

PART

4

Sustainability dimensions

Agriculture – including crops, livestock, forest, fisheries and aquaculture – is the main human activity responsible for natural resource management at the local and regional levels. Thirty percent of the earth's land is used for crops and pastures, and 70 percent of all abstracted freshwater is directed towards irrigation to produce the food that people and livestock need for a stable food supply. The results of such large-scale utilization of land and water resources are increasingly threatening environments.

Indiscriminate use of fertilizers and other chemicals can lead to significant pollution of air, water and soils, putting at risk pristine terrestrial and marine ecosystems downstream, and human health. For instance, agriculture is the main source of nitrate and ammonia pollution in both ground- and surface water and is a major contributor to phosphate pollution of waterways.

Emissions of greenhouse gases (GHGs) from agriculture, forestry and other land uses contribute significantly to the threat of global warming. The land sectors are responsible for nearly 30 percent of all

human-induced GHG emissions into the atmosphere, a contribution comparable to that of the energy sector and far exceeding total emissions from transportation. Crop and livestock production alone is responsible for half of the methane and two-thirds of the nitrous oxide emitted into the atmosphere by human activity.

Such negative impacts on air, soils and water have, in turn, a negative impact on agricultural production and human well-being. Increased soil salinity, aquifer depletion and land degradation reduce achievable yields, thus putting at risk farmers' ability to bridge production gaps and improve food security. Deforestation and unsustainable forest management lead to ecosystem degradation, with negative repercussions on the overall potential for a wide range of ecosystem services. Waste and nitrogen loads in aquaculture ponds, or genetic pollution of marine resources reduce resilience of the underlying natural systems without which aquaculture and marine resources cannot function.

However, it is increasingly recognized that with proper management, agricultural sectors have crucial positive externalities. In addition to food and fibre, these benefits include the provision of environmental services and amenities through water storage and purification, carbon sequestration and the maintenance of rural landscapes. In this context, research-driven sustainable pathways to agricultural intensification can save vast areas of natural forest and grasslands that would be developed in the absence of higher crop, meat and milk yields.

Both new and traditional demands for produce increase the pressure on scarce agricultural resources. While the agriculture sector will be forced to compete for land and water with expanding urban settlements and industrial zones, it will also be required to meet the growing demands of the emerging bio-based economy, increasingly through bioenergy and new emerging markets for renewable and sustainable industrial products.

Although agriculture will continue to be a major user of land and water, it will need to seek new ways of maintaining these resources to stay viable, and to minimize negative impacts on ecosystems and human well-being. Ensuring adequate food and water for all while achieving sustainable rural development hinges on renewed stewardship for the responsible management of natural resources, and therefore on a fully sustainable agriculture system.

Key Resources

The State of the World's Forests (SOFO)

The State of the World's Forests reports on the status of forests, recent major policy and institutional developments and key issues concerning the forest sector. It makes current, reliable and policy-relevant information widely available to facilitate informed discussion and decision-making with regard to the world's forests.

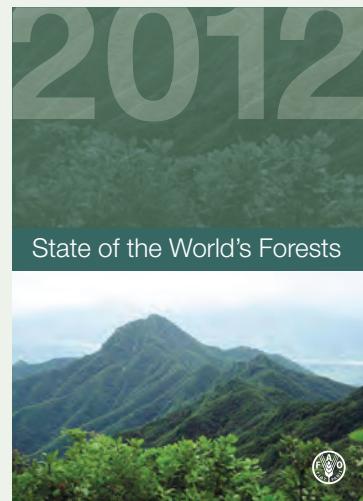

2012: The role of forests in human history

2011: Changing pathways, changing lives: forests as multiple pathways to sustainable development

2009: Society, forests and forestry: adapting for the future

Publication cycle: Biennial

Webpage: www.fao.org/forestry/sofo/en/

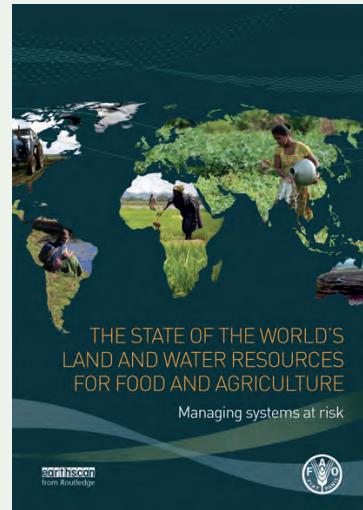

The State of the World's Land and Water Resources for Food and Agriculture (SOLAW)

The State of the World's Land and Water Resources for Food and Agriculture analyses a variety of options for overcoming constraints and improving resource management in these areas of heightened risk. By 2050, food production is projected to increase by about 70 percent globally and nearly 100 percent in developing countries. This incremental demand for food, together with demand from other competing uses, will place unprecedented pressure on many agricultural production systems across the world. These "systems at risk" are facing growing competition for land and water resources and they are often constrained by unsustainable agricultural practices. They therefore require particular attention and specific remedial action.

2011: Managing systems at risk

Webpage: www.fao.org/nr/solaw/en/

Land and Forestry

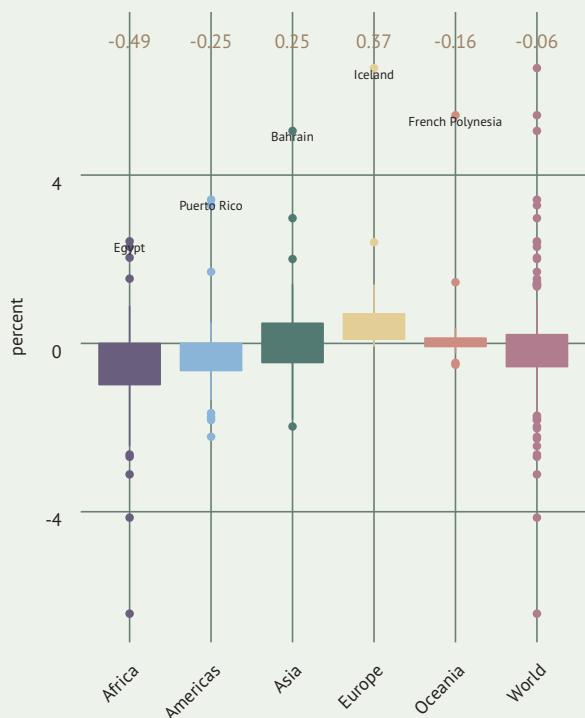

Forests play an essential role in mitigating climate change and providing products and ecosystem services that are essential to the prosperity of humankind. The latest estimate of the world's total forest area is more than 4 billion ha, corresponding to about 30 percent of total land area or an average of 0.6 ha per capita of human population. The five most forest-rich countries – the Russian Federation, Brazil, Canada, the United States of America and China – account for more than half of the planet's total forest area. Ten countries or areas have no forest at all, and an additional 54 have forest on less than 10 percent of their total land area.

Changes in land cover have caused the most pressing environmental issue in recent decades. Deforestation and land-use intensification, especially their impact on soil degradation, are at the heart of the issue. However, in much of the world, the current picture of land-cover change shows a continuing slowdown in the conversion of forests to areas for crop or livestock production and a steady growth of protected areas. At the global level, deforestation has decreased from an estimated 16 million ha per year in the 1990s to about 13 million ha per year in the last decade.

At the same time, afforestation and natural expansion of forests in some countries and areas have significantly reduced the net loss of forest area at the global level. The net change in forest area over the period 2000–2009 was estimated at -5.2 million ha per year, down by 35 percent per year in the prior decade. However, most of the loss of forest continued to take place in countries and areas in tropical regions, while most of the gain took place in temperate and boreal zones.

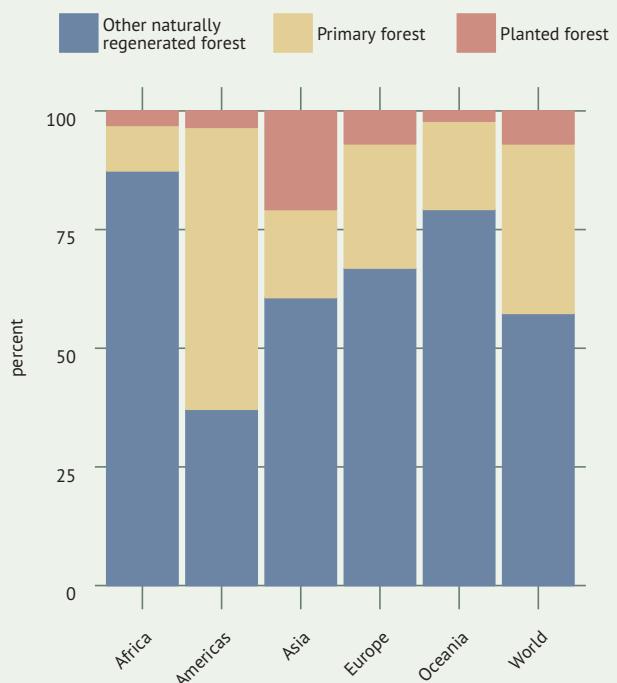

Forests, other wooded land and trees outside of forests can have important economic and social uses at the national level and/or for forest-dependent communities. Proper management of these resources is essential, to ensure that production and harvesting do not compromise these valuable options for future generations and the overall sustainability of forests over time. Good management includes monitoring removals of wood and non-wood forest products, designating forest areas for production and forest planting, and supporting afforestation and reforestation. The charts in this section highlight some of these trends towards sustainable forest management.

CHART 91: Annual growth rate in forest area
(1990-2009)

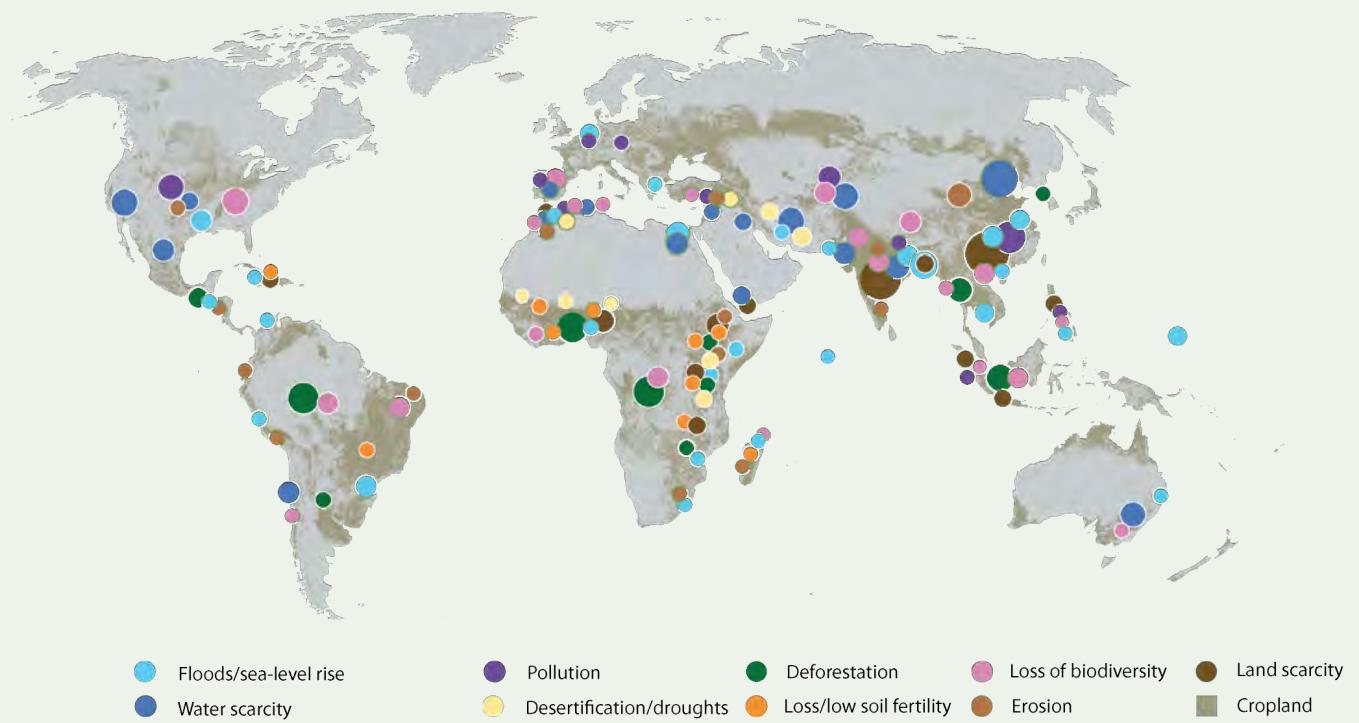

Source: FAO, Statistics Division (FAOSTAT).

CHART 92: Forest characteristics (2010)

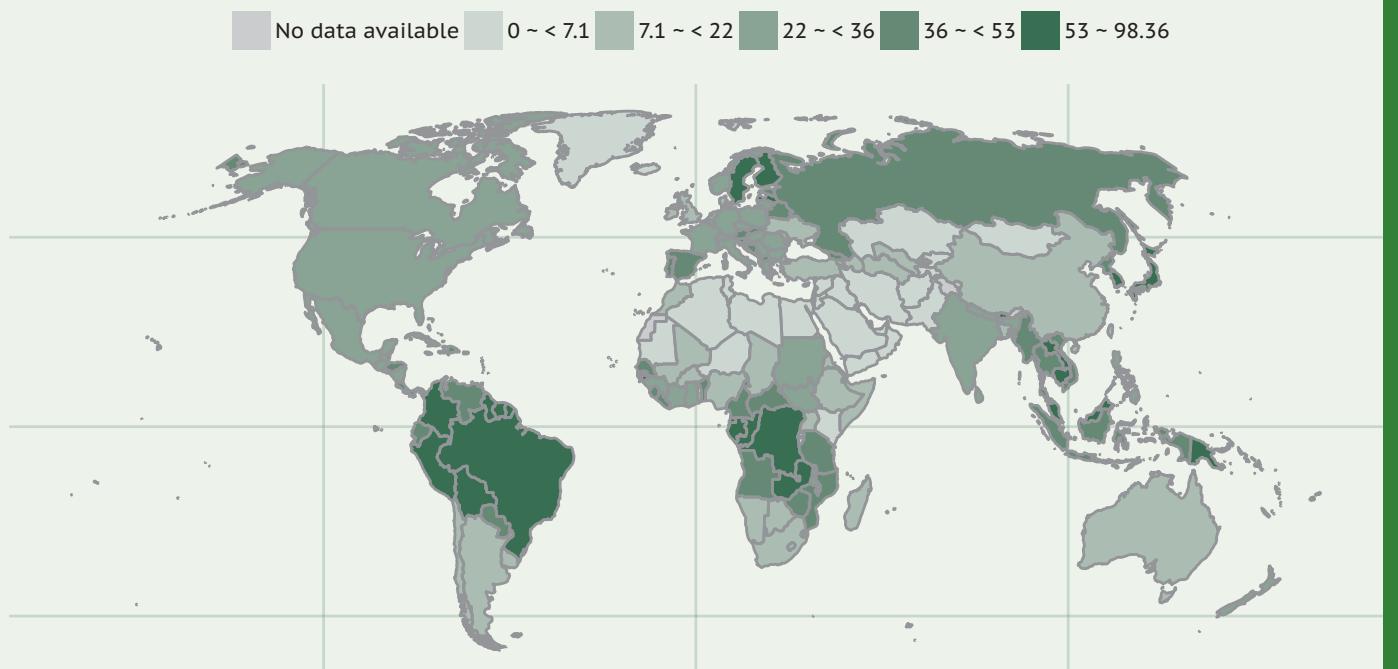

Source: FAO, Forestry Department.

MAP 54: Global distribution of risks associated with main agricultural production systems

Source: FAO, Land and Water Division.

MAP 55: Forest area as share of total land area (percent, 2009)

Source: FAO, Statistics Division (FAOSTAT).

On average, global production of the main forest products was between 1 and 4 percent higher in 2011 than in 2010. This shows that countries are slowly coming out of recession. For example, production of wood-based panels and paper in 2011 was above the pre-crisis levels of 2007 and appeared to be growing relatively strongly in most regions. On the other hand, global production of industrial roundwood – despite a 3 percent increase from 2010 – has not yet reached its pre-crisis levels.

In the markets for pulp and paper, overall growth was very modest over the period 2007–2011, with a growth trend of about 1 percent per year. However, this overall result conceals major differences at the regional level, with pulp and paper production and consumption increasing significantly in the Asia and the Pacific region, but generally declining in Europe and Northern America.

China is increasing its importance as a producer of forest products, becoming the world's second largest producer of sawnwood. The United States of America is the largest, with Canada in third place. China has also increased its lead over all other countries as a producer of wood-based panels, paper and paperboard. In 2011, China produced 11 percent of the world's sawnwood, 38 percent of panels and 26 percent of paper.

As the largest importer of industrial roundwood, sawnwood, pulp and wastepaper, and the largest exporter of wood-based panels, China also plays a key role in international trade in forest products. It is the fifth largest importer of paper and paperboard, despite a huge increase in domestic production since 2007. In 2011, China's imports of all forest products amounted to US\$43 billion, accounting for 16 percent of the global total.

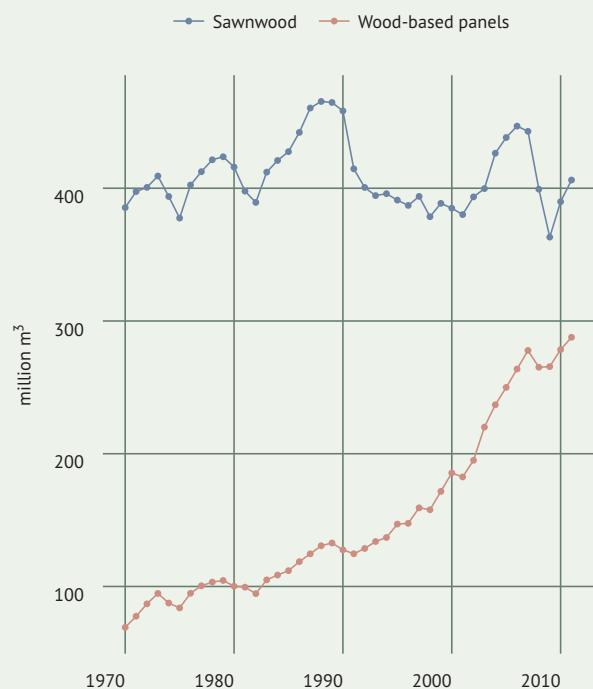

The structure of production and trade in the Russian Federation, the country with the most forest cover in the world, also changed between 2007 and 2011, with industrial roundwood exports declining by 29 million m³ – or nearly 60 percent – and sawnwood production increasing by 3 million m³ (8 percent). Over the same period, the Russian Federation increased its sawnwood exports by 13 percent.

A high proportion of Russian industrial roundwood exports previously went to China. This share fell between 2007 and 2009 because of log export restrictions in the Russian Federation. Nevertheless, Chinese imports of industrial roundwood have recovered, and several other major producing countries, including the United States of America, Canada and New Zealand, have expanded their exports to China.

Water

A very small proportion of the planet's water is available for human use. Of the 2.5 percent of the world's water that is freshwater, more than two-thirds is locked in glaciers, ice caps and permafrost, about one-third is groundwater. The remaining 1.3 percent of the world's total freshwater is surface water in rivers, lakes and swamps and in other forms such as ice and snow.

Global demand for water has risen sharply over the last century. Total annual water withdrawal (for agriculture, industries and municipalities) rose from less than 600 km³/year at the beginning of the twentieth century, to 1 350 km³/year in the middle of the century and more than 3 800 km³/year by the beginning of the twenty-first.

Precipitation provides some of the water needed by crops to satisfy their transpiration requirements. The soil, acting as a buffer, stores part of precipitation water as soil moisture, returning it to the crops in times of deficit. In humid climates, this mechanism is usually sufficient to ensure satisfactory growth in rainfed agriculture. In arid climates or during the dry season, irrigation is required to compensate for the deficit resulting from insufficient or erratic precipitation.

Today, irrigated agriculture accounts for about 70 percent of freshwater withdrawals throughout the world. Irrigation has been crucial for gains in food production. It reduces drought risk and encourages crop diversification, thus enhancing rural incomes.

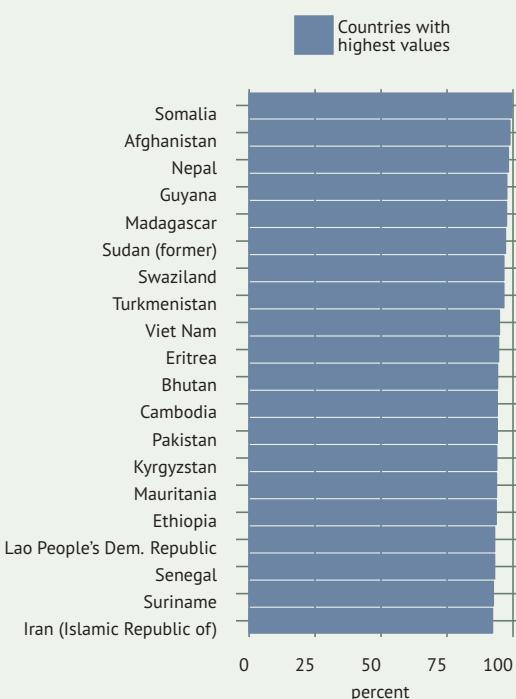

Increasing water productivity is therefore critical in many countries. It is also more generally necessary, to prevent the overextraction of groundwater, increase the infiltration of rainwater into soils, and reduce the deterioration of water quality owing to waterlogging and salinization. Some of these negative phenomena are fuelled by agricultural intensification, which affects water availability through increased contamination of ground- and surface water from fertilizers, pesticides and animal wastes.

Irrigation mismanagement can also contribute to waterlogging and salinization. Waterlogged soil results from overirrigation and inadequate drainage. It restricts plant growth and often precedes salinization. Generally, salinization results from the build-up of dissolved solids in soils, and can also occur in rainfed areas with inherently susceptible soils. Climate change makes solving these problems even more urgent. Appropriate measures can be implemented to limit the overextraction, waterlogging and salinization that can lead to considerable losses of irrigated land and result in unsustainably high operating costs.

Biodiversity

Biodiversity concerns the degree of variation of life forms within a given ecosystem and serves as a measure of the health of the environment. Biodiversity for food and agriculture includes the components of biological diversity that are essential for feeding human populations and improving the quality of life. It applies to the genetic, species and ecosystem levels and includes the variety and variability of ecosystems, animals, plants and microorganisms that are necessary to sustain human life and the key functions of ecosystems. It is the result of thousands of years of farming and breeding activities, land and forest utilization, and fisheries and aquaculture activities, combined with millions of years of natural selection.

Different varieties of the same species have statistically different nutrient contents. The nutrient content measured at the subspecies level should therefore be among the criteria used to decide which cultivars to promote to decrease micronutrient deficiencies.

Much of the human population lives in areas where food production and nature coexist. Agriculture's main impacts on biodiversity are varied. For instance, the expansion of agriculture can lead to losses of natural wildlife habitat and a reduction in the area of natural forests and wetlands, resulting in an attendant loss of species. It can also cause a general decline in the species richness of forests, pastures and field margins, and the reduction of wild genetic resources related to domesticated crops and livestock.

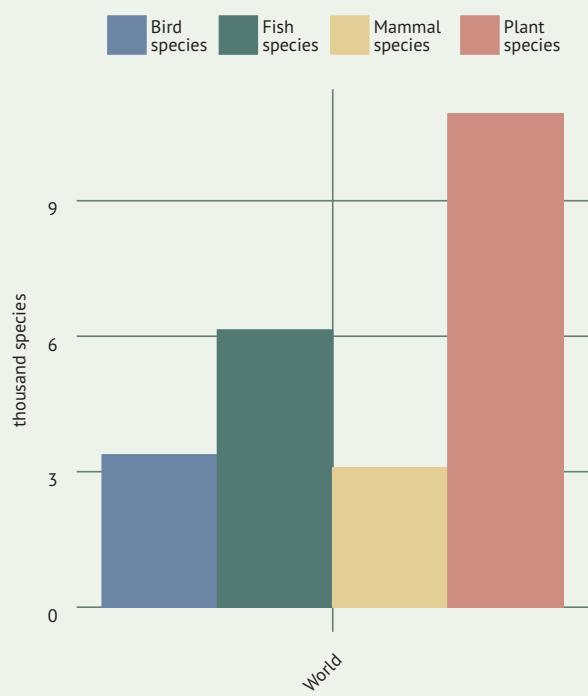

The intensification of agricultural production is putting biodiversity at risk. The conservation and sustainable use of biodiversity for food and agriculture play a critical role in the fight against hunger by ensuring environmental sustainability while increasing food and agriculture production. It is imperative to harvest resources sustainably, without compromising the natural capital – including biodiversity and ecosystem services – while capitalizing on biological processes.

To achieve sustainable increases in productivity, and provide a sounder ecological basis for agriculture, a large reservoir of genetic and species diversity needs to be maintained and sustainably used. Many traditional livestock farmers use herds or flocks of several species and breeds as a strategy for maintaining high diversity. Species combinations also enhance productivity in aquatic systems. Crop rotations, intercropping, alley farming and the use of several varieties of a single crop have all been shown to have beneficial effects on crop performance, nutrient availability, pest and disease control and water management. Ensuring diversity will help maintain and rehabilitate productive ecosystems, to supply future generations with abundant food and agriculture. Continuing to expand protected areas will also play a major role.

Agri-environmental indicators

Agricultural production systems require stewardship of their underlying ecosystems and respect of the natural resource boundaries within which they operate. In recent decades, however, increasing population and socio-economic pressures on the land, water and genetic resources that underpin the provision of food and other valuable environmental services are cause for concern, given that food production should roughly double by 2050 to satisfy the projected global population of 9 billion people. Agriculture already uses two-thirds of the freshwater resources withdrawn for human use, with irrigated crops providing about 40 percent of the total cereal harvest. Additional land suitable for good production is scarce, while the pressure to produce more food on marginal areas can lead to degradation and poverty.

Agri-environmental indicators are quantitative tools that help assess and quantify the status of and trends in the environmental performance of agriculture, facilitating the identification of effective management solutions and policy measures for avoiding potential damage, including soil and water degradation, air pollution and loss of biodiversity.

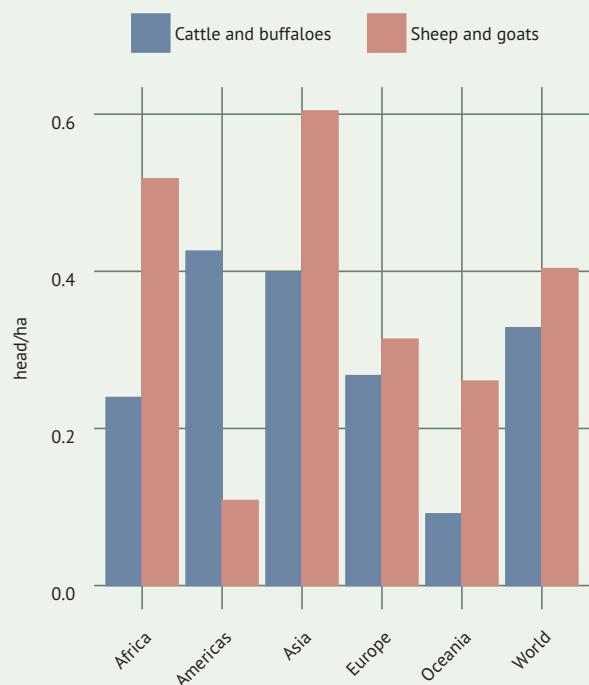

Most of the data presented in this section are from a selection of core indicators originally developed by OECD and Eurostat for their member countries, and recently expanded by FAO to achieve global coverage. They highlight critical trends that can help identify solutions for more sustainable production systems. In general, the indicators show different trends between developing and developed countries; for example, the agricultural area is decreasing in most developed countries but expanding in several developing ones. Increasing livestock density per hectare and growth in bio-fuels production can also be used to quantify the pressure that agriculture exerts on natural resources.

The indicators show considerable expansion of irrigated agricultural areas over the last decade, especially in developing countries, with the agriculture sector using the most water in most regions. Fertilizer consumption is increasing worldwide, although use is much lower in Africa than in other regions. Positive trends are also apparent; for instance, the share of area protected for environmental reasons has increased considerably in several countries over the last 20 years. The incidence of organic agriculture has also increased constantly; although its contribution remains small in developing countries, organic agriculture currently represents an important share in several developed countries.

Organic farming

Organic agriculture is a production management system that aims to promote and enhance ecosystem health, including biological cycles and the biological activity of soil. It is based on minimizing the use of external inputs, and represents a deliberate attempt to make the best use of local natural resources. Methods are selected to minimize pollution of air, soil and water. Organic agriculture comprises a range of land, plant and animal management procedures, circumscribed by a set of rules and limits that are usually enforced by inspection and certification schemes. Synthetic pesticides, mineral fertilizers, synthetic preservatives, pharmaceuticals, genetically modified organisms (GMOs), sewage sludge and irradiation are prohibited in all organic standards.

The land area under organic management has been steadily increasing worldwide for several decades, reaching 37.2 million ha in 2011, up from 11 million ha in 1999. An additional 32.5 million ha is certified as non-agriculture organic areas, mainly for the collection of wild products and beekeeping. Today, 1.8 million producers in 162 countries produce organic products, including crops, livestock, fish and wild-harvested products. Most production in developing countries is export-oriented, providing new income opportunities for smallholders.

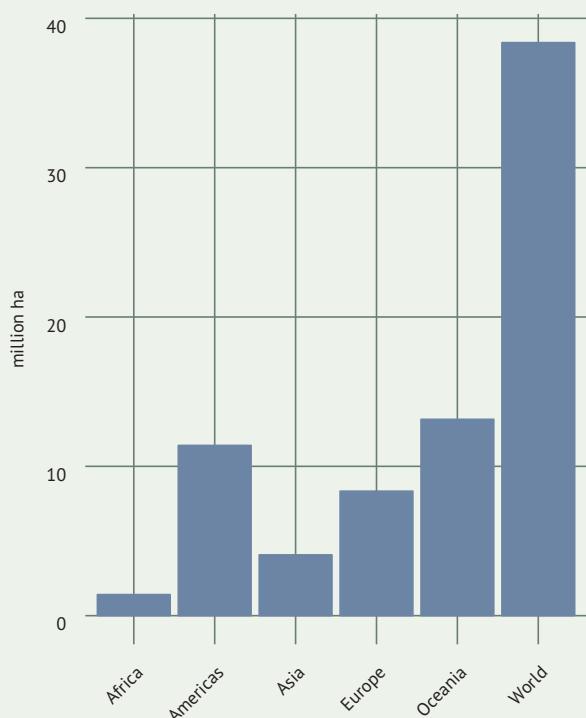

The total value of organic food and beverages sold in 2011 was almost US\$63 billion, some US\$4 billion higher than in 2010. The organic market has grown considerably since 2002, and – unlike the rest of the food sector – has continued to grow, despite the global economic slowdown. Although Northern America and Europe account for 90 percent of organic sales, organic markets are also expanding in developing countries, particularly in Asia.

Several countries have action plans for developing organic agriculture, and 86 currently have organic regulations. Countries set targets for the sector's growth, allocating resources to compensate farmers during, and sometimes after, the conversion period. At the international level, the general principles and requirements for organic food are defined by the Codex Alimentarius Commission. The Plant Production Guidelines were adopted in 1999, and the Animal Production Guidelines in 2011. Since 2005, the list of restricted substances has been regularly updated. Codex is currently expanding to include organic aquaculture and seaweed production. The growing interest in organic crop, livestock, forest and fish products is mainly driven by health and food-quality concerns, although the primary aim of organic production is to ensure that food production and processing methods respect the environment.

Bio-based economy

Agriculture is playing an increasingly important role in the bio-based economy, providing feedstocks for the production of liquid fuels, chemicals and advanced materials, such as natural fibre composites for industry. The emergence of green industries provides new opportunities for the rural sector, beyond traditional forestry and the supply of wood. Biological science has the potential both to make incremental efficiency improvements and to bring radical change in a wide range of sectors, including through the use of enzymes, fermentation and organisms for processes and products in the energy, chemical, pharmaceutical, food, textile, and pulp and paper industries.

The application of biological and material science to agriculture has the greatest potential in the energy, natural fibre composite and starch sectors. Much of this potential is already being realized, especially through the rapid growth of the biofuel sector. Currently, ethanol is produced from easily fermentable agricultural feedstocks such as sugar cane, sugar beet, cereal grains and cassava. Biodiesel is produced from vegetable oil (typically rapeseed, soybean and palm oils) using a process of chemical modification.

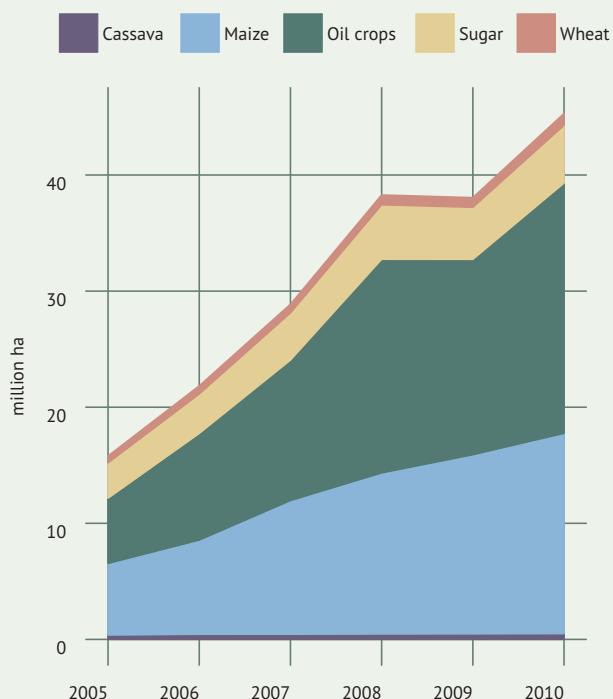

The emerging bio-based economy centres on energy efficiency, renewable feedstocks for polymer products, industrial processes that reduce carbon emissions, and recyclable materials. Natural fibres exemplify these attributes. For example, growing 1 tonne of jute fibre requires less than 10 percent of the energy used in the production of competing polypropylene.

The sustainability of a rapidly growing bio-based agricultural economy, especially one that relies on liquid fuels, has generated the “food-versus-fuel” debate. The links between bio-industries and food security are complex and multifaceted. Ensuring the sustainable development of biosectors becomes challenging when efforts are made to capture the potential benefits for development. For instance, the rapid growth and sheer scale of the biofuel sector has potentially negative implications for all four dimensions of food security – availability, access, stability and utilization – as it may increase the competition for land and water resources. However, it may also create new opportunities for employment, income generation and investment in production technologies, especially in countries with abundant marginal land and climates conducive to feedstock production where such land would be too costly to bring into food cultivation.

Climate change

The severity and pace of climate change in the twenty-first century is presenting an unprecedented challenge. Current global surface temperatures are now about 0.6°C higher than the average for the last century. This increase is consistent with model predictions of the effects of rising atmospheric concentrations of carbon dioxide (CO_2) and other GHGs, which are a result of human activity. Also in line with the same model simulations, the observed warming is greater at higher latitudes – particularly in the northern hemisphere, where most land masses are located – than in the tropics. At the same time, extreme temperature events are becoming more frequent, causing increasing damage to ecosystems, agriculture and human health.

Such worrisome trends will intensify in this century if emissions of anthropogenic GHGs continue to follow a business-as-usual scenario, with global atmospheric surface temperatures predicted to rise by at least 4°C by 2100. Moreover, the hydrological cycle will strengthen because of increased rates of evaporation from land and sea surfaces. As a result, rainfall may increase in the tropics and at higher latitudes, while decreasing over large continental interiors, with critically water-scarce areas of the world expected to become drier and hotter. More frequent climate extremes will increase the incidence and intensity of droughts and flood events worldwide. Finally, a sea-level rise will put millions of people at risk, presenting a significant challenge for rural, low-lying areas in many poor developing countries.

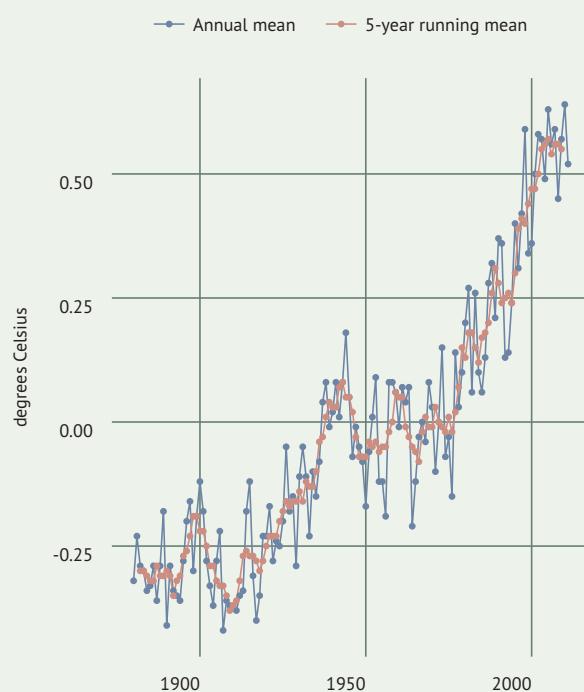

The future availability of water to match crops' water requirements will be particularly critical for agricultural production in arid and semi-arid regions, and in the southern, drier parts of Europe and Northern America. Runoff and groundwater recharge are both likely to decline dramatically in these areas. An excess of water may become a problem in specific areas. Where rainfall volume increases and becomes more intense, and where significant glacier melting alters water storage dynamics, a greater proportion of runoff may occur as flood flow. In particular, the expected loss of glaciers will have large impacts on some river systems, changing the availability of surface water for irrigation and the amount of groundwater recharge.

The poorest and most food-insecure regions around the globe will be the most vulnerable under climate change: first, already scarce land and water resources will likely become even more scarce; and second, insufficient technical and financial means will make adaptation to the new climate very difficult.

Greenhouse gas emissions

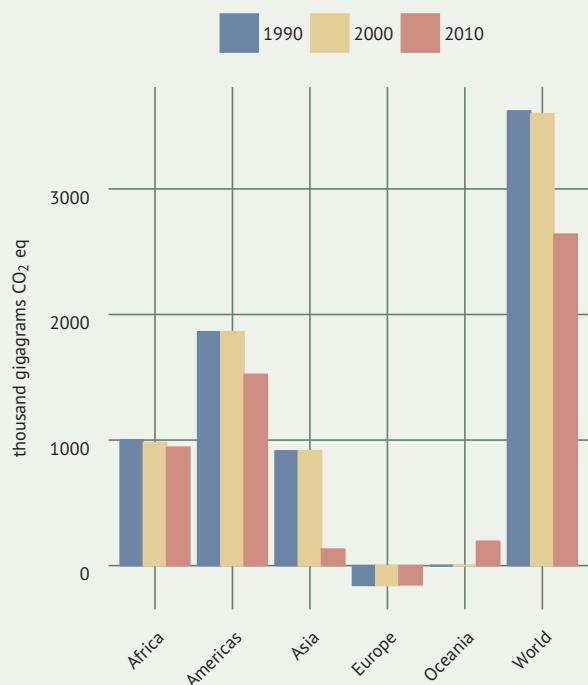

GHG emissions from agriculture, including crop and livestock production, forestry and associated land-use changes, are responsible for a significant fraction of human-induced emissions – up to 30 percent globally, according to the Intergovernmental Panel on Climate Change (IPCC). GHG emissions presented in this section are available from the newly launched FAOSTAT Emissions database.

GHG emissions from agriculture are dominated by non-CO₂ gases such as methane (CH₄) and nitrous oxide (N₂O), arising from crop and livestock production and management. These include emissions from the following categories: enteric fermentation, manure management systems, synthetic fertilizers, manure applied to soils, manure left on pastures, crop residues, rice cultivation, cultivated organic soils, and burning of crop residues. These emissions have increased by an average of 1.6 percent per year since 1990. Adding savannah burning and degraded organic soils under pasture, which are not currently available in FAOSTAT, total agricultural emissions in 2010 were estimated at 5 to 6 Gt CO₂/year.

In particular, emissions from the cultivation of organic soils are receiving increased attention because of their importance in terms of absolute carbon stock changes when peat lands are drained and degraded, thus becoming a significant source of GHG emissions (CO₂ and N₂O).

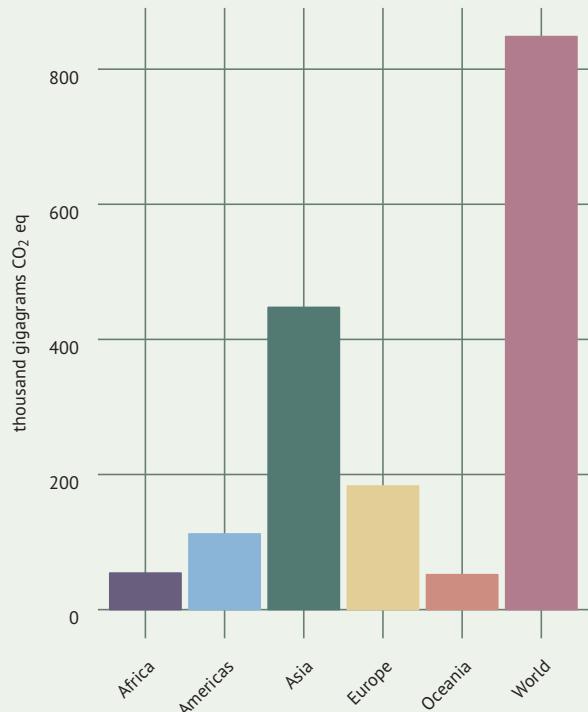

More in general, changes in carbon stocks and ecosystem functions linked to human activities such as land-use change and land management determine the GHG emissions and removals that are reported by countries for IPCC's Land Use, Land-Use Change and Forestry (LULUCF) categories. Activities that increase terrestrial carbon stocks over time lead to removal of CO₂ from the atmosphere, while activities that decrease total carbon stocks lead to net CO₂ and non-CO₂ emissions. Global GHG emissions from net forest conversion decreased from 3.6 Gt CO₂/year to 2.6 Gt CO₂/year during the period 1990–2010.
