

An introduction to soil spectroscopy

Bo Stenberg

Soil and Environment
Swedish university of Agricultural Sciences

Soil Visible and near infrared (vis-NIR) Spectroscopy

Vis-NIR spectroscopy

Frequency 28 000 – 4 000 cm^{-1}

Source for confusion:
NIR: 780-1000 nm
SWIR: 1000-2500 nm

Advantages with Vis-NIR

- + Rapid analysis in real-time
- + Minimum sample preparation
- + Non-destructive, Non-invasive
- + Flexible
- + Several parameters can be analyzed simultaneously
- + Rugged instruments for field analyses can be built

Visible and near infrared spectroscopy (vis-NIR)

- Absorption at different wavelengths hold information on the chemical composition of the material.
- In the visible region absorption is due to excitation of electrons.

- With longer wavelengths, the absorptions is due to vibrations in chemical bonds within molecules, with the primary absorption in the MIR and overtones and combinations in the NIR region.

Example for liquid H₂O

Absorption	Frequency	Wavelength
Fundamentals	ν_1, ν_2, ν_3	$\lambda_1, \lambda_2, \lambda_3$
1 st Overtone	$2\nu_1, 2\nu_2, 2\nu_3$	$\frac{1}{2}\lambda_1, \frac{1}{2}\lambda_2, \frac{1}{2}\lambda_3$
Combinations	$\nu_1 + \nu_2$ or $\nu_2 + \nu_3$	$1/(1/\lambda_1 + 1/\lambda_2)$ or $1/(1/\lambda_2 + 1/\lambda_3)$

	Fundamental	1 st Overtone	Combinations
	(λ nm)	(λ nm)	(λ nm)
ν_1	3050	1525	2031 ($\nu_1 + \nu_2$)
ν_2	6080	3040	
ν_3	2870	1435	1950 ($\nu_2 + \nu_3$)

What kind of information can be found in the vis-NIR?

- **Strong absorption by water (1400 & 1900 nm)**
- **Absorbption by vibrations of molecular bonds (C-H, O-H, N-H and C=O), Combination bands and overtones from longer wavelengths**

Successfully used for numerous applications:

- **Agriculture – Forage and grain quality, soil mapping...**
- **Food industry – Process and quality control...**
- **Pharmaceutical industry – Process and quality control...**
- **Medicine – Blood status, body fat...**
- **Petrochemical industry – quality, polymers, plastics...**
- **Etc.**

Pioneers for a wider use

William Herschel discovered NIR radiation in 1800

Karl Norris at USDA chose NIR for fast, quantitative determination of moisture, protein and oil in wheat in the 1950s. “Father of modern NIR spectroscopy”

He applied MLR for calibration in a publication in 1968 – the multivariate approach.

Phil Williams converted protein testing for Canada’s export wheat to NIRS on the first commercial instrument (Dickey-John) in 1975-1976. Spread the technology over the world.

John S. Shenk installed in 1978 a portable instrument in a mobile van that brought the technology to the farm, hay-markets, etc. Former of ISI software

Soil – complex and diverse

- Two main constituents – a mineral and an organic fraction
- Mixture of numerous minerals at different particle sizes
- Humus and residues at different degree of degradation and origin
- Structure

Main factors influencing soil spectra

Water

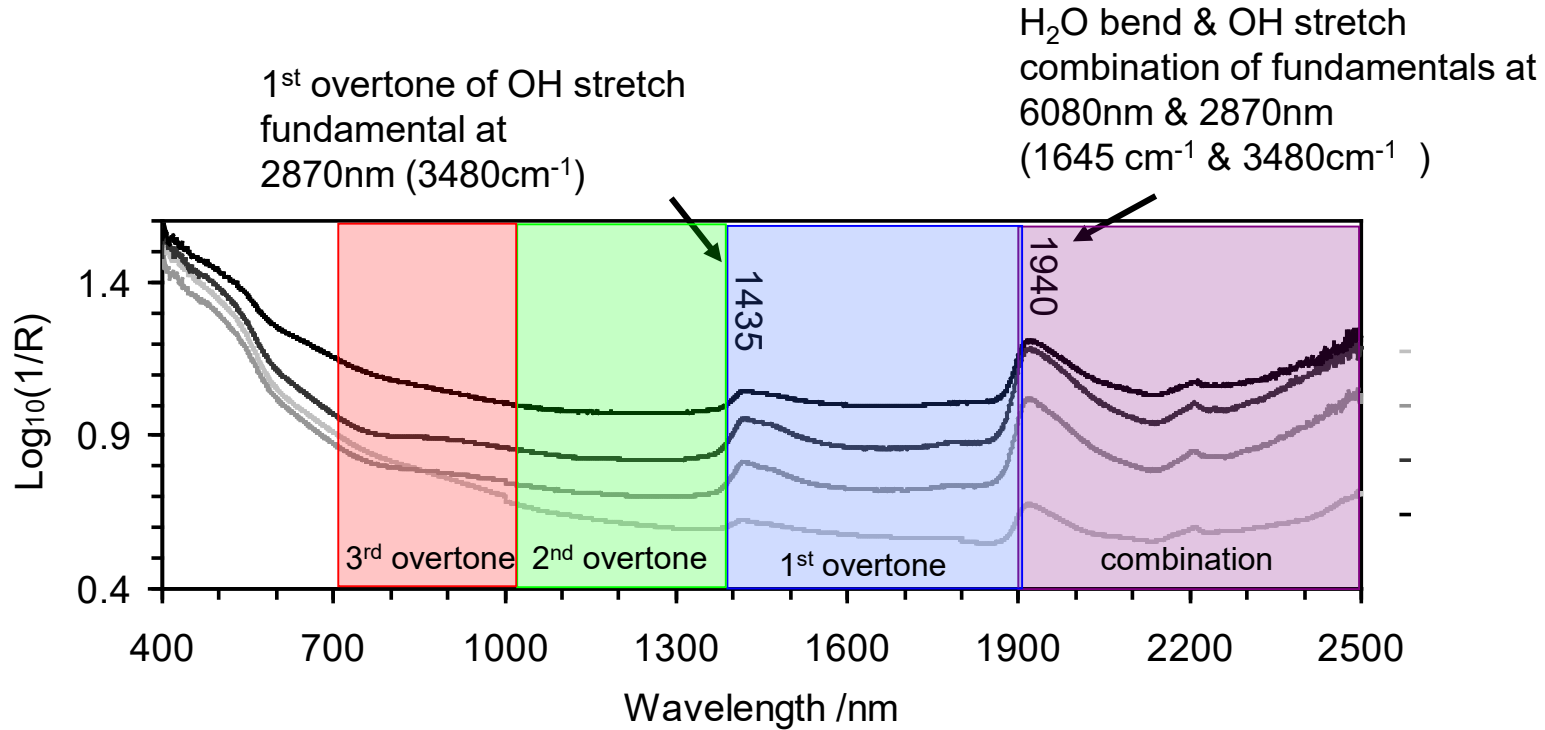

Clay minerals

Organic matter

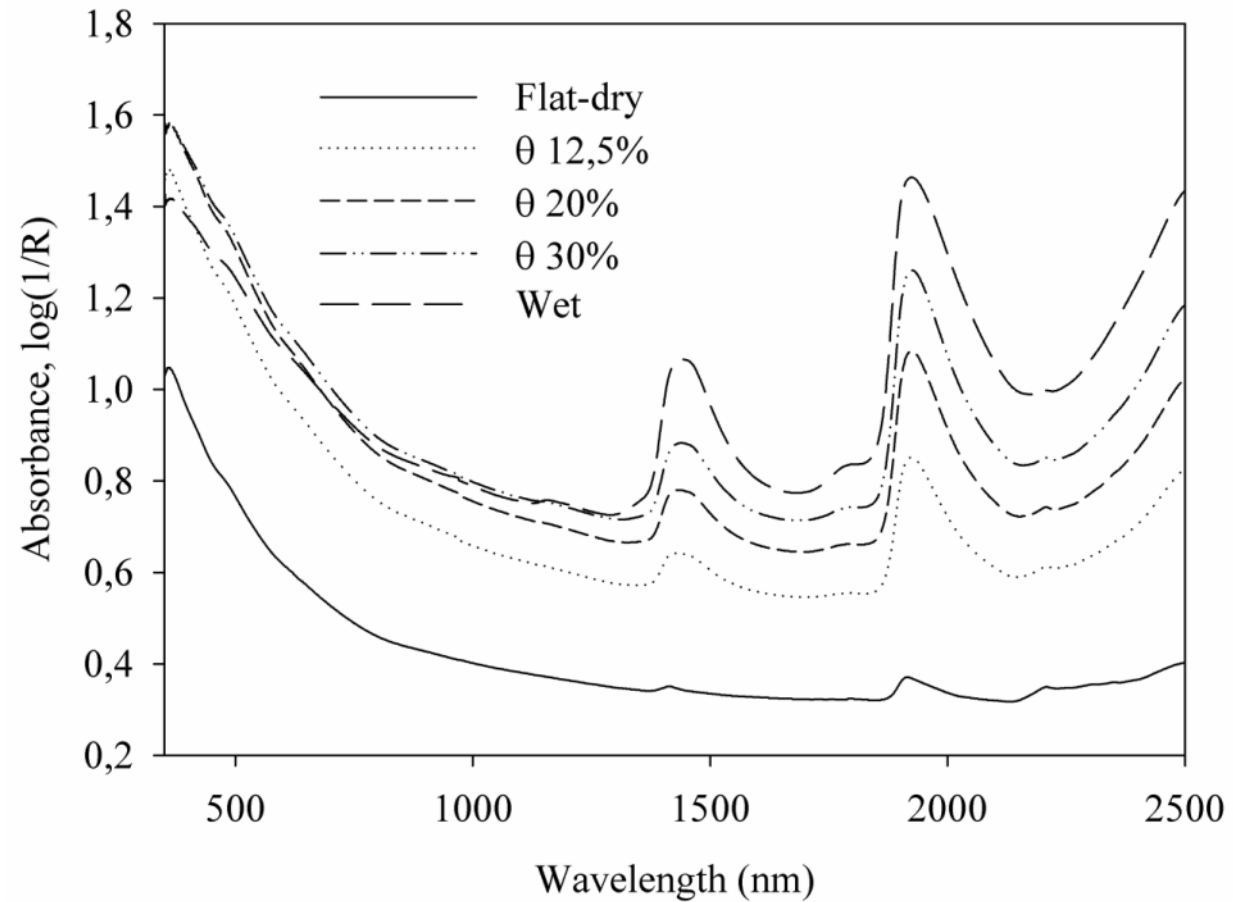

Structure

Main soil spectral features (Water)

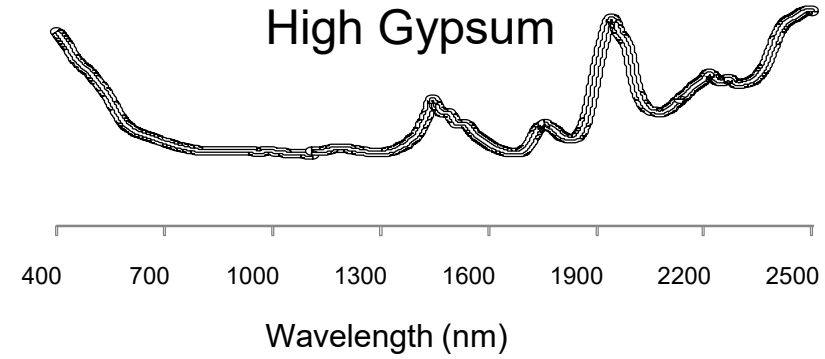

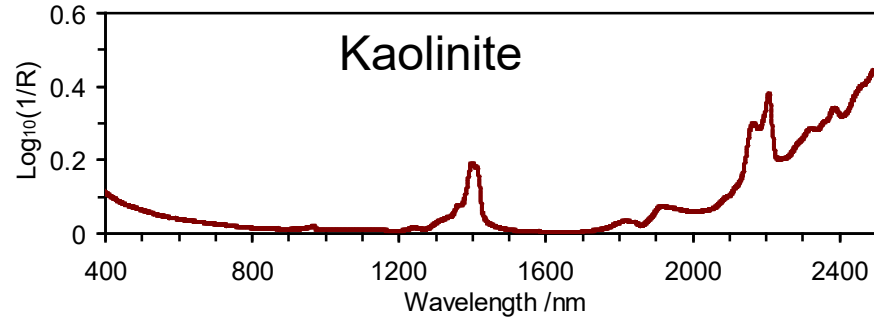

General influence of water on spectra

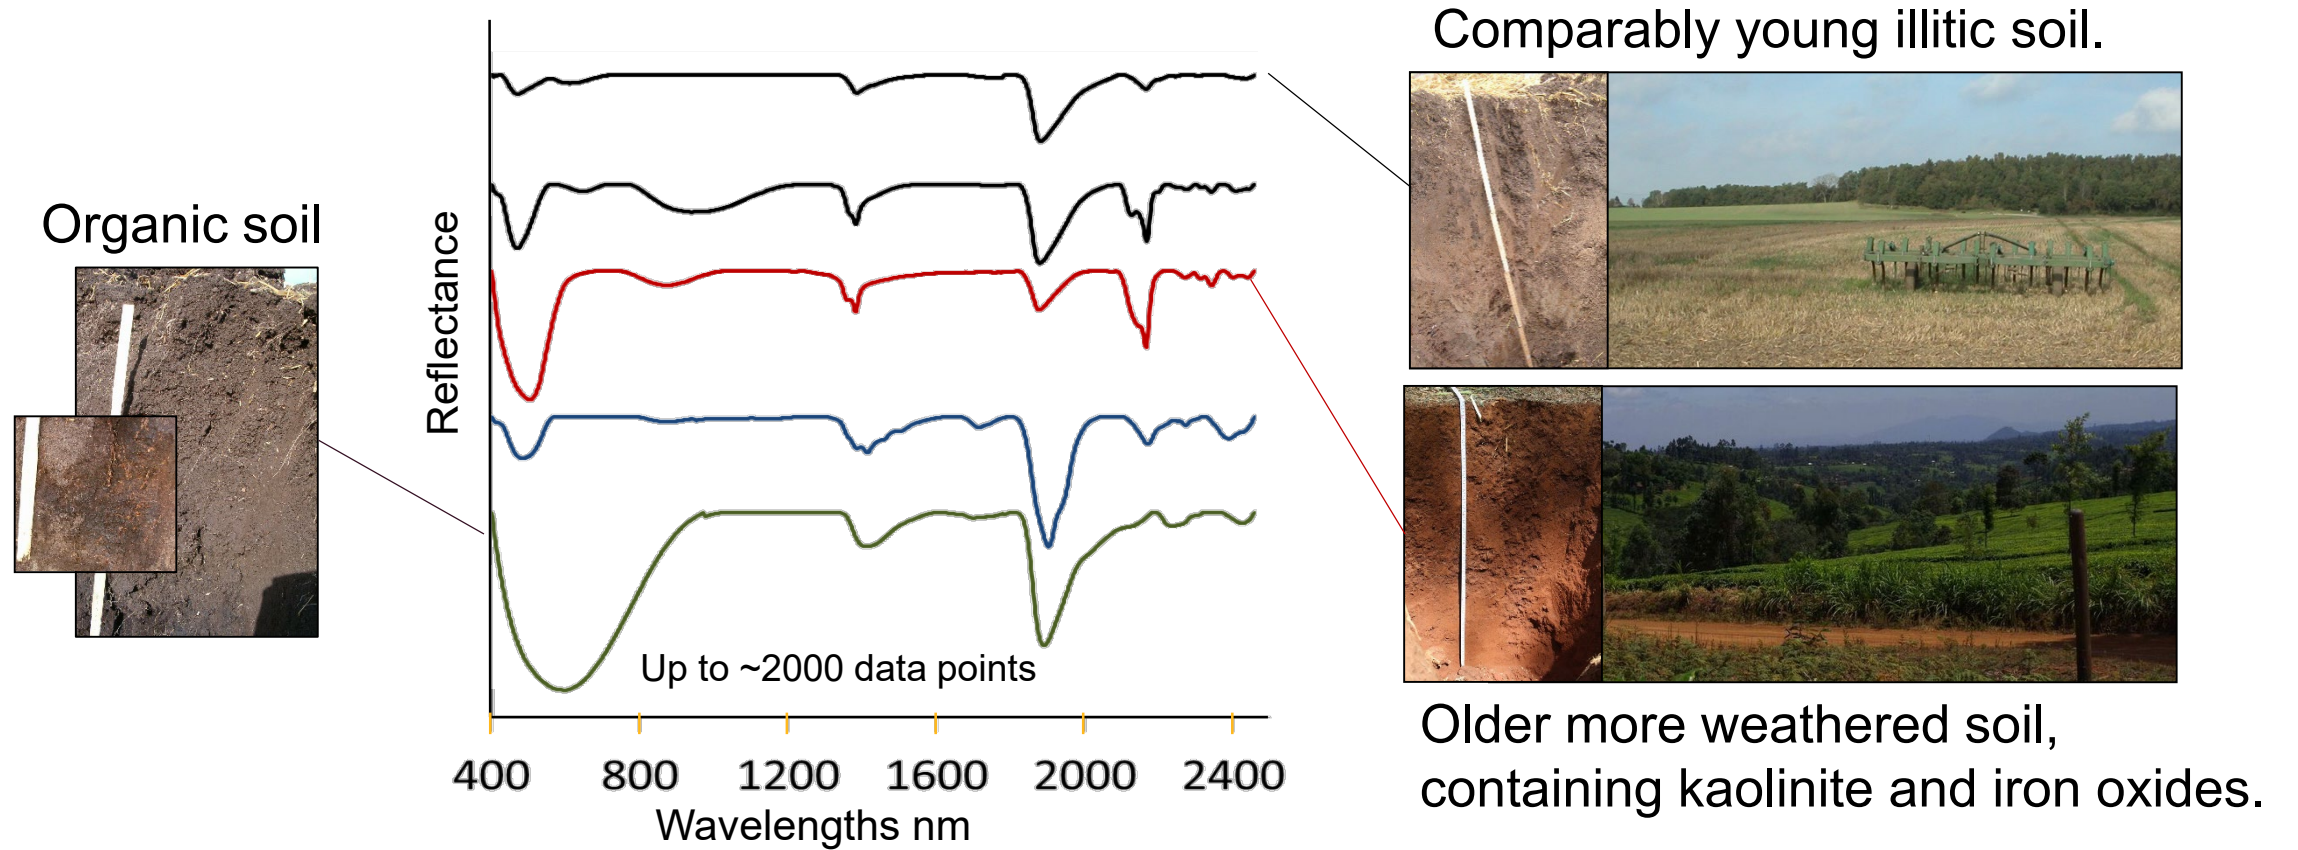

Clay fraction

- **Size fraction <math><0.002\text{ mm}</math> (**
- Secondary, layered clay minerals (illite, smectite, kaolinite, etc.)
- Primary minerals (quartz, feldspars, etc.)
- Carbonates
- Sesquioxides or metal oxides (gibbsite, goethite, hematite)

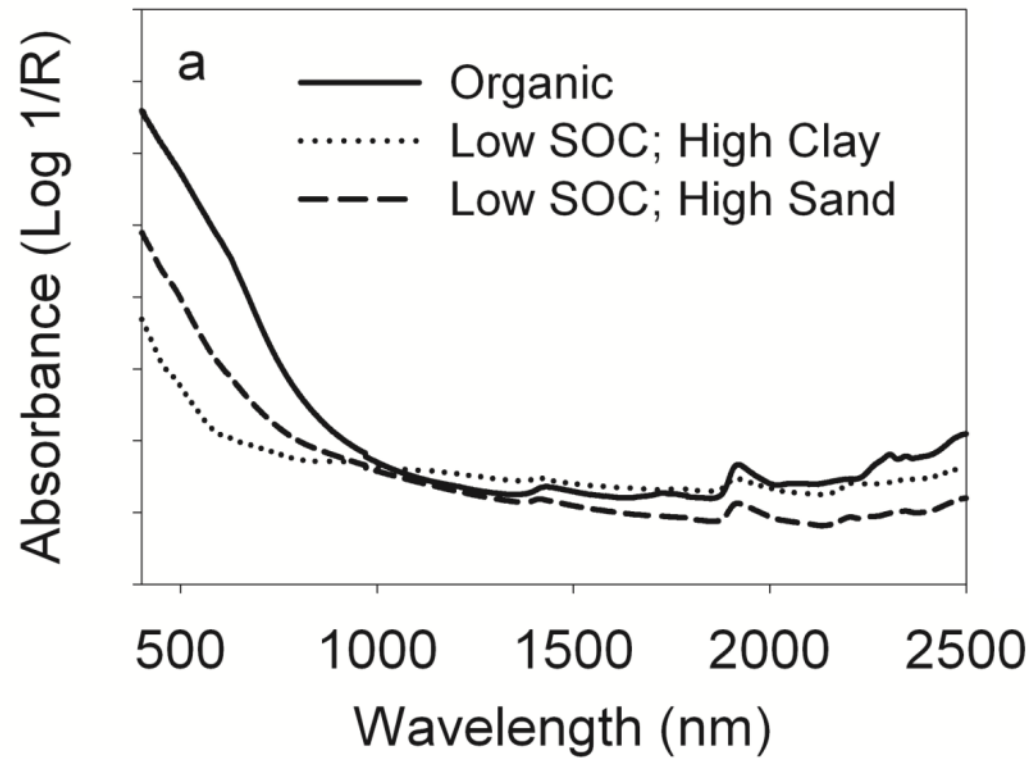

Vis-NIR clay mineral fingerprints

Natural soils – a mixture of everything

Effect of organic matter on soil spectra

Interaction between texture and SOM

100% Sand

0% Sand (~40% clay)

~0.5% SOC

~2% SOC

0% SOC

0% SOC

Common absorption bands of organic matter in soil

Alkyl fundamental at 3413 and 3509 nm in Mid-IR

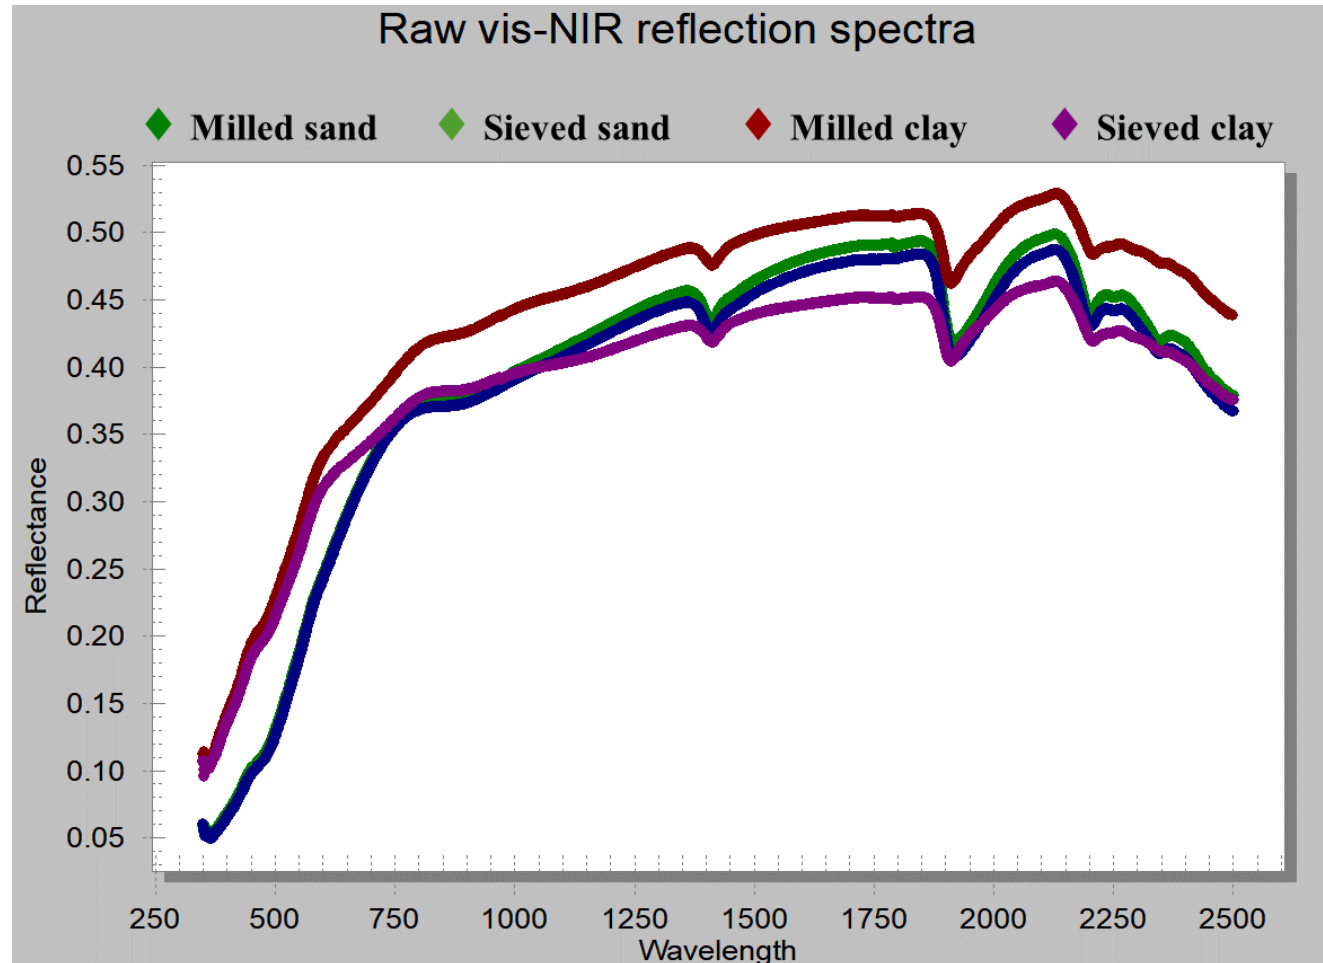

Example of alkyl groups

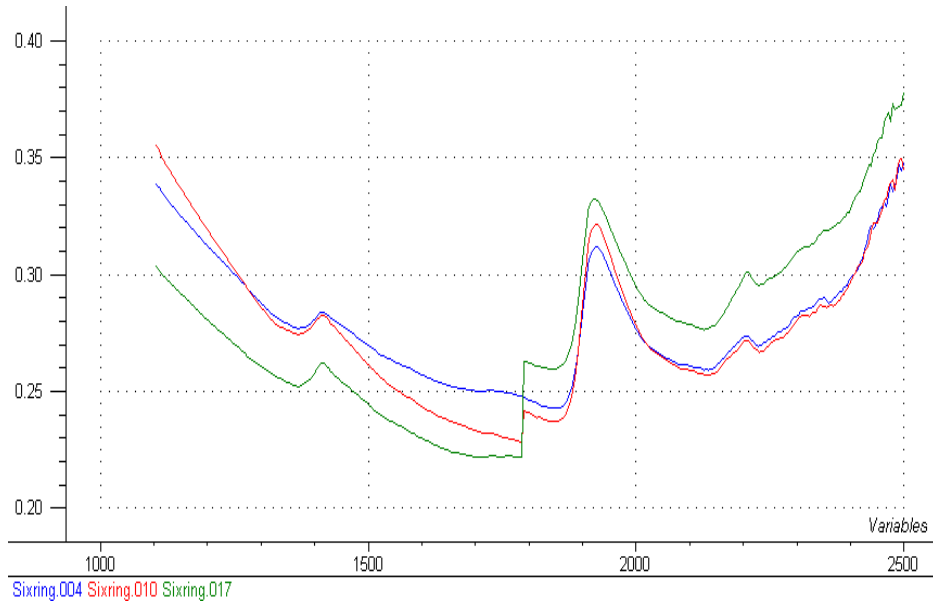

Effect of structure

- Sieving and grinding

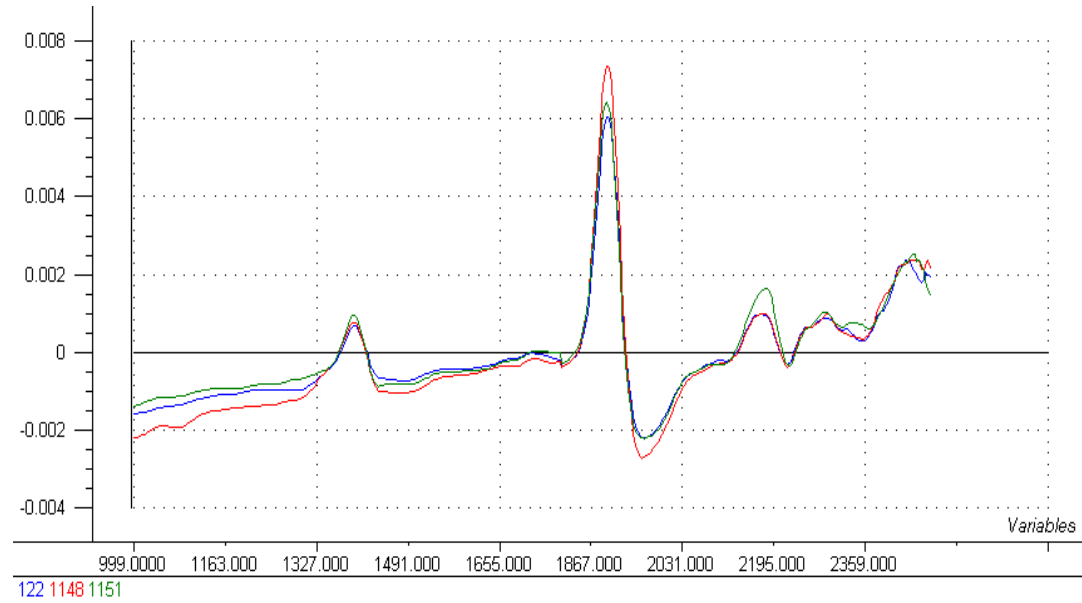

Scatter correction through transformation

Log 1/R

1st derivative

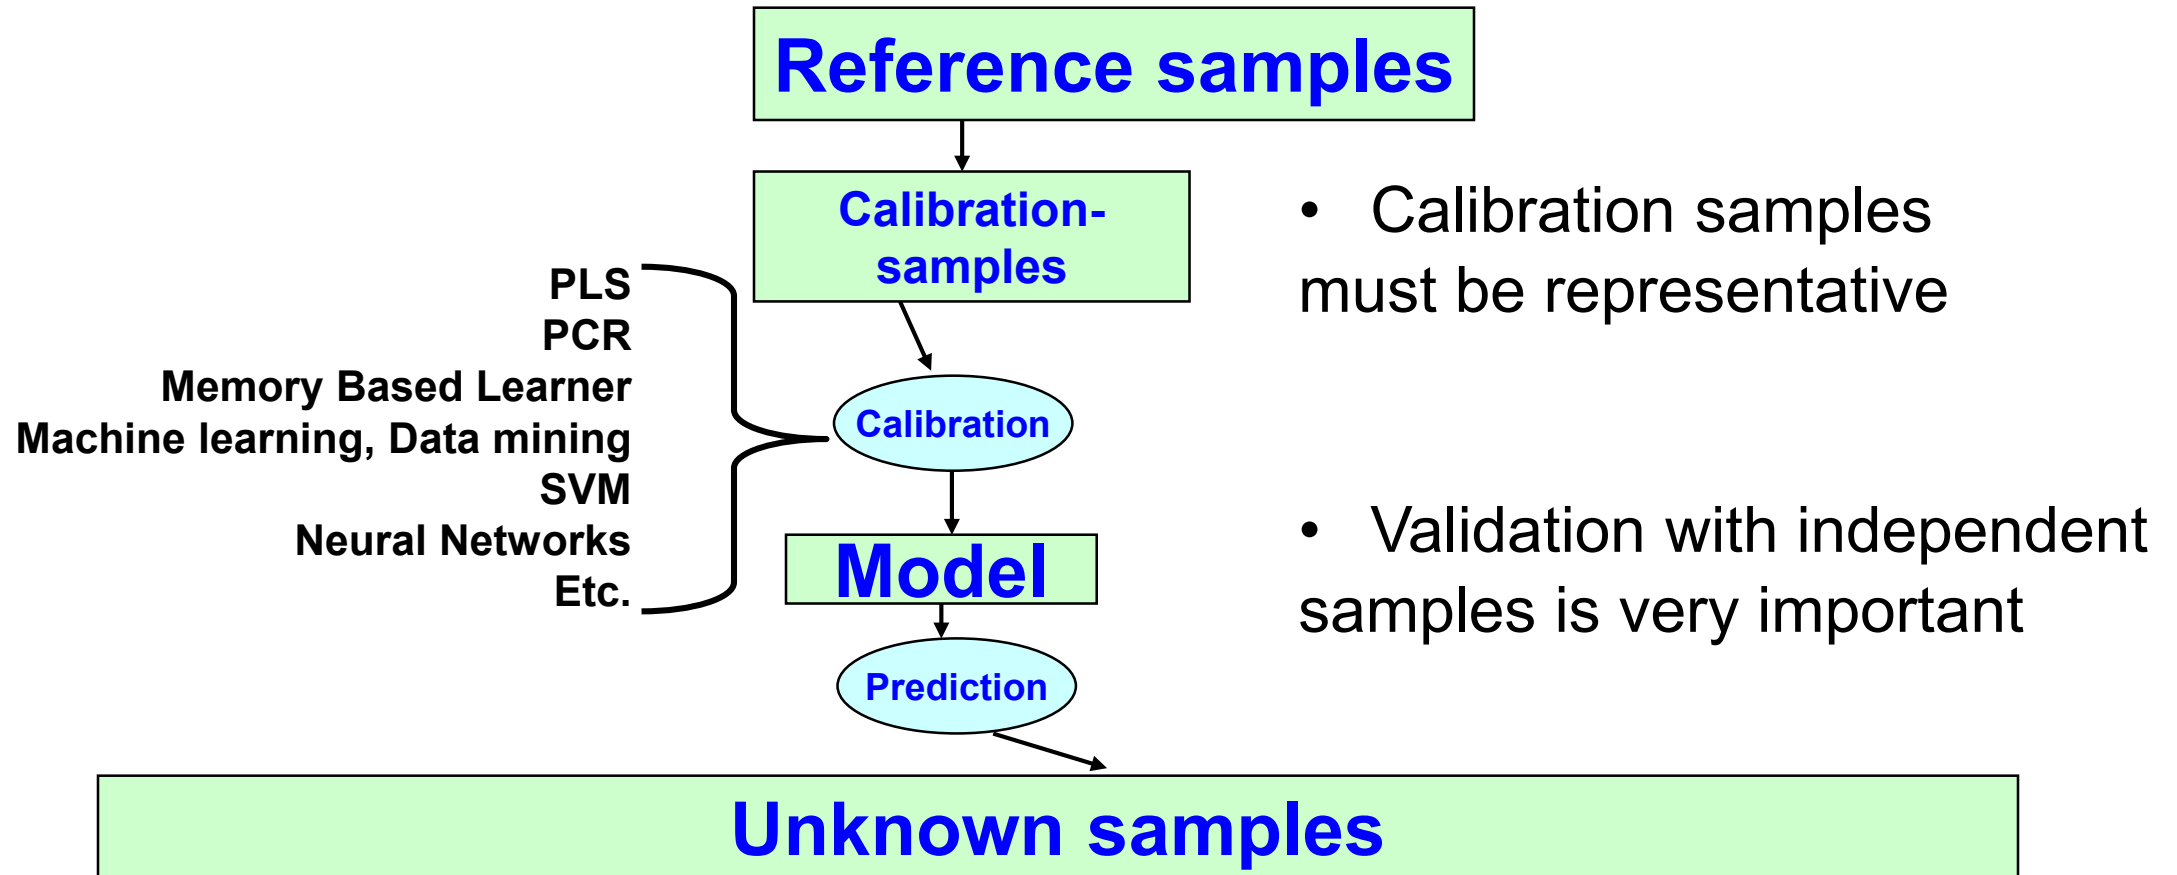

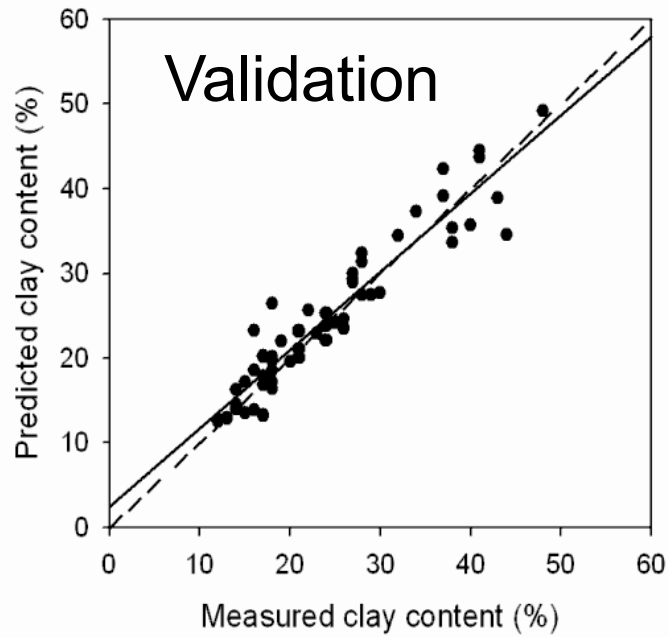

Plus and minus with diffuse reflectance

- + Rapid analysis in real-time
- + Minimum sample preparation
- + Non-destructive, Non-invasive
- + Flexible
- + Several parameters can be analyzed simultaneously
- + Rugged instruments for field analyses can be built
- Results can typically not be read directly, reference required
- Calibration is empirical

Principle for NIR predictions

- Based on empirical linear or non linear (data mining, machine learning etc.) calibrations

Prediction model relating :

Y-space to X-space
Dependent to independent
Clay to spectra

Prediction with deviation

Statistical estimates of model performance

- Validation statistics

- R^2 = Explained variance by model

- RMSE = Root Mean Squared Error

$$RMSEP = \sqrt{\left[\left(\sum_{i=1}^n d_i^2 \right) / n \right]}$$

- RPD = Ratio of performance to deviation = $\frac{\text{Stdev}}{\text{RMSE}}$

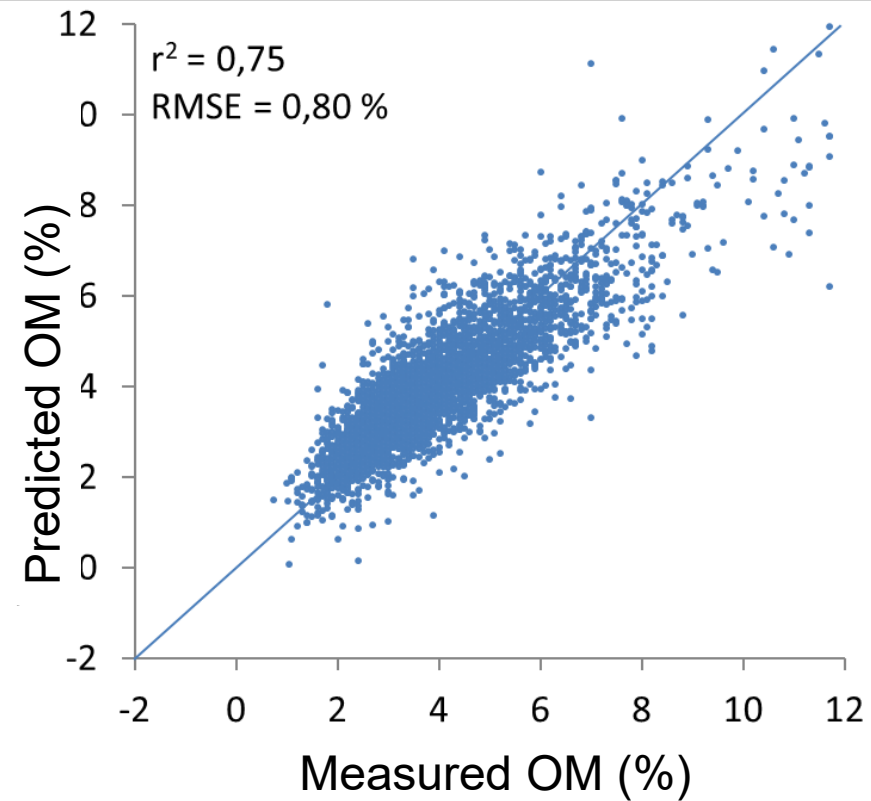

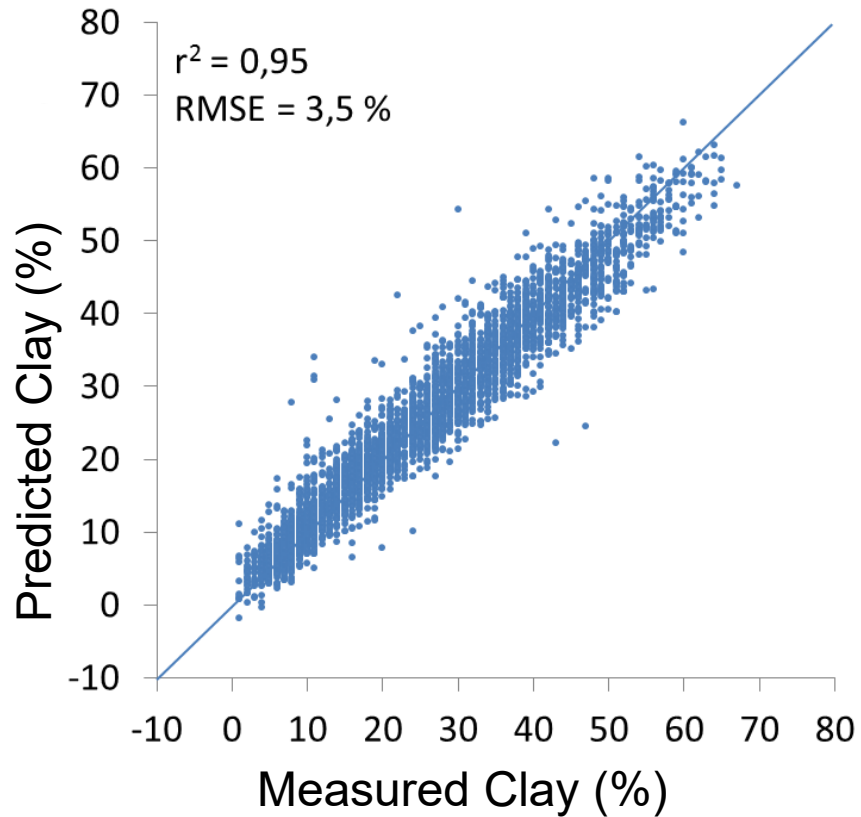

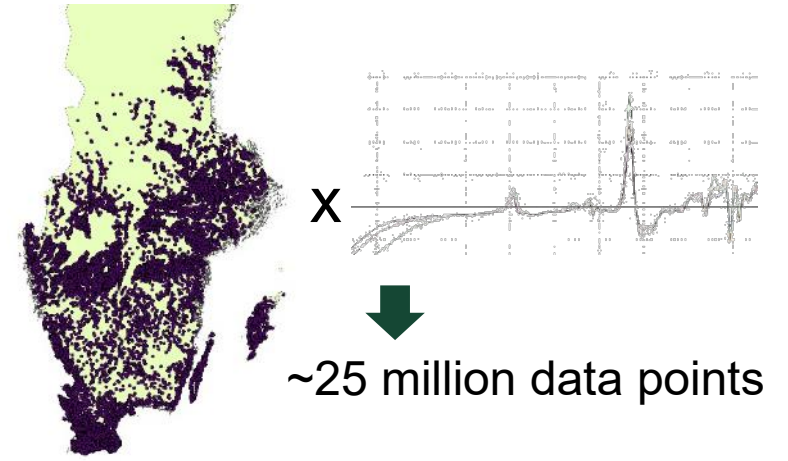

What is good enough?

Large soil spectral libraries (SSL)

- Much effort to build large SSL's and gain efficiency through general calibrations at the global/national/regional scale
- Many perform well when validated at their own scale

The Swedish national SSL ~12 000 samples Agricultural top soil

Large soil spectral libraries (SSL) for farm or field scale applications?

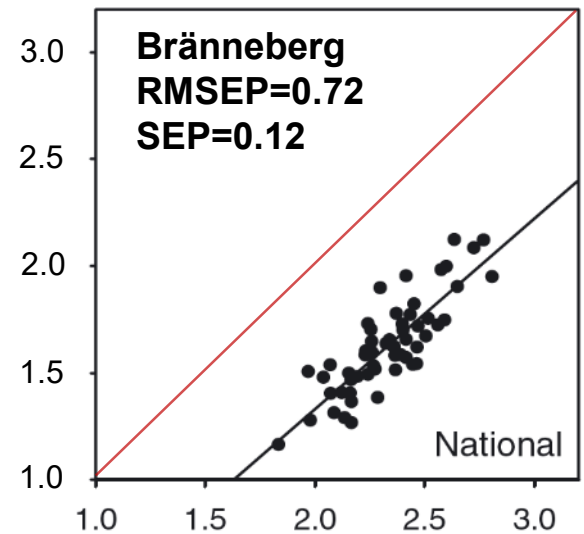

- Are large scale calibrations suitable to resolve small scale variations?
- Can this be better than local few-sample-calibrations (10-50 samples)

Large scale calibration **for predictions at the farm scale**

Predicted

Measured

Validation at the field scale

- We compared the National scale global PLS calibration with:
- The MBL (Memory Based Learner) PLS
- The National SSL spiked with 10-40 local samples
- PLS on 10-40 local samplas only

National and farm data sets

Instrument transfer

Piecewise Direct
Standardization

18 standard samples

Original FOSS

Transformed FOSS

FieldSpec

Våglängder (nm)

The Swedish national SSL ~12 000 samples Agricultural top soil

Memory Based Learner PLS in soil spectroscopy

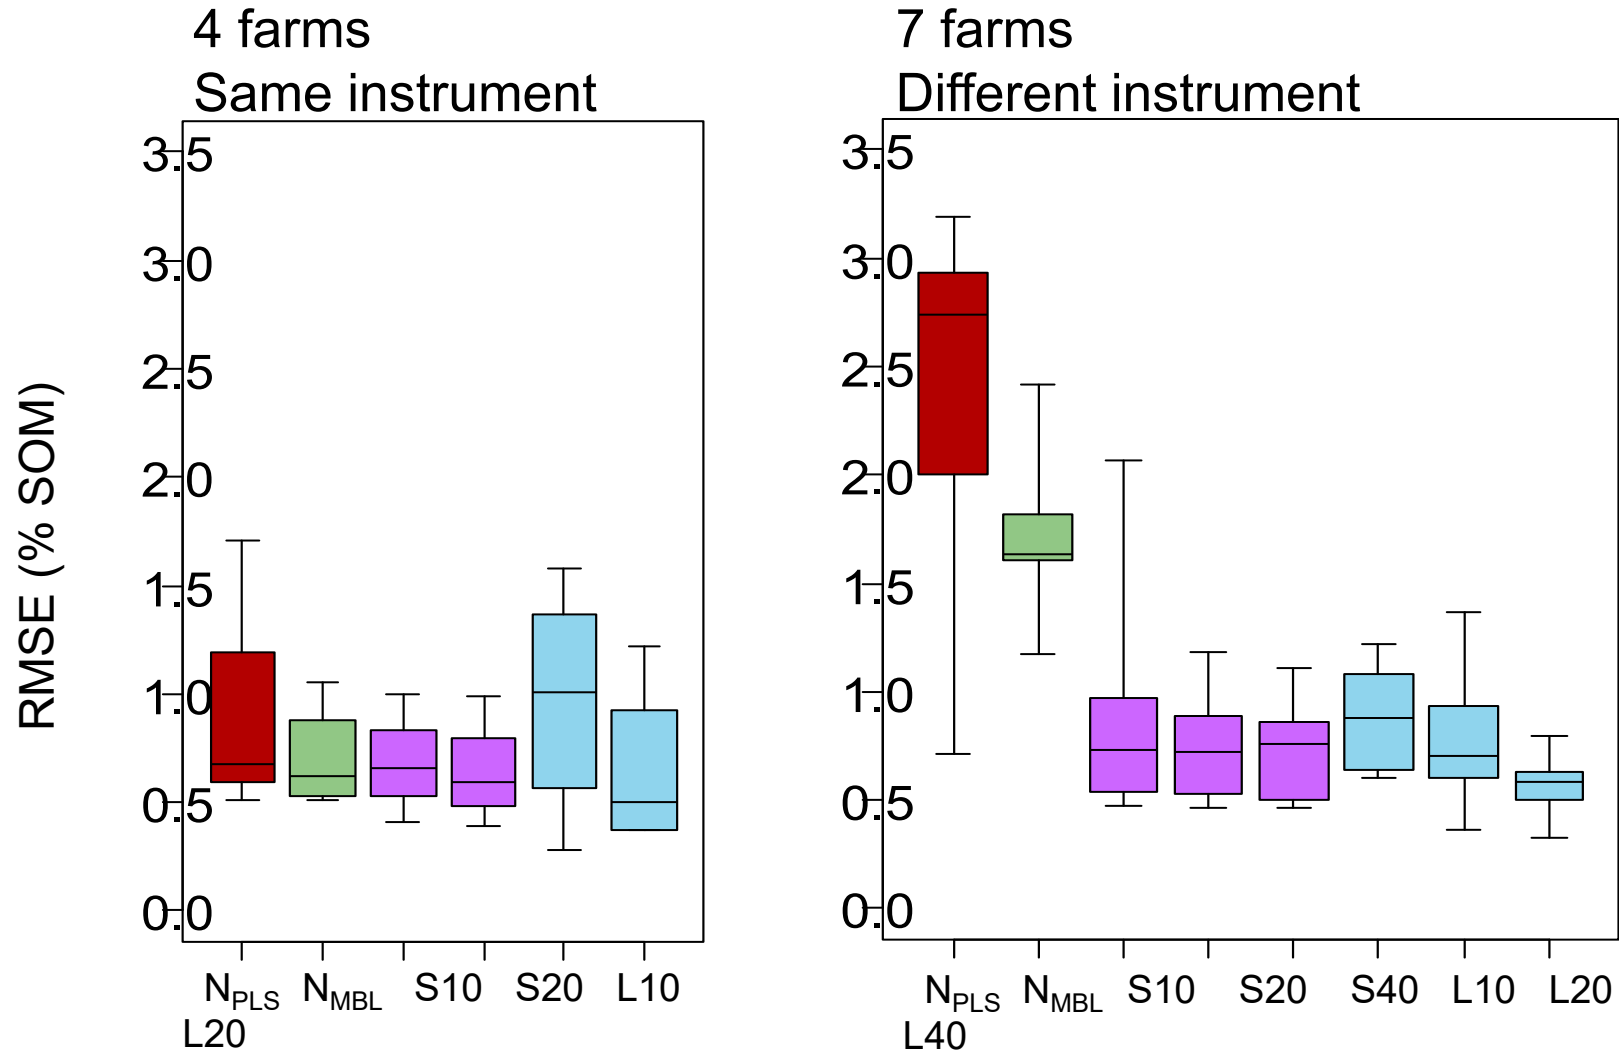

- For each sample to predict, a number of similar samples in the SSL are chosen for the calibration.
- Principal components distance using the spectral features
- *Ramirez-Lopez et al. 2013. The spectrum-based learner: A new local approach for modeling soil vis–NIR spectra of complex datasets. Geoderma, 195–196, p. 268-279*

Distribution of Farm RMSEP - Clay Content

Distribution of Farm RMSEP – SOM

Exampel of local predictions

Conclusions

- Large systematic errors with any national model
- Instrument transfer enhanced these systematic errors
- Spiking with N=10 reduced the systematic error to correspond to a local farm calibration with N=40
- Spiking reduced the instrument transfer effect substantially
- Wet chemistry on 10 local samples is affordable on most farms
- **Combining an SSL with few local samples combine the robustness and precision of many samples with the accuracy of local samples**
