

## PART

### Feeding the world

# 3

The world's population is set to grow considerably over the coming years, albeit at a slower rate than in the past, and with considerable differences across regions. Over the next four decades, the world's population is forecast to increase by 2 billion people to exceed 9 billion people by 2050. Recent FAO estimates indicate that to meet the projected demand, global agricultural production will have to increase by 60 percent from its 2005–2007 levels.

Urbanization and increasing incomes are major drivers of expected changes in consumption patterns. Over recent decades, many emerging economies of Western Asia, Northern Africa, Latin America and Eastern Asia have seen fast and significant changes in food consumption levels and patterns. Per capita food availability in these regions is now close to 3 000 kcal/day. Roots, tubers and coarse grains have gradually been replaced by increasing consumption of wheat, rice, sugar, vegetable oils, and meat and dairy products. In contrast, sub-Saharan Africa and Southern Asia are still well below the 2 500 kcal/person/day threshold. At the other extreme, Latin America consumes high per capita amounts of meat.

Over the coming decades, the burden of undernourishment is expected to decline in most regions. At the same time, changes in consumption patterns and shifts towards more sedentary lifestyles are likely to make other forms of malnutrition more prominent in both developed and developing countries. Diets are expected to become richer in fats – especially saturated fat – sugar and salt, while urbanization and the reduction of physical activities will likely result in lower calorie expenditures and more widespread obesity. Undernourishment and overnutrition may coexist, posing a “double burden of malnutrition” in many developing countries.

Over the past 50 years, growth of world crop production originated mostly from increased yields and higher cropping intensity. This pattern is expected to continue, given the limited opportunities and high costs associated with expanding agricultural land. At the global level, the rates of yield growth for most crops have been decelerating in recent decades, while yields continue to increase in absolute terms.

To date, yield gains have originated mostly from improved cropping techniques, fertilization and irrigation. Much can be achieved by narrowing the gap between average farm yields and potential yields, such as those obtained in experimental fields. In several developing countries, on the other hand, average yields are estimated to be much lower than their potential, failing to reach 30 percent in some cases. Depending on the context, low productivity can be the outcome of poor physical and market infrastructure, and wrong incentives. In addition, food availability can be improved by reducing wastage and post-harvest losses.

However, the intensification of production can be associated with significant negative environmental effects, including groundwater pollution, soil erosion and a loss in biodiversity. More sustainable use of the limited resource base requires substantial improvements in the management and use of land, water and inputs. Continuous investments are required in improved technologies to reduce losses in biodiversity and limit carbon emissions from agriculture.

Developing and transferring technology alone will not tackle yield gaps or reduce wastage or post-harvest losses. An enabling investment environment should also be established. Farmers are likely to adopt technologies only if there are sound incentives to do so: this calls for well-functioning input and output markets, improved infrastructure, and better finance and risk management tools.

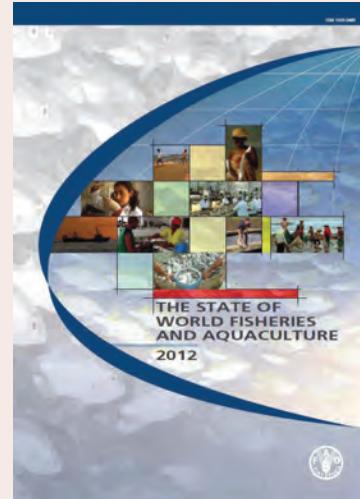

## Key Resources

### The State of World Fisheries and Aquaculture (SOFIA)

The State of World Fisheries and Aquaculture (SOFIA) is the flagship publication of the FAO Fisheries and Aquaculture Department. This premier advocacy document is published every two years to provide policy-makers, civil society and those whose livelihoods depend on the sector a comprehensive, objective and global view of capture fisheries and aquaculture, including associated policy issues.

Publication cycle: Biennial

Webpage:  
[www.fao.org/docrep/016/i2727e/i2727e00.htm](http://www.fao.org/docrep/016/i2727e/i2727e00.htm)

## Food Outlook

Food Outlook is a biannual publication focusing on developments affecting global food and feed markets. The sub-title "Global Market Analysis" reflects this focus on developments in international markets, with comprehensive assessments and forecasts on a commodity by commodity basis. Food Outlook maintains a close synergy with another major GIEWS publication, Crop Prospects and Food Situation, especially with regard to the coverage of cereals. Food outlook is available in English, French, Spanish and Chinese.

Publication cycle: Twice a year (May/June and November/December)

Webpage:  
[www.fao.org/giews/english/fo/index.htm](http://www.fao.org/giews/english/fo/index.htm)

November 2012	
Food Outlook	
Global Market Analysis	
<b>HIGHLIGHTS</b>	
Global market analysis	
Market summaries	
Market assessments	
Cereals	
Wheat, maize and milled products	
Rice	
Cereals: world supply and demand forecast is being revised slightly upwards in 2012/13 due to improved prospects for maize production in 2012 and, with a smaller reduction in 2013, for wheat and milled products.	
Milk	
Milk: supplies are expected to increase in 2012/13 due to a 2.1% growth forecast for 2012/13 milk and milled products, which is followed by a further increase in 2013/14.	
Cattle	
Cattle: world cattle prices, supply and demand balances in 2012/13 are currently tight with FAO's latest forecast showing a 1.1% increase in 2012/13, with a further slight rise in 2013/14.	
Pork	
Pork: world prices for pork are forecast to remain stable, supported by favourable production conditions. However, market demand together with very weak export demand has forced反省 to 2012/13.	
Lamb	
Lamb: world lamb output is expected to increase marginally in 2012/13 and may continue to do so in 2013/14, driven by growth in Africa, where consumption is strong, and the birth rate has been rising over the last decade. The market for lamb is currently balanced, with the production of lamb meat and milled products estimated to be reduced sharply, following a reduced demand.	
Cereals	
Cereals: world cereal production is forecast to reach a new record, more than sufficient to cover projected consumption. However, market demand together with very weak export demand has forced反省 to 2012/13.	
Meat	
Meat: world meat markets are undergoing a high level price, stagnating or slightly falling, compared with a year ago, reflecting a fall in the production of meat, especially in developed countries, and a decline in meat prices.	
Milk	
Milk: international prices of dairy products are rising in the last six months, especially in Asia, Africa and South America.	
Food	
Warming food demand International food prices are on the rise in the first half of 2012. The new food inflation index, which tracks food inflation across the world, has increased, based on data from 130 countries.	
Market indicators	
Statistical tables	
Market Indicators	
Statistical tables	
FAO Commodity Price Indices	

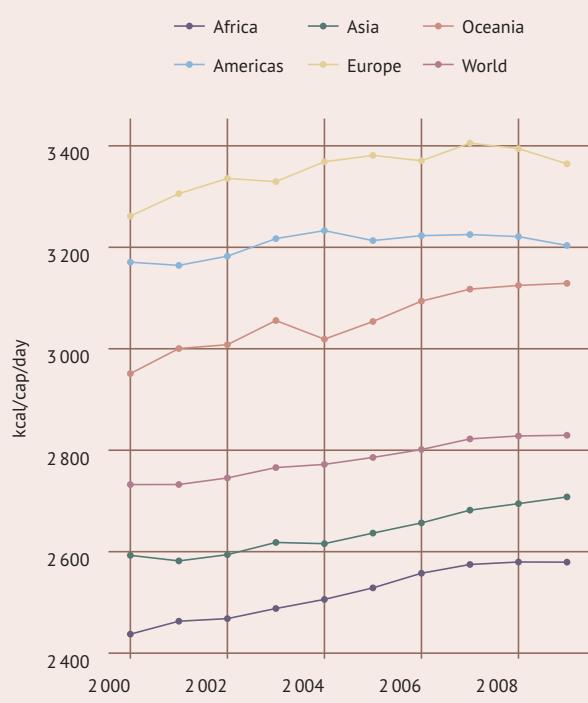

## Aggregate agriculture

In recent decades, the productive potential of global agriculture has exceeded population growth, resulting in a steady, albeit slow, increase in average per capita food availability. For the world as a whole, per capita food supply rose from about 2 200 kcal/day in the early 1960s to more than 2 800 kcal/day by 2009. At 3 370 kcal/person/day, Europe has the greatest average supply. Protein and fat supplies, measured in grams per person per day, have also increased over the past ten years, with fat supply outpacing proteins. However, supplies show considerable variability across regions, as shown in the charts.

Progress in supply per capita alone does not necessarily result in a reduction of hunger, given that food insecurity is often the result of lack of access, poor ability to utilize food, and unstable conditions. Progress in reducing the prevalence of undernourishment has slowed since 2007. High and volatile food prices and a slowdown in global economic growth have hampered the ability of poor people to purchase enough food. From the perspective of aggregate agriculture, the lack of access to enough food faced by part of the world's population creates a gap with the potential food demand that would materialize if access was adequate and there was effective market demand. This gap is likely to remain a feature of global food and agriculture for the foreseeable future, but the more it is reduced, the greater the incentive for agriculture to respond by making use of untapped production potentials. This is the case of certain developing areas where resources such as land and water are available.

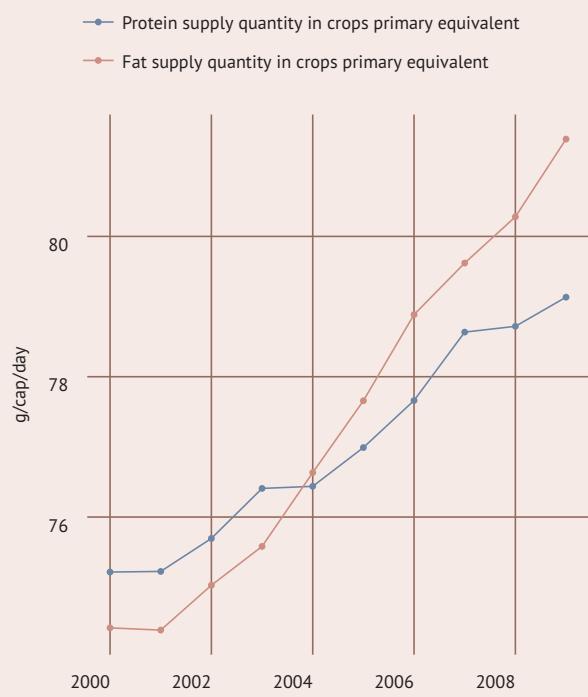

Growth in aggregate food demand is expected to slow, following lower population growth and increased saturation in high-income countries and emerging economies. At the same time, agricultural demand for non-food uses is expected to expand. In the last decade, the bio-based economy – in which the expansion of biofuels has been prominent – has offered considerable opportunities, but this additional demand also presents challenges. While offering new options for raising farm incomes, it can also increase prices, placing additional burdens on poor consumers and the world's natural resource base.

## Growth in crop production

In the past 50 years, global crop production has expanded threefold. This increase has been driven largely by higher yields per unit of land, and crop intensification resulting from multiple cropping and/or shortening of fallow periods. The expansion of arable land area allocated to crops has played a less important part in production increases.

However, these trends are not uniform across regions. For instance, most of the growth in wheat and rice production in developing countries in the land-scarce regions of Asia and Northern Africa has been the result of gains in yield, while expansion of harvested land is behind the rapid production growth of maize in Latin America and the Caribbean and in sub-Saharan Africa. Yield growth contributed only one-third of the increase in crop production in the latter region.

Over the past half century, global arable land increased by 67 million ha, as a result of two opposing trends: an increase of 107 million ha in developing countries and a decline of 40 million ha in developed countries. The arable land area in developed countries peaked in the mid-1980s, and has fallen at an accelerating rate ever since.

Major forces shaping the location and extent of crop production in the long term include land scarcity, access to technology, security of tenure, and social conditions such as gender-based rules and norms. Improved agro-ecological practices have combined with the availability of new technologies to promote commercially viable agricultural production.

For cereals, which occupy more than half of the world's harvested area, the slowdown in yield growth has been pronounced, dropping from 3 percent per annum in the 1960s to just over half that amount in the 1990s, before rising back to almost 2 percent in the last decade. Growth in global yields of other staples, such as pulses and root crops, has been much smaller – at well under 1 percent per annum over the past five decades. In contrast, yield growth in oil crops has been particularly dynamic, at about 3 percent per annum – the highest for any crops over the period.

## Trends in the crop sector

Cereals are the most important food source for human consumption. Of the approximately 2.3 billion tonnes of cereals currently produced, roughly 1 billion tonnes is destined for food use, 750 million tonnes is employed as animal feed, and the remaining 500 million tonnes is processed for industrial use, used as seed or wasted.

The growth rate of world cereal production fell to 1 percent per annum in the 1990s, down from 1.6 percent in the 1980s and almost 3 percent in the 1970s. Between 2000 and 2003, growth was almost zero, but has since increased to 2.3 percent.

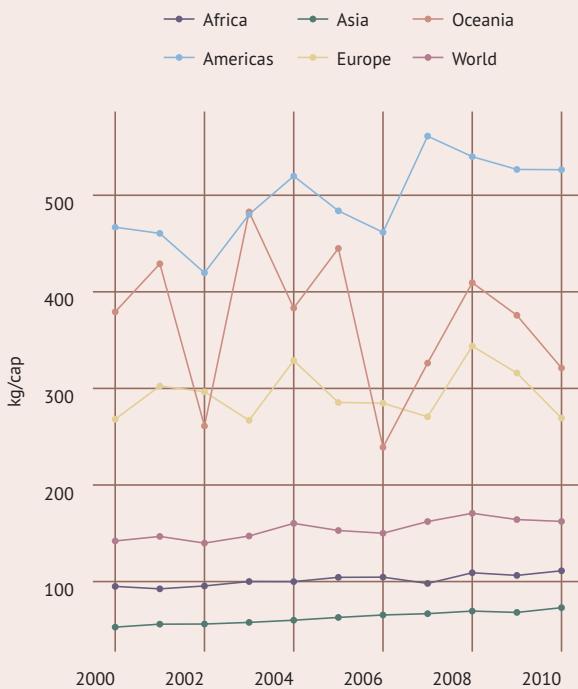

In several periods of the past, transient factors have temporarily altered the underlying trajectory of growth in the cereal sector, sometimes taking many years to dissipate: in the 1960s, growth was propelled by the green revolution; in the 1990s, production fell in transition economies, following economic downturns caused by the collapse of command economies; supply grew faster than demand in the second half of the 1990s, when Eastern Asian economies were hit by economic crisis and erratic weather; and low prices and an abundance of stocks depressed growth in the early 2000s. Global demand growth in recent years is expected to have been slowed by the economic downturns in many major consuming countries.

CHART 55: Per capita cereal production (2000-2010)

CHART 56: Per capita coarse grain production (2000-2010)

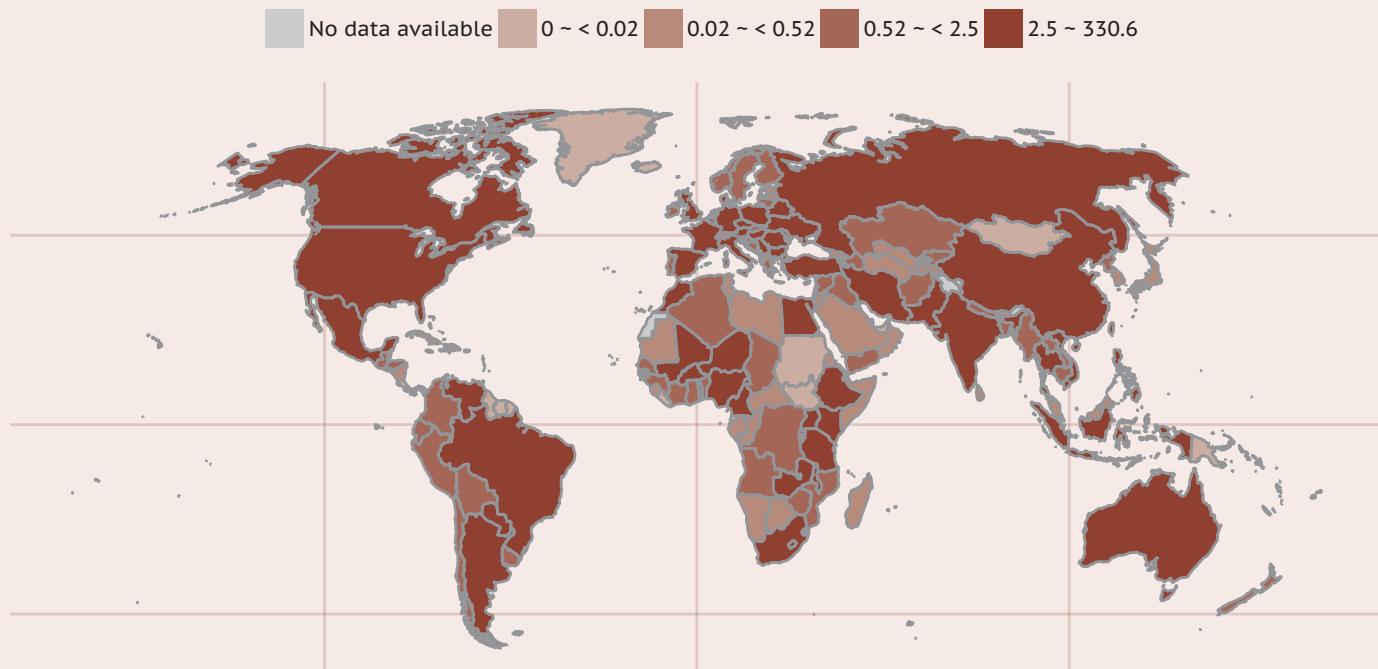

Source: FAO, Statistics Division (FAOSTAT).

MAP 34: Cereal producing countries (million tonnes, 2010)

Source: FAO, Statistics Division (FAOSTAT).

MAP 35: Coarse grain producing countries (million tonnes, 2010)

Source: FAO, Statistics Division (FAOSTAT).

Since 2005, a series of unfavourable weather episodes in major producing countries has combined with reduced levels of investment and stockholding to generate sudden increases in international prices. Increases in non-food uses of cereals, such as the use of cereal feedstocks in the fuel ethanol sector, have put additional pressure on prices, while creating incentives to increase production.

The geographical concentration of major grain supplies versus the geographical dispersion of demand suggests that trade will continue to be important in fulfilling grain requirements, particularly for wheat and maize. With most production located in the temperate zones of developed countries, increasing requirements in developing economies have increased the dependence on exports of these countries.

While rice is produced in vast areas of the world, the physical requirements for growing it are limited to certain zones. Economically viable cultivation typically requires high average temperatures during the growing season, abundant supplies of water applied in a timely manner, smooth land surfaces to facilitate uniform flooding and drainage, and a subsoil stratum that inhibits the percolation of water.

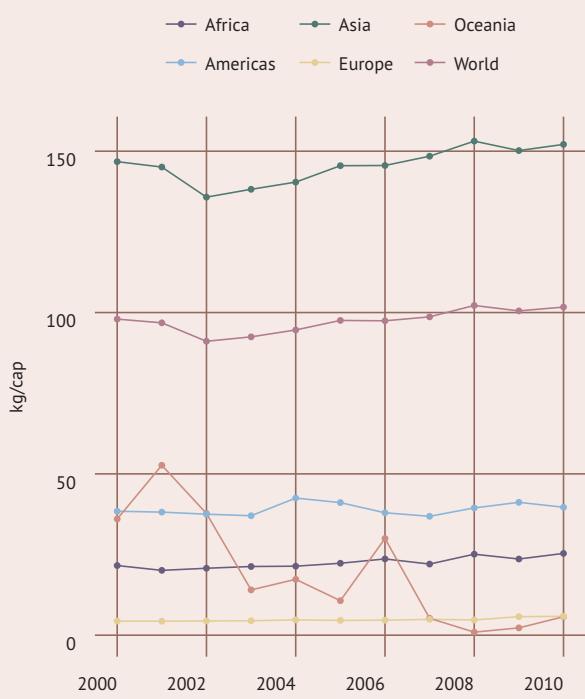

The bulk of world rice production is destined for food use, although some is used in domestic animal feeding. Rice is the primary staple for more than half the world's population, with Asia representing the largest producing and consuming region. In recent years, rice has also become an important staple throughout Africa.

More of the earth's surface is covered by wheat than by any other food crop. Wheat production is the third largest cereal production in the world, after maize and rice. In terms of dietary intake, however, wheat comes second to rice as a main food crop, given the more extensive use of maize as animal feed.

Wheat is a hardy crop that can grow in a wide range of environmental conditions and that permits large-scale cultivation and long-term storage, making it key to the emergence of urban societies for millennia. Currently, about 65 percent of the wheat crop is used for food, 17 percent for animal feed, and 12 percent in industrial applications, including biofuels.

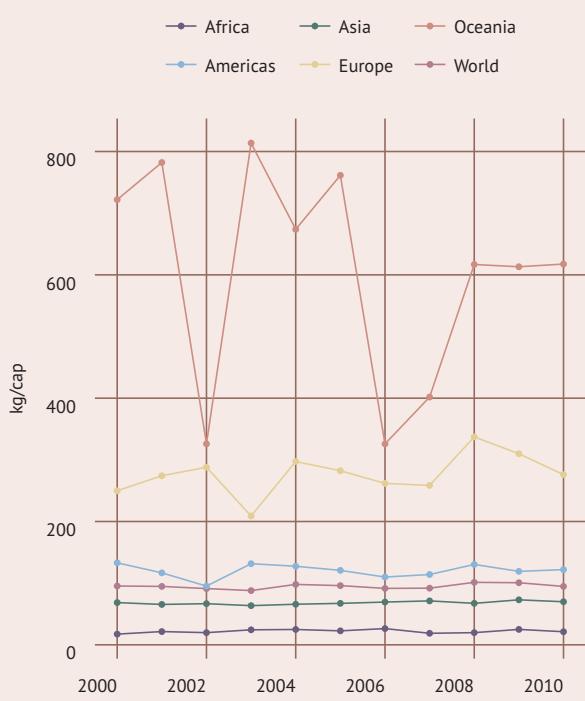

Growth in global wheat consumption has been facilitated by imports, particularly into developing countries, including both the many tropical non-wheat producing countries and those where increasing land and water constraints hinder production growth.

In recent decades, oil crop production has been among the most vibrant activities in world agriculture. Over the 2000–2010 decade alone, the sector grew by almost 5 percent per annum following growth of food consumption in developing countries. Most of this increase was in the form of vegetable oil, but direct consumption of soybeans, groundnuts and processed products other than oils also grew. There was rapid expansion in the production of oils with high protein content, such as soybean, which are used largely for direct consumption, with their oilmeals employed as feed. The four most important oil crops – oil-palm, soybean, rapeseed and sunflower seed – account for approximately 75 percent of world production. For several countries, including some major producers, these fast expanding oil crops were once rare, cultivated in only insignificant amounts if at all.

Although the oil crops sector is increasingly dominated by a small number of crops and countries, the more traditional crops continue to be a major element in the food supply of many countries. Examples include groundnuts and sesame seeds in the Sudan and Myanmar, coconuts in the Philippines and Sri Lanka, olive oil in Mediterranean countries, and cottonseed oil in the countries of Central Asia and the Sahel.

Pulses are important local food crops in the developing world. They are an essential source of protein in the diets of the world's poorest countries. In farming systems, pulses represent an input-saving and resource-conserving technology because their biological fixing of nitrogen reduces soil pathogens and the need for chemical fertilizer. For example, a substantial part of the historical growth in Australia's cereal yields is attributed to the introduction of legumes in rotation systems.

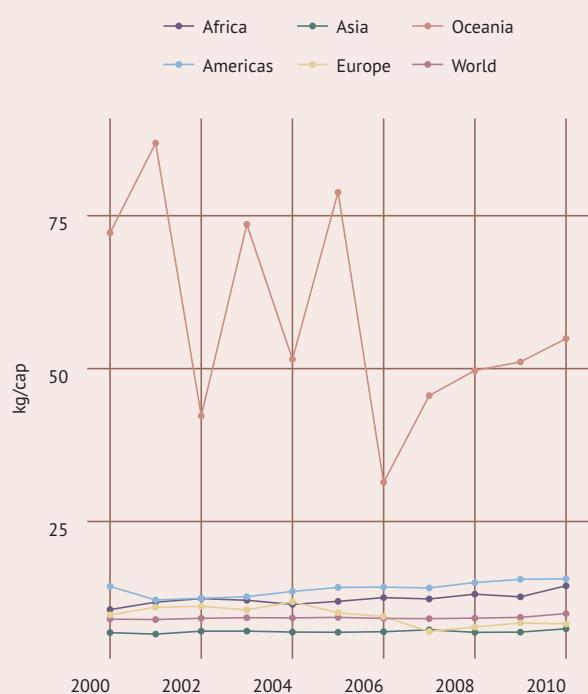

The nutritional and environmental benefits of pulses are being explored in sub-Saharan Africa, where production has increased over the last decade. At the global level, however, changes in consumer preferences and feed rations and the relegation of pulses to secondary crop status in the agricultural policies of other developing regions have led to stagnant production growth lagging behind population growth.

Root crops have traditionally been the mainstay of food consumption in several countries with low overall consumption levels, mainly in sub-Saharan Africa and in Latin America and the Caribbean. Changes in the production of these crops is an important determinant of changes in national average food consumption.

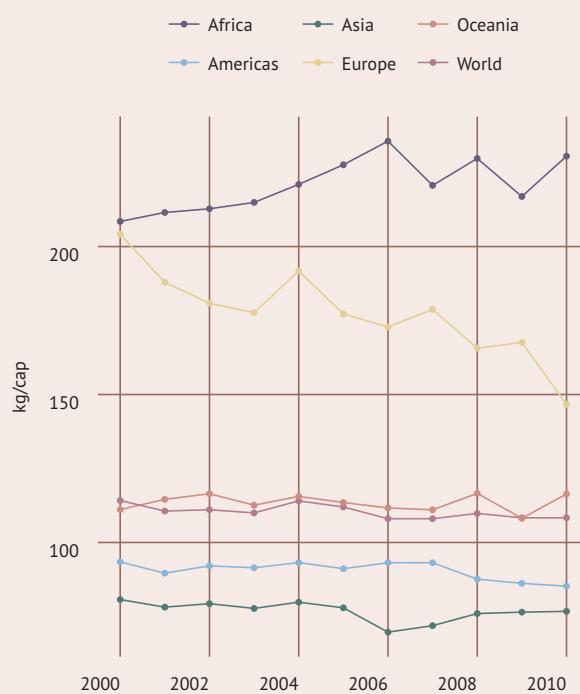

Few commodity groups exhibit such divergent trends in production across regions and economic status as root crops do. For instance, in Europe, per capita production of potatoes (a major regional staple) has been in long-term decline, while production in Africa and Asia has registered robust growth in the past decade or so, albeit from a much smaller base. In contrast, the sweet potato has undergone a precipitous decline: per capita production is currently one-third of the levels of the late 1970s, a trend that reflects a rapid fall in demand for sweet potatoes in China, especially for animal feed.

Currently, 156 million tonnes of sugar (raw equivalent) is produced in approximately 120 countries. Most sugar is derived from sugar cane, and the remainder from sugar beet. Sugar beet is a hardy biennial crop that is suited for cultivation in temperate climates, especially in the north. Approximately 50 countries are engaged in commercial sugar beet cultivation, with France the world's largest producer, followed by the United States of America.

Sugar cane is a genus of tropical grasses requiring strong sunlight and abundant water for normal growth. In contrast to sugar beet production, which has declined in recent decades, sugar cane cultivation has undergone strong growth, leading to a world production level of about 1.7 billion tonnes in 2011.

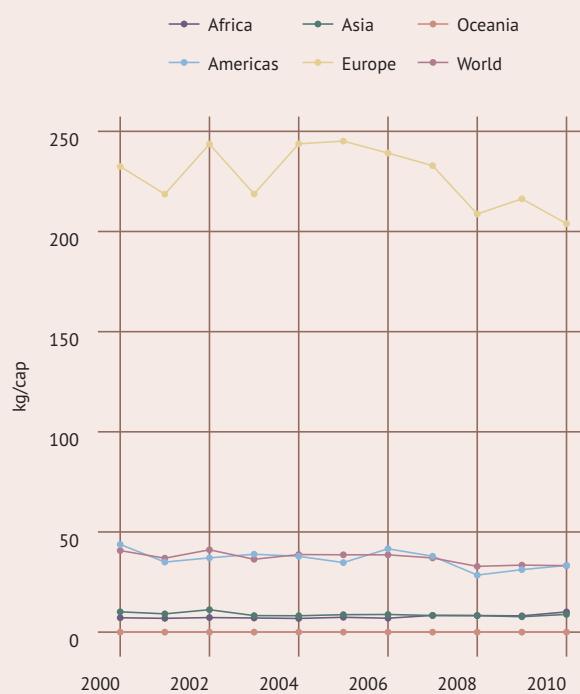

The global expansion of sugar cane has been in response to rising demand for sugar in food consumption and as a feedstock for ethanol production. The bulk of the increase has come from developing countries, with Brazil fuelling much of the growth; sugar cane production in Brazil doubled in the last decade.

MAP 41: Sugar producing countries (million tonnes, 2010)

Source: FAO, Statistics Division (FAOSTAT).

Global fruit and vegetable production has experienced a remarkable increase. Output has been growing at an annual rate of about 3 percent over the last decade. In 2011, almost 640 million tonnes of fruit and more than 1 billion tonnes of vegetables were gathered throughout the world.

World production growth has largely been driven by area expansion in Asia, especially China, which has emerged as the world's largest fruit and vegetable producer, with global output shares of about 20 percent for fruit, and more than 50 percent for vegetables. However, the familiar tendency for stagnant production growth in other developed regions also prevails in these commodities.

Strong growth rates in fruit and vegetable cultivation have also been recorded in food-insecure and low-income regions such as sub-Saharan Africa and Southern Asia. Horticultural crop production generates high economic returns per unit of land, offering promising income prospects, especially for smallholders and in areas where land is scarce. In addition, horticulture can contribute to poverty reduction by providing paid employment opportunities, because it is labour-intensive.

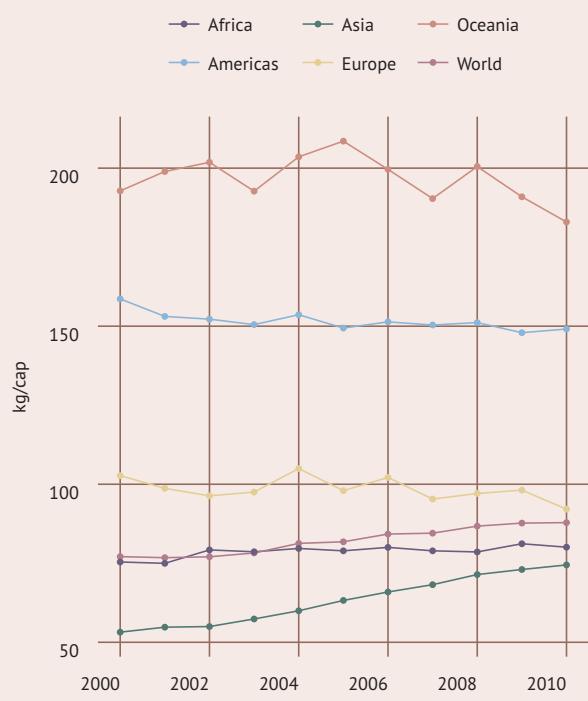

Beyond their monetary value, fruits and vegetables play an important role in improving diets. WHO estimates that low fruit and vegetable intake contributes to approximately 16 million disability-adjusted life years (DALYs, a measure of the potential life lost through premature mortality and the years of productive life lost through disability), and 1.7 million deaths worldwide are attributable to low fruit and vegetable consumption.

WHO and FAO recommend a minimum of 400 g of fruit and vegetables per day – excluding starchy root crops – for the prevention of chronic diseases such as heart disease, cancer, diabetes and obesity, and for the prevention and alleviation of several micronutrient deficiencies, especially in less developed countries. Meeting the rising global demand for fruits and vegetables can create opportunities for poor farmers in developing countries, but improved supply chain efficiency, lower post-harvest losses and investments in infrastructure will be necessary before farmers in many of these countries can reap the full benefits of cultivating these highly perishable crops.

## Trends in the livestock sector

Animals are used for a variety of reasons, including meat, eggs and dairy production, as well as for draught power or future breeding. Significant changes are occurring in the composition of livestock production (live animals). Growth has gradually declined for cattle, from almost 2 percent per year in the 1960s to less than 1 percent per year over the last decade. Pig stocks have experienced an even more radical decline, from a growth rate of more than 4 percent per year 50 years ago to only 0.8 percent per year since 2000. Poultry stocks continue to be significant, growing at an average of 3 percent per year.

The production of live animals – and the world food economy – is increasingly driven by a shift in diet and food consumption patterns towards livestock products. Over the last decade, consumption of meat in the developing countries of Asia – where the bulk of the world population increase has taken place – has been growing by about 3 percent per annum, and dairy product consumption by almost 5 percent. Aggregate agricultural output is affected by these trends, not only through the increase in livestock production itself, but also through the linkage of livestock production to the crop sector – which supplies feedstuffs, mainly cereals and oilseeds – and the fisheries sector.

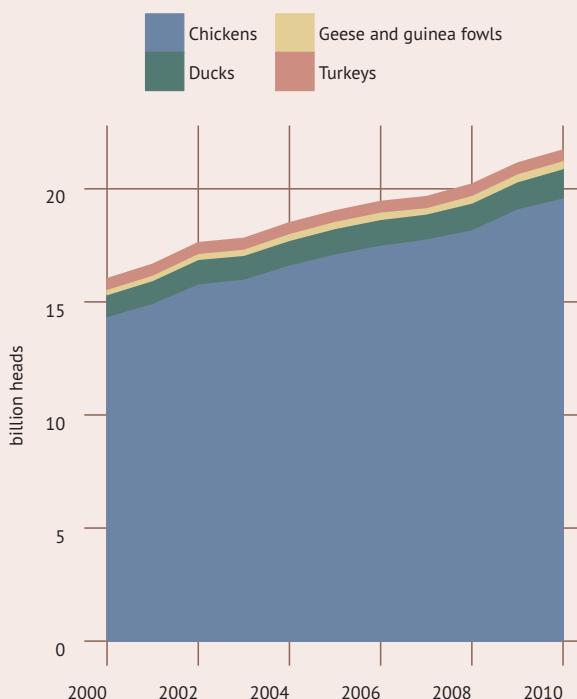

Globally, livestock production is the largest user of agricultural land. On the negative side, there are environmental implications associated with the expansion of livestock production. For example, through the expansion of land for livestock development, sector growth has been a prime force in deforestation in Latin America and the Caribbean and in overgrazing in other regions. Intensive, large-scale livestock operations, mostly in the industrial countries but increasingly also in developing regions, are a major source of environmental problems through effluent production. In parallel, growth in the ruminant sector contributes to greenhouse gas concentrations in the atmosphere through methane emissions and nitrous oxide from the waste of grazing animals.

CHART 65: Stocks of cattle and buffaloes, and sheep and goats (2000-2010)

CHART 67: Stocks of cattle and buffaloes, and sheep and goats (2010)

Source: FAO, Statistics Division (FAOSTAT).

CHART 68: Stocks of poultry birds (2010)

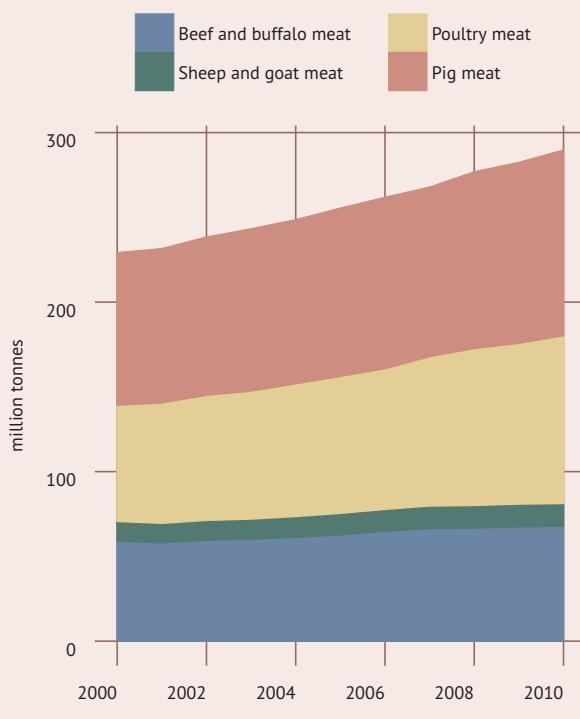

Source: FAO, Statistics Division (FAOSTAT).

Fast growth in the meat sector has been underpinned by rising demand for poultry meat, which has consistently increased at about three times the rate of population growth over each of the past five decades. For other meats, per capita production growth has been stagnant or negligible, especially for ruminants (beef, sheep and goats) and pigs (when China is excluded). Moreover, in many developing countries, where the need to increase protein consumption is greatest, the productive sector has not participated in the “livestock revolution”.

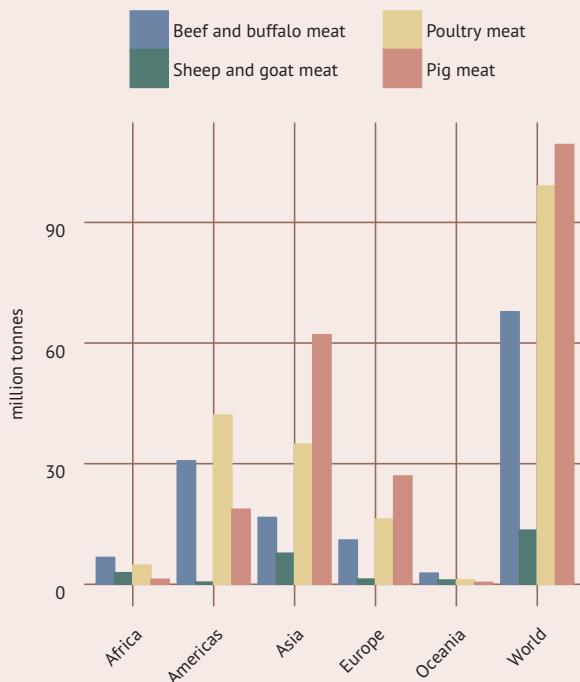

For instance, there are still about 20 developing countries where per capita meat consumption is below 10 kg/year, compared with an average of 80 kg/year in developed countries. Cultural or religious reasons may explain this feature in some countries, but low productive capacities are, by and large, the main cause in many.

**CHART 69: Meat production (2000-2010)**

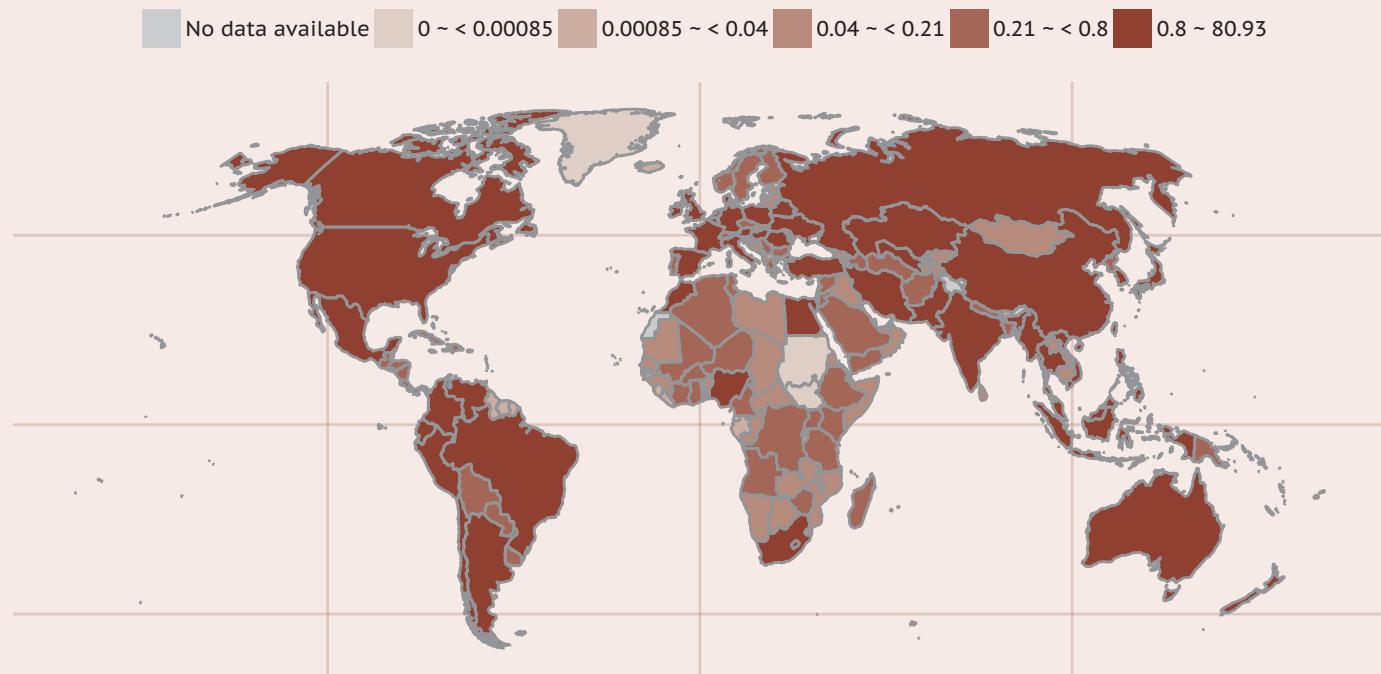

Source: FAO, Statistics Division (FAOSTAT).

**CHART 70: Meat production by type (2010)**

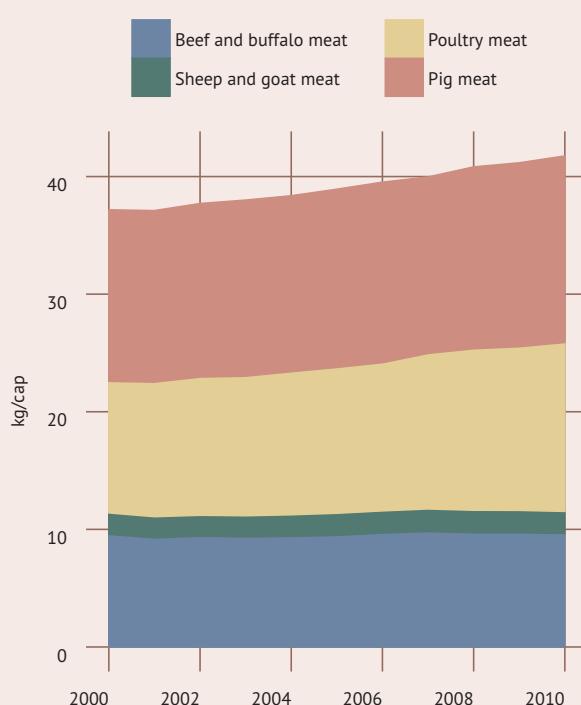

Source: FAO, Statistics Division (FAOSTAT).

MAP 45: Meat producing countries (million tonnes, 2010)

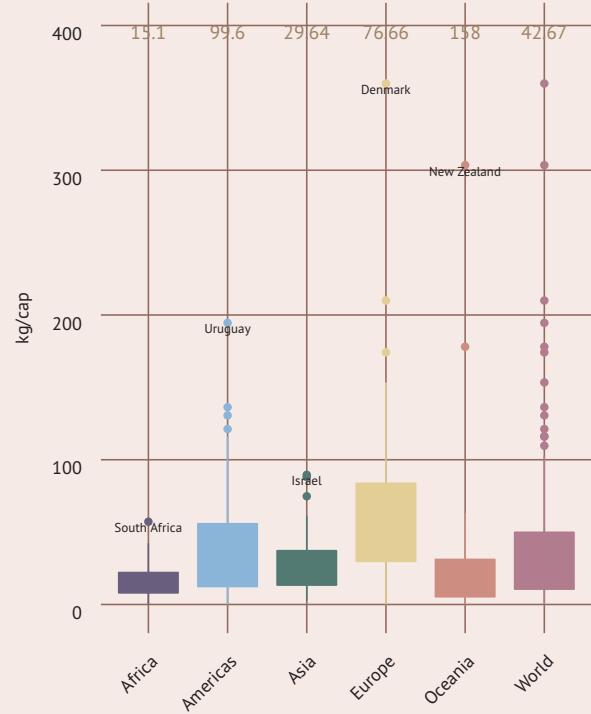

Source: FAO, Statistics Division (FAOSTAT).

CHART 71: Per capita meat production (2000-2010)

Source: FAO, Statistics Division (FAOSTAT).

CHART 72: Per capita meat production (2010)

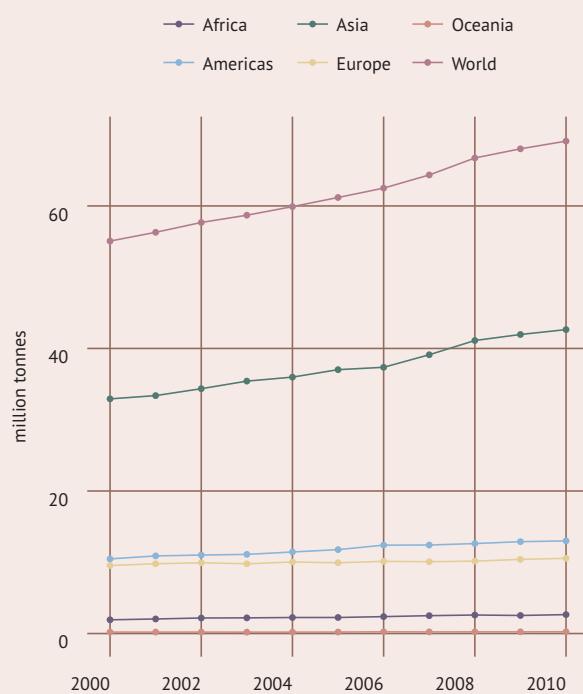

Source: FAO, Statistics Division (FAOSTAT).

Growth of world milk production and consumption has been far less buoyant. Until recently, per capita growth was largely stagnant, remaining unchanged for several decades. Per capita consumption in developing countries continues to be well below that in industrial countries, partly reflecting consumption habits as well as low incomes and poverty, but the gap is gradually closing, especially in Eastern and Southern Asia. For example, in Eastern Asia, per capita dairy intake has more than doubled in the past decade.

Feed demand for cereals is often considered a dynamic element that conditions the growth of the cereals sector, especially in developed countries. Recently, however, particularly in developing regions, this dynamism has been largely absent and growth in livestock production has by far outstripped growth in compound feed demand. Therefore, the world is obtaining more meat, milk and eggs per kilogram of cereal-based feed, which points to productivity gains in livestock production. Some of these improvements are linked to changes in the composition of livestock production, as poultry requires far smaller quantities of cereal feed per kilogram of meat than, for instance, beef. Other forces have also led to the reduced grain-meat ratios. Among these is the growing use of oilmeals in livestock feeding. World output of soybeans, which are mainly processed into oil and high-protein oilmeal, grew by more than 4 percent per annum in the last decade and by 5 percent in the 1990s. By implication, the production and consumption of soybean meal as feed has risen by the same levels, suggesting a relative increase in the feed use of oilmeals at the expense of feed-grains. A principal factor has been the expansion of livestock production systems in developing countries with lower average grain-meat ratios.

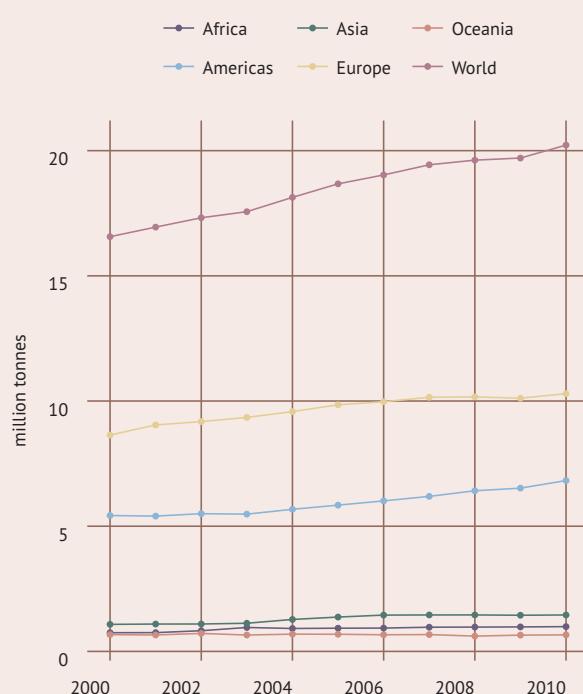

The continued growth of developing countries' share in world livestock output is associated with a shift from grazing and "backyard" production to stall-fed systems, relying on concentrated feeds. Consequently, changes in production systems tend to raise the average grain-meat ratios of these developing countries, thus compensating for the opposite trends that result from improvements in productivity.

## Trends in the fisheries sector

In 2010, capture fisheries and aquaculture supplied the world with 148 million tonnes of fish, crustaceans and molluscs. Of this, 128 million tonnes was used as human food, providing an estimated per capita food supply of about 19 kg (live weight equivalent). Globally, fish provides about 17 percent of the population's average per capita intake of animal protein.

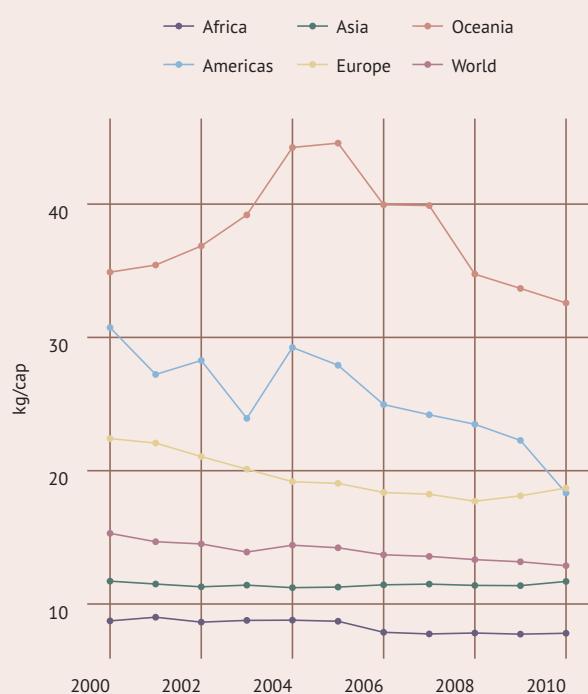

Although capture fisheries dominate world output, aquaculture accounts for a growing percentage of total fish supply, rising from a share of approximately 13 percent in 1990 to 40 percent in 2010. Aquaculture provides close to half (47 percent) of all fish supplies destined for direct human food consumption.

Most of the fish landed and not used for direct human consumption is processed into fishmeal and oil for use as animal feed, mainly for carnivorous aquatic species (such as shrimp, salmon, trout, eels, sea bass and sea bream), but also for pigs, chickens, household pets, cattle, etc.

Worldwide, capture fisheries and aquaculture provide a source of income and livelihood for 55 million people through direct employment; overall there are more than 220 million jobs in the global fish industry. Millions of rural dwellers – many of them women, particularly in Asia and Africa – are involved in seasonal or occasional fishing activities and have few alternative sources of income and employment. Employment in aquaculture is increasing more rapidly than world population growth and now accounts for one-quarter of all the workers directly involved in the fisheries sector. Employment in fishing is decreasing in capital-intensive economies.

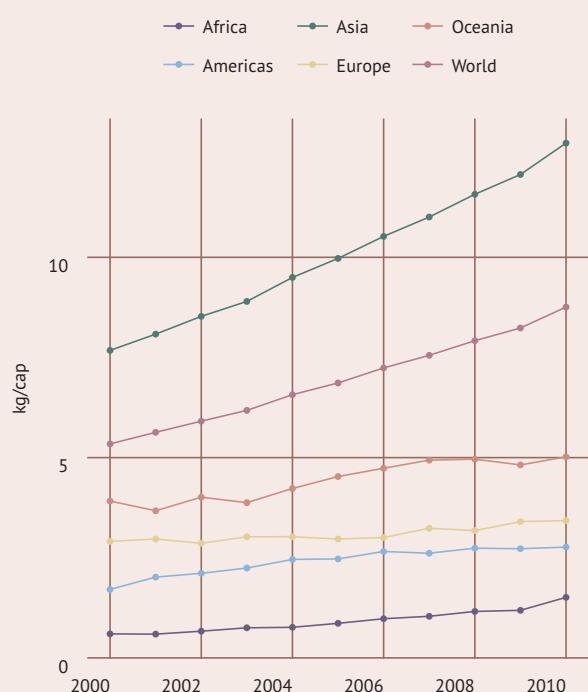

Over the 2000–2010 decade, the production of capture fisheries fluctuated between 90 and 95 million tonnes per annum, with more than half of the global catch coming from the Pacific Ocean. Global production is typically influenced by variations in catches of anchoveta (Peruvian anchovy) – a species extremely susceptible to oceanographic conditions determined by El Niño Southern Oscillation – in the Southeast Pacific. Fluctuations in other species and regions tend to compensate for each other to a large extent.

Major marine stocks are shrinking rapidly. The proportion of stocks estimated to be under- or moderately exploited declined from 40 percent in the mid-1970s to 12 percent in 2009. In contrast, the proportion of overexploited, depleted or recovering stocks increased from 10 percent in 1974 to 30 percent in 2009. The proportion of fully exploited stocks has remained relatively stable at about 50 to 60 percent since the 1970s. As a whole, these figures indicate that global marine capture production is unlikely to increase, unless effective management plans are put in place to rebuild overfished stocks. While there is a degree of uncertainty about these estimates, the apparent increasing trend in the percentage of overexploited, depleted and recovering stocks and the decreasing trend in underexploited and moderately exploited stocks give cause for concern. At the same time, however, there are encouraging signs of steady progress in restoring overfished stocks and marine ecosystems through effective management in some areas.

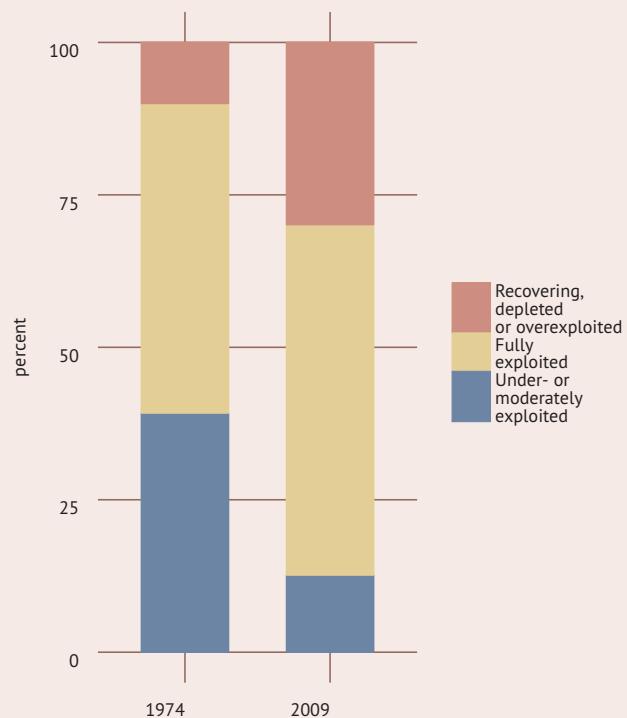

Inland fisheries are vital for livelihoods in many parts of the world and also for diets, because they provide high-quality protein, essential nutrients and minerals that are often difficult to obtain from other food sources. In recent years, inland water fishery production has expanded to over 10 million tonnes, accounting for more than 10 percent of global capture production. However, the state of inland fishery resources and the ecosystems that support them is not generally well known, and the reliability of data on inland water catches reported by several countries remains questionable. There is a growing appreciation of the need to improve inland fishery statistics.

Aquaculture represents the fastest-growing, animal-based food production sector, with 60 million tonnes of production in 2010; aquaculture growth continues to outpace population growth. Great strides in breeding technology, system design and feed technology in the second half of the twentieth century have enabled the expansion of commercially viable aquaculture across species and in volume. China alone produced more than 60 percent of global aquaculture production, while Asia as a whole accounted for about 90 percent. In quantity terms, aquaculture production has been dominated by species that feed low on the food chain in their natural habitats, such as carp, characins and tilapias. Aquaculture also provides dominant shares of the total production of several high-priced species such as salmon, shrimp, prawns, eels, oysters and scallops. The shares of aquaculture products in international trade is increasing, not only for high-priced products but also for a broad range of other species.

## Trends in agricultural trade

Most of the food consumed worldwide is grown locally. Where there is not enough local production to meet demand, global trade has been instrumental in filling the gap. The scale of food and agricultural trade today is unprecedented. In real terms, the value of international flows has increased around fivefold over the past 50 years, reflecting global trends in the overall volume of trade. However, this expansion has been unevenly distributed across regions. For much of the period, high-income countries outpaced developing regions, although several of the latter have comparative advantages in food and agricultural production.

At the global level, barring changes in stocks, agricultural production should be equal to consumption. However, differing growth rates can be observed for individual countries and country groups, depending on changes in their net agricultural trade positions. In general, the growth rates of production in most developing regions have been slightly smaller than those of demand, as these countries' agricultural imports have grown faster than their exports, thus gradually eroding their traditional surpluses in agricultural trade (excluding fishery and forestry products). By the turn of the 1990s, the trend was that surplus diminished and became a net deficit.

Traditionally, developing countries have been net importers of products from temperate agriculture – especially cereals – net exporters of rice, and net importers of wheat and coarse grains. Wheat is the largest deficit item in the developing country food basket. Between 1970 and 2010, more than half of the increment in wheat consumption was met by increased wheat imports, and several countries became totally dependent on imports for wheat. Map 51, which shows trade flows in terms of value, highlights the key roles played by the United States of America, Canada and Australia as wheat export hubs. The great majority of developing countries have been increasing their net imports, such as Saudi Arabia, the Republic of Korea, Egypt and Algeria.

At the same time, net exporting developing countries have been increasing their exports in recent decades. India and China have joined the traditional net exporters of Southern America, such as Brazil and Argentina, and the rice exporters of Asia, including Thailand. India and China have become net exporters of other cereals. China's net exports of coarse grains have grown from about the mid-1980s, and India has been an occasional net exporter of wheat since 2000.

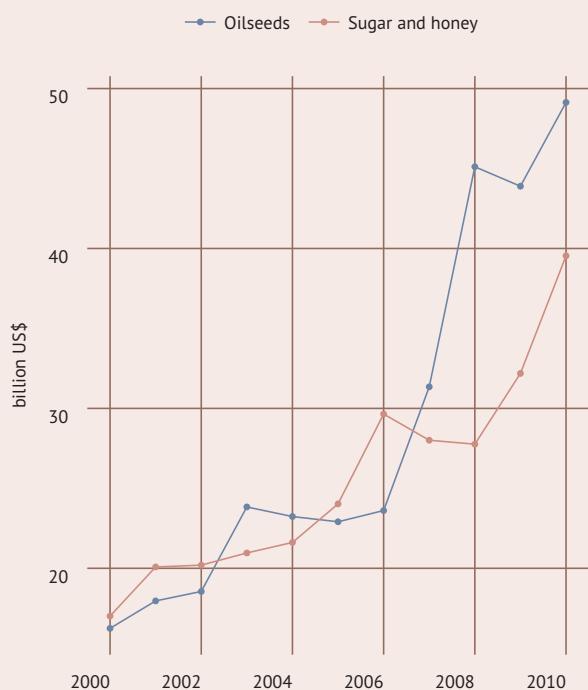

The overall net deficit in food and agricultural trade of developing countries as a group would be much deeper were it not for the exceptional performance of some emerging agro-exporters, notably Brazil. This country has gained a prominent position as an exporter of oilseeds and livestock products. China's large-scale imports of agricultural products in the last decade, especially raw materials and primary commodities, have also had an impact on this trend.

Fruit and vegetables have witnessed consistent increases in the net exporter position of many countries. This product aggregate has become the most important in value terms. Over the 2000–2010 decade, the fruit and vegetables sector has grown by more than 11 percent per year at the global level, by almost 20 percent in Africa and by 17 percent in Asia, but Europe continues to be the largest exporter. International trade in vegetable oils has also grown rapidly, at 17 percent per year. Asian countries accounted for more than half of global exports in 2010, because of rapidly rising net exports from countries such as Malaysia and Indonesia. Imports into China have gained much prominence, and Argentina and Brazil remain the major exporters from Latin America.

As a whole, developing countries' traditionally large trade surpluses of sugar have diminished rapidly since the early 1990s, as several developing countries became major importers. This shrinkage also reflects domestic support and trade protection in some major sugar importing countries. Globally, sugar and honey exports grew by 11 percent over the last decade. Most of this growth was driven by the Americas and Asia. Oilseed exports also grew very quickly, at more than 15 percent per year.

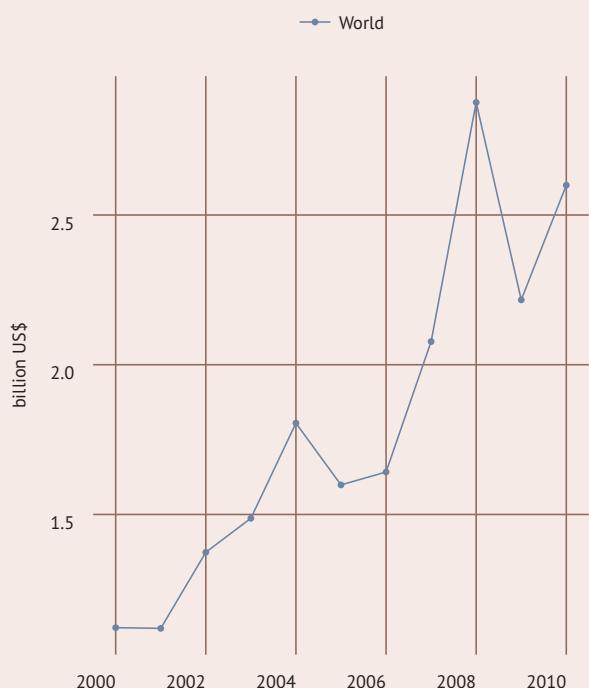

In many emerging economies, agriculture has been gradually moving towards increased commercialization of high-value foods, such as poultry, pork and fish. For poultry and fish, trade expansion has far outpaced domestic consumption. The aggregate value of net fishery exports from developing countries now exceeds the total value of the traditional mainstays of agricultural exports, such as coffee, tea, cocoa, bananas and sugar.

MAP 52: Major trade flows of pig meat (US\$, 2010)

Source: FAO, Statistics Division (FAOSTAT).

Global exports of coffee, tea, cocoa and spices almost tripled between 2000 and 2010, from US\$29 billion in 2000 to US\$79 billion in 2010. Coffee alone accounted for about a third of this expansion. Germany and Brazil are major players among importers and exporters, respectively. Despite domestic turmoil, Côte d'Ivoire has also re-emerged as a major coffee exporter, with volumes growing by almost 20 percent since 2007.

Increased trade integration has provided consumers with a greater variety of products at lower prices, produced through increasingly complex value chains. However, the distribution of benefits along value chains can be quite uneven. In the case of coffee, for instance, in the 1970s it was estimated that only about 20 percent of the total value of the final product was retained by primary producers, while companies from consuming countries retained about 50 percent. In recent years, this asymmetry has increased: the value share retained by primary producers is thought to have dropped to about 10 percent, while that retained by companies in consuming countries surged to more than 75 percent.

The prospects for developing countries to benefit substantially from international trade depend on several complex factors. Increasing product differentiation, safety requirements and concerns about the carbon footprints of products are likely to bring about significant compliance costs for exporters. For developing countries, access to foreign markets may demand increased investments; and policies for promoting exports will need to look well beyond tariffs and subsidies towards the establishment of standards and producers' networks.

In general, the agricultural trade balance is a poor predictor of economic performance. For some countries, a declining agricultural trade balance is associated with economic development and progress towards more diversification and increased welfare. For example, in the Republic of Korea a growing agricultural deficit has gone hand-in-hand with high growth rates, economic development and increased food consumption. A declining balance can also reflect rapid demand growth, such as in China, where increasing importation of oilseeds and vegetable oils contributed to improved food consumption and was paid for by rapidly growing earnings from exported manufactured products.

On the other hand, a declining agricultural trade balance can also be associated with negative economic and developmental outcomes, such as in countries that depend heavily on shrinking export earnings and are forced to divert scarce foreign exchange to pay for growing food imports bills. In these cases, food imports can contribute to the build-up of unsustainable foreign debts. Even more negative outcomes can be found where increasing food imports are not associated with rising per capita food consumption and improved food security, but are necessary just to sustain minimum levels of food consumption. This is a not an uncommon situation.
