concentrations of 0.001 mg/kg (LOQ) and 0.01 mg/kg (10× LOQ). Mean recoveries per concentration level were in a range of 83.2–116 percent, with acceptable RSD values within the range of 2–14 percent.

The LOQ for each analyte was demonstrated to be 0.001 mg/kg in each matrix. For coffee beans, roasted coffee and instant coffee the calculated LODs were 0.0003 mg/kg for each analyte and both transitions (30 percent of the LOQ).

Table 6 RAM 465/02: Recoveries of emamectin B1a benzoate and emamectin B1b benzoate and their metabolites in coffee beans, roasted coffee and instant coffee

Method 465/02 is considered suitable for determination of emamectin benzoate (B1a and B1b) in grape (fruits), potato (tubers) and tomato (fruits) and emamectin benzoate (B1a and B1b) and its avermectin-like metabolites in coffee (bean), roasted coffee and instant coffee.

Method GRM004.06A

The method is suitable for the determination of B1a, B1b, 8,9-ZMa, AB1a, MFB1a and FAB1a in broad bean (dry), lettuce, orange, tobacco (dry leaves), walnut, and wheat (grain) (Tessier and Braid, 2013).

The analytical method involves extraction of emamectin benzoate from crops with acetonitrile by shaking with QuEChERS salts. The extract was centrifuged, and an aliquot diluted with ultra-pure water (50/50, v/v).

For dry crops such as tobacco (dry leaves), walnuts and dried broad beans, a sub sample is wetted with ultra-pure water and allowed to soak before extraction. The extract is centrifuged, and an aliquot evaporated to dryness. The extract is re-suspended in acetonitrile and diluted with ultra-pure water (50/50, v/v).

Final determination is by HPLC with triple quadrupole mass spectrometric detection (LC-MS/MS).

Table 7 Ion transitions for emamectin benzoate and its metabolites for method GRM004.06A

Analyte	Ion Transition (***m/z***)	
	Primary	Confirmatory
Emamectin B1a benzoate (B1a, NOA426007)	886.4 → 158.2	886.4 → 82.1
Emamectin B1b benzoate (B1b, NOA422390)	872.4 → 158.2	872.4 → 82.0
Emamectin isomer 8, 9-Z (8,9-ZMa, NOA438376)	886.4 → 158.1	886.4 → 82.1
Emamectin metabolite L'649 (AB1a, NOA438309)	872.4 → 144.1	872.4 → 68.1
Emamectin metabolite L'599 (MFB1a, NOA415692)	914.4 → 186.1	914.4 → 154.1
Emamectin metabolite L'831 (FAB1a, NOA415693)	900.4 → 140.0	900.4 → 112.1

Method GRM006.06A was validated for determination of B1a, B1b, 8,9-ZMa, AB1a, MFB1a and FAB1a in broad bean (dry), lettuce, orange, tobacco (dry leaves), walnut, and wheat (grain). Summary validation data from Tessier, 2013, S12-03679 was provided within the analytical method report.

The magnitude of the matrix effects was insignificant (<20 percent suppression or enhancement) in lettuce, orange, wheat grain and dried broad beans and non-matrix matched standards should be used for calibration. In walnuts, the magnitude of the matrix effects was insignificant for B1a and AB1a but was

significant (>20 percent suppression or enhancement) for B1b, 8,9-ZMa, MFB1a and FAB1a and matrix-matched standards should normally be used for calibration if analysing for these analytes. The magnitude of the matrix effects was considered significant for all analytes in tobacco and matrix-matched standards should normally be used for calibration.

Method linearity was validated over the range of 0.025 to 5 ng/mL for lettuce and 0.05 to 10 ng/mL for broad bean (dry), orange, tobacco (dry leaves), walnut, and wheat (grain). Correlation coefficients (r) were >0.99 for all matrices and transitions.

The accuracy of the method was assessed based on the determined recovery rates. Samples were fortified at concentrations of 0.001 mg/kg (LOQ) and 1 mg/kg (1000× LOQ). Mean recoveries per concentration level were in a range of 70–100 percent, with acceptable RSD values within the range of < 0.5–19 percent.

The LOQ for each analyte was demonstrated to be 0.001 mg/kg in each matrix. The calculated LODs (3× background noise) for all analytes in all validated commodities were less than or equivalent to 0.0003 mg/kg (≤ 30 percent of the LOQ) for both transitions.

Table 8 GRM004.06A: Recoveries of emamectin B1a benzoate and emamectin B1b benzoate and their metabolites in broad bean (dry), lettuce, orange, tobacco (dry leaves), walnuts and wheat (grain)

Method GRM004.06A was also validated for the determination of B1a, B1b, 8,9-ZMa, AB1a, MFB1a and FAB1a in apricot, cotton, melon and zucchini (Sayed, 2020, S20-05346).

Matrix effects on detector response caused by apricot (for B1a, B1b, AB1a and MFB1a), melon (for B1a, AB1a and FAB1a) and zucchini (for B1b, AB1a and 8,9-ZMa) were considered insignificant, nevertheless matrix matched standards were used for quantification. Matrix effects caused by apricot (for 8,9-ZMa and FAB1a), melon (for B1b, 8,9-ZMa and MFB1a), zucchini (for B1a, MFB1a and FAB1a) and cotton (for all analytes) were considered significant and therefore matrix matched standards were used for quantification.

The final injection extracts of emamectin benzoate (B1a and B1b), 8,9-ZMa, AB1a, MFB1a and FAB1a showed stability at 4°C for a period of 11 days for apricots and zucchini and 9 days for melons and cotton.

Method linearity was validated over the range of 0.05 to 5 ng/mL for apricot, melon and zucchini and 0.05 to 10 ng/mL for cotton (matrix-matched calibration solutions). Correlation coefficients were >0.99 for each transition.

The accuracy of the method was assessed based on the determined recovery rates. Samples were fortified at concentrations of 0.001 mg/kg (LOQ) and 0.01 mg/kg (10× LOQ). Mean recoveries per concentration level were in a range of 70–111 percent, with acceptable RSD values within the range of 1–20 percent.

The LOQ for each analyte was demonstrated to be 0.001 mg/kg in each matrix. The calculated LODs (3× background noise) for all analytes in all validated commodities were less than 0.0003 mg/kg (<30 percent of the LOQ) for both transitions.

Table 9 RAM 465/02: Validation recoveries of emamectin B1a benzoate and emamectin B1b benzoate in apricot, melon, zucchini and cotton

Method GRM004.06A is suitable for the determination emamectin benzoate and its metabolites in apricot, broad bean (dry), cotton, lettuce, melon, orange, tobacco (dry leaves), walnut, and wheat (grain) and zucchini.

QuEChERS method (foods of plant origin) (enforcement)

The multi-residue QuEChERS method (EN 15662:2009-2) was validated for the determination of residues of emamectin benzoate (B1a and B1b) in broad beans (dry), orange (whole fruit), lettuce, tea (black, dry), tobacco (dried leaves), walnut, and wheat (grain) (Garrigue, 2019, BPL19-0017).

Samples are extracted by agitation with ultra-pure water and acetonitrile (50/50, v/v) followed by addition of magnesium sulphate, sodium chloride, sodium citrate dibasic sesquihydrate and sodium citrate tribasic dihydrate and further agitation. After centrifugation, an aliquot is purified via SPE clean-up. After further centrifugation, an aliquot is diluted with ultra-pure water (50/50, v/v) prior to quantification by HPLC with tandem mass spectrometric detection (LC-MS/MS, positive ion spray).

Table 10 Ion transitions for emamectin benzoate (B1a and B1b) for QuEChERS method

Analyte	Ion Transition (***m/z***)	
	Primary	Confirmatory
Emamectin B1a benzoate (B1a, NOA426007)	886.5 → 158	886.4 → 82
Emamectin B1b benzoate (B1b, NOA422390)	872.4 → 158	872.4 → 82

Matrix effects on detector response caused by broad beans (dry), lettuce, walnut and wheat (grain) matrices for emamectin B1a and emamectin B1b were considered insignificant (< 20 percent) and therefore solvent standards were used for quantification. Matrix effects on detector response caused by orange (whole fruit), black tea and tobacco matrices for emamectin B1a and emamectin B1b were considered significant and therefore matrix matched standards were used for quantification.

The final injection extracts of B1a and B1b showed stability at a range of 2–14 °C for a period of 14 days in broad bean (dry) and wheat (grain), 11 days for tobacco (dry leaves), 10 days for lettuce, 9 days for tea (black, dried) and 8 days in orange (whole fruit) except for B1b in walnut and dried broad bean where the mean recoveries were below 70 percent (69 percent in walnut and 66 percent in dried broad bean) although the difference from the original analysis was within ± 20 percent of the initial values. The report recommended that final extracts for B1b in walnut and broad bean (dry) are analysed within 24 hours after extraction.

The linearity of the detector response was confirmed by injecting at least five solvent or matrix matched standards covering the working range of 0.025 to 2 ng/mL. The lower margin of the linearity test was 25 percent of the LOQ and the upper margin was at least 20 percent above the highest concentration in the final extracts. Correlation coefficients were > 0.99 for each transition.

The accuracy of the method was assessed based on the determined recovery rates. Samples were fortified at concentrations of 0.001 mg/kg (LOQ) and 0.01 mg/kg (10× LOQ). Mean recoveries per concentration level were in a range of 75–110 percent, with acceptable RSD values within the range of 1–10 percent.

The LOQ was found to be 0.001 mg/kg for both analytes in all validated matrices. The LOD for both analytes was calculated (3× background) for both the primary and confirmatory transitions in all validated matrices and was less than 0.0003 mg/kg (< 30 percent of the LOQ).

Table 11 QuEChERS method: Recoveries of emamectin B1a benzoate and emamectin B1b benzoate in broad bean (dry), lettuce, orange, tea (black, dried), tobacco (dry leaves), walnuts and wheat (grain)

An independent laboratory validation (ILV) for the QuEChERS method (EN 15662:2008) was conducted in lettuce, orange, tea and tobacco crop matrices (Homazava, 2019, 20190183).

Significant matrix effects on the LC-MS/MS detector response were observed in tobacco (for B1a and B1b) and tea (for B1b only). Therefore, all sample extracts were evaluated with multi-point calibrations based on matrix-matched calibration standards for both analytes in these two matrices. For lettuce and orange, the matrix effects were found to be insignificant and therefore all sample extracts were evaluated with multi-point calibrations based on solvent calibration standards for both analytes in these two matrices.

The linearity of the LC-MS/MS detector response was confirmed by injecting eight solvent or matrix matched standard solutions, covering a working range of 0.05 ng/mL to 10 ng/mL (equivalent to 0.00025–0.05 mg/kg). The lower margin of the linear range was at least 30 percent of the LOQ and the upper margin was higher by at least 20 percent above the highest concentrations in the final extracts. Correlation coefficients were > 0.99 for each transition.

The accuracy of the method was assessed based on the determined recovery rates. Samples were fortified at concentrations of 0.001 mg/kg (LOQ) for lettuce, orange, tea and tobacco and 0.02 mg/kg (20× LOQ) for tea (black, dried), 0.05 mg/kg (50× LOQ) for orange (whole fruit) and 1.0 mg/kg (1000× LOQ) for lettuce and tobacco (dry leaves). Mean recoveries per concentration level were in a range of 83–107 percent, with acceptable RSD values within the range of 0.4–4 percent.

The LOQ was found to be 0.001 mg/kg for both analytes in all validated matrices. The LOD for both analytes was calculated (3× background) for both the primary and confirmatory transitions in all validated matrices and was less than 0.0003 mg/kg (<30 percent of the LOQ).

The QuEChERS enforcement method for plant commodities is considered suitable for determination of emamectin (B1a and B1b).

QuEChERS method (foods of animal origin) (enforcement)

The multi-residue QuEChERS method (DIN EN 15662:2018), first developed for foods of plant origin, was validated for the determination of residues of emamectin benzoate (B1a and B1b) in animal matrices muscle (cattle), liver (cattle), kidney (cattle), fat (cattle), milk (cattle) and eggs (poultry)) (Mechelke, 2021, 20200259).

Samples are extracted by agitation with ultra-pure water and acetonitrile (50/50, v/v) followed by addition of magnesium sulfate, sodium chloride, trisodium citrate dihydrate and disodium hydrogen citrate and further agitation. After centrifugation, an aliquot of the upper acetonitrile layer is purified via SPE clean-up (primary and secondary amine + magnesium sulphate). After further agitation and centrifugation, an aliquot transferred to an auto sampler vial. A small amount of 5 percent formic acid in acetonitrile is added. An aliquot thereof is diluted in water (50/50, v/v) prior to quantification by HPLC with triple quadrupole mass spectrometric detection (LC-MS/MS, positive ion spray).

Table 13 Ion transitions for emamectin benzoate (B1a and B1b) for QuEChERS method

Analyte	Ion Transition (***m/z***)	
	Primary	Confirmatory
Emamectin B1a benzoate (B1a, NOA426007)	886 → 158	886 → 82
Emamectin B1b benzoate (B1b, NOA422390)	872 → 158	872 → 82

Significant matrix effects on the LC-MS/MS detector response were observed in muscle (for B1a and B1b) and milk and fat (for B1b only). Therefore, all sample extracts were evaluated with multi-point calibrations based on matrix-matched calibration standards for both analytes in these three matrices. For liver and kidney (cattle) matrix effects were found to be insignificant. Nevertheless, all sample extracts were evaluated with multi-point calibrations based on matrix-matched calibration standards for both analytes in these two matrices. For eggs, matrix effects were found to be insignificant (<20 percent suppression or enhancement). Therefore, all sample extracts were evaluated with multi-point calibrations based on solvent calibration standards for both analytes in eggs.

The final injection extracts of B1a and B1b showed stability at a range of 2–8 °C for a period of 7–8 days for all validated matrices.

The linearity of the detector response was confirmed by injecting at least five solvent or matrix matched standards covering the working range of 0.03 to 5 ng/mL in milk (cattle) and 0.03 to 2.5 ng/mL in muscle (cattle), liver (cattle), kidney (cattle), fat (cattle) and eggs. The lower margin of the linearity test

was 30 percent of the LOQ and the upper margin was at least 20 percent above the highest concentration in the final extracts. Correlation coefficients were > 0.99 for each transition.

The accuracy of the method was assessed based on the determined recovery rates. Samples were fortified at concentrations of 0.001 mg/kg (LOQ) and 0.01 mg/kg (10× LOQ). Mean recoveries per concentration level were in a range of 77–102 percent, with acceptable RSD values within the range of 1–9 percent.

The LOQ was found to be 0.001 mg/kg for both analytes in all validated matrices. The LOD for both analytes was calculated (3× background) for both the primary and confirmatory transitions in all validated matrices and was less than 0.0002 mg/kg (< 30 percent of the LOQ).

Table 14 QuEChERS method: Recoveries of emamectin B1a benzoate and emamectin B1b benzoate in muscle (cattle), liver (cattle), kidney (cattle), fat (cattle), milk (cattle) and eggs

An independent laboratory validation (ILV) for the QuEChERS method was conducted in cattle fat and liver (Baumy, 2021, RNB20-00065).

Significant matrix effects on detector response caused by liver (for B1a only) were observed, therefore matrix matched standards were used for quantification. Matrix effects on detector response caused by liver (for B1b only) and fat (for B1a and B1b) were considered insignificant, nevertheless matrix matched standards were used for quantification.

The linearity of the LC-MS/MS detector response was confirmed by injecting seven matrix matched standard solutions, covering a working range of 0.03 ng/mL to 5 ng/mL (equivalent to 0.0003–0.05 mg/kg). The lower margin of the linear range was at least 30 percent of the LOQ and the upper margin was higher by at least 20 percent above the highest concentrations in the final extracts. Correlation coefficients were > 0.99 for each transition.

The accuracy of the method was assessed based on the determined recovery rates. Samples were fortified at concentrations of 0.001 mg/kg (LOQ) in both matrices and 0.2 mg/kg (200× LOQ) for fat and 0.8 mg/kg (800× LOQ) for liver. Mean recoveries per concentration level were in a range of 77–104 percent, with acceptable RSD values within the range of 1–14 percent.

The LOQ was found to be 0.001 mg/kg for both analytes in both validated matrices. The LOD for both analytes was calculated (3× background) for both the primary and confirmatory transitions in both validated matrices and was less than 0.0003 mg/kg (< 30 percent of the LOQ).

Table 15 QuEChERS method: ILV recoveries of emamectin B1a benzoate and emamectin B1b benzoate in cattle fat and liver

Matrix	Analyte	No. of tests	Spiking level (mg/kg)	Primary			Confirmatory

The QuEChERs enforcement method for animal commodities is considered suitable for determination of emamectin (B1a and B1b).

Stability of pesticide residues in stored analytical samples

The 2011 JMPR considered storage stability in numerous crops and concluded that emamectin B1a benzoate and emamectin B1b benzoate were stable when stored at -20 °C or lower for at least 27 months (804 days) in plant commodities with high water content (tomatoes and green beans with pods), at least 18 months (545 days) in plant commodities with high starch content (potatoes), and at least 9 months (273 days) in plant commodities with high oil content (cottonseed), and special plant commodities (cotton gin trash). Avermectin-like metabolites 8,9-ZMa, AB1a, MFB1a, and FAB1a were stable when stored frozen at -20 ˚C or lower for at least 18 months in plant commodities with high water content (tomatoes and green beans with pods), at least 18 months commodities with high starch content (potatoes), while 8,9-

ZMa was stable for at least 6 months in commodities with high oil content (cottonseed), and special commodities (cotton gin trash).

A new study was conducted to evaluate the freezer storage stability of the residues of emamectin benzoate and its metabolites in frozen orange (whole fruit) (Ford, 2018, CEMR-7499). Homogenised samples of whole oranges were fortified with 0.1 mg/kg of standard solution containing B1a, B1b, 8,9-ZMa, AB1a, MFB1a or FAB1a and stored at -18 °C for 3, 6, 9, 12, 18 and 24 months until analysis. The samples were analysed using procedures described in residue analytical method GRM004.06A. Residues of emamectin benzoate and its metabolites are stable in whole orange when stored deep frozen at <-18 °C for up to 24 months with no significant decrease (> 30 percent as compared to the zero-time value) in the observed residue levels after frozen storage for up to 24 months.

Table 16 Stability of emamectin benzoate in orange (whole fruit) following storage at <-18 °C

Matrix	Analyte	Fortification level (mg/kg)	Days of storage	Percent concurrent recovery (mean)	Percent stored recovery (mean)	Percent remaining (mean)
Orange (whole fruit)	B1a	0.10	0	89.6, 87.8, 89.5, 89.5, 86.8 (88.6)	-	-

Matrix	Analyte	Fortification level (mg/kg)	Days of storage	Percent concurrent recovery (mean)	Percent stored recovery (mean)	Percent remaining (mean)
			760	73.1, 70.6 (71.9)	70.7, 68.8 (69.7)	83

Notes:

Percent remaining = (Mean stored recovery/Mean 0 day recovery) × 100

Storage stability data were included in the magnitude of residue study conducted for emamectin benzoate on basil and chives (Samoil, 2017, IR-4 PR NO. 07137). The concurrent storage stabilities were found to be acceptable for emamectin B1a benzoate, emamectin B1b benzoate, 8,9-ZMa, FAB1a and MFB1a when stored at <-15 °C for approximately 56 months (1670–1672 days) for fresh basil and approximately 52 months (1548–1551 days) for dry chives. This represented approximately 102 percent of the storage interval for fresh basil trial samples (1637 days) and approximately 92 percent of the storage interval for dry chive trial samples (1659 days for B1a). The mean storage stability recoveries for AB1a (fresh and dry) < 60 percent as summarised below.

Table 17 Summary of storage stability recoveries of emamectin benzoate and its metabolites in basil and chives following storage at <-15 °C

Matrix	Analyte	Approx. Spike level (mg/kg)	Days of storage	Sample size (n)	Observed residue (mg/kg)	Percent stored spike	Percent Mean store spike
Basil (fresh leaves and stems)	B1a	0.120	1670	3	0.081, 0.093, 0.084	67, 78, 70	72
	B1b	0.005	1670	3	0.004, 0.003, 0.003	61, 61, 84	69
	8,9-ZMa	0.050	1671	4	0.042, 0.039, 0.041, 0.047	84, 79, 83, 94	85
	AB1a	0.120	1672	3	0.058, 0.081, 0.053	48, 67, 44	53
	FAB1a	0.005	1671	6	0.004, 0.003, 0.003, 0.003, 0.004, 0.004	71, 62, 63, 64, 79, 71	68
	MFB1a	0.005	1672	3	0.004, 0.005, 0.005	90, 98, 106	98
Chives (dry leaves)	B1a	0.120	1548	4	0.094, 0.085, 0.093, 0.093	78, 71, 77, 77	76
	B1b	0.005	1551	3	0.004, 0.003, 0.003	71, 70, 64	68
	8,9-ZMa	0.050	1552	3	0.039, 0.040, 0.036	78, 81, 73	77
	AB1a	0.120	1551	3	0.075, 0.060, 0.053	62, 50, 44	52
	FAB1a	0.005	1552	3	0.004, 0.002, 0.003	83, 52, 54	63
	MFB1a	0.005	1551	1	0.004, 0.004, 0.003	70, 75, 59	68

Storage stability data were included in the magnitude of residue studies conducted for emamectin benzoate on tea (Ogiyama, 2019a, JP2018C324, Ogiyama, 2019b, JP2018C081 and Morita, 2020, JP2019C109). The data demonstrated the stability of emamectin B1a benzoate in dried tea leaves stored at <-20 °C for a time period that accommodates the storage period in the residue study.

Samples of dried green tea leaves were fortified at a nominal rate of 0.01 mg/kg and stored frozen at *ca.* -20 °C. Two stored samples were analysed following 19, 24, 35 days (Ogiyama, 2019b, JP2018C081), 38 days (Ogiyama, 2019a, JP2018C324) and 96 days (Morita, 2020, JP2019C109). At each timepoint, an untreated control and a concurrent recovery were also analysed. Residues of emamectin B1a benzoate were determined using the validated analytical tea method with an LOQ 0.001 mg/kg.

Table 18 Stability of emamectin benzoate in tea leaves following storage at <-20 °C

Matrix	Analyte	Fortification level (mg/kg)	Days of storage	percent concurrent recovery (mean)	percent stored recovery (mean)	percent remaining (mean)	Study Reference

Notes:

Percent remaining = (Mean stored recovery/Mean concurrent 0 day recovery) × 100.

Storage stability data were included in the magnitude of residue trials conducted for emamectin benzoate on Chinese broccoli (Thongsam, 2017, APSRDD trials 01-06). The concurrent storage stabilities were found to be acceptable for emamectin B1a benzoate when stored at <-18 °C for approximately 9 months (270 days) as summarised below.

Table 19 Summary of storage stability recoveries of emamectin B1a benzoate in Chinese broccoli following storage at <-18 °C

Matrix	Analyte	Fortification level (mg/kg)	Days of storage	percent concurrent recovery (mean)	percent stored recoveries (mean)	percent remaining (mean)	Study Reference
Chinese broccoli (Whole commodity)	B1a	0.05	0	(83)	88, 78 (83)	-	Thongsam, 2017, APSRDD trials 01-06
			7	(95)	96, 94 (94)	113	
			14	(88)	84, 78 (82)	99	
			30	(82)	80, 84 (82)	99	

Matrix	Analyte	Fortification level (mg/kg)	Days of storage	percent concurrent recovery (mean)	percent stored recoveries (mean)	percent remaining (mean)	Study Reference
			60	(80)	80, 82 (81)	98	
			90	(95)	94, 96 (95)	114	
			180	(80)	78, 82 (80)	96	
			270	(96)	90, 80 (85)	102	

Notes:

Percent remaining = (0 day percent stored Mean stored recovery/Mean 0 day stored recovery) × 100.

Concurrent recoveries from supervised residue trials

Concurrent recoveries for each study were generally acceptable as summarised below.

Table 20 Summary of concurrent recoveries of emamectin benzoate and its metabolites from the supervised trials

USE PATTERN

Emamectin benzoate is registered for use in several countries for control of insects on several commodities as is indicated in the JMPR 2011 and 2014 evaluations. Additional label information on brassica head and stem vegetables, brassica leafy vegetables, herbs, leafy vegetables, soya bean and tea has been submitted to the present Meeting. Registered uses made available to this Meeting are presented below.

Table 21 Registered uses of emamectin benzoate, relevant to the present evaluation

Crop	Country	Formulation		Application					WHP / PHI (days)	Notes
		Active substance content	Type	Method	Rate (g ai/ha)	Max No.	Spray volume (L/ha)	Spray interval (days)		
Brassica Head and Stem Vegetables	United States	5 percent	SG	Foliar spray	8.4-16.8 Max. 101 g ai/ha/season	-	Ground min. 94 Aerial: 47-187	7	7	Field or greenhouse – not stated. DO NOT graze

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received supervised residue trials on basil, broccoli, cauliflower, Chinese broccoli, coffee, lettuce leaf, mustard greens, soya bean, spinach, and tea.

Crop group	Subgroup	Commodity (Code)	Table No.
Bulb vegetables (009)	Green Onions (009B)	Chives (VA 2605)	Table 22
Brassica vegetables (except brassica Leafy vegetables) (010)	Flowerhead brassicas (010A, VB 0042)	Broccoli (VB 0400)	Table 23 and 24
		Cauliflower (VB 0404)	Table 25 and 26
Leafy vegetables (including brassica leafy vegetables) (013)	Leafy greens (013A)	Lettuce, Leaf (VL 0482)	Table 27
		Spinach (VL 0502)	Table 27 and 28
	Brassica Leafy vegetables (013B)	Chinese broccoli (VL 0401)	Table 29
		Mustard greens (VL 0485)	Table 30
Pulses (015)	Dry beans (015A)	Soya bean (dry) (VD 0541)	Table 31
Seed for beverages and sweets (024)	-	Coffee (SB 0716)	Table 32 and 33
Herbs (027)	Herbs (herbaceous plants) (027A)	Basil (HH 0722)	Table 34
Teas (066)	Teas from *Camellia sinensis* (066A)	Tea, green, black (fermented and dried) (DT 1114)	Table 35

All trials were well documented with field and analytical reports. The studies included method validation including recoveries with spiking at residue levels similar to those occurring in samples from the supervised trials. Mean concurrent recoveries were acceptable for all studies. Dates of analysis and/or duration of sample storage were also provided. Samples were collected and stored frozen immediately or soon after sampling. Although trials included control plots, no control data are recorded in the Tables because, unless noted, residues in control samples did not exceed the LOQ. Residues are not adjusted for recoveries.

Chives

The Meeting received information on supervised residues trials for the use of emamectin benzoate on chives (Samoil, 2017, IR-4 PR No. 07137).

Four supervised residue trials on chives (4 harvest trials) were conducted in the United States in 2008. At each location, emamectin benzoate (5 percent SG) was applied as a foliar directed application to chives six times at 7(±1) day intervals.

At all sites, duplicate untreated control and treated basil samples were harvested by hand at commercial maturity, 7 days after the last treatment. A minimum of ~0.5 kg for fresh leaves were harvested at all sites.

All fresh samples were placed into a freezer <3 hours after sampling and stored frozen at <-18°C until analysis.

All samples were analysed in accordance with analytical method RAM 465/01. The LOQ was 0.001 mg/kg for B1a, B1b, 8,9-ZMa, AB1a and MFB1a and at 0.002 mg/kg for FAB1a in fresh chives and was 0.001 mg/kg for B1a, B1b, 8,9-ZMa, AB1a and MFB1a and at 0.01 mg/kg for FAB1a in dry chives. The LOD was 0.0001 mg/kg for Bla, B1b, 8,9-ZMa and AB1a, 0.0002 mg/kg for MFB1a and 0.0005 mg/kg for FAB1a. In dry chives, due to high ion suppression LOD for FAB1a was 0.002 mg/kg and the LOD for MFB1a at 0.0005 mg/kg.

Notes:

Mean values are in the parenthesis and calculated from unrounded results.

[a] Adjuvant: Silwet, 0.25 percent included in last three applications.

[b] Adjuvant: Activator 90, 0.25 percent included in all applications.

[c] Adjuvant: NIS Surfactant 80/20, 0.25 percent included in all applications.

[d] Adjuvant: R-11, 0.25 percent included in all applications.

Flowerhead brassicas

Broccoli

The Meeting received information on supervised residues trials for the use of emamectin benzoate on broccoli and sprouting broccoli conducted in France (2005), Germany, Spain and the United Kingdom (2008). Both studies (Oliver-Kang, 2006a, CEMR-2654 and Marshall, 2009b, T009258-07-REG) were considered by the 2011 JMPR.

Notes:

[1] Sum1a, expressed as MAB1a = sum of MAB1a plus its avermectin-like metabolites, corrected for molecular weight (MAB1a + 1.000 × 8,9-ZMa + 1.016 × AB1a + 0.9693 × MFB1a + 0.9844 FAB1a). Metabolites < LOQ were assumed not to be present.

Leafy vegetables

Spinach

The Meeting received information on supervised residue trials on spinach and leaf lettuce.

Ten supervised residue trials with emamectin benzoate on spinach (6) and leaf lettuce (4) were conducted in the United States between 1997 and 2005 (Vincent, 1998, ABR-98047 and Ediger and Oakes, 2005, T002301-03). All trials were conducted under field conditions. In all trials, emamectin benzoate was applied as a SG formulation containing 5 percent emamectin benzoate. The test substance was applied four to six times as a foliar application at a nominal rate of 16.8 g ai/ha, with a nominal application interval of 7 ± 1 day and a PHI of 7 days. A non-ionic surfactant was added as an adjuvant to all applications at a rate of 0.1 percent.

Samples of leaf lettuce and spinach were collected from all trials at 7 days after the final application. Decline trials also sampled at 0, 3 and 7 days, and 10 or 14 days after the final application. Samples were collected and stored frozen prior to analysis. Samples were stored for a maximum of 9.6 months prior to analysis. Data previously evaluated by the JMPR on high water content commodities demonstrated storage stability for at least over 27 months when stored at ≤-18 °C.

For the trials conducted in 1997, samples were analysed for residues of emamectin benzoate and photodegradates using the validated analytical method ARM 244-92-3 (rev. 1) with an LOQ of 0.005 mg/kg. The HPLC Fluorescence method was considered by the 2011 JMPR. Since the 8,9-ZMa/b isomers cannot be distinguished from the parent by the analytical method used in these trials, residue levels for B1a and B1b include residues of its 8,9- ZMa/b isomers. Additionally, all samples were also analysed for the photodegradates AB1a, and FAB1a + MFB1a as presented below.

Notes:

Mean values are in the parenthesis and calculated from unrounded results.

Adjuvant: Non-ionic surfactant, 0.1 percent included in all applications.

The trials conducted in 2005, samples were analysed for residues of emamectin benzoate and its metabolites using the validated analytical method ARM 244-92-3 (rev. 1) with modifications to the clean-up and instrumental analysis with the LOQ remaining at 0.005 mg/kg. Chromatographic separation was achieved using contemporary columns with analysis by high performance liquid chromatography with triple quadrupole mass spectrometer detection (LC-MS/MS) with column switching. MS/MS detections of

emamectin benzoate (B1a, B1b, 8,9-ZMa, AB1a, FAB1a and MFB1a) was accomplished by monitoring the transitions of the molecular ions to the daughter ions using electrospray ionization in the positive mode similar to the instrumentation and transitions used in the other newer methods discuss is this evaluation. The results of this analysis are presented below.

Brassica leafy vegetables

The Meeting received information on supervised residues trials for the use of emamectin benzoate on brassica leafy vegetables (Chinese broccoli and Mustard greens).

Chinese broccoli

Six non-GLP field trials on Chinese broccoli were conducted in Thailand in 2017 to 19. In all trials, emamectin benzoate was applied as an EC formulation containing 1.92 percent emamectin benzoate. The test substance was applied twice as a foliar application at a nominal rate of 14.5 g ai/ha with a retreatment interval of 7 days.

At all sites, duplicate untreated control and treated samples of Chinese broccoli (> 2 kg) were collected at 0, 1, 3, 5, 7, 10 and 14 days after last application. All samples were received by the laboratory on the day of sampling, stored frozen at -18 °C, and analysed with ~1 month of sampling.

Samples were analysed for emamectin B1a benzoate in accordance with QuEChERS method EN 15662.2008. The LOQ for the method was 0.005 mg/kg.

Soya bean (dry)

The Meeting received information on supervised residues trials for the use of emamectin benzoate on soya beans.

Twenty supervised trials involving the use of emamectin benzoate on soya beans were conducted in the United States during 2018 (Bledsoe, 2019, TK0347414) to determine the magnitude of residues of emamectin benzoate (B1a and B1b) and its metabolites 8,9-ZMa, AB1a, MFB1a and FAB1a. The test substance was an emulsifiable concentrate (EC) formulation (A10325A) with a nominal composition of 19.2 g ai/L. All trial sites established one control and one treated plot of soya bean. Treatment plots received three broadcast foliar spray applications of the test substance at the nominal rate of 17 g ai/ha with a retreatment interval of 7±1 days. Applications were targeted at 42±3 days before harvest (DBH), 35±2 DBH (7±1 days after first application; DAT1), and 28±1 DBH (7±1 days after second application; DAT2).

Control samples and duplicate treated samples were collected normal commercial harvest (28±1 days after last application (DALA). Additional duplicate treated (P2) soya bean seed samples were collected at three sites targeting 21±1, 25±1, 32±1, and 35±1 DALA to determine residue decline.

Samples of soya bean seed were stored frozen between -10 °C to -25 °C until analysis. The maximum duration between sampling an analysis was 10.1 months. Data previously evaluated by the JMPR on high oil content commodities demonstrated emamectin B1a benzoate is stable for at least 9 months of frozen storage.

All samples were analysed in accordance with an analytical method RAM 465/02. The LOQ was 0.001 mg/kg for all analytes.

Coffee

The Meeting received information on supervised residues trials for the use of emamectin benzoate on coffee.

Four supervised residue trials on coffee were conducted in Brazil in 2020 (Evangelista, 2020, S19-23395 and Alves, 2020a, S19-23631-L1). At all locations, the treatment plots received two foliar applications of emamectin benzoate (50 g/kg WG) applied nominally at 25 g ai/ha at 51 days before harvest (DBH) and 30 days later (21 DBH) at a spray volume of 400 L/ha. The applications were applied in a spray volume of 410-438 L/ha of water and included addition of 0.1 percent adjuvant.

At all sites, duplicate untreated control and treated coffee (cherry) samples (3.7–10.5 kg) were collected at 21, 30 and 45 days after last application (DALA). After collection, the coffee cherries were left in the field for drying in sunshine for 10–37 days prior to processing. Following processing, at least 1 kg of coffee beans were transferred to a freezer within 24 hours of processing and stored frozen at <-20 °C. All samples were analysed within 135 days of collection.

All samples were analysed in accordance with analytical method RAM 465/02. The LOQ was 0.001 mg/kg for all analytes. The LOD was 0.0003 mg/kg for all analytes. Analysis results for B1a and B1b were reported in Evangelista, 2020, S19-23395 with results for 8,9-Z, AB1a, FAB1a and MFB1a reported in Alves, 2020a, S19-23631-L1 as presented below.

Notes:

Mean values are in the parenthesis and calculated from unrounded results.

Adjuvant: Ochima non-ionic surfactant, 0.25 percent included for all applications.

A further study was received which determined the magnitude of residues of emamectin benzoate B1a, emamectin benzoate B1b and its metabolites 8,9-ZMa, AB1a, MFB1a and FAB1a in coffee; dry green beans, roasted coffee and instant coffee (Delongui, 2022, LBS20033).

Four supervised residue trials on were conducted in Brazil in 2021. At all locations, the treatment plots received two foliar applications of emamectin benzoate (50 g/kg WG) applied at 25 g ai/ha at 51 days before harvest (DBH) and 30 days later (21 DBH) at a spray volume of 400 L/ha. The applications were applied in a spray volume of 400–411 L/ha of water and included addition of 0.1 percent adjuvant. The two processing trials involved a further treatment plot with applications at 125 g ai/ha (5×).

At all sites, duplicate untreated control and treated coffee (cherry) samples (6.2–11.6 kg) were collected at 10, 15, 21, 25 and 30 days after last application (DALA). After collection, the coffee cherries were dried by placing inside plastic raffia bags were placed on a clean plastic tarp for 13–17 days prior to processing. Following processing, at least 1 kg of green coffee beans were transferred to a freezer within 24 hours of processing and stored frozen at ≤-20 °C. All samples were analysed within 135 days of collection.

All samples were analysed in accordance with analytical method RAM 465/02. The LOQ was 0.001 mg/kg for all analytes. The LOD was 0.0003 mg/kg for all analytes. Analysis results for B1a and B1b were reported in Evangelista, 2020, S19-23395 with results for 8,9-Z, AB1a, FAB1a and MFB1a reported in Alves, 2020a, S19-23631-L1 as presented below.

Notes:

Mean values are in the parenthesis and calculated from unrounded results.

Adjuvant: Ochima non-ionic surfactant, 0.1 percent included for all applications.

Basil

The Meeting received information on supervised residues trials for the use of emamectin benzoate on basil (Samoil, 2017, IR-4 PR No. 07137).

Four supervised residue trials on basil were conducted in the United States in 2008. At each location, emamectin benzoate (0.05 lb ai SG) was applied as a foliar directed application to basil six times at 7 day intervals. The individual application rates ranged from 16.4–17.5 g ai/ha and totalled 100.4–103.1 g ai/ha per season. The first application was applied at 39–41 days before normal harvest of the basil. The applications were applied in a spray volume of 242–390 L/ha of water and included a non-ionic surfactant or crop oil type additive.

At all sites, duplicate untreated control and treated basil samples were harvested by hand at commercial maturity, 7 days after the last treatment. A minimum of approximately 0.5 kg for fresh leaves and stems were harvested at all sites and a minimum of approximately 0.25 kg of dried leaves and stems also sampled at the New Mexico trial site. Additionally, at the North Carolina decline trial site, duplicate fresh basil samples were also taken from the treated plot at 0, 3 and 9 days after treatment.

All fresh samples were placed into a freezer, <4 hours after sampling and generally stored frozen at <-18 °C until analysis.

All samples were analysed in accordance with analytical method RAM 465/01. The LOQ was 0.001 mg/kg for B1a, B1b, 8,9-Z, AB1a and MFB1a in fresh and dry basil and, for FAB1a, at 0.002 mg/kg in fresh basil and at 0.01 mg/kg in dry basil. The LOD was 0.0001 mg/kg for Bla, B1b, 8,9-ZMA and AB1a, 0.0002 mg/kg for MFB1a and 0.0005 mg/kg for FAB1a.

Notes:

[a] Adjuvant: Induce, 0.25 percent included in all applications.

[b] Adjuvant: Chem-nut, 0.25 percent included in all applications except the initial application.

[c] Adjuvant: Agridex, 1.0 percent included in all applications except the initial application.

Tea

The Meeting received information on supervised residues trials for the use of emamectin benzoate on tea.

Eight supervised trials involving the use of emamectin benzoate on tea were conducted in Japan during 2018-2019 (Ogiyama, 2019a, JP2018C324, Ogiyama 2019b JP2018C081 and Morita, 2020, JP2019C109) to determine the magnitude of residues of emamectin benzoate B1a, emamectin benzoate B1b and its metabolites 8,9-ZMa, AB1a, MFB1a and FAB1a. At all locations, the treatment plots received a single foliar application of 1 percent emamectin benzoate (10 g/L EC) applied at the leaf ages between sprouting and 6 leaf stage at 1000-fold dilution and spray volumes of 3000–4000 L/ha.

Separate plots in each trial were sampled at 7, 14 and 21 days after application. Tea leaves (picked at leaf ages between 2–6 leaf) were steamed using a conveyor belt steaming machine at the conditions of 1 metre of tea leaves/45 seconds (60 kg of tea leaves/hour) or using an autoclave for 60 seconds. Samples were then dried at 80 °C for 120–135 minutes using an air-permeable drying machine or a convection oven to produce dried green tea leaves. At the laboratory, each sample was cut to pieces (about 1 cm square), mixed well, pulverized using a mill, sealed, and stored at about -20 °C for a maximum of 82 days until analysis.

All samples were analysed in accordance with an analytical method for tea similar to RAM 465/01. The LOQ was 0.001 mg/kg for all analytes. The LOD was 0.0005 mg/kg for all analytes.

Table 35 Residues of emamectin benzoate (B1a, B1b, 8,9-Z, AB1a, FAB1a and MFB1a) in dried green tea leaves and tea infusions after foliar spray with an EC formulation (10 g/L emamectin)

FATE OF RESIDUES IN STORAGE AND PROCESSING

Residues after processing

The fate of emamectin benzoate residues during processing of raw agricultural commodities was investigated in basil, chives, coffee, tea and soya beans.

Soya bean

Two processing trials were conducted in the United States in 2018 to demonstrate the effect of processing on residues of emamectin benzoate in soya beans. Treatment plots for the processing trials received three broadcast foliar spray applications at an exaggerated (5×) nominal rate of 84 g ai/ha. Soya bean seeds sampled from these trials were processed into pollards, soy sauce, miso, flour (defatted) and aspirated grain fractions. As residues in soya bean seed samples were all <LOQ only the aspirated grain fractions were analysed.

All samples were analysed in accordance with analytical method RAM 465/02. The limit of quantitation (LOQ) was 0.001 mg/kg for all analytes.

Residues of emamectin B1a benzoate concentrated when soya bean seeds were processed to aspirated grain fractions. Actual processing factors cannot be quantified noting that all residues in soya bean seed prior to processing were below the LOQ (< 0.001 mg/kg).

Table 38 Summary of residues of emamectin benzoate (B1a, B1b, 8,9-ZMa, AB1a, FAB1a and MFB1a) in soya beans and the aspirated grain fractions at 28-29 DALA after foliar spray with an EC formulation (19.2 g/L emamectin)

Trial No., Location, Year, Crop (Variety)	Analyte	Commodity		Mean processing factor[1] (PF)

Notes:

Mean results are reported in the parenthesis.

[1] Processing factor = Mean residue in the processed commodity / Mean residue in the RAC. For censored data (<LOQ), the finite LOQ value for the relevant analyte has been used for calculations.

[2] Where residues in the unprocessed commodity (RAC) were <LOQ no processing factor can be quantified and are reported as NC (Not Calculated). If residues were observed at <LOQ in the RAC and ≥LOQ in the processed commodity they are reported as NC (observed to concentrate).

Coffee

Two processing trials were conducted in Brazil in 2021 to demonstrate the effect of processing on residues of emamectin benzoate in coffee. Samples of treated coffee (the cherry) (129–355 kg) were collected at 21 days after last application (DALA). After collection, the coffee cherries were dried by

placing inside plastic raffia bags placed on a clean plastic tarp for 16 days prior to processing. After drying and processing, green coffee beans (45–75 kg) were transferred to a freezer within 24 hours (stored at -20 °C). Green coffee beans were processed by roasting the dry coffee beans to create roasted coffee and then the remaining coffee was milled and extracted with water and then lyophilized, producing instant coffee. At least 1kg of roasted and instant coffee were collected and frozen at -20 °C until analysis.

All samples were analysed in accordance with analytical method RAM 465/02. The limit of quantitation (LOQ) was 0.001 mg/kg for all analytes.

Residues of emamectin and its metabolites decreased in roasted or instant coffee (PF=<1). No residues were observed above the LOQ in roasted or instant coffee.

Table 37 Residues of emamectin benzoate (B1a, B1b, 8,9-ZMa, AB1a, FAB1a and MFB1a) in coffee beans, roasted coffee and instant coffee at 21 DALA after foliar spray with a WG formulation (50 g ai/kg)

Notes:

Mean results are reported in the parenthesis.

[1] Processing factor = Mean residue in the processed commodity / Mean residue in the RAC. For censored data (<LOQ), the finite LOQ value for the relevant analyte has been used for calculations.

[2] Where residues in the unprocessed commodity (RAC) were <LOQ no processing factor can be quantified and are reported as NC (Not Calculated). Where residues are >LOQ in the RAC and <LOQ in the processed commodity the processing factor is reported as less than (<).

Basil and Chives

Two trials were conducted in the United States in 2008 to assess residues in dried basil and chives. A minimum of approximately 0.5 kg of fresh basil (leaves and stems) or fresh chives (leaves) was harvested at 6–7 days after 6 foliar applications of emamectin benzoate (5 percent SG) and stored frozen (≤-15 °C) until processing and analysis. For dried samples, the samples were dried in an oven for 24 hours at 47 °C (basil) and 54 °C (chives). After cooling, at least 0.25 kg of dried samples were transferred to a freezer and stored frozen (≤-15 °C) until analysis.

All samples were analysed in accordance with analytical method RAM 465/01. The LOQ was 0.001 mg/kg for B1a, B1b, 8,9-ZMa, AB1a and MFB1a in fresh and dry basil and chives, 0.002 mg/kg for FAB1a in fresh basil and chives and 0.01 mg/kg in dry basil and chives. The LOD was 0.0001 mg/kg for Bla, B1b, 8,9-ZMa and AB1a, 0.0002 mg/kg for MFB1a in fresh and dried basil and chives and, for FAB1a, at 0.0005 mg/kg in dried basil and 0.002 mg/kg in dried chives.

Residues of emamectin benzoate were observed to concentrate in dried basil and chives with processing factors for B1a of 6.4 for dried basil and 5.0 for dried chives as presented below.

Table 36 Residues of emamectin benzoate (B1a, B1b, 8,9-ZMa, AB1a, FAB1a and MFB1a) in fresh and dry basil and chives at 6-7 DALA after foliar spray with an SG formulation (50 g ai/kg)

Notes:

Mean results are reported in the parenthesis.

[1] Processing factor = Mean residue in the processed commodity / Mean residue in the RAC. For censored data (<LOQ), the finite LOQ value for the relevant analyte has been used for calculations.

[2] Where residues in the unprocessed commodity (RAC) were <LOQ no processing factor can be quantified and are reported as NC (Not Calculated). If residues were observed at <LOQ in the RAC and ≥LOQ in the processed commodity they are reported as NC (observed to concentrate).

Where residues are >LOQ in the RAC and <LOQ in the processed commodity the processing factor is reported as less than (<).

Tea

Eight processing trials were conducted in Japan in 2018/19 to demonstrate the effect of processing on residues of emamectin benzoate in tea leaves. Samples of dried green tea leaves (>200 g) were collected at 7, 14 and 21 days after application (DAA). At the laboratory, each sample was cut to pieces (about 1 cm square), mixed well, sealed, and stored at about -20 °C for a maximum of 82 days until analysis. Tea infusions were prepared from the unpulverized tea leaves (9 grams) by addition of boiling water (540 mL), which was allowed to stand for 5 minutes and then filtered. Only the 7 DAA samples have been summarized below.

All samples were analysed in accordance with an analytical method for tea similar to RAM 465/01. The LOQ was 0.001 mg/kg for all analytes.

Residues of emamectin and its metabolites decreased in tea infusions (Mean PF=< 0.01). No residues were observed above the LOQ in tea infusions except for one result for B1a at 0.002 mg/kg (Mean PF = < 0.002).

Table 39 Summary of residues of emamectin benzoate (B1a, B1b, 8,9-ZMa, AB1a, FAB1a and MFB1a) in dried green tea and tea infusions at 7 DAA after foliar spray with an EC formulation (10 g/L emamectin)

Notes:

Mean results are reported in the parenthesis.

[1]Processing factor = (Mean residue in the processed commodity/60) / Mean residue in the RAC. For censored data (<LOQ), the finite LOQ value for the relevant analyte has been used for calculations.

[2]Where residues in the unprocessed commodity (RAC) were <LOQ no processing factor can be quantified and are reported as NC (Not Calculated).

Where residues are >LOQ in the RAC and <LOQ in the processed commodity the processing factor is reported as less than (<).

APPRAISAL

Emamectin benzoate is a foliar insecticide derivative of abamectin, which is isolated from fermentation of *Streptomyces avermitilis*, a naturally occurring soil actinomycete. It acts by stimulating the release of γ-aminobutyric acid, an inhibitory neurotransmitter, thus causing insect paralysis within hours of ingestion, and subsequent insect death 2–4 days later. It is also registered for use as a veterinary drug in the treatment of sea lice infestations in salmon and trout in several countries.

Emamectin benzoate was considered for the first time for toxicology and residues by the 2011 JMPR and for new uses by the 2014 JMPR. An ADI of 0–0.0005 mg/kg bw and ARfD of 0.02 mg/kg bw were established.

The Definition of the residue for compliance with the MRL and for the estimation of the dietary exposure for plant and animal commodities*: emamectin B1a benzoate.*

The residue is not fat soluble.

The Meeting received new information on analytical methodology, storage stability and additional supervised residues trials on basil, chives, coffee, flowerhead brassica vegetables, leafy vegetables (including brassica leafy vegetables), soya bean and tea.

Methods of analysis

The Meeting received description and validation data for QuEChERS analytical methods for determination of emamectin B1a benzoate and emamectin B1b benzoate in plant and animal commodities for enforcement as well as a QuEChERs method for determination of emamectin B1a benzoate, emamectin B1b benzoate, and its metabolites 8,9-ZMa, AB1a, MFB1a, and FAB1a in plant commodities. New description and validation data was also received for method RAM 465 in plant commodities.

Method RAM 465/01 was evaluated by the 2011 JMPR and is considered sufficiently validated for emamectin B1a benzoate, emamectin B1b benzoate and the avermectin-like metabolites 8,9-ZMa, AB1a, MFB1a, and FAB1a in high water, high starch, high acid, and high oil matrices. New validation data was provided for RAM 465/02 demonstrating the modified method is valid for determination of emamectin B1a benzoate, emamectin B1b benzoate and the avermectin-like metabolites 8,9-ZMa, AB1a, MFB1a, and FAB1a in coffee commodities (green beans, roasted and instant coffee), grapes, potatoes and tomatoes. The LOQ for this method is 0.001 mg/kg for each matrix and analyte.

Method GRM004.06A involves acetonitrile extraction with QuEChERs salts and final determination by HPLC with triple quadrupole mass spectrometric detection (LC-MS/MS). The method was sufficiently validated for emamectin B1a benzoate, emamectin B1b benzoate and the avermectin-like metabolites 8,9-ZMa, AB1a, MFB1a, and FAB1a in apricots, broad beans (dry), cotton, lettuces, melons, oranges, tobacco (dry leaves), walnuts, wheat (grain) and zucchinis. The LOQ was 0.001 mg/kg for each matrix and analyte.

QuEChERs multi-residues methods for enforcement were validated for the determination of parent emamectin benzoate (B1a and B1b) in both plant (EN 15662:2009-2) and animal (DIN EN 15662:2018) commodities. Both methods involve extraction in acetonitrile/water with QuEChERS salts followed by SPE clean-up, dilution, and quantification by HPLC with triple quadrupole mass spectrometric detection (LC/MS-MS, positive ion spray). The plant commodity method was validated in broad beans (dry), lettuces, oranges, tea, tobacco, walnuts and wheat grain. The animal commodity method was validated in muscle (cattle), liver (cattle), kidney (cattle), fat (cattle) and eggs. The LOQ was 0.001 mg/kg for each matrix and analyte.

The Meeting concluded that methods RAM465/02 and GRM004.06A are suitable analytical methods to measure emamectin B1a benzoate, emamectin B1b benzoate and the avermectin-like metabolites 8,9-ZMa, AB1a, MFB1a, and FAB1a for plant commodities and that QuEChERS multi-residues methods are now available for analysis of emamectin B1a benzoate and emamectin B1b benzoate in both plant and animal commodities.

Stability of pesticide residues in stored analytical samples

The 2011 JMPR found that emamectin B1a benzoate and emamectin B1b benzoate were stable when stored at -20 °C or lower for at least 27 months (804 days) in plant commodities with high water content (tomatoes and green beans with pods), at least 18 months (545 days) in plant commodities with high starch content (potatoes), and at least 9 months in plant commodities with high oil content (cottonseed), and special plant commodities (cotton gin trash) and recommended that storage stability information on a high acid commodity would be desirable.

A storage stability study on a high acid commodity (orange) was provided to the current Meeting demonstrating residues of emamectin benzoate and its metabolites are stable for up to 24 months in whole orange when stored deep frozen.

In storage stability studies conducted concurrently with the supervised residues trials residues of emamectin benzoate and its metabolites were observed to be stable for at least 56 months in fresh basil and 52 months in dried chives, at least 3 months in dried tea leaves and at least 9 months in Chinese broccoli when stored frozen. These durations generally covered the longest period of storage for all samples obtained from supervised residue trials with only minor exceptions for dried chives (56 months stored, demonstrated stability 52 months) and soya beans (10 months stored, demonstrated stability of 9 months in high oil matrices). The Meeting considered any potential losses would be minor and the data for dried chives and soya beans remains valid.

Results of supervised residue trials on crops

The Meeting received supervised residue trials for emamectin benzoate on basil, chives, coffee, broccoli, cauliflower, Chinese broccoli, lettuce leaf, mustard greens, spinach and tea.

Chives

In the United States, the critical GAP for herbs (including chives) is three foliar applications of emamectin benzoate at up to 16.8 g ai/ha (maximum of 50.4 g ai/ha per year) with a retreatment interval of 7 days and a harvest withholding period of 7 days.

The Meeting noted the cGAP for chives is for three applications whilst six applications were applied in the trials. Given the rapid decline of emamectin B1a benzoate and the RTI of 7 days it was concluded that the earlier applications would not contribute significantly to the final residue and the trials were considered suitable for maximum residue level estimation.

In independent trials approximating the critical GAP, residues of emamectin B1a benzoate in fresh chive leaves were (n=4): < 0.001, 0.001 (2) and 0.005 mg/kg (n=4).

The Meeting estimated a maximum residue level of 0.01 mg/kg, an STMR of 0.001 mg/kg and an HR of 0.006 (from a single sample) mg/kg for emamectin B1a benzoate in chives.

Flowerhead brassicas

In Italy, the critical GAP for broccoli and cauliflower is a maximum three foliar applications at 14.2 g ai/ha with a minimum retreatment interval of 7 days and a harvest withholding period of 3 days.

Broccoli

In the independent trials approximating cGAP in Italy, residues of emamectin B1a benzoate in broccoli at 3 DALA were (n=5): < 0.001, 0.001, 0.002, 0.002, and 0.004 mg/kg.

Cauliflower

In the independent trials approximating cGAP in Italy, residues of emamectin B1a benzoate in cauliflower were (n=12): < 0.001 (9) and 0.001 (3) mg/kg.

For the Italian GAP, the five trials on broccoli were considered sufficient to make a recommendation for broccoli individually. Based on the dataset for cauliflower the maximum residue level would be 0.002 mg/kg with an STMR at 0.001 mg/kg and a HR at 0.001 mg/kg.

The Meeting agreed to estimate the maximum residue level for the subgroup of flowerhead brassicas based on the dataset for broccoli. The Meeting estimated a maximum residue level of 0.007 mg/kg, an STMR of 0.002 mg/kg and an HR of 0.004 mg/kg for emamectin B1a benzoate in flowerhead brassicas, subgroup of.

Spinach

In the United States, the critical GAP for leafy vegetables (including spinach) is six foliar applications of emamectin benzoate at 16.8 g ai/ha (maximum of 101 g ai/ha per season) with a retreatment interval of 7 days and a harvest withholding period of 7 days.

In the independent trials approximating cGAP in the United States, residues of emamectin B1a benzoate in spinach were (n=6): < 0.005 (2), 0.006 (2), 0.007 and 0.024 mg/kg.

The Meeting estimated a maximum residue level of 0.05 mg/kg, an STMR of 0.006 mg/kg and an HR of 0.036 (from a single sample) mg/kg for emamectin B1a benzoate in spinach.

Brassica leafy vegetables

Chinese broccoli

In Thailand, the GAP for Chinese broccoli is two foliar applications of emamectin benzoate at 14.4 g ai/ha with a retreatment interval of 7 days and a harvest withholding period of 3 days.

In the independent trials matching cGAP in Thailand, residues of emamectin B1a benzoate in Chinese broccoli were (n=6): < 0.005 (5) and 0.12 mg/kg. The HR was 0.14 mg/kg (from a single sample).

Mustard greens

In the United States, the critical GAP for brassica leafy vegetables is six foliar applications of emamectin benzoate at 16.8 g ai/ha (maximum of 101 g ai/ha per season) with a retreatment interval of 7 days and a harvest withholding period of 14 days.

In the independent trials matching cGAP in the United States, residues of emamectin B1a benzoate in mustard greens were (n=6): < 0.005 (2), 0.008, 0.011, 0.014 and 0.108 mg/kg (STMR = 0.01 mg/kg).

The Meeting noted that Mustard greens are a representative crop for the subgroup and concluded the dataset for mustard greens was sufficient for estimation of a maximum residue level for the subgroup of brassica leafy vegetables.

The Meeting estimated a maximum residues level of 0.2 mg/kg, an STMR of 0.01 mg/kg and a HR of 0.219 (from a single sample) mg/kg for the subgroup of brassica leafy vegetables. This maximum residue level will also cover the expected residues of emamectin benzoate for the Thailand GAP for Chinese broccoli.

Soya bean (dry)

In the United States, the critical GAP for soya beans is three foliar applications of emamectin benzoate at 16.8 g ai/ha (maximum of 50.4 g ai/ha per year) with a retreatment interval of 7 days and a harvest withholding period of 28 days.

In the independent trials matching cGAP in the United States residues of emamectin B1a benzoate in soya beans (dry) were (n=19): < 0.001 (19) mg/kg.

The Meeting estimated a maximum residue level of 0.001(*) mg/kg for soya beans (dry). The Meeting noted that residues of emamectin B1a benzoate were also < 0.001 mg/kg (LOQ) following application at 5× rate and concluded an STMR of 0 mg/kg for soya beans (dry) was appropriate.

Basil

In the United States, the critical GAP for herbs is three foliar applications of emamectin benzoate at up to 16.8 g ai/ha (maximum of 50.4 g ai/ha per year) with a retreatment interval of 7 days and a harvest withholding period of 7 days.

The Meeting noted that the cGAP for basil is for three applications whilst six applications were applied in the trials. Given the rapid decline of emamectin B1a benzoate and the RTI of 7 days it was concluded that the earlier applications would not contribute significantly to the final residue and the trials were considered suitable for maximum residue level estimation.

In independent trials approximating the critical GAP, residues of emamectin B1a benzoate in fresh basil leaves and stems were (n=4): 0.001, 0.004, 0.005, and 0.028 mg/kg.

The Meeting estimated a maximum residue level of 0.06 mg/kg, an STMR of 0.0045 mg/kg and an HR of 0.032 (from a single sample) mg/kg for emamectin B1a benzoate in basil leaves.

Tea

In Japan, the critical GAP for tea is one foliar application of emamectin benzoate at 1000-fold dilution (1 g ai/100L) applied at 7 days before plucking.

In the independent trials matching cGAP in Japan, residues of emamectin B1a benzoate in dried green tea leaves were (n=8): 0.003, 0.004, 0.007, 0.008, 0.010, 0.011, 0.022 and 0.066 mg/kg.

The Meeting estimated a maximum residue level of 0.1 mg/kg and an STMR of 0.009 mg/kg for emamectin B1a benzoate in Tea, Black, Green dried and fermented.

Fate of residues during processing

The fate of emamectin benzoate residues during processing of raw agricultural commodities was investigated in basil, chives, tea and soya beans.

The studies showed that emamectin B1a benzoate concentrated in dried basil (PF=6.4) and dried chives (PF=5.0) but did not concentrate in tea infusions (PF=0.002). Emamectin B1a benzoate was also observed to concentrate in soya bean aspirated grain fractions with finite results of 0.005 and 0.021 mg/kg observed however no finite residues were observed in the RAC therefore a processing factor

cannot be estimated. The Meeting noted residues in the soya bean aspirated grain fractions at 5× cGAP and agreed that expected residues at cGAP would be low and not contribute significantly to the livestock dietary burdens.

Table 40 Processing factors, STMR-Ps and HR-Ps for emamectin B1a benzoate, used for dietary risk assessment and MRL estimation.

Raw commodity	Processed commodity	Processing factor	STMR-P = $STMR_{RAC}$ × PF (mg/kg)	HR-P = HR_{RAC} × PF (mg/kg)	MRL_{RAC} × PF (mg/kg)	Recommended MRL (mg/kg)
Basil	Dried basil	6.4	0.0045 × 6.4 = 0.029	0.032 × 6.4 = 0.205	0.06 × 6.4 = 0.4	0.4
Chives	Dried chives	5.0	0.001 × 5.0 = 0.005	0.005 × 5.0 = 0.025	0.01 × 5.0 = 0.05	0.05
Tea	Tea infusion	0.002	0.009 × 0.002 = 0.000018	-	-	-

Based on the estimated maximum residue level of 0.06 mg/kg, the HR and STMR in basil at 0.032 mg/kg and 0.0045 mg/kg respectively, and the processing factor (6.4) for dried basil, the Meeting estimated a maximum residue level in dried basil (DH 0722) of 0.4 mg/kg (HR-P = 0.205 mg/kg, STMR-P = 0.029 mg/kg).

Based on the estimated maximum residue level of 0.01 mg/kg, the HR and STMR in chives at 0.005 mg/kg and 0.001 mg/kg respectively, and the processing factor (5.0) for dried chives, the Meeting estimated a maximum residue level in dried chives (DH 0727) of 0.05 mg/kg (HR-P = 0.025 mg/kg, STMR-P = 0.005 mg/kg).

Residues in animal commodities

Cattle

Based on the uses considered, kale and turnip tops (brassica leafy vegetables subgroup), soya bean seed and soya bean aspirated grain fractions may be part of the diet. It is noted that the soya bean GAP does not allow grazing or cutting for stock feed.

Estimation of livestock dietary burden

Dietary burdens were calculated for beef cattle and dairy cattle based on feed items presented above. The dietary burdens estimated using the most recent version of the OECD livestock dietary burden calculator diets are presented in Annex 6 and summarised below.

Table 41 Estimated maximum and mean dietary burdens of cattle (emamectin B1a benzoate).

	Animal dietary burden: emamectin B1a benzoate, ppm of dry matter diet							
	United States-Canada		European Union		Australia		Japan	
	max	mean	max	Mean	max	mean	max	mean
Beef cattle	0.0002#	0.0002#	0.2262❶	0.0302❸	0.1734#	0.0276#	-	-
Dairy cattle	0.1153	0.0155	0.2025❷	0.0232	0.1948#	0.0248❹#	-	-

Notes:

❶ Highest maximum beef or dairy cattle dietary burden suitable for MRL estimates for mammalian tissues.

❷ Highest maximum dairy cattle dietary burden suitable for MRL estimates for mammalian milk.

❸ Highest mean beef or dairy cattle dietary burden suitable for STMR estimates for mammalian tissues.

❹ Highest mean dairy cattle dietary burden suitable for STMR estimates for milk.

The use of emamectin in Australia for brassica leafy vegetables and root and tuber vegetables prohibits the grazing, waste crop or produce for stock food being fed to livestock therefore kale leaves and turnip tops have not been included in the dietary burden calculations for Australia.

The maximum dietary burdens for beef cattle and dairy cattle are estimated to be 0.2302 ppm in the feed (dry weight) and 0.2051 ppm in the feed (dry weight) respectively.

Poultry

From all uses of emamectin benzoate considered by the JMPR, soya bean seed is the only significant feed item consumed by poultry. Given finite residues are not observed in soya bean seed the poultry burden is expected to be insignificant.

Animal commodity maximum residue levels

Cattle

A ruminant feeding study was evaluated by the 2011 JMPR. Lactating Holstein-Friesian cows were dosed daily with emamectin benzoate at 0, 0.03, 0.09 and 0.30 mg/kg dry matter in feed for 28 consecutive days. As noted by the 2011 JMPR, the analytical method could not discriminate between emamectin B1a benzoate and 8,9-ZMa, therefore residues are the sum of both. Since metabolism studies showed that 8,9-ZMa is not formed in livestock, values reported represent the mean and highest residues of emamectin B1a benzoate only. Maximum emamectin B1a benzoate residues at the highest dose were 0.12 mg/kg in liver, 0.042 mg/kg in kidney, 0.015 mg/kg in fat and 0.0061 mg/kg in muscle. Mean residues of emamectin B1a benzoate at the highest dose were 0.097 mg/kg in liver, 0.037 mg/kg in kidney, 0.013 mg/kg in fat, 0.0058 mg/kg in muscle and 0.0032 mg/kg in milk.

The calculations used to estimate highest total residues for use in estimating maximum residue levels, STMR and HR values are shown below.

For maximum residue level estimation, the high residues in the tissues and milk were calculated by interpolating the maximum dietary burden (0.19 ppm) between the relevant feeding levels (0.09 and 0.30 ppm) from the dairy cow feeding study and using the highest tissue concentrations from individual animals within those feeding groups and using the mean milk concentration from those feeding groups.

The STMR values for the tissues and milk were calculated by interpolating the mean dietary burden (0.018 ppm) between the relevant feeding levels (0 and 0.03 ppm) from the dairy cow feeding study and using the mean tissue and milk concentrations from those feeding groups.

Table 42 Residues of emamectin B1a benzoate in animal commodities

	Feed Level (ppm) for milk residues	Emamectin B1a benzoate residues (mg/kg) in milk	Feed Level (ppm) for tissue residues	Emamectin B1a benzoate (mg/kg)			
				Muscle	Liver	Kidney	Fat
HR Determination (beef or dairy cattle)							
Feeding Study	0.09 0.30	0.008 0.0032	0.09 0.30	0.0020 0.0061	0.029 0.12	0.013 0.042	0.0066 0.015
Dietary burden and estimate of highest residue	0.2025	0.0021	0.2262	0.0046	0.088	0.032	0.012
STMR Determination (beef or dairy cattle)							
Feeding Study	0	0	0	0	0	0	0

	Feed Level (ppm) for milk residues	Emamectin B1a benzoate residues (mg/kg) in milk	Feed Level (ppm) for tissue residues	Emamectin B1a benzoate (mg/kg)			
				Muscle	Liver	Kidney	Fat
	0.03	< 0.0005	0.03	< 0.002	0.0086	0.0037	0.0021
Dietary burden and estimate of highest residue	0.0248	< 0.0005	0.0302	< 0.002	0.0071	0.0031	< 0.002

The Meeting estimated a maximum residue level for emamectin B1a benzoate of 0.003 mg/kg in milks, 0.005 mg/kg in meat from mammals other than marine mammals, 0.1 mg/kg in mammalian offal to replace the previous recommendations for milks, meat and offal and confirmed the previous recommendation of 0.02 mg/kg in mammalian fat. The residue in animal commodities is not considered fat soluble.

RECOMMENDATIONS

On the basis of the data from supervised trials the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits.

Definition of the residue for compliance with the MRL and for dietary risk assessment for plant and animal commodities: *emamectin B1a benzoate. The Meeting considers the residue not fat soluble.*

Summary of recommendations are presented below.

Table 43 Residue levels suitable for establishing maximum residue limits and for IEDI and IESTI estimations

CCN	Commodity name	Recommended maximum residue level (mg/kg)		STMR or STMR-P (mg/kg)	HR or HR-P (mg/kg)
		New	Previous		
HH 0722	Basil, leaves	0.06	-	0.0045	0.032

DT 1114	Tea, Black, Green, dried and fermented	0.1	-	0.009	-
	For dietary risk assessment and/or dietary burden calculations				
	Tea infusion	-	-	0.000018	-

DIETARY RISK ASSESSMENT

Emamectin benzoate is also registered for use as a veterinary drug in salmon and trout in several countries with Joint FAO/WHO Expert Committee on Food Additives (JECFA) recommending maximum residues levels for muscle and fillet (muscle + skin) at 0.1 mg/kg. The median residue (0.037 mg/kg) and MRL level reported by JECFA Meeting 78 (2013) have been used for dietary exposure estimations.

Long-term dietary exposure

The International Estimated Daily Intake (IEDI) for emamectin B1a benzoate was calculated for the food commodities for which STMRs were estimated and for which consumption data were available.

The International Estimated Daily Intakes of emamectin B1a benzoate for the 17 GEMS/Food cluster diets, based on estimated STMRs were 2–20 percent of the maximum ADI of 0.0005 mg/kg bw.

The Meeting concluded that the long-term dietary exposure to residues of emamectin B1a benzoate from uses that have been considered by the JMPR is unlikely to present a public health concern.

Acute dietary exposure

The ARfD for emamectin B1a benzoate is 0.02 mg/kg bw. The International Estimate of Short Term Intakes (IESTIs) for emamectin B1a benzoate were calculated for the food commodities and their processed commodities for which HRs/HR-Ps or STMRs/STMR-Ps were estimated by the present Meeting and for which consumption data were available. The IESTIs varied from 0–70 percent of the ARfD for children and 0–60 percent for the general population.

The Meeting concluded that acute dietary exposure to residues of emamectin B1a benzoate from uses considered by the present Meeting is unlikely to present a public health concern.

FAMOXADONE (208)

First draft prepared by Dr M Doherty, the Environmental Protection Agency, United States of America

EXPLANATION

Famoxadone was evaluated for the first time by JMPR 2003 when an acceptable daily intake (ADI) of 0–0.006 mg/kg bw and an acute reference dose (ARfD) of 0.6 mg/kg bw were established.

The definition of the residue for compliance with MRLs and for dietary assessment is famoxadone. The residue is fat-soluble.

The current Meeting received information on analytical methods, storage stability, and field trials to support new MRLs in commodities of caneberry, bulb onion, green onion, cucurbits, fruiting vegetables, and hops.

METHODS OF RESIDUE ANALYSIS

AMR 2801-93

This method was evaluated by the 2003 JMPR and found to be suitable for analysis of famoxadone residues in various plant matrices, including cereal grains, straws, and forages, with LOQs of 0.02 mg/kg for foods and 0.05 mg/kg for feeds. This method was used for analysis of residues in Winter wheat and Winter barley. In wheat matrices at the lowest fortification level (0.1 mg/kg), recoveries were 101±11 percent (n=6) in forage, 97±15 percent (n=3) in grain, and 96–101 percent (n=2) in straw.

AMR 3705-95 RV2

This method (DeMario, D., *et al*., 1998, Report ARM 3705-95 RV2) was not previously reviewed by the JMPR. Residues are extracted with acetonitrile/water followed by salting out to separate the solvents. The acetonitrile phase is partitioned against hexane to remove fats and other non-polar interferents. Famoxadone residues are cleaned-up using Florisil chromatography and the analysed by gas chromatography with a nitrogen-phosphorus detector (GC-NP). Method ARM 3705-95 RV2 was used for the analysis of residues in caneberry, cucurbit vegetables, fruiting vegetables, and hops (samples in Study 07796). Mean recoveries across all matrices ranged from 81 to 117 percent, with relative standard deviations of ≤ 20 percent (Table 2). The method was validated for these matrices with an LOQ of 0.02 mg/kg (0.4 mg/kg in hops).

Samples of dry bulb onion, green onion, and hops (samples in Study A7796) were analysed for residues using this method with modifications (Table 1). The method with modifications gave mean recoveries 74 to 105 percent (RSD ≤ 7 percent) for hops and 79–90 percent (RSD ≤ 7 percent) for green onion. The modified method was validated with LOQs of 0.05 mg/kg in hops and 0.5 mg/kg in green onion (while recoveries were satisfactory at 0.02 mg/kg in green onion, there were too few replicates (n=3) to validate that level as the LOQ).

Table 1 Summary of analytical methods

STABILITY OF RESIDUES IN STORED ANALYTICAL SAMPLES

Data on the stability of famoxadone was provided for caneberry, cucurbit vegetables, onion, and hops. Data were generated concurrently with the field trials cited below.

The results (Table 3) indicate that residues are stable in high water, high acid, and high oil content commodities during frozen storage for at least the storage durations examined (0.8 to 2 years, depending on the commodity).

Table 3 Summary of stability data for residues of famoxadone residues under frozen conditions

Matrix	Storage time, days [A)]	Procedural recovery, percent	Fortification level, mg/kg	Residue remaining, mg/kg	Mean percent remaining
Caneberry	215-216	92, 100	0.5	96, 100, 102	99
Cucumber	0	91, 107	0.3	102, 106	104
	28	103, 104	0.3	93	93
	96	87, 88	0.3	100, 103	102
	180	99, 102	0.3	95, 98	96
	313	94, 99	0.3	90, 99	94
Onion, dry bulb	873 [B)]	88	0.5	79, 90, 91	87
Onion, green	796	90	0.5	71, 77, 82	77
Hops	252	76, 82	0.4	70, 85	78

Notes:

[A)] 0-day data were provided only for cucumber.

[B)] Two days prior to the termination of the storage stability study, a complete thaw of samples, with temperatures above 0°C, occurred for about 36 hours.

USE PATTERN

Registered labels describing the use of famoxadone were submitted to the present Meeting for caneberries, onions, cucurbit vegetables, fruiting vegetables, wheat, barley, and hops (Table 4).

Table 4 Registered uses of famoxadone submitted to the 2022 JMPR

Use site	Country	Formulation		Application					PHI, days
		Conc.	Type	Rate, kg ai/ha/applic	Rate, kg ai/ha/year	Water, L/ha*	Max No.	Interval, days	
Caneberries [A)]	United States	25 percent	DF	0.175	1.26	187 / 47	n.s.	5	0
Bulb vegetables [B)]				0.175	1.47	187 / 47	n.s.	5	3
Cucurbit vegetables [C)]				0.175	0.56	187 / 47	4	5	3

RESULTS OF SUPERVISED RESIDUE TRIALS ON CROPS

The Meeting received data from supervised residue trials conducted on caneberries, onion (bulb and green), cucurbit vegetables (cucumber, cantaloupe. Summer squash), peppers, tomatoes, and hops. In addition, the Meeting received residue decline data for wheat and barley forage as support for green onion (high-water crop category).

The field trial reports included method validation data, as recoveries from spiked samples at levels reflecting those observed in the field trial samples; dates from critical events during the study, including application, harvest, storage, and analysis; as well as detailed information on the field site and treatment parameters. Analytical reports were sufficiently detailed and included example chromatograms and example calculations. Samples were analysed by the method described above for plant commodities.

The field trial study designs included control plots. Measured residues from control plots were <LOQ and are not included in the summary tables in this evaluation. In all cases, the applied material was co-formulated with cymoxanil.

When calculating average residues, values below the LOQ were assumed to be at the LOQ. In the summary tables, residue values leading to maximum residue estimations and used for long-term dietary risk assessment are underlined. The highest individual values selected for estimating acute dietary risks are in bold font. Values reported are below the method limit of detection are reported as ND.

Supervised trials for famoxadone:

Cane berries

Seven field trials were conducted in Canada (three trials) and the United States (four trials) during the 2003 season (Carpenter, D., 2006, Report 08766) using a WG formulation. Treatment consisted of six foliar applications of ca. 0.84 kg ai/ha, on generally a 7-day interval. Harvest occurred 0 days after the last application. Deviations to the application parameters were noted for the three trials conducted in Canada.

Following harvest, samples (≥ 454 g) samples were frozen within 1.1 to 4.5 hours of collection and shipped, frozen, to the analytical laboratory. Upon arrive at the facility, samples were put into frozen storage. Prior to analysis, samples were homogenized in the presence of dry ice and then returned to frozen storage. Samples were stored for a maximum of 181 days prior to analysis.

Samples were analysed for residues of famoxadone using Method AMR 3705-95 RV2. Concurrent recovery data indicate that the method is suitable, with an LOQ of 0.02 mg/kg.

Dry bulb and green onion

Twelve field trials (eight dry bulb onion and 4 green onion) were conducted in the United States during the 2002 growing season (Carpenter, D., 2007, Report 08303). Treatment generally consisted of seven foliar applications of famoxadone (WG formulation) at ca. 0.22 kg ai/ha with a retreatment interval of 5–6 days. Harvest occurred 3 days after the last application.

Following harvest, samples (≥ 12 bulb onions; and approximately 1.8 kg green onion) were frozen within 2.5 hours (bulb onion) or 1 hour (green onion) of collection and transported, frozen, to the laboratory. In preparation for analysis, samples were homogenized in the presence of dry ice and returned to frozen storage. Samples were maintained in frozen storage except for the dry bulb onion samples (including storage stability samples) which thawed for approximately 36 hours toward the end of the study. Dry bulb onions were stored for a maximum of 916 days and green onions for a maximum of 795 days prior to analysis. The limit of demonstrated stability in frozen dry bulb onion is 873 days.

Samples were analysed for residues of famoxadone using the modified version of Method AMR 3705-95 RV2, described above. Concurrent recovery data for green onion indicate that the method is suitable.

Notes:

A) Applications began on 4 Sept 2002

B) Applications began on 26 Aug 2002

Fruiting vegetables, Cucurbits

Seventeen field trials were conducted in the United States during the 1997 and 1998 growing seasons (Nathan, E., 1999, Report AMR 4340-97). Treatment consisted of up to seven foliar applications at either 0.14 or 0.21 kg ai/ha, on a 5-day interval. Samples were harvested 3 days after the last application.

Following harvest, samples (generally 12 fruits for cucumbers and cantaloupe, 24 fruits for summer squash) were put into put into frozen storage within 2.5 hours of collection. Samples were shipped frozen to the facility and were immediately placed into frozen storage. Prior to analysis, samples were cryogenically homogenized and returned to frozen storage. Samples were stored for a maximum of 263 days prior to analysis.

Samples were analysed for residues of famoxadone using the method Method AMR 3705-95. Concurrent recovery data indicate that the method is suitable.

Table 7 Residues of famoxadone in cucurbit vegetables from residue trials in the United States (1997-1998)

Fruiting vegetables other than cucurbits

Two studies were submitted to the Meeting. In the first study (McClory, J., 2001, DuPont-3723), field trials were conducted in the United States during the 2000/2001 growing season with tomato (n=13) and bell and non-bell peppers (n=11). Treatment consisted of six applications of a WG formulation, each at 0.21 kg ai/ha on approximately a 5-day interval. Samples were harvested approximately 3 DALA. For tomatoes and bell peppers, samples were 24 fruits (or 12 fruits from large-fruiting varieties); for non-bell peppers, samples were 2 kg of fruits.

Following harvest, samples were bagged and put into put into frozen storage within 2 hours of collection. Samples were shipped frozen to the facility and were immediately placed into frozen storage. Prior to analysis, samples were cryogenically homogenized and returned to frozen storage. Samples were stored for a maximum of 181 days prior to extraction.

In the second study (Hornshuh, M., 2003, Dupont-9822), four trials were conducted in the United States during the 2002 growing season with tomato. Application, timing, and harvest parameters were the same as described in the previous study, and samples were placed into storage within 3 hours of collection. Samples were stored for a maximum of 148 days prior to extraction.

For both studies, samples were analysed for residues of famoxadone using the Method AMR 3705-95. Concurrent recovery data indicate that the method is suitable.

Table 8 Residues of famoxadone in tomato and pepper from residue trials in the United States

Notes:

[A)] Replicate analyses.

Hops

Four field trials were conducted in the United States during the 2000 (Thompson, D., 2005, Report No. 07796; three trials) or 2014 (Homa, K., 2016, Report A7796; one trial) seasons using a DF formulation of famoxadone. Treatment consisted of six foliar applications, each at ca. 0.28 kg ai/ha, on a 7-day interval. Samples of mature hop cones were harvested at approximately 7 DALA and dried using a crop dryer or a kiln. After drying, samples (approximately 0.5 kg) were bagged and put into put into frozen storage prior to transport to the analytical facility. Samples were shipped frozen to the facility and were immediately placed into frozen storage. Prior to analysis, samples were cryogenically homogenized and returned to frozen storage. Samples were stored for a maximum of 205 days prior to analysis. Concurrent storage stability (Report 07796) samples demonstrated that residues were stable for at least 253 days of frozen storage.

Samples were analysed for residues of famoxadone using Method AMR 3705-95. Concurrent recovery data indicate that the method is suitable.

Forage of cereals

Field trial residue decline studies in winter barley (Dubey, L., *et al*., 1996, Report AMR 2971-94) and winter wheat (Dubey, L., *et al*., 1996, Report AMR 2831-93) were submitted to the Meeting as support for the high-water content commodities above. Field trials for cereal foods and feeds were evaluated by the 2003 Meeting and Codex MRLs have been established for cereal commodities.

Two field trials were conducted in *winter barley* during the 1994 growing season in France and Germany (one trial each). Application consisted of two treatments, each at 0.2 kg ai/ha, on a 30-day interval. Samples of green forage (ca. 1 kg each) were collected immediately prior to and at multiple times after the last application. Samples were placed into frozen storage after collection from the field and during transportation to the analytical facility. Samples were homogenized using a cutter and stored for up to 386 days prior to analysis. Residues of famoxadone were analysed using Method AMR 2801-93, which was evaluated by the 2003 Meeting and found to be suitable.

Two field trials were conducted in *winter wheat* during the 1994 growing season in Germany and France (one trial each). Application consisted of three treatments, each at 0.2 kg ai/ha, on a 30-day interval. Samples of green forage (ca. 1 kg each) were collected immediately prior to and at multiple times after the last application. Samples were placed into frozen storage after collection from the field and during transportation to the analytical facility. Samples were homogenized using a cutter and stored for up to 318 days prior to analysis. Residues of famoxadone were analysed using Method AMR 2801-93, which was evaluated by the 2003 Meeting and found to be suitable.

APPRAISAL

Famoxadone (ISO common name) is an oxazolidinedione fungicide belonging to the quinol inhibitor family, which inhibits mitochondrial respiration of fungi. It was evaluated for the first time by JMPR 2003, which established an acceptable daily intake (ADI) of 0–0.006 mg/kg bw and an acute reference dose (ARfD) of 0.6 mg/kg bw. Famoxadone was scheduled at the Fifty-first Session of the CCPR for the evaluation of additional MRLs in 2021 and rescheduled to the 2022 JMPR.

The definition of the residue for compliance with MRLs and for dietary assessment is famoxadone. The residue is fat-soluble.

The current Meeting received information on analytical methods and supervised residue trials to support new MRLs in cane berries, bulb vegetables, cucurbit vegetables, fruiting vegetables, and hops.

Methods of residue analysis

The Meeting received method validation and concurrent recovery data for use of Method AMR 2801-93 (reviewed by 2003 JMPR) and Method AMR 3705-95 RV2. All methods were demonstrated to have adequate performance for recovery of famoxadone, with an LOQ of 0.02 mg/kg in most commodities tested; exceptions are Winter barley and wheat forage (0.1 mg/kg) and dried hops cones (0.05 mg/kg).

Stability of residues in stored analytical samples

Concurrent storage stability data were provided for cane berry, cucumber, bulb onion, green onion, and hops (dried cones). Residues of famoxadone were stable in the tested commodities for at least the tested storage durations:

Cane berry: at least 216 days (7 months),

Cucumber: at least 313 days (10.3 months),

Bulb onion: at least 873 days (28.7 months),

Green onion: at least 796 days (26.2 months), and

Hops (dried cones): at least 252 days (8.3 months).

Results of supervised residue trials on crops

The Meeting received data from supervised residue trials and GAP information on cane berries; bulb and green onion; cucumber, cantaloupe, and summer squash; tomatoes and peppers, and hops. In addition, the meeting received residue decline data for forage of Winter barley and Winter wheat to supplement data submitted to the 2003 Meeting and to provide support for other high-water commodities for which residue decline data were not available.

Cane berries

The GAP for cane berries is from the United States. The label allows multiple applications at a maximum rate of 0.175 kg ai/ha, on a 5-day interval, with a 0-day PHI. The maximum number of applications is not specified. Based on the listed annual limit of 1.26 kg ai/ha, the application pattern for the cGAP is one application at 0.035 kg ai/ha followed by 7 applications at 0.175 kg ai/ha.

Field trials in the United States were conducted with 6 applications on generally a 7-day interval (generally ranging from 6–8 days with one trial having one application done at a 12-day interval) at a rate of approximately 0.21 kg ai/ha, with harvest 0 DALA. The Meeting agreed that an application 35 days before harvest would not contribute significantly to residues and that the difference in retreatment

interval between the cGAP and the trials for one application would not affect residue levels by more than 25 percent. Therefore, the Meeting agreed that the field trials for cane berries are suitable for estimating residues.

Residues of famoxadone in cane berries from independent trials approximating the critical GAP were (n=7): 0.44, 0.83, 1.0, 1.1, 2.0, 2.6, and 6.0 mg/kg.

Noting that the registered use corresponds to the Codex Subgroup of cane berries (FB 2005), the Meeting estimated a maximum residue level of 10 mg/kg for famoxadone in the Subgroup of cane berries, an STMR of 1.1 mg/kg, and an HR of 6.6 mg/kg (from a single sample).

Bulb vegetables

The GAP for bulb vegetables is from the United States and consists of multiple applications each at 0.175 kg ai/ha, on a 5-day interval, with a 3-day PHI. A maximum number of applications is not specified. Based on the maximum rate per crop cycle of 1.47 kg ai/ha, the application pattern for the cGAP is one application at 0.07 kg ai/ha followed by 8 applications at 0.175 kg ai/ha.

Onion, bulb

Field trials in the United States were conducted with 6 or 7 applications on generally a 6-day interval (ranging from 4-8 days) at a rate of approximately 0.19 kg ai/ha, with harvest 2-3 DALA. The Meeting agreed that the initial applications from the cGAP would not likely contribute significantly to residues at harvest and that the trials were suitable for estimating residues.

From independent trials approximating the critical GAP, residues of famoxadone in bulb onion were (n=7): < 0.02 (4), 0.06, 0.078, and 0.22 mg/kg.

The Meeting estimated a maximum residue level of 0.4 mg/kg, an STMR of 0.02 mg/kg, and an HR of 0.23 mg/kg (from a single sample) for famoxadone in the subgroup of bulb onion.

Onion, green

Field trials in the United States were conducted with 7 applications on generally a 6-day interval (ranging from 4-6 days) at a rate of approximately 0.19 kg ai/ha, with harvest 3 or 4 DALA. The Meeting agreed that the initial applications from the cGAP would not likely contribute significantly to residues at harvest and that the trials were suitable for estimating residues.

From independent trials approximating the critical GAP, residues of famoxadone in green onion were (n=4): 1.4, 3.8, 4.4, and 15 mg/kg.

The Meeting agreed that four trials was insufficient for estimating residues in green onions.

Cucurbit vegetables

The 2003 JMPR recommended maximum residue level for famoxadone in cucumber and summer squash, each at 0.2 mg/kg based on a GAP from Italy. The Meeting received a more critical GAP from the United States consisting of 4 applications each at 0.175 kg ai/ha, on a 5-day interval, with a 3-day PHI. The new GAP applies to the group of cucurbit vegetables.

Field trials in the United States were conducted in cucumber, summer squash, and melon with 7 applications on generally a 5-day interval (ranging from 4–8 days) at approximate rates of either 0.14 or 0.21 kg ai/ha in side-by-side trials, with harvest 3 DALA. Residue-decline data for cucurbit vegetables were insufficient to provide a robust estimation of half-life. The Meeting agreed that for cucumber and summer squash, the first three applications from the field trials would not lead to significant residues at

harvest due to significant growth dilution and that the trials for those crops are suitable for making recommendations. As both 0.14 and 0.21 kg ai/ha fall within 25 percent of the cGAP application rate of 0.175 kg ai/ha, the Meeting chose whichever result from the side-by-side trials was greater when making its residue estimates. For melons, fruit development is slower than for cucumber and squashes, and the Meeting agreed that contributions to residues at harvest from the first few applications could not be excluded; therefore, the trials in melons did not reflect the cGAP.

Fruiting vegetables, Cucurbits – Cucumbers and Summer Squashes

Cucumber

Residues of famoxadone in cucumber from independent trials were (n=6): < 0.02, 0.048, 0.054, 0.064, 0.12, and 0.16 mg/kg.

Summer squash

Residues of famoxadone in summer squash from independent trials were (n=5): 0.028, 0.064, 0.17, 0.22, and 0.26 mg/kg.

The Meeting noted that the recommended representative commodities for the subgroup of cucumber and summer squashes are cucumber and summer squash and that the median residues from cucumber and summer squash trials are within five-fold. The residue populations are different (Mann-Whitney H test). Based on the dataset from summer squash, the Meeting estimated a maximum residue level of 0.6 mg/kg, an STMR of 0.17 mg/kg, and an HR of 0.37 mg/kg (from a single sample) to make a recommendation for the subgroup of fruiting vegetables, cucurbits – cucumbers and summer squashes and withdrew its previous separate recommendations for cucumber and summer squash.

Tomatoes

The GAP for tomato is from the United States and consists of multiple applications each at 0.14 kg ai/ha, on a 5-day interval, with a 3-day PHI. A maximum number of applications is not specified. Based on the listed limit of 1.26 kg ai/ha per crop cycle, the application pattern for the cGAP is 9 applications at 0.14 kg ai/ha. The 2003 Meeting recommended a maximum residue level of 2 mg/kg in tomato based on registered uses in Greece (up to 8 applications at 0.11 kg/ha, 3-day PHI).

Field trials in the United States were conducted with 6 applications, each at 0.21 kg ai/ha, generally on a 5-day retreatment interval (ranging from 4-6 days), with harvest 3 DALA. The Meeting agreed that the first three applications from the field trials would not lead to significant residues at harvest due to significant growth dilution and that the trials are suitable for estimating residues.

Residues of famoxadone in tomatoes from independent trials conducted at an exaggerated rate were (n=17): 0.14 (2), 0.15 (2), 0.17 (2), 0.23, 0.24, 0.30, 0.33, 0.40, 0.42, 0.50, 0.62, 0.68, and 0.71 mg/kg.

After scaling (factor = 0.67), residues were (n=17): 0.093 (2), 0.10 (2), 0.11 (2), 0.15, 0.16, 0.20, 0.22, 0.24, 0.27, 0.28, 0.33, 0.41, 0.45, and 0.47 mg/kg.

The Meeting noted that these residues are accommodated by the 2003 recommendation and confirmed its previous recommendation of a maximum residue level of 2 mg/kg, and STMR of 0.1 mg/kg and an HR of 1.1 mg/kg for famoxadone in tomato.

Peppers

The GAP for peppers is from the United States and consists of multiple applications each at 0.175 kg ai/ha, on a 5-day interval, with a 3-day PHI. A maximum number of applications is not specified. Based on

the listed limit of 1.26 kg ai/ha per crop cycle, the application pattern for the cGAP is one application at 0.035 kg ai/ha followed by 7 applications at 0.175 kg ai/ha.

Field trials in the United States were conducted with 6 applications on generally a 5-day interval (ranging from 4–7 days) at a rate of 0.21 kg ai/ha, with harvest 3 DALA. The Meeting agreed that an application 35 days before harvest would not contribute significantly to residues at harvest and that the trials are suitable for estimating residues of famoxadone in peppers.

Residues of famoxadone in bell and *chili* peppers from independent trials approximating the critical GAP were (n=11): 0.078, 0.16, 0.20, 0.34, 0.36, *0.47*, *0.51*, *0.60*, 0.63, 0.68, and *3.6* mg/kg.

The Meeting noted that the registration allows for use on bell and chili peppers, but not on other members of the Subgroup of peppers. The Meeting estimated a maximum residue level of 5 mg/kg, an STMR of 0.47 mg/kg, and an HR of 3.7 mg/kg (from a single sample) for famoxadone in each of peppers, sweet (including pimento or pimiento) and peppers, chili.

For dried chili peppers, the Meeting used the default factor of 10 to estimate a maximum residue level of 50 mg/kg for famoxadone in peppers chili, dried, an STMR of 4.7 mg/kg, and an HR of 37 mg/kg.

Hops

The critical GAP for hops is from the United States and consists of six applications, each at 0.14 kg ai/ha, on a 6-day interval, with a 7-day PHI.

Residues of famoxadone in hops (dried cones) from independent trials approximating the critical GAP but at a 2× rate were (n=5): 14, 15, 26, 42, and 46 mg/kg. After scaling to an application rate of 0.14 kg ai/ha, residues were (n=5): 7.0, 7.5, 13, 21, and 23 mg/kg.

The Meeting estimated a maximum residue level of 50 mg/kg and an STMR of 13 mg/kg for hops (dry).

Fate of residues during processing

No new data on fate of residues during processing were submitted to the Meeting. The 2003 Meeting evaluated the effects of processing on residues in tomato commodities. The current Meeting confirmed its previous recommendations with respect to tomato RAC, and by extension, processed tomato commodities.

Residues in animal commodities

The recommendations made by the current Meeting did not include animal feed items; therefore, the Meeting confirmed its previous recommendations for residues in animal commodities.

RECOMMENDATIONS

On the basis of the data obtained from supervised trials, the Meeting concluded that the residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessments.

Definition of the residue for compliance with the MRL and dietary risk assessment for plant and animal commodities: *famoxadone.*

The residue is fat-soluble.

Table 11 Recommendations for residues of famoxadone from the 2022 JMPR

CCN	Crop/Commodity	MRL, mg/kg		STMR or STMR-P, mg/kg	HR or HR-P, mg/kg
		New	Previous		
VC 0424	Cucumber	W	0.2	--	--
MU 1100	Hops, dried	50	--	13	--
HS 0444	Peppers chili, dried	50		4.7	37
VO 0444	Peppers, chili	5	--	0.47	3.7
VO 0445	Peppers, sweet (including pimento or pimiento)	5	--	0.47	3.7
VC 0431	Squash, Summer	W	0.2	--	--
VA 2031	Subgroup of bulb onions	0.4	--	0.02	0.23
FB 2005	Subgroup of cane berries	10	--	1.1	6.6
VC 2039	Subgroup of fruiting vegetables, cucurbits – cucumbers and summer squashes	0.6	--	0.17	0.37
VO 0448	Tomato	2	2	0.1	1.1

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The ADI for famoxadone is 0–0.006 mg/kg bw. The International Estimated Daily Intakes (IEDIs) for famoxadone were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the JMPR. The results are shown in Annex 3 of the 2022 JMPR Report.

The IEDIs ranged from 1–20 percent of the maximum ADI. The Meeting concluded that long-term dietary exposure to residues of famoxadone from uses considered by the JMPR is unlikely to present a public health concern.

Acute dietary exposure

The ARfD for famoxadone is 0.6 mg/kg bw. The International Estimate of Short-Term Intakes (IESTIs) for famoxadone were calculated for the food commodities and their processed commodities for which HRs/HR-Ps or STMRs/STMR-Ps were estimated by the present Meeting and for which consumption data were available. The results are shown in Annex 4 of the 2022 JMPR Report.

The IESTIs varied from 0–20 percent of the ARfD for children and 0–9 percent of the ARfD for the general population. The Meeting concluded that acute dietary exposure to residues of famoxadone from uses considered by the present Meeting is unlikely to present a public health concern.

FENAZAQUIN (297)

First draft prepared by Dr M Lee, Andong National University, Republic of Korea

EXPLANATION

Fenazaquin is a quinazoline insecticide/acaricide. Its mode of action involves contact and ovicidal activity against a broad spectrum of mites in various crops. It was first evaluated by JMPR in 2017 for toxicology and residues and then a follow-up evaluation of additional uses was made by the 2019 Extra Meeting.

The 2017 JMPR established an ADI of 0–0.05 mg/kg bw and an ARfD of 0.1 mg/kg bw, applying to fenazaquin, tertiarybutylphenylethanol (TBPE) and 4-hydroxyquinazoline. Further, the Meeting concluded that 2-hydroxy-fenazaquin acid is present as a major metabolite in rat feces, therefore, it is covered by studies of the parent compound.

In 2017, JMPR defined the residue definitions for plant and animal commodities. For plant commodities, the residue definition is fenazaquin for compliance with the MRL and for dietary risk assessment. For animal commodities, correction of the definition for compliance with MRL was made by the 2019 Extra JMPR. The current residue definition for animal commodities is the sum of fenazaquin and 2-hydroxy-fenazaquin acid for compliance with the MRL and the sum of fenazaquin, 2-hydroxy-fenazaquin acid and tautomeric forms of 4-hydroxyquinazoline for dietary risk assessment. The residue is fat-soluble.

Fenazaquin was scheduled at the Fifty-second Session of the CCPR for evaluation of additional uses by the 2022 JMPR. The Meeting received information on residue trials on avocado, berries (blueberry, raspberry, grape, strawberry), citrus fruits (lemon, orange, grapefruit), pome fruits (apple, pear), stone fruits (cherry, peach, plum), fruiting vegetables (cucumber, cantaloupe, Zucchini squash, tomato, peppers), beans and peas (with pods, succulent without pods and dried) and mint. Processing and storage stability studies were also submitted. In addition, a confined rotational crop study and a new analytical method were provided.

Confined rotational crop study

A confined rotational crop study with fenazaquin was conducted using lettuce, radish and wheat at 30 day, 120, and 365 day plant back intervals [Dohn, D.R., 2010, Report 637-001]. Two radiolabelled forms of [$^{1\,4}$C-phenyl] fenazaquin and [^{14}C-quinazoline] fenazaquin were applied to the bare soil (sandy loam) of test plots located outdoors with a target application rate of 505 g/ha (actually, 550–556 g/ha). The applications for the 30 day PBI (February 3, 2009) occurred 90 days after the applications for the 120 day PBI. The applications for the 365 day PBI were made on the same day with the applications for the 30 day PBI.

Crop samples were homogenized in the presence of dry ice. The samples (total radioactive residues, >0.01 mg/kg of fenazaquin equivalents) were extracted twice with acetonitrile:water (1:1, v/v) and once with acetonitrile. The combined supernatants were partitioned twice with dichloromethane and the post extracted solids were subjected to combustion analysis. The aqueous and dichloromethane phases from the partitioning (or only aqueous phase) were analysed by HPLC using authentic reference standards: fenazaquin, 2-oxy-fenazaquin, fenazaquin acid, 4-hydroxyquinazoline (metabolite unique to the quinazoline label) and TBPE (metabolite unique to the phenyl label). The presence fenazaquin, 2-oxy-fenazaquin, and fenazaquin acid were confirmed by TLC in extracts from the 30 day PBI radish roots. Total radioactive residues (TRRs) were measured by combustion analysis/LSC.

Table 1 Total Radioactive Residues in rotational crops measured by combustion analysis

RAC	30-day PBI		120-day PBI		365-day PBI	
	Quinazoline label	Phenyl label	Quinazoline label	Phenyl label	Quinazoline label	Phenyl label

Wheat grain	0.047±0.001	0.069±0.004	0.045±0.001	0.039±0.000	0.010±0.001	0.017±0.001

Notes:

Values are from combustion/LSC of five replicate sub-samples.

The TRRs from the two labels were in similar levels, and gradually declined with increasing PBIs, except for phenyl label wheat forage and hay (highest at 365 day PBI), phenyl label wheat straw (highest 30 day PBI and lowest 120 day PBI) and quinazoline label wheat forage and straw (highest at 120 day PBI).

In the study report, the percent TRR values on each component, subtotal extracted and PES were derived from the sum of subtotal extracted and PES. The ratio (all cases with label and PBI) of the reported percent TRR over the percent TRR calculated with the combustion analysis TRR value was 91.0–98.2 percent in lettuce (immature, mature), 83.3–125 percent in radish (roots, tops), 86.7–97.1 percent in wheat grain and 88.9–105 percent in wheat animal commodity (forage, hay, straw). As these differences did not give significant effects on the interpretation on results of this study, herein the percent TRR value from the study report was used as it is.

Extractability of residues (all cases with label and PBI) using organic solvents was 58.8–61.1 percent TRR in immature lettuce, 51.2–63.9 percent TRR in mature lettuce, 72.7–80.6 percent TRR in radish roots, 61.9–85.7 percent TRR in radish tops, 65.7–91.4 percent TRR in wheat forage, 49.6–69.6 percent TRR in wheat hay, 47.2–72.4 percent TRR in wheat straw and 28.6–49.3 percent TRR in wheat grain.

Notes:

n.a. Not analysed.

n.d. Not detected.

Parent fenazaquin was found at a greater level than 10 percent TRR or 0.01 mg/kg only in 30 day PBI radish roots, representing phenyl label 28.6 percent TRR (0.026 mg/kg) and quinazoline label 29.0 percent TRR (0.031 mg/kg). In the radish roots of 120 day PBI, fenazaquin residues were found at < 0.01 mg/kg (16 percent TRR) in both labels (for 365 day PBI, phenyl label sample, extracted but not analysed by HPLC and quinazoline label sample, not extracted).

Wheat grain	n.a.	n.a.	n.a.	n.a.	n.a.	n.a.

Notes:

n.a. Not analysed.

For metabolites, 4-hydroxyquinazoline was detected in all tested crops except for wheat grain, representing low levels of ≤ 13.8 percent TRR or ≤0.012 mg eq/kg. The other identified metabolites (2-oxy-fenazaquin, fenazaquin acid and 4-*tert*-butylphenyl alcohol), where measured, were found at very low levels of ≤4.5 percent TRR or ≤ 0.004 mg eq/kg. In addition to these metabolites, a polar peak (< 0.013 mg eq/kg) and multiple minor components (each <0.016 mg eq/kg, except for two components in wheat hay of 0.023 mg eq/kg and 0.035 mg eq/kg and one component in wheat straw of 0.064 mg eq/kg) were present in the rotational crops.

RESIDUE ANALYSIS

Analytical methods

A new method for analysis of fenazaquin was submitted to the JMPR, which was used in storage stability tests of apple, peach and tomato. The method involved a sample separation method by QuEChERS and determination by LC-MS/MS (m/z 307→57 for quantification, m/z 307→131 for qualification). Method validation results, included in the storage stability study, showed that mean recovery of fenazaquin fortified at levels of 0.01 and 0.1 mg/kg in apple, peach and tomato ranged from 86-118 percent (RSDs, ≤12 percent). The LOQ for fenazaquin was 0.01 mg/kg in the matrices. A separate method validation study [Lakaschus, S., Amann, S., 2012; Report No. S11-03100] on the new analytical method was submitted, which revealed the method is sufficiently acceptable for analysis of fenazaquin residues in the matrices of plant commodity.

In all the crop field trials and processing studies (mint, orange, plum, and tomato processing except for grape), the analytical method used consisted of processes of extraction with acetonitrile, a

partition between water and methylene chloride, clean-up step using SPE cartridge, and determination by LC-MS/MS (m/z 307.0→161.2 for quantification, m/z 307.0→147.2 for confirmation). The method was based on the method included in the Report 024119-1, considered validated by the 2017 JMPR. Method validation results from the submitted study reports to this JMPR showed that the mean recovery of fenazaquin from various plant matrices fortified at levels of 0.01-0.1/0.5/1.0/2.0 mg/kg ranged from 72–118 percent (RSDs, ≤17 percent)). In concurrent recovery, most of the individual values ranged from 70–120 percent. The LOQ value was 0.01 mg/kg in the matrices.

For some storage stability tests (grape, cucurbit, orange) and a grape processing study, the analytical method used for the analysis of fenazaquin consisted of processes extraction by macerating and heating (for cucurbit, without heating) with acetonitrile:water (90:10, v/v; for orange peel, 75:25, v/v), partitioning into hexane, clean-up step by SPE cartridge (florisil and sequentially aminopropyl) and determination by GC-MS (selected ion, 145.1, 160.0 amu; for grape processing study, additionally 117.0 amu). The method was based on the method R A4167, considered as validated by the 2017 JMPR. Method validation results on grape processing matrices showed that mean recovery of fenazaquin at fortification levels of 0.01 and 1.0 mg/kg ranged from 74–93 percent (RSDs, ≤13 percent). The concurrent recovery values were in the range of 75–101 percent. The LOQ value was 0.01 mg/kg in the matrices.

All analytical methods mentioned above are considered acceptable for the analysis of residue. The recovery results from method validation and concurrent recovery test are shown in Table 4 and Table 5, respectively.

For plant commodities, information on other residues than parent such as fenazaquin dimer (included in the study reports submitted) were not reviewed in this JMPR evaluation

Notes:

* Using the analytical method R A4167 (GC-MS).

For the other matrices, using the analytical method included in the Report 024119-1 (LC-MS/MS).

STABILITY OF RESIDUES IN STORED ANALYTICAL SAMPLES

The stability of fenazaquin residues on frozen storage was studied in apple, tomato, peach, cucumber, melon, grape and orange with results shown in Table 6. In all studies, fenazaquin was fortified at 0.1 mg/kg. Residues of fenazaquin were not detected in the control samples, except for orange (control values in orange samples, not reported).

Residues of fenazaquin were stable for at least 12 months in apple, tomato and peach when frozen stored at below -18 °C [Lakaschus & Gizler, 2013; Report S11-03099]; for at least 379 days in cucumber, at least 372 days in melon pulp and at least 376 days in melon peel at -10 to -27 °C [Butcher, 1994; Report GHE-P-3798]; at least 389 days in grape at -16 to -27 °C [Gambie, et al., 1994; Report GHE-P-3404]; at least 399 days in orange flesh and at least 371 days in orange peel at -27 to -15 °C [Gambie & Draper, 1993; Report GHE-P-3154].

Notes:

[a] Recovery was not corrected by procedural recovery.

[b] In orange (flesh, peel), all results were corrected for control values (not reported).

USE PATTERN

The Meeting received information on the GAP of fenazaquin registered in the United States. The information with regard to this evaluation by the Meeting are summarised in Table 7.

Table 7 Registered use of fenazaquin (SC 200 g/L) in United States

Crop	Application				PHI, days	Remarks
	Method	No.	Volume, L/ha	Rate. kg ai/ha		
Citrus fruit Group (10-10) (Grapefruit, Lemon, Orange)	Foliar spray	1	≥935 G*	0.359-0.538 (0.538 kg ai/ha/year)	7	Not before petal fall
Pome fruit Group (11-10) (Apple, Pear)	Foliar spray	1	≥468 G*	0.359-0.538 (0.538 kg ai/ha/year)	7	Not before petal fall
Stone fruit Group (12-12) (Cherry, Peach, Plum)	Foliar spray	1	≥468 G*	0.359-0.538	3	Not before petal fall
	Post-harvest foliar spray	1		0.359-0.538		Max 1.08 kg ai/ha/season
Caneberry Subgroup (13-07A)	Foliar spray	1	≥468 G*	0.359-0.538	7	

Crop	Application				PHI, days	Remarks
	Method	No.	Volume, L/ha	Rate. kg ai/ha		
(Raspberry)				(0.538 kg ai/ha/year)		
Bushberry Subgroup (13-07B) (Blueberry)	Foliar spray	1	≥468 G*	0.359-0.538 (0.538 kg ai/ha/year)	7	
Small fruit vine climbing Subgroup, except Fuzzy kiwifruit (13-07F) (Grape)	Foliar spray	1	≥468 G*	0.359-0.538 (0.538 kg ai/ha/year)	7	Not before petal fall
Low growing berry Subgroup (13-07G) (Strawberry)	Foliar spray	1	≥468 G*	0.359-0.538 (0.538 kg ai/ha/year)	1	Not before petal fall
Avocado	Foliar spray	1	≥935 G*	0.359-0.538 (0.538 kg ai/ha/year)	7	
Cucurbit vegetables Group (9) (Cucumber, Cantaloupe, Summer squash)	Foliar spray	1	≥234 G*	0.359-0.538 (0.538 kg ai/ha/year)	3	
Fruiting vegetables Group (8-10) (Tomato, Pepper)	Foliar spray	1	≥234 G*	0.359-0.538 (0.538 kg ai/ha/year)	3	
Edible-podded legume vegetable Subgroup (6A) (Snap bean, snap pea)	Foliar spray	1	≥187 G*	0.359-0.538 (0.538 kg ai/ha/year)	7	
Succulent pea and bean Subgroup (6B) (Lima bean, Garden pea)	Foliar spray	1	≥187 G*	0.359-0.538 (0.538 kg ai/ha/year)	7	
Dried shelled pea and bean (except soybean) Subgroup (6C) (Pinto bean, Australian winter pea)	Foliar spray	1	≥187 G*	0.359-0.538 (0.538 kg ai/ha/year)	7	
Mint (Peppermint, spearmint)	Foliar spray	1	≥187 G*	0.359-0.538 (0.538 kg ai/ha/year)	7	Apply before bloom

Notes:

The table shows the GAP information on the crops (avocado and the crops in the parenthesis) for which residue trials were submitted.

* Ground application (air application is also allowed with different spray volume).

Restrictions on all crops:

Only ground sprayer, airblast and aerial applications are permitted.

Do not plant rotational crops, other than those on this label, within 30 days of this application. Do not plant root, tuber and bulb vegetables within 120 days of this application.

Crop groups:

Citrus fruit group (10-10): Australian desert lime; Australian finger-lime; Australian round lime; Brown River finger lime; calamondin; citron; citrus hybrids; grapefruit; Japanese summer grapefruit; kumquat; lemon; lime; Mediterranean mandarin; mount white lime; New Guinea wild lime; orange, sour; orange, sweet; pummelo; Russell River lime; satsuma mandarin; sweet lime; tachibana orange; Tahiti lime; tangelo; tangerine (mandarin); tangor; trifoliate orange; uniq fruit; cultivars, varieties, and/or hybrids of these.

Pome fruit group 11-10: Apple; azarole; crabapple; loquat; mayhaw; medlar; pear; pear, Asian; quince; quince, Chinese; quince, Japanese; tejocote; cultivars, varieties, and/or hybrids of these.

Stone fruit group 12-12: Apricot; apricot, Japanese; capulin; cherry, black; cherry, Nanking; cherry, sweet; cherry, tart; Jujube, Chinese; nectarine; peach; plum; plum, American; plum, beach; plum, Canada; plum, cherry; plum, Chickasaw; plum, Damson; plum, Japanese; plum, Klamath; plum, prune; plumcot; sloe; cultivars, varieties, and/or hybrids of these.

Caneberry subgroup 13-07A: Blackberry; loganberry; raspberry, black and red; wild raspberry; cultivars, varieties, and/or hybrids of these.

Bushberry subgroup 13-07B: Aronia berry; blueberry, highbush; blueberry, lowbush; buffalo currant; Chilean guava; cranberry, highbush; currant, black; currant, red; elderberry; European barberry; gooseberry; honeysuckle, edible; huckleberry; jostaberry; Juneberry (Saskatoon berry); lingonberry; native currant; salal; sea buckthorn; cultivars, varieties, and/or hybrids of these

Small fruit vine climbing subgroup, except fuzzy kiwifruit 13-07F: Amur river grape; gooseberry; grape; kiwifruit, hardy; maypop; schisandra berry; cultivars, varieties, and/or hybrids of these.

Low growing berry subgroup 13-07G: Bearberry; bilberry; blueberry, lowbush; cloudberry; cranberry; lingonberry; muntries; partridgeberry; strawberry; cultivars, varieties, and/or hybrids of these.

Cucurbit vegetables group 9: Chayote (fruit); Chinese waxgourd (Chinese preserving melon); citron melon; cucumber; gherkin; gourd, edible (includes hyotan, cucuzza, hechima, Chinese okra); *Momordica* spp (includes balsam apple, balsam pear, bittermelon, Chinese cucumber); muskmelon (includes cantaloupe); pumpkin; squash, summer; squash, winter (includes butternut squash, calabaza, hubbard squash, acorn squash, spaghetti squash); watermelon.

Fruiting vegetables group 8-10: African eggplant; bush tomato; bell pepper; cocona; currant tomato; eggplant; garden huckleberry; goji berry; groundcherry; martynia; naranjilla; okra; pea eggplant; pepino; non-bell pepper; roselle; scarlet eggplant; sunberry; tomatillo; tomato; tree tomato; cultivars, varieties, and/or hybrids of these

Edible-podded legume vegetable subgroup 6A: Bean (*Phaseolus* spp.) (includes runner bean, snap bean, wax bean); bean (*Vigna* spp.) (includes asparagus bean, Chinese longbean, moth bean, yardlong bean); jackbean; pea (*Pisum* spp.) (includes dwarf pea, edible-podded pea, snow pea, sugar snap pea); pigeon pea; soybean (immature seed); sword bean.

Succulent pea and bean subgroup 6B: Bean (*Phaseolus* spp.) (includes lima bean (green)); broad bean (succulent); bean (*Vigna* spp.) (includes blackeyed pea, cowpea, southern pea); pea (*Pisum* spp.) (includes English pea, garden pea, green pea); pigeon pea.

Dried shelled pea and bean (except soybean) subgroup 6C: Dried cultivars of bean (*Lupinus* spp.) (includes grain lupin, sweet lupin, white lupin, and white sweet lupin); (*Phaseolus* spp.) (includes field bean, kidney bean, lima bean (dry), navy bean, pinto bean, tepary bean); bean (*Vigna* spp.) (includes adzuki bean, blackeyed pea, catjang, cowpea, Crowder pea, moth bean, mung bean, rice bean, southern pea, urd bean); broad bean (dry); chickpea; guar; lablab bean (hyacinth bean); lentil; pea (*Pisum* spp.) (includes field pea); pigeon pea.

RESIDUES RESULTING FROM SUPERVISED TRIALS ON CROPS

The Meeting received residue trials on avocado, berries (blueberry, raspberry, grape, strawberry), citrus fruits (lemon, orange, grapefruit), pome fruits (apple, pear), stone fruits (cherry, peach, plum), fruiting vegetables (cucumber, cantaloupe, Zucchini squash, tomato, peppers), beans and peas (with pods, succulent without pods and dried) and mint. The detailed information is summarised in Tables 8–23.

Citrus fruits

Supervised residue trials on lemon (five trials), orange (12 trials) and grapefruit (six trials) were conducted in the United States during 2008-2009 [Belcher, T.I., 2010; Report No. GR08-576].

Treated plots received one foliar application of the test substance (SC 200 g/L) at a rate of 0.50–0.51 kg ai/ha in lemon, 0.50–0.53 kg ai/ha in orange and 0.50–0.51 kg ai/ha in grapefruit. The foliar spray including a non-ionic surfactant was made seven or eight days prior to normal fruit harvest, using tractor mounted airblast orchard sprayers or miniblast sprayers. The spray volume was 635–1909 L/ha in lemon, 321–2194 L/ha in orange and 478–1518 L/ha in grapefruit. Duplicate samples from treated plot were

collected, each sample comprising of at least 24 fruit, weighing a minimum of 2 kg. Collected samples were stored frozen until analysis with a maximum storage period of 326 days. A subsample of fruit collected from treated each plot was peeled and flesh sample was also analysed. No fenazaquin residue was detected in the flesh samples of lemon, orange and grapefruit. Orange trials included two decline studies (1, 3, 7, 10, and 14 days after treatment) and one processing study (Trial 08-576.11).

Notes:

[a] Not independent trials, conducted at the same location with the same treatment date.

[b] Not independent trials, conducted at the same location with the same harvest date.

[c] Not independent trials, conducted at the same location with a close treatment date, 3 days apart.

Fenazaquin residues were not detected (<0.01 mg/kg) in the flesh samples of lemon, orange and grapefruit,

Pome fruits

Supervised field trials on apple (12 trials) and pear (six trials) trees were conducted in the United States in 2008 [Riley, M., 2010; Report No. GR08-575].

Treated plots received one foliar application of the test substance (SC 200 g/L) at a rate of 0.50–0.53 kg ai/ha in apple and 0.50–0.51 kg ai/ha in pear. The foliar spray including a non-ionic surfactant was made seven days prior to normal harvest, using tractor-mounted airblast orchard sprayers or miniblast sprayers. The spray volume was 542–2068 L/ha in apple and 471–1876 L/ha in pear. Duplicate samples from treated plot were collected, each sample comprising of at least 24 fruit, weighing a minimum of 2 kg. Collected samples were stored frozen until analysis with a maximum storage period of 181 days. Apple trials included two decline studies (1, 3, 7, 9 or 10, and 14 days after treatment).

Stone fruits

Supervised residue trials on cherry (six trials), plum (six trials) and peach (nine trials) were conducted in the United States during 2008–2009 [Carringer, S.J., 2010; Report No. TCI-08-215].

Treated plots received one pre-harvest foliar application of the test substance (SC 200 g/L) at a rate of 0.50 kg ai/ha in cherry, 0.50–0.53 kg ai/ha in plum and 0.48–0.52 kg ai/ha in peach. The foliar spray including a non-ionic surfactant was made three days prior to normal fruit harvest, using airblast application equipment. The spray volume was 608–1833 L/ha in cherry, 496–1908 L/ha in plum and 514–1946 L/ha in peach. Duplicate samples from treated plot were collected, comprising of at least 24 fruit, weighing a minimum of 2 kg (cherry samples, ≥ 1 kg). Collected samples were stored frozen until analysis with a maximum storage period of 127 days. Trials of cherry, plum and peach included each one decline study (0, 3, 7, 12 or 14 days after treatment). In one trial (Trial TCI-08-215-17), an additional plot was treated for a processing study.

Berries and other small fruits

Raspberries and blueberries

Supervised residue trials on raspberries (five trials) and blueberries (high bush, six trials) were conducted in the United States in 2008 [Wyatt D.R., 2010; Report No. TCI-08-214].

Treated plots received one foliar application of the test substance (SC 200 g/L) at a rate of 0.50–0.53 kg ai/ha in raspberries and 0.50–0.52 kg ai/ha in blueberries. The foliar spray including a non-ionic surfactant was made six or seven days prior to normal fruit harvest, using airblast or handheld vertical boom sprayers. The spray volume was 571–1871 L/ha in raspberries and 524–1235 L/ha in blueberries. Duplicate samples from treated plot were collected, each sample comprising of a minimum of 0.5 kg. Collected samples were stored frozen until analysis with a maximum storage period of 82 days. The trials of raspberry and blueberry included each one decline study (0, 7, 10, and 14 days after treatment).

Grapes

Supervised residue trials on grapes (12 trials) were conducted in the United States in 2008 [Belcher, T.I., 2010; Report No. GR08-577].

Treated plots received one foliar application of the test substance (SC 200 g/L) at a rate of 0.50–0.51 kg ai/ha. The foliar spray including a non-ionic surfactant was made seven days prior to normal fruit harvest, using tractor mounted or backpack airblast sprayers. The spray volume was 422–697 L/ha. Duplicate samples from treated plot were collected, each sample comprising of at least 12 grape bunches, weighing a minimum of 1 kg. Collected samples were stored frozen until analysis with a maximum storage period of 281 days.

Strawberry

Supervised residue trials on strawberry (eight trials) were conducted in the United States during 2008-2009 [Wyatt, D.R., 2010; Report No. TCI-08-213].

Treated plots received one foliar application of the test substance (SC 200 g/L) at a rate of 0.49–0.52 kg ai/ha. The foliar spray including a non-ionic surfactant was made one days prior to normal fruit harvest, using ground broadcast equipment. The spray volume was 767–917 L/ha. Duplicate samples from treated plot were collected, each sample weighing a minimum of 1.1 kg. Collected samples were stored frozen until analysis with a maximum storage period of 110 days. The trials included one decline study (0, 1, 7 and 10 days after treatment).

Fruiting vegetables, Cucurbits

Cucumber, Summer squash and melons

Supervised residue trials on cucumber (six trials), summer squash (zucchini five trials) and cantaloupe (six trials) were conducted in the United States in 2008 [Korpalski, S.J., 2010; Report No. GR08-582].

Treated plots received one foliar application of the test substance (SC 200 g/L) at a rate of 0.50–0.52 kg ai/ha in cucumber, 0.50–0.51 kg ai/ha in summer squash and 0.49–0.52 kg ai/ha in melons. The foliar spray including a non-ionic surfactant was made three days prior to normal fruit harvest, using backpack or tractor-mounted sprayers. The spray volume was 183–236 L/ha in cucumber, 186–191 L/ha in summer squash and 185–194 L/ha in melons. Duplicate samples from treated plot were collected and each sample consisted of at least 12 fruits. Collected samples were stored frozen until analysis with a maximum storage period of 274 days.

Fruiting vegetables, other than Cucurbits

Tomato and peppers (Chili and sweet)

Supervised residue trials on tomatoes (12 trials), sweet pepper (six trials) and chili pepper (three trials) were conducted in the United States in 2008 [Carringer, S.J., 2010; Report No. TCI-08-216].

Treated plots received one foliar application of the test substance (SC 200 g/L) at a rate of 0.50–0.52 kg ai/ha. The foliar spray including a non-ionic surfactant was made three days prior to normal fruit harvest in tomato, 0.49–0.52 kg ai/ha in sweet pepper and 0.50 kg ai/ha in chili pepper, using ground broadcast equipment. The spray volume was 131-309 L/ha in tomato, 112–281 L/ha in sweet pepper and 140–281 L/ha in chili pepper. Duplicate samples from treated plot were collected and each sample was comprised of a minimum of 12 large or 24 small fruit weighing at least 2 kg. Collected samples were stored frozen until analysis with a maximum storage period of 278 days. The trials on tomato and sweet pepper included each one decline study (0, 2 or 3, 7 and 14 days after treatment). Samples from the one trial (TCI-08-216-08) were used for a processing study.

Legume vegetables

Beans and peas, with pods

Supervised residue trials on beans with pods (snap bean nine trials) and peas with pods (snap peas three trials) were conducted in the United States in 2009 [Korpalski, S.J., 2010; Report No. 09-00522].

Treated plots received one foliar application of the test substance (SC 200 g/L) at a rate of 0.50–0.53 kg ai/ha in beans with pods and 0.48–0.53 kg ai/ha in peas with pods. The foliar spray including a non-ionic surfactant was made seven days prior to normal harvest, using ground boom sprayers with multiple nozzles. The spray volume was 187–194 L/ha in beans with pods and 180–197 L/ha in peas with pods. Duplicate samples from treated plot were collected and each sample ranged from approximately 1 to 2 kg. Collected samples were stored frozen until analysis with a maximum storage period of 238 days.

Succulent beans and peas, without pods

Supervised residue trials on succulent beans without pods (lima bean six trials) and succulent peas without pods (garden pea 5 trials) were conducted in the United States in 2009 [Korpalski, S.J., 2010; Report No.09-00521].

Treated plots received one foliar application of the test substance (SC 200 g/L) at a rate of 0.50–0.52 kg ai/ha in succulent beans without pods and 0.50 kg ai/ha in succulent peas without pods. The foliar spray including a non-ionic surfactant was made seven days prior to normal harvest, using ground boom sprayers with multiple nozzles. The spray volume was 184–192 L/ha in succulent beans with pods and 188–192 L/ha in succulent peas without pods. Duplicate samples from treated plot were collected and each sample ranged from approximately 0.32–2.75 kg (0.32-0.45 kg shelled bean in the Trial 09-

521.04; ≥1 kg in the other trials). After shelling, samples were stored frozen until analysis with a maximum storage period of 233 days.

Pulses

Beans and peas, dry

Supervised residue trials on dry beans (pinto bean nine trials) and dry peas (Australian winter pea five trials) were conducted in the United States in 2009 [Korpalski, S.J., 2010; Report No.09-00523].

Treated plots received one foliar application of the test substance (SC 200 g/L) at a rate of 0.50–0.52 kg ai/ha in dry beans and 0.50 kg ai/ha in dry peas. The foliar spray including a non-ionic surfactant

was made seven or eight days prior to normal harvest, using ground boom sprayers with multiple nozzles. The spray volume was 183–194 L/ha in dry beans and 169–188 L/ha in dry peas. Duplicate samples from treated plot were collected and each shelled sample weighted at least 1 kg. Before shelling, beans samples from four trials (09-523.02, 09-523.06, 09-523.07 and 09-523.09) were field dried for 1, 5, 8 and 13 days, respectively, under ambient temperature or 0–1 °C, and pea samples from one trial (Trial 09-523-14) were air dried for 3 days under ambient conditions. The other bean and pea samples were shelled on the same day with harvest. Bean and pea samples were stored frozen until analysis with a maximum storage period of 144 days. For collection of pea vine and hay samples, treatment was made to another plot.

Herbs

Mint

Supervised residue trials on mint (five trials; four peppermint and one spearmint) were conducted in the United States in 2008 [Wyatt, D.R., 2010; Report No. TCI-08-217].

Treated plots received one foliar application of the test substance (SC 200 g/L) at a rate of 0.49–0.52 kg ai/ha. The foliar spray including a non-ionic surfactant was made seven days prior to normal harvest, using ground broadcast equipment. The spray volume was 140–215 L/ha. Duplicate samples from treated plot were collected and each sample weighted a minimum of 1 kg. Mint samples (fresh tops, leaves and stems) were stored frozen until analysis with a maximum storage period of 155 days. The trials included one decline study (0, 7, 10 and 14 days after treatment). In one trial (TCI-08-217-05), an additional plot was treated for a processing study (peppermint oil).

Animal feeds

Pea vines and hay

Supervised residue trials on dry pea [Korpalski, S.J., 2010; Report No.09-00523] included an additional plot for collecting vine and hay samples.

Treated plots received one foliar application of the test substance (SC 200 g/L) at a rate of 0.50–0.52 kg ai/ha. The foliar spray including a non-ionic surfactant was made seven days prior to normal harvest, using ground boom sprayers with multiple nozzles. The spray volume was 186–198 L/ha. Duplicate samples from treated plot were collected and each sample weighted 1.1–1.8 kg in vines and 0.57–0.82 kg in hay. Hay samples were field dried for 5–13 days under ambient conditions (moisture content after drying, 10–20 percent). Collected samples were stored frozen until analysis with a maximum storage period of 140 days in vines and 219 days in hay.

Notes:

* Growth in the trial (09-523.14), where planted in late summer and treated in the fall, was slower than the other trials where early treatment occurred at the typical early-summer timing.

FATE OF RESIDUES IN STORAGE AND PROCESSING

The Meeting received processing studies simulating commercial practices on orange, plum, grapes, tomato and mint. Details on field trial were described in the section of residues resulting from supervised trials on crops, except for grape.

Mint (oil)

In one supervised field trial on mint [TCI-08-217], an additional plot was treated at 2.67 kg ai/ha (5× the maximum label rate) and a sample of fresh mint (tops and leaves) was taken 7 days after treatment. After drying in the field for 3 days, this mint hay sample (20 kg) was further air-dried for 3 hours to achieve a moisture content of < 50 percent and duplicate sub-samples were taken for analysis. The dried mint hay (15 kg) was subjected to steam distillation (steam injected for 1–2 hours in steam retort) to produce peppermint oil (35 mL).

Orange (juice, oil and dried pulp)

Sample of orange was obtained from a plot treated at 2.53 kg ai/ha (5× the maximum label rate) [GR08-576]. The harvest orange was processed into juice, dried pulp and oil fractions. The residue concentration in the peeled orange (flesh) was also analysed.

Plum (prune)

Sample of plum was obtained from a plot treated at 2.50 kg ai/ha (5× the max. label rate) [TCI-08-215]. The fresh prunes were washed and then air dried at 68–79 ˚C until when the appropriate moisture content (approximately 27 percent) was achieved.

Grape (wine, juice and raisin)

Three residue trials were conducted during the 2007 growing season in Southern and Northern France [Simek, I., 2009, Report No. R A7167]. In each trial, one foliar application with a SC formulation (200 g/L) was treated on the plot at a rate of 1.0 kg ai/ha. Grapes were harvested 21 days after application. The grape samples were processed into red wine, juice (clarified and pasteurized) and raisin (moisture content, 16 percent).

Tomato (past and puree)

Sample of tomato was obtained from a plot treated at 2.54 kg ai/ha (5× the max. label rate) [TCI-08-216]. The harvest tomato was processed into paste and puree.

Notes:

Residue concentration of fenazaquin is a mean value of duplicate analyses, except for grape studies.

APPRAISAL

Fenazaquin is a quinazoline insecticide/acaricide. It was first evaluated by JMPR in 2017 for toxicology and residues. Subsequently, additional uses were evaluated by the 2019 Extra JMPR Meeting.

The 2017 JMPR established an ADI of 0–0.05 mg/kg bw and an ARfD of 0.1 mg/kg bw, applying to fenazaquin, tertiarybutylphenylethanol (TBPE), 4-hydroxyquinazoline and 2-hydroxy-fenazaquin acid. Residue definition for plant commodities is fenazaquin for compliance with the MRL and for dietary risk assessment. For animal commodities, the residue definition is the sum of fenazaquin and 2-hydroxy-fenazaquin acid for compliance with the MRL and the sum of fenazaquin, 2-hydroxy-fenazaquin acid, and tautomeric forms of 4-hydroxyquinazoline for dietary risk assessment. The residue is fat-soluble.

Fenazaquin was scheduled at the Fifty Second Session of the CCPR for evaluation of additional uses by the 2022 JMPR. The Meeting received information on residue trials (avocado, berries, citrus fruits, pome fruits, stone fruits, fruiting vegetables, beans and peas, and mint), processing and storage stability. In addition, a confined rotational crop study and a new analytical method were provided.

Confined rotational crop study

A confined rotational crop study with [^{14}C-phenyl] and [^{14}C-quinazoline] fenazaquin was conducted using lettuce, radish and wheat at 30, 120, and 365 day plant back intervals. Radiolabelled fenazaquin was applied to the bare soil at a rate of 550–556 g/ha. Total radioactive residues from the two labels were in similar levels, and gradually declined with increasing PBIs in the food commodities. The total radioactive residues were 0.004–0.055 mg eq/kg in immature lettuce, 0.008–0.067 mg eq/kg in mature lettuce, 0.008–0.104 mg eq/kg in radish roots, 0.007–0.030 mg eq/kg in radish tops, 0.009–0.129 mg eq/kg in wheat forage, 0.013–0.189 mg eq/kg in wheat hay, 0.025–0.243 mg eq/kg in wheat straw and 0.010–0.069 eq/kg in wheat grain.

Extractability of residues using organic solvents was 58.8–61.1 percent TRR in immature lettuce, 51.2–63.9 percent TRR in mature lettuce, 72.7–80.6 percent TRR in radish roots, 61.9–85.7 percent TRR in radish tops, 65.7–91.4 percent TRR in wheat forage, 49.6–69.6 percent TRR in wheat hay, 47.2–72.4 percent TRR in wheat straw and 28.6–49.3 percent TRR in wheat grain.

Only in 30-day PBI radish roots, parent fenazaquin was found at a greater level than 10 percent TRR or 0.01 mg/kg, representing 28.6–29.0 percent TRR (0.026–0.031 mg/kg). In all tested rotational crops except for wheat grain, metabolite 4-hydroxyquinazoline was detected, but did not exceed the level of 13.8 percent TRR or 0.012 mg eq/kg. The other identified metabolites were also found in the crops, but at low levels of below 4.5 percent TRR or 0.004 mg eq/kg, in addition, many minor components present at very low levels below 0.016 mg eq/kg were found, except for two components in wheat hay (0.023 mg eq/kg and 0.035 mg eq/kg) and one component in wheat straw (0.064 mg eq/kg).

The Meeting concluded that type and amount of residues in rotational crops would not impact on the current residue definition for plant commodities, and that significant residues are not expected in leafy vegetable, root and tuber vegetable or cereals grown as rotational crops.

Environmental fate

The 2017 JMPR concluded that fenazaquin is moderately persistent in soil under field conditions (DT_{50} values ranging from 26-114 days) and that the photolysis of fenazaquin in soil, under sunlight conditions, was an important degradation pathway (soil surface DT_{50} of 15 days).

Methods of analysis

Analysis of fenazaquin residue was conducted using analytical methods evaluated and considered suitable by previous JMPRs. The recovery test results from the studies submitted to the current Meeting were acceptable and the LOQs of fenazaquin were 0.01 mg/kg. In some storage stability tests, a new method employing QuEChERs and LC-MS/MS was used. The Meeting considered this method was sufficiently validated with LOQ of 0.01 mg/kg in apple, tomato, grape, peach and orange matrices.

Stability of residues in stored analytical samples

The Meeting received storage stability studies for fenazaquin in high water commodities (apple, cucumber, melon, peach, tomato) and high acid commodities (grape, orange). The results demonstrated that residues of fenazaquin were stable for at least 12 or 13 months in the stored frozen matrices, respectively.

In the previous JMPR, the Meeting considered fenazaquin residues are stable when stored frozen for up to 3.5 months for high starch commodity (maize grain) and at least 17 months for high oil commodity (almond nutmeat). For high protein commodities, the information was not available to the Meeting.

The frozen sample storage intervals in the field trials were all within the acceptable storage stability periods.

Results of supervised residue trials on crops

The US GAP provided to the Meeting permits a single foliar application of 0.538 kg ai/ha (0.538 kg ai/ha/year) fenazaquin on all registered crops. All residue trials submitted to this Meeting were conducted with a single foliar application in the United States.

Citrus fruits

The US GAP (1×0.538 kg ai/ha, 7-day PHI) covers the commodities in the Codex citrus fruits group and residue trials on lemon, orange and grapefruit matched this GAP.

Orange

In whole oranges, residues were (n= 10 from independent trials): 0.08, 0.09, 0.11, 0.11, 0.12, 0.13, 0.15, 0.15, 0.19 and 0.23 mg/kg. In flesh, residues of fenazaquin were not detected, all <0.01 mg/kg (n=10).

The Meeting estimated a maximum residue level of 0.4 mg/kg, an STMR of 0.01 mg/kg and an HR of 0.01 mg/kg for the Subgroup of oranges, sweet, sour. The median (whole fruit) residue was 0.125 mg/kg.

Lemon

In whole lemons, residues were (n=5): 0.02, 0.04, 0.08, 0.11 and 0.12 mg/kg. In flesh, residues of fenazaquin were not detected, all <0.01 mg/kg (n=5).

The Meeting estimated a maximum residue level of 0.3 mg/kg, an STMR of 0.01 mg/kg and an HR of 0.01 mg/kg for the Subgroup of lemons and limes. For kumquat, the Meeting estimated an STMR of 0.08 mg/kg and an HR of 0.12 mg/kg for whole fruit. The median (whole fruit) residue is 0.08 mg/kg.

Grapefruit

In whole grapefruits, residues were (n=5 from independent trials): 0.03, 0.04, 0.07, 0.11 and 0.14 mg/kg. In flesh, residues of fenazaquin were not detected, all <0.01 mg/kg (n=5)

The Meeting estimated a maximum residue level of 0.3 mg/kg, an STMR of 0.01 mg/kg and an HR of 0.01 mg/kg for the Subgroup of pummelo and grapefruits. The median (whole fruit) residue is 0.07 mg/kg.

Mandarin

For the Subgroup of mandarins, the Meeting agreed to extrapolate the residue data set for lemons to estimate a maximum residue level.

The Meeting estimated a maximum residue level of 0.3 mg/kg, an STMR of 0.01 mg/kg and an HR of 0.01 mg/kg for the Subgroup of mandarins. The median (whole fruit) residue is 0.08 mg/kg.

Pome fruits

The US GAP (1×0.538 kg ai/ha, 7-day PHI) covers the commodities in the Codex pome fruit group except Japanese persimmon and residue trials on apple and pear matched this GAP.

In apple, residues were (n=11 from independent trials): <0.01, 0.02, 0.03, 0.04, 0.05, 0.08, 0.09, 0.11, 0.12, 0.13, and 0.15 mg/kg with the highest analytical value of 0.18 mg/kg.

In pear, residues were (n=5 from independent trials): 0.12, 0.14, 0.15, 0.23 and 0.28 mg/kg with highest analytical value of 0.29 mg/kg.

The median residues in the datasets for apple and pear are within a 5-fold difference, however, the Mann-Whitney test showed that the residues were not from the same population. For pears, with higher residues, only five trial results were available, and the Meeting considered that 5 trials were not enough to support a pome fruit group maximum residue level.

For apples, the Meeting estimated a maximum residue level of 0.3 mg/kg, an STMR of 0.08 mg/kg and an HR of 0.18 mg/kg.

For pears, the Meeting agreed there were insufficient trials to estimate a maximum residue level.

Stone fruits

The US GAP (1×0.538 kg ai/ha, 3-day PHI) covers the commodities in the Codex stone fruits group and residue trials on cherries, plums and peaches matched this GAP, although residues were measured in fruit without stones.

The 2017 JMPR concluded that for stone fruit, residues measured in fruit without stones would overestimate whole-fruit residues by about 10 percent and that correcting for this factor would lead to the same maximum residue level estimation.

The median residues in the datasets for cherries, plums and peaches are within a 5-fold difference, however, the Kruskal-Wallis test showed that these data sets were not from the same population. Therefore, the Meeting decided to estimate separate recommendations for the subgroups.

Cherry

In cherries (without stones), residues were (n=5 from independent trials): 0.26, 0.47, 0.56, 0.84 and 0.91 mg/kg with highest analytical value of 0.97 mg/kg.

The Meeting agreed there were insufficient trials on cherries to estimate a maximum residue level.

Peach

In peaches (without stones), residues were (n=9): 0.20, 0.21, 0.24, 0.26, 0.38, 0.41, 0.44, 0.65 and 0.89 mg/kg with highest analytical value of 1.2 mg/kg.

The Meeting estimated a maximum residue level of 1.5 mg/kg, an STMR of 0.38 mg/kg and an HR of 1.2 mg/kg for the Subgroup of peaches.

Plums

In plums (without stones), residues were (n=6): <0.01, 0.016, 0.11, 0.18, 0.18 and 0.24 mg/kg with highest analytical value of 0.25 mg/kg

The Meeting estimated a maximum residue level of 0.5 mg/kg, an STMR of 0.145 mg/kg and an HR of 0.25 mg/kg for the Subgroup of plums.

Cane berries

The US GAP (1×0.538 kg ai/ha, 7-day PHI) covers the commodities in the Codex cane berries subgroup and in residue trials on raspberries matching this GAP (PHI 7 days), residues were (n=5): 0.18, 0.18, 0.18, 0.24 and 0.36 mg/kg with highest analytical value of 0.41 mg/kg.

The Meeting estimated a maximum residue level of 0.7 mg/kg, an STMR of 0.18 mg/kg and an HR of 0.41 mg/kg for the Subgroup of cane berries.

Bush berries

The US GAP (1×0.538 kg ai/ha, 7-day PHI) covers the commodities in the Codex bush berries subgroup and in residue trials on blueberries matching this GAP (PHI 7 days), residues were (n=6): 0.17, 0.23, 0.23, 0.24, 0.31 and 0.41 mg/kg with highest analytical value of 0.42 mg/kg.

The Meeting estimated a maximum residue level of 0.8 mg/kg, an STMR of 0.235 mg/kg and an HR of 0.42 mg/kg for the Subgroup of bush berries.

Small fruit vine climbing

The US GAP (1×0.538 kg ai/ha, 7-day PHI) covers the commodities in the Codex small fruit vine climbing subgroup and in residue trials on grapes matching this GAP (PHI 7 days), residues were (n=12): 0.05, 0.05, 0.07, 0.10, 0.18, 0.18, 0.20, 0.22, 0.28, 0.32, 0.32 and 0.33 mg/kg with highest analytical value of 0.40 mg/kg.

The Meeting estimated a maximum residue level of 0.7 mg/kg, an STMR of 0.19 mg/kg and an HR of 0.4 mg/kg for the Subgroup of small fruit vine climbing.

Low growing berries

The US GAP (1×0.538 kg ai/ha, 3-day PHI) covers the commodities in the Codex low growing berries subgroup and in residue trials on strawberries matching this GAP, residues were (n=8): 0.078, 0.35, 0.41, 0.46, 0.52, 0.56, 0.65 and 1.2 mg/kg with highest analytical value of 1.2 mg/kg

The Meeting estimated a maximum residue level of 2 mg/kg, an STMR of 0.49 mg/kg and an HR of 1.2 mg/kg for the Subgroup of low growing berries.

Avocado

The US GAP for avocado is 1×0.538 kg ai/ha, 7-day PHI and in residue trials matching this GAP, residues in avocados (without stones) were (n=5): 0.032, 0.037, 0.045, 0.049 and 0.082 mg/kg. In avocado flesh, residues were (n=5): <0.01 (4) and 0.01 mg/kg.

Based on information available from other avocado residue studies, stones do not make up more than 15 percent of the whole fruit weight and the Meeting concluded that correcting the reported residues to express them on a whole fruit basis would lead to the same maximum residue level estimation.

The Meeting estimated a maximum residue level of 0.15 mg/kg, an STMR of 0.01 mg/kg and an HR of 0.01 mg/kg for avocado.

Fruiting vegetables, Cucurbits

The US GAP (1×0.538 kg ai/ha, 3-day PHI) covers the commodities in the Codex fruiting vegetables, Cucurbits and residue trials on cucumber, summer squash and melons matched the GAP.

In cucumber, residues were (n=6): 0.03, 0.04, 0.05, 0.06, 0.07 and 0.17 mg/kg.

In Summer squash, residues were (n=5): 0.04, 0.06, 0.08, 0.08 and 0.13 mg/kg.

In melons, residues were (n=6): 0.02, 0.05, 0.05, 0.07, 0.09 and 0.15 mg/kg.

The median residues in the datasets for cucumber, summer squash and melons are within a 5-fold difference and the Kruskal-Wallis test showed that the residues were not from different populations. Therefore, the Meeting decided to estimate recommendations for the group of fruiting vegetables, Cucurbits.

The combined residues were (n=17): 0.02, 0.03, 0.04, 0.04, 0.05, 0.05, 0.05, 0.06, 0.06, 0.07, 0.07, 0.08, 0.08, 0.09, 0.13, 0.15 and 0.17 mg/kg with highest analytical value of 0.19 mg/kg.

The Meeting estimated a maximum residue level of 0.3 mg/kg, an STMR of 0.06 mg/kg and an HR of 0.19 mg/kg for the Group of fruiting vegetables, Cucurbits.

Tomatoes

The US GAP (1×0.538 kg ai/ha, 3-day PHI) covers the commodities in the Codex subgroup of tomatoes (PHI, 3 days) and in residue trials on tomatoes, residues were (n=11 from independent trials): 0.029, 0.029, 0.037, 0.038, 0.046, 0.052, 0.058, 0.061, 0.065, 0.071 and 0.19 mg/kg with highest analytical value of 0.19 mg/kg.

The Meeting estimated a maximum residue level of 0.3 mg/kg, an STMR of 0.052 mg/kg and an HR of 0.19 mg/kg for the Subgroup of tomatoes.

Peppers

The US GAP (1×0.538 kg ai/ha, 3-day PHI) covers the commodities in the Codex subgroup of peppers and in residue trials matching this GAP, residues in sweet peppers (6) and *chili peppers* (3) were (n=9): 0.018, 0.054, 0.056, 0.056, 0.079, *0.082*, *0.12*, 0.12 and *0.19* mg/kg with highest analytical value of 0.22 mg/kg.

The Meeting estimated a maximum residue level of 0.3 mg/kg, an STMR of 0.079 mg/kg and an HR of 0.22 mg/kg for the Subgroup of peppers (except martynia, okra and roselle).

For dried chili peppers, the Meeting applied the default concentration factor of 10 to the data set for fresh peppers and estimated a maximum residue level of 3 mg/kg, an STMR of 0.79 mg/kg and an HR of 2.2 mg/kg for dried chili pepper.

Eggplant

The US GAP (1×0.538 kg ai/ha, 3-day PHI) covers the commodities in the Codex subgroup of eggplants and in line with the 2018 JMPR recommendation that residue data on tomatoes or peppers (whichever is higher) could be extrapolated to eggplants, the Meeting agreed to extrapolate the data for peppers to estimate a maximum residue level of 0.3 mg/kg, an STMR of 0.079 mg/kg and an HR of 0.22 mg/kg for the Subgroup of eggplants

Legume vegetables

The US GAP (1×0.538 kg ai/ha, 7-day PHI) covers all commodities in the Codex legume vegetables group (except underground beans and peas) and residue trials on snap beans with pods, snap peas with pods, lima beans without pods and garden pea without pods matched this GAP.

Plant metabolism studies previously evaluated by the JMPR covered fruit (apple, orange, grape) and cereals (maize). As plant metabolism studies covering pulses and oilseeds or a third crop from a group different to fruits or cereal grains were not available, the Meeting could not estimate dietary intake of residues in legume vegetables.

Beans and peas with pods

In snap beans with pods, residues were (n=6): 0.09, 0.094, 0.099, 0.1, 0.17 and 0.18 mg/kg and in snap peas with pods, residues were (n=3): 0.041, 0.1 and 0.13 mg/kg.

The Meeting agreed to combine the data for beans and peas with pods for mutual support to estimate subgroup maximum residue levels.

The combined data set for snap beans and snap peas is (n=9): 0.041, 0.09, 0.094, 0.099, 0.1, 0.1, 0.13, 0.17 and 0.18 mg/kg

The Meeting estimated but did not recommend a maximum residue level of 0.4 mg/kg for the Subgroups of beans with pods and peas with pods because a dietary intake assessment could not be completed.

Beans and peas without pods

In lima beans without pods, residues were (n=5): <0.01 (4) and 0.017 mg/kg and in garden peas without pods, residues were (n=5): <0.01 (5).

The Meeting agreed to combine the data for beans and peas without pods for mutual support to estimate subgroup maximum residue levels.

The Meeting estimated but did not recommend a maximum residue level of 0.02 mg/kg for the Subgroups of beans with pods and peas without pods because a dietary intake assessment could not be completed.

Pulses

The US GAP (1×0.538 kg ai/ha, 7-day PHI) covers all commodities in the Codex dry beans and dry peas subgroups and residue trials on pinto bean (dry) and Australian winter pea (dry) matched this GAP.

Plant metabolism studies previously evaluated by the JMPR covered fruit (apple, orange, grape) and cereals (maize). As plant metabolism studies covering pulses and oilseeds or a third crop from a group different to fruits or cereal grains were not available, the Meeting could not estimate dietary intake of residues in pulses.

Dry beans

In pinto bean (dry), residues were (n=9): <0.01, <0.01, 0.014, 0.016, 0.018, 0.028, 0.033, 0.088 and 0.17 mg/kg in Australian winter pea (dry), residues were (n=5): <0.01, 0.011, 0.013, 0.014 and 0.052 mg/kg.

The median residues in the datasets for are within a 5-fold difference and the Kruskal-Wallis test showed that the residues were from the same population. Therefore, the Meeting decided to estimate subgroup maximum residue levels.

The combined data set is (n=14): <0.01, <0.01, <0.01, 0.011, 0.013, 0.014, 0.014, 0.016, 0.018, 0.028, 0.033, 0.052, 0.088 and 0.17 mg/kg.

The Meeting estimated but did not recommend a maximum residue levels of 0.3 mg/kg for the Subgroup of dry beans (except soya bean) and the Subgroup of dry peas because a dietary intake assessment could not be completed.

Mints

In residue trials on mint matching the US GAP for peppermint and spearmint (1×0.538 kg ai/ha, 7-day PHI), residues in mint (fresh) were (n=5): 0.57, 0.64, 0.93, 1.6 and 5.3 mg/kg with highest analytical value of 5.5 mg/kg.

Plant metabolism studies previously evaluated by the JMPR covered fruit (apple, orange, grape) and cereals (maize). As plant metabolism studies covering leafy commodities or a third crop from a group different to fruits or cereal grains were not available, the Meeting could not evaluate the residue data on mints.

Residues in animal feeds

Pea vines and hays

In the residue trials on peas matching the US GAP (PHI, 7 days), residues in pea vines were (n=5): 0.26, 1.5, 1.7, 1.8 and 3.8 mg/kg with highest analytical value of 4.5 mg/kg and in pea hay, residues were (n=5): 0.78, 5.3, 6.8, 9.5 and 22 mg/kg with highest analytical value of 23 mg/kg

As no recommendations for legume vegetable food commodities were made (because no metabolism study was available for leafy commodities), the Meeting did not estimate animal feed intake from residues in pea vines or hay.

Fate of residues during processing

The Meeting received information on the fate of fenazaquin during processing of on orange, plum, grapes, tomato and mint. In the mint oil processing study, residue data for fresh mint was not reported. Therefore, the Meeting could not estimate a processing factor for mint oil.

Processing factors were calculated for fenazaquin (for maximum residue level estimation and for calculating livestock dietary burdens) and for total residues (for risk assessment).

Where residues concentrated in the processed food commodities, maximum residue levels were estimated using the estimated maximum residue levels for the raw commodities and applying the calculated best estimate processing factors.

Table 25 Estimated maximum residue levels for processed commodities

Commodity	Processing factors		Fenazaquin
	Calculated Processing Factors #	Best Estimate	Maximum Residue Level (mg/kg)
Orange			MRL=0.4
Citrus oil	78.7	78.7	32
Grapes			MRL=0.7
Dried grapes	2.2, 2.2, 2.9	2.2	1.5
Plums			MRL=0.5
Dried prunes	4.8	4.8	2.4

Notes:

The ratio of the residues in the processed item divided by the residue in the Raw Agricultural Commodity.

The Meeting estimated a maximum residue level of 40 mg/kg for citrus oil.

The Meeting estimated a maximum residue level of 1.5 mg/kg for dried grapes.

The Meeting estimated a maximum residue level of 3 mg/kg for dried prunes.

For processed food and feed commodities, STMR-Ps, median-Ps and HR-Ps (where relevant) were calculated using the STMRs or median residues for the raw commodities and applying the calculated best estimate processing factors.

Table 26 Calculated STMR-Ps and HR-Ps for processed food and feed commodities

RAC	Processing factors		Fenazaquin residue (mg/kg)	
	Calculated Processing factors #	Best Estimate	STMR-P	HR-P
Lemon			Median=0.08

Residues in animal commodities

Farm animal feeding studies

The 2019 JMPR evaluated a 28-day dairy cow feeding study where animals were dosed with 12.5 ppm, 37.5 ppm or 125 ppm fenazaquin by capsule. Milk samples were taken daily, milk and cream samples were taken from the Day-25 collection and analysed for fenazaquin. Liver, muscle, kidney and fat samples were taken about 8 hours after the last dose and analysed for fenazaquin and 2-OH fenazaquin acid.

Residues of fenazaquin in milk plateaued after 3 days and in tissues were highest in fat and lower in liver and kidney and in muscle were <LOQ at the highest dose. Similarly, residues of 2-OH fenazaquin acid were <LOQ in muscle. The highest levels of 2-OH fenazaquin acid were found in liver, with lesser amounts in kidney.

Table 27 Residues in milk and tissues from cattle dosed for 28 days with fenazaquin in the diet

Tissue	Dose level, ppm	Residues, mg eq/kg [a]									
		Fenazaquin		2-OH fenazaquin acid		4-OH quinazoline [b]		Fenazaquin + 2-OH fenazaquinacid		Fenazaquin + 2-OH fenazaquinacid + 4-OH quinazoline	
		max	mean	max	mean	max	mean	max	mean	max	mean
Liver	12.5	Not analysed		0.017	0.014	0.018	0.011	0.027	0.024	0.045	0.039

Milk	37.5	<0.01	<0.01	<0.0025 [d]	<0.0025 [d]	<0.015	<0.015	<0.00125	<0.0125	<0.0275	<0.0275
	125	0.046	0.031	0.0115 [d]	0.00775 [d]	0.069	0.0465	0.0575	<0.0125	0.13	<0.0175

Notes:

[a] For fenazaquin and 2-OH fenazaquin acid reported as not analysed or <LOQ mg/kg, residues were assumed to be 0.01 mg/kg and combined residues are listed as <combined fenazaquin-equivalent LOQs only when all residues were reported as <0.01 mg/kg.

[b] Calculated from 2-OH fenazaquin acid by a factor of 0.75 (liver) or 0.25 (milk) from the goat metabolism study evaluated by the 2017 JMPR. Residues in fat were assumed to be zero.

[c] Perirenal fat (highest concentrations).

[d] For milk, residues calculated from fenazaquin by a factor of 0.25 (for 2-OH fenazaquin acid) or 1.5 (for 4-quinazoline).

Farm animal dietary burden

The 2019 JMPR estimated maximum and mean dietary burdens of 0.133 ppm in cattle (arising from consumption of almond hulls). For the additional uses considered by the current Meeting, citrus pulp, dry, tomato pomace and apple pomace are relevant for farm animal dietary burden calculation (cattle only).

The Meeting considered that residues of 2-hydroxy-fenazaquin acid and 4-hydroxyquinoline detectable in those feeds would have little effect on levels of dietary burdens and estimated dietary burdens based on only fenazaquin residues.

Table 28 Estimated maximum and mean dietary burdens of farm animals

	Animal dietary burden: fenazaquin ppm, of dry matter diet							
	United States-Canada		European Union		Australia		Japan	
	max	mean	max	mean	max	mean	max	mean
Beef cattle	0.002	0.0025	0.04	0.04	0.18❶	0.18❷	-	-
Dairy cattle	0.15	0.15	0.022	0.022	0.17❸	0.17❹	-	-

Notes:

❶ Highest maximum beef or dairy cattle dietary burden suitable for MRL estimates for mammalian tissues.

❷ Highest mean beef or dairy cattle dietary burden suitable for STMR estimates for mammalian tissues.

❸ Highest maximum dairy cattle dietary burden suitable for MRL estimates for mammalian milk.

❹ Highest mean dairy cattle dietary burden suitable for STMR estimates for mammalian milk.

For dietary risk assessment, the Meeting estimated residues using the approach adopted by the 2019 Extra JMPR, using conversion factors calculated from the metabolism study to estimate unmeasured residues of 2-OH fenazaquin acid (0.25×fenazaquin) and 4-OH quinazoline (1.5×fenazaquin) in milk and unmeasured residues of 4-OH quinazoline in liver (0.75×2-OH-fenazaquin acid) and kidney (0.25×2-OH-fenazaquin acid).

Table 29 Maximum residue level, STMR and HR in mammalian animal commodities

	Feed level (ppm) for milk	Residues (mg eq/kg) in milk	Feed level (ppm) for tissues	Residues (mg eq/kg) in			
				Muscle	Liver	Kidney	Fat
MRL (beef or dairy cattle) based on fenazaquin+2-OH fenazaquin acid							
Feeding study	37.5	<0.0125	12.5	<0.019	0.027	<0.019	0.056
Dietary burden and highest residue	0.17	<0.000057	0.18	<0.00027	0.00039	<0.00027	0.0008
STMR (beef or dairy cattle) based on fenazaquin+2-OH fenazaquin acid+4-OH quinazoline							
Feeding study	37.5	<0.0275	12.5	<0.019	0.039	<0.021	0.045
Dietary burden and highest residue	0.17	<0.00013	0.18	<0.00027	0.00056	<0.0003	0.00065
HR (beef or dairy cattle) based on fenazaquin+2-OH fenazaquin acid+4-OH quinazoline							
Feeding study	37.5	<0.0275	12.5	<0.019	0.045	<0.019	0.056
Dietary burden and highest residue	0.18	<0.00013	0.18	<0.00027	0.00065	<0.0003	0.00081

Based on the anticipated residues, the Meeting estimated maximum residue levels of 0.02 (*) mg/kg for milks; milk fats; meat (from mammals other than marine mammals; as fat); edible offal (mammalian) and mammalian fats (except milk fats).

The Meeting estimated STMRs of 0 mg/kg for milks and meat (from mammals other than marine mammals and 0.00065 mg/kg for mammalian fats (except milk fats).

The Meeting estimated HRs of 0 mg/kg for meat (from mammals other than marine mammals and 0.00081 mg/kg for mammalian fats (except milk fats).

For mammalian edible offal, the Meeting estimated an STMR of 0.00056 mg/kg and a HR of 0.0065 mg/kg (based on residues in liver).

For poultry, since none of the feed items were applicable, the Meeting did not estimate maximum residue levels for eggs or poultry commodities.

RECOMMENDATIONS

On the basis of the data obtained from supervised trials, the Meeting concluded that residue levels listed below are suitable for establishing maximum residue limits and for IEDI and IESTI assessments.

Definition of the residue for compliance with the MRL and for dietary risk assessment for plant commodities: *Fenazaquin.*

Definition of the residue for compliance with the MRL for animal commodities: *Sum of fenazaquin and 2-hydroxy-fenazaquin acid, expressed as fenazaquin equivalents.*

Definition of the residue for dietary risk assessment for animal commodities: *Sum of fenazaquin, and 2-hydroxy-fenazaquin acid and tautomeric forms of 4-hydroxyquinazoline, expressed as fenazaquin equivalents.*

The residue is fat-soluble.

Table 30 Residue levels suitable for establishing maximum residue limits and for IEDI and IESTI assessments

DIETARY RISK ASSESSMENT

Long-term dietary exposure

The ADI for fenazaquin is 0–0.05 mg/kg bw. The International Estimated Daily Intakes (IEDIs) for fenazaquin were estimated for the 17 GEMS/Food Consumption Cluster Diets using the STMR or STMR-P values estimated by the JMPR. The results are shown in Annex 3 of the 2022 JMPR Report.

The IEDIs ranged from 0–2 percent of the maximum ADI. The Meeting concluded that long-term dietary exposure to residues of fenazaquin from uses considered by the JMPR is unlikely to present a public health concern.

Acute dietary exposure

The ARfD for fenazaquin is 0.1 mg/kg bw. The International Estimate of Short Term Intakes (IESTIs) for fenazaquin were calculated for the food commodities and their processed commodities for which HRs/HR-Ps or STMRs/STMR-Ps were estimated by the present Meeting and for which consumption data were available. The results are shown in Annex 4 of the 2022 JMPR Report.

The IESTIs varied from 0–60 percent of the ARfD for children and 0–20 percent of the ARfD for the general population. The Meeting concluded that acute dietary exposure to residues of fenazaquin from uses considered by the present Meeting is unlikely to present a public health concern.

FLUAZAINDOLIZINE (327)

First draft prepared by Dr D.J. MacLachlan, Department of Agriculture, Fisheries and Forestry, Canberra Australia

Fluazaindolizine is a nematicide for the control of plant parasitic nematodes. At the Fifty-first Session of CCPR it was scheduled for the evaluation as a new compound in 2021 and rescheduled to the 2022 JMPR. Fluazaindolizine is to be used for annual crops (e.g., fruiting vegetables, cucurbits, root vegetables, row crops) and certain perennial crops (e.g., citrus, tree nuts, stone fruits). Application methods include drip, drench, in furrow spray with or without soil incorporation either before or at planting, with the option for follow-up in crop treatment.

IDENTITY

Common name:	Fluazaindolizine
IUPAC name:	8-Chloro-N-[(2-chloro-5-methoxyphenyl)sulfonyl]-6-(trifluoromethyl)imidazo[1,2-a]pyridine-2-carboxamide
CAS name:	8-Chloro-N-[(2-chloro-5-methoxyphenyl)sulfonyl]-6-(trifluoromethyl)-imidazo[1,2-a]pyridine-2-carboxamide
CAS number:	1254304-22-7
Synonyms:	DPX-Q8U80
Structural formula:	Molecular formula:	$C_{16}H_{10}Cl_2F_3N_3O_4S$
Molecular weight:	468.24 g/mol

vapour pressure	PAI (Gas Saturation method): 2.04×10^{-7} Pa at 20 °C 4.12×10^{-7} Pa at 35 °C 6.02×10^{-7} Pa at 50 °C (extrapolation): 2.12×10^{-7} Pa at 20 °C 2.57×10^{-7} Pa at 25 °C	Anand 2014 DuPont-36640
Vapour pressure of the metabolites:	IN-F4106: 4.45×10^{-5} Pa at 20 °C and 4.95×10^{-5} Pa at 25 °C. IN-QEK31: 2.88×10^{-8} Pa at 20 °C and 3.69×10^{-8} Pa at 25 °C IN-VM862: 1.319 Pa	Pushpalatha 2016a DuPont-42578 Pushpalatha 2016b DuPont-40413 Pushpalatha 2017 DuPont-48540
Henry's Law constant at 20 °C (calculated):	pH 4: 4.5 Pa/m^3/mol pH 7: 4.6 Pa/m^3/mol pH 9: 0.35 Pa/m^3/mol	Anand 2014 DuPont-36640
Octanol-water partition coefficients	pH 4, log K_{ow} = 2.24±0.07; pH 7, log K_{ow} = -0.16±0.01; pH 9, log K_{ow} = -0.71±0.03; in distilled water log K_{ow} = 0.81±0.06	Pushpalatha 2013 DuPont-35462
Octanol-water partition coefficients metabolites	IN-A5760 mean log K_{ow} 0.22 IN-F4106 mean log K_{ow} 0.73 IN-VM862 mean log K_{ow} 1.77 IN-QEK31 pH 4, log K_{ow} 0.58±0.03 pH 7, log K_{ow} -1.29±0.01 pH 9, log K_{ow} 1.52±0.00 IN-REG72 pH 4, log K_{ow} 1.84±0.09 pH 7, log K_{ow} 0.03±0.01 pH 9, log K_{ow} -0.49±0.02	Anand 2016 DuPont-39230
Solubility in water	PAI (measured at 20 °C): 0.0561±0.0036 g/L in distilled water; 0.0221±0.0013 g/L at pH 4; 2.1479±0.0310 g/L at pH 7, 2.8455±0.0888 g/L at pH 9	Pushpalatha 2013 DuPont-35461
Solubility in water, metabolites	(measured at 20°C) IN-QEK31 0.16±0.01 g/L distilled water 0.25±0.02 g/L pH 4 1.45±0.02 g/L pH 9 IN-F4106 0.83±0.04 g/L distilled water 0.81±0.01 g/L pH 4 1.06±0.05 g/L pH 9 IN-REG72 0.057±0.001 g/L distilled water 0.19±0.001 g/L pH 4 2.9±0.14 g/L pH 9 IN-A5760 9.72±0.17 g/L distilled water 8.84±0.34 g/L pH 4 10.27±0.36 g/L pH 9 IN-VM862 0.33±0.00 g/L distilled water 0.38±0.01 g/L pH 4 0.45±0.01 g/L pH 9	Pushpalatha 2015a DuPont-38078 Pushpalatha 2015b DuPont-38079 Pushpalatha 2015c DuPont-38581 Pushpalatha 2015d DuPont-40417 Pushpalatha 2016 DuPont-39514
Solubility in organic solvents	PAI (measured at 20 °C) Acetonitrile 35.05±3.31 g/L Methanol 3.47±0.196 g/L Acetone 99.76±3.73 g/L Ethyl acetate 27.62±1.08 g/L 1,2-dichloroethane 19.29±3.53 g/L o-xileno 1.247±0.041 g/L	Moorthy 2012 DuPont-35460

Property	Results	Reference
	n-octanol 2.00±0.19 g/L n-hexane 0.002±0.001 g/L	
Hydrolysis	Both imidazo[1,2-a]pyridine-5,8a-^{14}C]fluazaindolizine and [Phenyl-^{14}C(U)]fluazaindolizine are: Stable at pH 4 (<10 percent degradation at 50°C for 30 days) Stable at pH 7 (No degradation at 50°C for 30 days) Stable at pH 9 (No degradation at 50°C for 30 days)	Anand 2013 DuPont-35131
Hydrolysis of metabolites	The hydrolysis of IN-QEK31 at 50±0.5°C after 5 days of incubation was <3 percent in pH 4, 7 and 9 buffer solutions. IN-QEK31 is considered to be stable ($t_{1/2}$ at 25°C >1 year) at pH 4, 7 and 9. The hydrolysis of IN-F4106 at 50±0.5°C after 5 days of incubation was <6 percent in pH 4, 7 and 9 buffer solutions. IN-F4106 is considered to be stable ($t_{1/2}$ at 25°C>1 year) at pH 4, 7 and 9.	Yogeesha 2015 DuPont-40399 Manikandan 2015 DuPont-42585
Photolysis	Photolytic half-life of fluazaindolizine (radiolabelled at two different sites) in sterile aqueous buffer solution (pH 4 and 9) at 20 °C were 1.1 days and 1.2 days, respectively in a continuous irradiated system. Conversion to 12-hour sunlight days results in half-life of 2.3 days. A large number of degradation products were formed, and more than a dozen were identified. No single product exceeded >10 percent of the applied amounts.	Bell & Jewkes 2015 DuPont-37450
Dissociation constant	pK_a = 5.6 ± 0.07 at 20 °C	Anand 2013 DuPont-35459
Dissociation constant (metabolites)	IN-F4106 pK_a = 9.46± 0.03 at 20 °C IN-QEK31 pK_a = 4.55 ± 0.01 at 20 °C	Pushpalatha 2016a DuPont-40416 Pushpalatha 2016b DuPont-42582
photochemical oxidative degradation	The estimated rate constant for addition of hydroxyl radicals (OH) to the pyrimidine and phenyl aromatic rings of fluazaindolizine in the gas phase is 3.9×10^{-12} cm^3 molecule^{-1} sec^{-1}. The estimated half-life in 12-hour daylight is ~32.6 hours.	Sharma 2018 DuPont-36631
Surface tension	67 ± 0.1 dynes/cm at an average recorded temperature of 20.5 °C	Manikandan 2013 DuPont-36639
Molar extinction coefficient	Neutral: ε =6839 L mol^{-1} cm^{-1} (log ε = 3.83) at 298nm Acidic: ε = 50155 L mol^{-1} cm^{-1} (log ε = 4.70) at 235nm Basic: ε = 50207 L mol^{-1} cm^{-1} (log ε = 4.70) at 235 nm	Shubha 2015 DuPont-37833

Notes:

PAI: pure active ingredient

TGAI: technical grade active ingredient

METABOLISM AND ENVIRONMENTAL FATE

The metabolite summary below provides a reference for the numbering scheme used in the current evaluation.

Degradation compounds from metabolism of fluazaindolizine in plants, animals, and the environment

Code Names, MW	Chemical name, CAS number	Chemical structure	Where found
Fluazaindolizine $C_{16}H_{10}Cl_2F_3N_3O_4S$ MW: 468.23 DPX-Q8U80	8-Chloro-N-[(2-chloro-5-methoxyphenyl)sulfonyl]-6-(trifluoromethyl)-imidazo[1,2-a]pyridine-2-carboxamide CAS number: 1254304-22-7		Parent, active substance

Code Names, MW	Chemical name, CAS number	Chemical structure	Where found
