#### CHLORMEQUAT (015)

### **EXPLANATION**

Chlormequat was evaluated in the CCPR Periodic Review Programme in 1994. The Meeting estimated maximum residue levels for a number of commodities, but they were recorded as only Guideline Levels because the ADI was withdrawn. As an ADI was allocated by the 1997 JMPR, the 1994 estimates were then recommended for use as MRLs. The 1994 JMPR had requested further information on feeding studies with cows and poultry, analytical methods for animal products, processing studies on cotton seed and residue studies on mushrooms grown on straw with a residue level of 15 to 20 mg/kg.

At the 30th Session of the CCPR, it was noted that animal transfer studies on poultry and cattle would be available in 1998.

The compound was reviewed again for toxicology in 1999, when an acute reference dose was allocated and the Meeting recommended that an acute risk assessment should be carried out.

A dairy cattle and a poultry feeding study, analytical methods for the determination of chlormequat residues in water, cereals, pears and animal products as well as the results of trials on pears and cereals were reported to the present Meeting by the manufacturers (CCC Task Force). The government of the Netherlands reported the official method of analysis for chlormequat in pears. Information on national MRLs and GAP was provided by the governments of Germany, Poland and The Netherlands.

#### METHODS OF RESIDUE ANALYSIS

#### **Analytical methods**

The methods used in the past were based on semi-quantitative thin-layer chromatographic or photometric determination (JMPR, 1994). These involved a lengthy clean-up process, with poor reproducibility and high values in samples from untreated control plots. Recent methods are based on head-space gas chromatography after pyrolysis in an alkaline medium, ion-pair HPLC with conductivity detection, or LC-MS.

<u>Cereals</u>. Caddy and Carroll (1982) adapted the colorimetric method of Mooney and Pasarela (1967) for the determination of chlormequat in barley grain and straw. After methanolic extraction, clean-up was by chromatography on a column of alumina with an acetone/methanol mixture. The residue was determined colorimetrically as a dipicrylamine-chlorocholine chloride complex. The LOD was 0.1 mg/kg.

Chlormequat residues in grain and straw samples were determined by Byast and Tolhurst (1990, 1992), with extraction and clean-up procedures based on those of Mooney and Pasarela (1967). After extraction with methanol and clean-up on an alumina column, the sample was derivatized with sodium thiophenolate to form a volatile ether for gas chromatography with a flame photometric detector in the sulfur mode. The LOD was 0.1 mg/kg but the lowest fortification level was 1 mg/kg for wheat and barley (recoveries: grain 95%, straw 103%) and 2 mg/kg for rye and triticale (grain 73-80%, straw 73-84%).

An analytical method for the determination of chlormequat in cereal forage, straw, grain, bran, flour and oat flakes was validated by Schneider (1992, 1993). The compound was extracted with methanol, and an aliquot of the methanol extract concentrated, transferred with water to a C-18

cartridge, and the eluate cleaned up further by ion exchange. Identification was by GLC with an FID after pyrolytic decomposition of the chlormequat to acetylene by heating an alkaline medium in a closed tube for 15 min at 200°C. The recoveries are shown in Table 1. The LOD for all samples was 1 mg/kg. High values were found in the untreated control samples.

Table 1. Recoveries of chlormequat chloride from forage, grain, straw and processed cereal products (Schneider 1993).

| Sample  | Fortification level, mg/kg | Recovery, mg/kg        | Mean, mg/kg              | SD, mg/kg | CV, % |
|---------|----------------------------|------------------------|--------------------------|-----------|-------|
| Forage  | 0                          | 1.9, 1.8, 2, 1.9       | 1.9                      | 0.056     | 2.9   |

SD: standard deviation

CV: coefficient of variation

<sup>1</sup>after substraction of mean blank value

Fegert (1996) validated the BASF method 314/1 for wheat and barley (forage, grain and straw). The compound was extracted with water/acetone (1:2). After liquid-liquid partition with dichlormethane/water the active ingredient was isolated as an ion-pair with sodium tetraphenyl borate as complexing reagent, extracted with hydrochloric acid and further purified by alumina column chromatography. Determination was based on ion-pair HPLC with column switching. The compound was paired with hexanesulfonic acid and chromatography was on a neutral, hydrophobic column with an aqueous/acetonitrile mobile phase and suppressed conductivity detection. (Dionex ion chromatograph; pre-column PRP-1, 150 x 4.1 mm, 10  $\mu$ m; analytical column PRP-1, 250 x 4.1 mm, 10  $\mu$ m). The LOD for chlormequat chloride residues was 0.5 mg/kg in straw and 0.05 mg/kg in all other samples. Control samples fortified with chlormequat chloride at 0.05, 0.5 and 5 mg/kg showed mean recoveries ranging from 71.4% ± 2.7% to 94.6% ± 3.4% (Table 2).

Table 2. Recoveries of chlormequat chloride from fortified forage, grain and straw of cereals (Fegert, 1996).

| Sample       | Fortification | Recovery, %        | Mean, % | SD, % | CV, % |
|--------------|---------------|--------------------|---------|-------|-------|
|              | level, mg/kg  |                    |         |       |       |
| Wheat forage | 0.05          | 80, 82, 78, 75, 77 | 78      | 2.6   | 3.3   |
| -            | 5             | 77, 75, 75, 76, 74 | 76      | 0.9   | 1.2   |
| Wheat grain  | 0.05          | 81, 79, 95, 78, 81 | 83      | 7.0   | 8.5   |
| -            | 5             | 74, 73, 73, 70, 67 | 71      | 2.7   | 3.8   |
| Wheat straw  | 0.5           | 81, 83, 82, 84, 83 | 83      | 1.4   | 1.7   |
|              | 5             | 79, 79, 79, 81, 81 | 80      | 1.3   | 1.6   |

| Sample        | Fortification level, mg/kg | Recovery, %        | Mean, % | SD, % | CV, % |
|---------------|----------------------------|--------------------|---------|-------|-------|
| Barley forage | 0.05                       | 74, 75, 76, 76, 75 | 75      | 0.7   | 1.0   |
|               | 5                          | 87, 87, 88, 85, 82 | 86      | 2.2   | 2.6   |
| Barley grain  | 0.05                       | 85, 83, 96, 87, 85 | 87      | 4.8   | 5.5   |
|               | 5                          | 93, 89, 86, 89, 93 | 90      | 2.7   | 3.0   |
| Barley straw  | 0.5                        | 97, 97, 93, 98, 89 | 95      | 3.4   | 3.6   |
|               | 5                          | 93, 90, 93, 92, 93 | 92      | 1.4   | 1.6   |

BASF Method 314/1 was also validated for wheat grain by Schulz (1996a) and Kuhlmann (1977) with samples fortified at 0.05 mg/kg and 5 mg/kg. Schulz obtained a mean recovery and coefficient of variation of 81% and 6.5% respectively from 5 determinations at each level, with only small peaks in the control samples in the relevant retention time range, corresponding to <0.05 mg/kg as chlormequat chloride. Kuhlmann (1997) reported a mean recovery and coefficient of variation of 89.8% and 7.14% respectively from two analyses at each level.

Schneider (1997a) validated the GC-MS "Dr G. Krebs Analytik Method DrK120" in which chlormequat chloride is determined in wheat grain from a decomposition fragment formed in the injector of the gas chromatograph by comparison with an internal standard. Validation was at fortification levels of 0.05 and 5 mg/kg. The mean recovery was 92%  $\pm$  7.6%, with values around 0.05 mg/kg in the untreated control samples.

A study by Sasturain (1997) was designed to demonstrate that contract and official laboratories in Germany are capable of analysing residues of chlormequat in wheat grain. An interlaboratory evaluation (ring test) using spiked samples (level 1 = 0.08 mg/kg, level 2 = 2.8 mg/kg) was carried out at four laboratories using method DrK120 and BASF method 314/1. The mean recovery and the coefficient of variation were 106.3% and 24.5% for level 1, and 98.2% and 2% for level 2, showing a correlation between the levels of chlormequat chloride and the precision of the results. There were no false positive results. The results indicate that the laboratories' findings do not depend on the analytical method but on the expertise and experience of each laboratory with the individual methods.

<u>Pears</u>. The official analytical method of The Netherlands for the determination of chlormequat in plant material (Anon., 1996) has been applied to pears. A methanol extract is cleaned by ion-exchange and alumina chromatography, then evaporated to dryness and heated in an alkaline medium in a closed tube at 215°C to convert chlormequat to acetylene, which is determined in the head-space by gas chromatography with flame-ionisation detection. The LOD of chlormequat in pears was 0.01 mg/kg.

A new analytical method relying on quantification by tandem liquid chromatography with mass spectrometric detection (LC-MS-MS) was validated for pears (Quirijns and van Dam, 1999; Quirijns, 1999). Chlormequat chloride was extracted from the plant material with water after homogenization. After filtration, 20  $\mu$ l of the extract was injected on to a 100 x 3 mm I.D. 5  $\mu$ m Spherisorb CN column with a 10 x 3 mm I.D. R2 guard column. Isocratic elution was with a mobile phase of methanol/water/1 M aqueous ammonium acetate (50:49:1) at a flow rate of 0.3 ml/min. MS/MS data were acquired by selecting the ion at m/z 122 as the precursor ion and the ion at m/z 58 as the product ion. The multiplier was run at 1200 V.

The recovery and repeatability are shown in Table 3. The limit of detection was 0.007 mg/kg. The LOD claimed by the authors was 0.1 mg/kg, but as the lowest fortification level was 0.29 mg/kg the validated LOD is 0.3 mg/kg.

| Chlormequat chloride added, $mg/kg$ (N = 6) | Mean recovery, % | SD, % |
|---|------------------|-------|
| 0.29  | 106              | 2.7   |
| 2.9   | 105              | 1.6   |
| 9.8   | 89               | 2.6   |

Table 3. Recovery and repeatability of chlormequat determination in pears (Quirijns and van Dam, 1999).

<u>Animal products</u>. Weidenauer (1999a,b) validated an ion-pair HPLC method to determine chlormequat in fortified poultry and dairy cow products. Samples of hen eggs, meat, liver and fat, and cow milk, meat, liver, kidney and fat were homogenized, extracted with a mixture of acetone and water (2:1), and passed through a cation exchange column. Chlormequat was eluted with diluted HCl and the eluant evaporated. The dry residue was re-dissolved in water and washed with dichloromethane, and the aqueous phase was evaporated to dryness. The residue was then transferred to an alumina column, eluted with a mixture of acetonitrile and methanol, and the eluate evaporated to dryness. The residue was transferred via methanol to water for analysis by ion-pair chromatography with column switching. The mobile phase was hexanesulfonic acid (2mmol/l)/CH<sub>3</sub>CN (97:3) in a gradient system. A Hamilton PRP-1, 15 cm x 4.1 mm column was used as pre-column and the analyte was transferred to the separation column by means of a motor driven switch valve during a period of about 1-1.5 min. A Hamilton PRP-1, 25 x 4.1 mm column was used for analyte determination. A Dionex CDM-2 conductivity detector with background conductivity suppression was used for detection. Under these conditions the retention time for chlormequat was about 22 min.

In the hen trial, no residues of chlormequat were found at or above the LOD of 0.05 mg/kg in any control samples of meat, liver, fat or eggs. At spike levels of 0.05-0.5 mg/kg the average recovery from tissues was 80% with a relative standard deviation of 9.5%, and from eggs 83.5% with a relative standard deviation of 16% (Table 4).

| Sample    | Fortification level, mg/kg | Measured value, mg/kg | Recovery, %     |
|-----------|----------------------------|-----------------------|-----------------|
| Hen meat  | 0                          | n.d. <sup>1</sup>     |                 |
|           | 0.05                       | 0.042                 | 84              |
|           | 0.5                        | 0.38                  | 75.5            |

<sup>1</sup> not detected

<sup>2</sup> corrected for control

No residues of chlormequat were found at or above the LOD of 0.05 mg/kg in any control sample of cow meat, liver, kidney or fat. 0.037 mg/kg was detected in one kidney control sample. The average recovery from the tissues was 86% at spike levels of 0.05 and 0.5 mg/kg with a relative standard deviation of 18.9% (Table 5).

Table 6 shows the recoveries of chlormequat chloride from spiked milk, skimmed milk and cream. Only two milk and one cream control samples showed interference peaks at the retention time of chlormequat. At spike levels of 0.01-0.2 mg/kg, the average recovery of chlormequat chloride was 84.7% from milk and 88.8% from skimmed milk and cream with relative standard deviations of 14.6% and 21% respectively.

Table 6. Recoveries of chlormequat chloride from fortified cow milk, skimmed milk and cream (Weidenauer, 1999b).

<sup>1</sup>corrected for control

<u>Water</u>. Mackenroth and Sasturain (1995) validated BASF method 370 for the determination of chlormequat in tap water, leachate (lysimeter) water, and water from a small stream and the German Rhine river (surface waters). A 1000 ml sample of water was extracted with dichloromethane to remove non-polar components. The ion-pairing reagent, sodium tetraphenyl borate, was then added and chlormequat was partitioned into dichloromethane, then re-extracted from the dichloromethane phase with 2 M hydrochloric acid. The HCl phase was taken to dryness, and the residue re-dissolved in acetonitrile/methanol (95:5 v/v) and cleaned up on an acid alumina column. The eluate was concentrated to dryness, dissolved in ultra-pure water and quantified by ion chromatography (Dionex ion chromatograph with suppressed conductivity detection; pre-column PRP-1, 150 x 4.1 mm, 10  $\mu$ m; analytical column PRP-1, 250 x 4.1 mm, 10  $\mu$ m). The mobile phase for the pre-column and analytical column consisted of a 2 mM hexanesulfonic acid solution and acetonitrile (95:5 v/v). The LOD was

 $0.05 \mu g/l$ , with mean recoveries at that level of 106% from tap water, 82% from lysimeter water, 77% from Rhine river water and 76% from stream water (Table 7).

Table 7. Recoveries of chlormequat chloride from water (Mackenroth and Sasturain, 1995).

SD: standard deviation

CV: coefficient of variation

BASF Method 370 was also validated by Schulz (1996b, 1997) for tap water and by Kuhlmann (1997) for drinking water. Five samples of tap water and 2 samples of drinking water were each fortified at 0.05  $\mu$ g/l and 5  $\mu$ g/l. The mean recovery and the coefficient of variation were 90.5% and 10.9% respectively for tap water and 102.7% and 7.4% respectively for drinking water. No peak was observed in the control tap water.

Schneider (1997b) validated Dr G. Krebs Analytik Methods DrK086 and DrK199 for drinking water. In DrK086 disodium ethylenediaminetetraacetate (ETDA) was added to complex the calcium ions in the water. The sample was made alkaline with sodium hydroxide beads and chlormequat was extracted with a solution of dipicrylamine in dichloromethane, then back-extracted with 1 N hydrochloric acid and taken to dryness. The residue was transferred with methanol to a thick-walled screw-top centrifuge tube, taken to dryness and 5% potassium hydroxide added. The centrifuge tube was closed and heated for 15 min at 200°C to pyrolyse the chlormequat in the alkaline solution. After cooling, 250  $\mu$ l of the gas phase was injected into the GC. The acetylene produced was determined by GLC with an FID. The LOD of the method was 0.05  $\mu$ g/l (Table 8).

Table 8. Recoveries of chlormequat chloride from water by method DrK086 (Schneider, 1997b).

| Addition, µg/l | Measured value, µg/l | Recovery, % |
|----------------|----------------------|-------------|
| 0              | 0.0074               |             |
| 0.05           | 0.054                | 107         |
| 0.05           | 0.053                | 106         |
| 5              | 4.9                  | 99          |

In DrK119 determination was by GC-MS, the chlormequat being decomposed in the injector of the gas chromatograph as in DrK120 for wheat grain. An internal standard is used. Fortification levels were 0.05, 0.1 and 0.3  $\mu$ g/l. Because the control samples contained apparent residues of about 0.025  $\mu$ g/l, the results at 0.05  $\mu$ g/l could not be relied upon and the LOD was 0.1  $\mu$ g/l (Table 9).

| 0.3               | 0.25                 | 81                      | 0.22                        | 73                    |           |                           |             |       |

The inter-laboratory ring test on wheat grain described above (Sasturain, 1997) was also carried out with drinking water spiked at 0.11 and 0.25  $\mu$ g/l by five laboratories using methods DrK086, DrK119 and BASF 370. The mean recoveries and the coefficients of variation were 85.5% and 5.8% at 0.11  $\mu$ g/l, and 96% and 9% at 0.25  $\mu$ g/l, showing satisfactory accuracy and reproducibility. There were no false positive results.

#### Stability of pesticide residues in stored analytical samples

The stability of chlormequat residues in animal products stored in freezers (milk, eggs and edible tissues) was investigated by Weidenauer (2000). Control and treated samples from the animal feeding studies A-49-97-05 (Weidenauer, 1999a) and A-49-97-06 (Weidenauer, 1999b) were used for the trial. The eggs were broken and homogenized without shells with a spatula, and the fat and liver were homogenized using a Tecator homogenizer. Aliquots of about 500 g were placed in plastic boxes and stored at  $\leq$ -18°C. Whole milk was not homogenized. The HPLC method of Weidenauer (1999a,b) described above was used. Table 10 shows the individual results and the corresponding recoveries.

#### **USE PATTERN**

The main use of the plant growth regulator chlormequat is to consolidate the stems of cereals to prevent lodging. In pears, common uses are to inhibit vegetative growth and promote flowering in the following season. The Meeting was provided with information on currently registered uses by the governments of The Netherlands, Germany and Poland as well as by the Task Force members BASF, Ciba Speciality, Nufarm and UCB (Table 11).

| Crop  | Country        | Product,         | Application       | 1                        |             |  |     | PHI,     |

<sup>3</sup>Information by the government of The Netherlands (Olthof, 2000): GAP for pears will be changed in the near future

### **RESIDUES RESULTING FROM SUPERVISED TRIALS**

The Meeting received new information on supervised residue trials on pears and cereals as well as on animal feeding studies, and the trials reported in 1994 on which the current MRL recommendations are based were re-evaluated for the estimation of STMRs and HRs. Residue data on pears, cereals (grains, forage and fodder) and rape are summarized in Tables 12-26.

Table 12. Residue trials on pears reported to the 1994 and 2000 JMPRs.

Table 13. Residue trials on cereals in Austria 1965-1970, to 2000 JMPR.

Table 14. Residue trials on summer barley in the UK 1983/84, reported to the 2000 JMPR.

Table 15. Residue trials on summer barley, reported to the 1994 JMPR.

Table 16. Residue trials on winter barley, reported to the 1994 JMPR.

Table 17. Residue trials on oats, reported to the 2000 JMPR.

Table 18. Residue trials on oats, reported to the 1994 JMPR.

Table 19. Residue trials on triticale in the UK 1989, reported to the 2000 JMPR.

Table 20. Residue trials on rye, reported to the 2000 JMPR.

Table 21. Residue trials on rye, reported to the 1994 JMPR.

Table 22. Residue trials on wheat, reported to the 2000 JMPR.

Table 23. Residue trials on summer wheat, reported to the 1994 JMPR.

Table 24. Residue trials on winter wheat, reported to the 1994 JMPR.

Table 25. Residue trials on maize, reported to the 1994 JMPR.

Table 26. Residue trials on rape seed, reported to the 1994 JMPR.

Residue levels and application rates were reported as chlormequat chloride, but the residues are generally recalculated as cation in the Appraisal. When residues were not detected they are shown as below the LOD (e.g. <0.1 mg/kg). Residues, application rates and spray concentrations have generally been rounded to two significant figures but for residues approximating the LOD to one significant figure. HRs and STMRs from the trials conducted according to maximum GAP have been used for the estimation of maximum residue levels. These results are double underlined.

<u>Pears (Table 12)</u>. The trials from the Netherlands on which the recommended MRL was based were not correctly evaluated by the 1994 JMPR: each trial included 4 field replicates, so only one figure from each trial should have been selected for the estimation of a maximum residue level. Further supervised trials on pears were carried out in 1998/99 in France.

<u>Cereals</u> (Table 13). In 1965 and 1967-1970 numerous residue trials were carried out in Austria to determine chlormequat in cereals (Bayzer, 1966, 1968, 1984). Analysis was by semi-quantitative thinlayer chromatography (Dragendorff reagent) after extraction with ethanol, separation from other quartenary ammonium compounds by ion-exchange chromatography and preparative TLC. The LOD was reported as 0.1 mg/kg, but no validation was carried out. Control samples were not included. The trials were reported to the present Meeting.

Table 13. Residues of chlormequat chloride in cereals in Austria 1965-1970.

<u>Barley</u>. Six supervised trials carried out in 1983/84 in the UK were reported to the Meeting. No information on PHIs or analytical methods was reported. The grain and straw samples were harvested at ripening. A further trial was reported from Latvia but no information was included on application rates or analytical methods (Table 14).

The trials reported to the 1994 JMPR which complied with current GAP, and from which the present Meeting estimated a maximum residue level, are shown for summer barley in Table 15 and for winter barley in Table 16.

<u>Oats</u>. The trials reported to the 2000 JMPR are shown in Table 17. High values were found in untreated control plots in four trials in Austria (1992). Semi-quantitative thin-layer chromatographic or colorimetric methods were used to analyse the samples from one trial in Germany and one in the UK which could be evaluated.

The results of trials reported to the 1994 JMPR which were used by the present Meeting for the estimation of maximum residue levels for grain, straw and forage are shown in Table 18.

<u>Rye and triticale</u> (Tables 19, 20). Four trials on triticale and two on winter rye were carried out by Byast and Tolhurst (1990). No chlormequat residues were found in any of the untreated control samples or in the treated grain. Two trials on rye were carried out in Austria in 1992 by Pfarl (1993a,b) and analysed by Schneider (1993) as described above.

The residue data reported to the 1994 JMPR which the present Meeting re-evaluated for the estimation of maximum residue levels are shown in Table 21.

<u>Wheat</u>. Data from trials in Austria (2), Germany (3) and the UK (8) were reported to the Meeting (Table 22). High chlormequat values in the untreated control plots were found in the two trials in Austria (1992). Semi-quantitative thin-layer chromatographic or colorimetric methods were used for analysis in the trials in Germany and the UK. A further trial was reported in Latvia but no information on application rates or analytical methods was included.

The residue data reported to the 1994 JMPR which complied with current GAP and which the present Meeting used to estimate maximum residue levels are shown in Tables 23 and 24.

# Livestock feeding trials

<u>Hens</u>. Four groups each of four laying Lohmann brown hens were dosed with 0, 0.72, 2.16 or 7.2 mg chlormequat chloride bird/day for 28 days, equivalent to 0, 6, 18 or 60 ppm in the feed (Weidenauer, 1999a). The hens in each group were killed after the last dose and tissue samples collected. Two additional groups of 12 hens were dosed at the highest level for 28 days and allowed to recover after the last dose for 2 or 7 days. The tissues from the birds in each group were then analysed. Eggs from the hens in each group were analysed as indicated in Table 29.

The eggs and tissues were analysed for chlormequat as described in "Analytical methods" (Weidenauer, 1999a). The LOD was 0.05 mg/kg. Table 27 shows sampling, freezing, shipping, homogenization, extraction, and analysis dates. The information on storage stability (Weidenauer, 2000) was inadequate.

NA: not applicable <sup>1</sup> Groups 4-12 were each of 4 hens. Groups 13 and 14 were each of 12 hens and the 3 samples were each composites of 4 hens. <sup>2</sup>half of the LOD (0.025 mg/kg) used for calculation of mean

<u>Cows</u>. A feeding study was carried out on lactating cows by Weidenauer (1999b). Groups of three Holstein dairy cows were dosed with chlormequat chloride for 28 consecutive days at 0, 240, 720 or 2400 mg/animal/day, or 0, 0.4, 1.3 or 4 mg/kg bw/day, equivalent to 0, 12, 36 or 120 ppm in the diet on a dry weight basis. Two extra cows were treated at the high dose level for 28 days and slaughtered 2 or 7 days after their last dose. The doses were equivalent to 0, 0.31, 1.01 and 3.1 mg/kg bw/day calculated as chlormequat cation.

Milk was collected from each cow throughout the study. After the final dose, three cows in each group were slaughtered and tissue samples collected. Milk and tissue samples were analysed for chlormequat chloride as described above ("Analytical methods", Weidenauer, 1999b). The LOD of the ion-pair chromatography method was 0.01 mg/kg for milk and 0.05 mg/kg for tissues.

Table 30 shows the sampling, freezing, shipping, sample preparation, extraction, and analysis dates. The information on storage stability (Weidenauer, 2000) was inadequate.

Table 34. Cream and fat content of the milk samples (Weidenauer, 1999b).

# FATE OF RESIDUES IN STORAGE AND PROCESSING

# In storage

No information.

## In processing

Rye and oat grain from supervised trials (Pfarl, 1993b) were processed to rye bran and flour and oat flakes by Schneider (1993) but no details of the processing were reported. Brüggemann and Ocker (1988) prepared oat flakes and wheat flour according to commercial practice.

\* At or about the LOQ

### APPRAISAL

Chlormequat was evaluated within the CCPR periodic review programme in 1994. The Meeting estimated maximum residue levels for a number of commodities, which were recorded as guideline levels only, since the ADI was withdrawn. The 1994 JMPR noted that feeding studies in farm animals and analytical methods for residues in animal products would be desirable. As an ADI was allocated by the 1997 JMPR, the estimates made in 1994 were recommended for use as MRLs in 1997.

The CCPR at its thirtieth session noted that animal transfer studies in poultry and cattle would be available in 1998.

The compound was reviewed toxicologically again in 1999, when an acute RfD was allocated. The 1999 JMPR recommended that an evaluation of residues should be scheduled shortly so that an acute risk assessment could be concluded.

Analytical methods for the determination of residues of chlormequat in water, cereals, pears, and animal products, data on stability in storage of animal products, data on residues in pears and cereals, and the results of a feeding study in dairy cattle and poultry were made available to the Meeting by the manufacturers. The Netherlands submitted its official method of analysis for chlormequat in pears. Information on national MRLs and GAP was provided by the governments of Germany, The Netherlands, and Poland.

## Methods of analysis

Chlormequat is difficult to analyse because of its chemical nature and because the residue must be separated from native quarternary ammonium compounds in plant material. Older methods involve lengthy clean-up, liquid-liquid partition or column chromatography (ion-exchange, alumina), and semi-quantitative thin-layer chromatographic or photometric detection, but these methods allow only poor reproducibility. More recent methods are based on head-space gas chromatography after pyrolysis of chlormequat to acetylene in an alkaline medium, HPLC by ion-pair chromatography with conductivity detection, or liquid chromatography with mass spectrometric detection.

For cereal grains, the LOQ was 0.05 mg/kg with ion-pair chromatography and 1 mg/kg with head-space gas chromatography with flame ionization detection. The latter method resulted in high values in samples from untreated control plots. The liquid chromatography-mass spectrometric method was used to determine chlormequat residues in pears (LOQ, 0.3 mg/kg).

The ion chromatographic method was validated for animal products, resulting in LOQs of 0.05 mg/kg for eggs and tissues and 0.01 mg/kg for milk. The ion chromatographic technique was also used to analyse chlormequat in water, with an LOQ of 0.05 mg/l.

## Stability of residues in stored analytical samples

Two samples each of milk, eggs, liver, and fat from farm animals fed chlormequat were stored for 25-33 months at -18 °C. The remaining compound represented 76-140% of the initial concentration in milk, 45-100% in eggs, 60-82% in liver, and 71-90% in fat, with great variation. The Meeting was not able to decide whether chlormequat is stable in enzyme-containing matrices and noted that the study was inadequate.

## **Results of supervised trials**

The present Meeting received the results of new supervised trials on pears and cereals. These data and those reported by the 1994 JMPR on which the recommended MRLs for numerous commodities are based were re-evaluated in the view of current GAP and to estimate STMR and HR values.

Chlormequat is registered for use on *pear* in Belgium (at four to five applications of 1.4 kg ai/ha, 0.24 kg ai/hl, 600 l water/ha), Denmark (at two applications of 0.75-1.8 kg ai/ha, 0.075-0.18 kg ai/hl, 1000 l water/ha), The Netherlands (at one or two applications of 0.75-2.3 kg ai/ha, 0.094-0.15 kg ai/hl, 800-1500 l water/ha), and Spain (at five to six applications of 0.9 kg ai/ha, 0.1 kg ai/hl, 900 l water/ha). The PHIs range from 42 days in Denmark to 90 days in The Netherlands, or treatment is fixed at a certain growth stage (Belgium, Spain).

Six trials carried out in The Netherlands in 1968 were not included in the assessment as no information on the spray concentration was received, but the application rates used in two trials conducted in 1983 (two applications of 1.1-1.8 kg ai/ha, 0.11-0.18 kg ai/hl, 1000 l water/ha) were

acceptable in respect of GAP in The Netherlands. The concentrations of residues were 5.3 and 6.9 mg/kg (calculated as chlormequat chloride) 124 and 113 days after the last treatment, respectively. Two further trials (four applications of 1.2-1.6 kg ai/ha, 0.2 kg ai/hl, 600 l water/ha; PHI, 90 and 101 days) complied with the Belgian GAP. The concentrations of residues were 1.6 and 8.1 mg/kg, calculated as chlormequat chloride.

Eight supervised trials were conducted in France in 1998 and 1999. Those carried out in 1998 were in accordance with the Belgian GAP (five applications of 1.4-1.5 kg ai/ha, 0.24 kg ai/hl, 600 l water/ha). The concentrations 44 or 45 days after the last treatment were 4, 4.6, 5.6, and 7.5 mg/kg, calculated as chlormequat chloride. In 1999, only one application was given. The rates used in these trials were not compatible with a currently registered GAP.

The concentrations of residues found in the trials conducted according to GAP were, in rank order (median in italics), 1.6, 4, 4.6, **5.3**, **5.6**, 6.9, 7.5, and 8.1 mg/kg calculated as chlormequat chloride or 1.2, 3.1, 3.6, **4.1**, **4.3**, 5.3, 5.8, 6.3 mg/kg calculated as chlormequat cation. The Meeting estimated a maximum residue level of 10 mg/kg, confirming the previous recommendation, an STMR value of 4.2 mg/kg, and a HR value of 6.3 mg/kg for pears, calculated as chlormequat cation.

The Meeting received the results of numerous supervised trials on *barley* carried out in the UK, but these data could not be evaluated as high values were determined in samples from untreated plots and no information was submitted about the analytical method used. Trial carried out in Latvia in 1998 and in Hungary in 1991 provided no information on application rates or the analytical method used.

| Country       | No. of | Concentration of residues, calculated                                | In accordance with GAP of |
|---------------|--------|--|---------------------------|
|               | trials | as chlormequat chloride, mg/kg                                       |                           |
| Summer barley |        |  |                           |
| Denmark       | 4      | <0.05 (2 trials), 0.05, 0.3  | Netherlands, Belgium      |
| Germany       | 2      | 0.17, 0.62   | Netherlands, Belgium      |
| Sweden        | 7      | <0.05 (4 trials), 0.1, 0.19, 0.73                                    | Netherlands               |
| UK            | 3      | 0.18, 0.24, 0.37   | UK                        |
| Winter barley |        |  |                           |
| Denmark       | 1      | 0.05   | Netherlands               |
| France        | 11     | <0.05 (3 trials), 0.16, 0.18, 0.21, 0.24, 0.29, 0.3 (2 trials), 0.35 | Netherlands, Belgium      |
| Germany       | 5      | 1.3, 1.6, 1.6, 2.1, 2.3  | Germany                   |
| Germany       | 2      | 0.17, 0.18   | Netherlands, Belgium      |
| Sweden        | 1      | 0.42   | Netherlands, Belgium      |
| Switzerland   | 2      | 0.23, 0.29   | Netherlands, Belgium      |
| UK            | 9      | <0.05 (2 trials), 0.05, 0.07, 0.15, 0.24, 0.36, 0.43, 0.58           | UK                        |

The supervised trials reported by the 1994 JMPR that are in accordance with current GAP were re-evaluated:

The 47 values for residues, in rank order, were <0.05 (11 trials), 0.05 (3 trials), 0.07, 0.1, 0.15, 0.16, 0.17 (2 trials), 0.18 (3 trials), **0.19**, 0.21, 0.23, 0.24 (3 trials), 0.29 (2 trials), 0.3 (3 trials), 0.35, 0.36, 0.37, 0.42, 0.43, 0.58, 0.62, 0.73, 1.3, 1.6 (2 trials), 2.1, and 2.3 mg/kg calculated as chlormequat chloride, or <0.04 (11 trials), 0.04 (3 trials), 0.05, 0.08, 0.12 (2 trials), 0.13 (2 trials), 0.14 (3 trials), **0.15**, 0.16, 0.18, 0.19 (3 trials), 0.22 (2 trials), 0.23 (3 trials), 0.27, 0.28, 0.29, 0.33 (2 trials), 0.45, 0.48, 0.57, 1.0, 1.2 (2 trials), 1.6, and 1.8 mg/kg calculated as chlormequat cation.

The Meeting estimated a maximum residue level of 2 mg/kg to replace the previous recommendation of the 1994 JMPR (0.5 mg/kg), an STMR value of 0.15 mg/kg, and a HR value of 1.8 mg/kg for barley, calculated as chlormequat cation.

The Meeting received the results of four supervised trials on *oats* carried out in 1993 in Austria, but the data could not be evaluated as high values were determined in samples from untreated plots. One trial in Germany and one in the UK were conducted in accordance with Belgian and British GAP, respectively. The concentrations were 3 and 0.8 mg/kg in oat grains, calculated as chlormequat cation.

The trials carried out in accordance with current GAP and summarized by the 1994 JMPR were re-evaluated:

| Country | No. of | Concentration of residues, calculated       | In accordance with |
|---------|--------|---|--------------------|
|         | trials | as chlormequat chloride, mg/kg              | GAP of             |
| Germany | 16     | 0.09, 0.14, 0.45, 0.51, 0.9, 1.1, 1.2,      | Belgium, Finland   |
|         |        | 1.5, 1.6, 1.7, 1.8, 1.9, 2.0, 2.4, 2.4, 3.3 | Netherlands        |
| Germany | 2      | 1.5, 3.7                                    | Germany            |
| UK      | 3      | 0.1, 0.63, 9.2                              | UK                 |

The 23 values (21 from submissions in 1994, two from submissions in 2000), in rank order, were 0.09, 0.1, 0.14, 0.45, 0.51, 0.63, 0.8, 0.9, 1.1, 1.2, *I.5* (2 trials), 1.6, 1.7, 1.8, 1.9, 2.0, 2.4, 2.4, 3, 3.3, 3.7, and 9.2 mg/kg calculated as chlormequat chloride, or 0.07, 0.08, 0.11, 0.35, 0.39, 0.49, 0.62, 0.7, 0.85, 0.93, *I.2* (3 trials), 1.3, 1.4, 1.5, 1.6, 1.9 (2 trials), 2.3, 2.6, 2.9, and 7.1 mg/kg calculated as chlormequat cation.

The Meeting estimated a maximum residue level of 10 mg/kg, confirming the previous recommendation, an STMR value of 1.2 mg/kg, and a HR value of 7.1 mg/kg for oats, calculated as chlormequat cation.

*Triticale, rye and wheat* have comparable use patterns in GAP of Belgium, Denmark, Germany, and the UK. The Meeting received the results of four trials each on triticale and on rye (2.5-5 kg ai/ha) in the UK, which were not in accordance with GAP (maximum, 1.7 kg ai/ha). Two Austrian trials each on rye and wheat could not be evaluated as high values were determined in samples from untreated plots. Eight trials on wheat in the UK could not be evaluated as information on the analytical method used was not submitted. One trial of wheat was carried out in Latvia in 1998, but no information on the application rate or the analytical method used was received. In two trials conducted in Germany in 1988, the application rates were acceptable with regard to British, Italian, and Finnish GAP (1.5-1.7 kg ai/ha); the concentrations were 0.2 and 0.24 mg/kg, calculated as chlormequat chloride.

| Country      | No. of trials | Concentration of residues, calculated as chlormequat chloride, mg/kg | In accordance with GAP of        |
|--------------|---------------|--|----------------------------------|
| Summer rye   |               |  |                                  |
| Germany      | 4             | 0.06, 1.5, 2.1, 2.6  | Belgium                          |
| Winter rye   |               |  |                                  |

| Germany      | 6             | 0.17, 0.23, 0.28, 0.31, 0.34, 0.37                                   | Denmark, UK                      |

The supervised trials in accordance with current GAP and summarized by the 1994 JMPR were re-evaluated:

| Country | No. of trials | Concentration of residues, calculated as chlormequat chloride, mg/kg | In accordance with GAP of        |
|---------|---------------|--|----------------------------------|
| Germany | 2             | 0.28, 0.62   | Belgium, Germany,<br>Netherlands |
| UK      | 2             | 0.05, 1.4  | UK                               |

The concentrations of residues in 26 trials in *rye grain*, in rank order, were <0.05 (2 trials), 0.05, 0.06, 0.07, 0.08, 0.09 (2 trials), 0.22, 0.24, 0.3 (2 trials), **0.33**, **0.34**, 0.43, 0.45 (2 trials), 0.62, 0.88, 1.2, 1.4, 1.5, 1.8, 1.9, 2.1, and 2.6 mg/kg calculated as chlormequat chloride, or <0.04 (2 trials), 0.04, 0.05 (2 trials), 0.06, 0.07 (2 trials), 0.17, 0.19, 0.23 (2 trials), **0.26** (2 trials), 0.33, 0.35 (2 trials), 0.48, 0.68, 0.93, 1.1, 1.2, 1.4, 1.5, 1.6, and 2 mg/kg calculated as chlormequat cation.

The concentrations of residue in 35 trials in *wheat grain* (33 from 1994, 2 from 2000) were <0.05 (3 trials), 0.05, 0.09, 0.15, 0.17, 0.2, 0.23, 0.24, 0.28 (2 trials), 0.31 (2 trials), 0.32, 0.33, 0.34, **0.37**, 0.39, 0.41, 0.44 (2 trials), 0.48, 0.52, 0.59 (2 trials), 0.62, 0.68, 0.81, 1.2, 1.3 (2 trials), 1.4, and 1.5 (2 trials) mg/kg calculated as chlormequat chloride, or <0.04 (3 trials), 0.04, 0.07, 0.12, 0.13, 0.16, 0.18, 0.19, 0.22 (2 trials), 0.24 (2 trials), 0.25, 0.26 (2 trials), **0.29**, 0.3, 0.32, 0.34 (2 trials), 0.37, 0.4, 0.46 (2 trials), 0.48, 0.53, 0.63, 0.93, 1 (2 trials), 1.1, and 1.2 (2 trials) mg/kg calculated as chlormequat cation.

As the use patterns are comparable and the STMR values are close, the two data sets were combined: <0.04 (5 trials), 0.04 (2 trials), 0.05 (2 trials), 0.06, 0.07 (3 trials), 0.12, 0.13, 0.16, 0.17, 0.18, 0.19 (2 trials), 0.22 (2 trials), 0.23 (2 trials), 0.24 (2 trials), 0.25, **0.26** (4 trials), 0.29, 0.3, 0.32, 0.33, 0.34 (2 trials), 0.35 (2 trials), 0.37, 0.4, 0.46 (2 trials), 0.48 (2 trials), 0.53, 0.63, 0.68, 0.93 (2 trials), 1 (2 trials), 1.1 (2 trials), 1.2 (3 trials), 1.4, 1.5, 1.6, and 2 mg/kg calculated as chlormequat cation.

The Meeting estimated a maximum residue level of 3 mg/kg, an STMR value of 0.26 mg/kg, and a HR value of 2 mg/kg, calculated as chlormequat cation, for rye and wheat, and recommended that these values be extrapolated to triticale. The previous MRL recommended by the 1994 JMPR for rye (3 mg/kg) was confirmed, whereas that for wheat (2 mg/kg) was replaced.

Chlormequat is registered for use on *rape seed* in Belgium (at 0.69 kg ai/ha) and in the UK (at 1.9 kg ai/ha). No new GAP and no data on residues were submitted.

The 1994 JMPR estimated a maximum residue level of 5 mg/kg for rape seed on the basis of one British and nine German trials. The concentrations of residues, in rank order, were 1.7, 2.1, 2.2, 2.3, **2.6**, 2.7, 2.9, 3,7, 4.3, and 5.8 mg/kg calculated as chlormequat chloride or 1.3, 1.6, 1.7, 1.8, 2, **2.1**, 2.2, 2.8, 3.3, 4.5 mg/kg calculated as chlormequat cation.

The Meeting estimated an STMR value of 2.05 mg/kg for rape seed.

The 1994 JMPR estimated a maximum residue level of 20 mg/kg (fresh weight) for *dry straw and fodder of barley, oats, rye, and wheat*. The 2000 JMPR considered the results of all the available supervised trials conducted according to current GAP:

| Country             | No. of | Concentration of residues, calculated as chlormequat  | In accordance with   |
|---------------------|--------|---|----------------------|
|                     | trials | chloride, mg/kg                                       | GAP of               |
| Summer barley straw |        |   |                      |
| Denmark             | 4      | 1.3, 2.7, 4.3, 4.4                                    | Netherlands, Belgium |
| Germany             | 2      | 4, 4.4  | Netherlands, Belgium |
| UK                  | 3      | 1.6, 1.6, 4.9   | UK                   |
| Winter barley straw |        |   |                      |
| Denmark             | 1      | 0.9   | Netherlands          |
| France              | 11     | 0.36, 1.8, 2.4, 2.8, 3.1, 4.4, 4.7, 5.4, 5.5, 8.5, 11 | Netherlands, Spain   |
| Germany             | 5      | 5.8, 6.2, 6.4, 8.7, 12                                | Germany              |

| Country            | No. of | Concentration of residues, calculated as chlormequat            | In accordance with   |
|--------------------|--------|---|----------------------|
| 2                  | trials | chloride, mg/kg   | GAP of               |
| Germany            | 2      | 5.8,9   | Netherlands, Belgium |

| UK                 | 2      | 0.5, 5.4  | UK                   |

Two further trials each on oats and wheat were submitted to the current JMPR. The residues of chlormequat chloride were 0.7 and 3 mg/kg in oat straw and 0.5 and 0.9 mg/kg in wheat straw (fresh weight).

The concentrations of residues (fresh weight) in 39 trials with *barley straw*, in rank order, were 0.36, 0.9, 0.98, 1, 1.1, 1.3, 1.6 (2 trials), 1.8, 2.2, 2.4 (3 trials), 2.7, 2.8, 3.1, 4, 4.2, 4.3, **4.4** (3 trials), 4.5, 4.7, 4.9, 5.4, 5.5, 5.8 (2 trials), 6.2, 6.4, 8.5, 8.7, 8.9, 9, 11, 12 (2 trials), and 16 mg/kg calculated as chlormequat chloride or 0.28, 0.7, 0.76, 0.78, 0.85, 1, 1.2 (2 trials), 1.4, 1.7, 1.9 (3 trials), 2.1, 2.2, 2.4, 3.1, 3.3 (2 trials), **3.4** (3 trials), 3.5, 3.7, 3.8, 4.2, 4.3, 4.5 (2 trials), 4.8, 5, 6.6, 6.8, 6.9, 7, 8.5, 9.3, 9.3, and 12 mg/kg calculated as chlormequat cation.

The concentrations in 23 trials with *oat straw*, were 0.48, 0.7, 0.9, 1.2 (2 trials), 1.3, 1.6, 1.9 (2 trials), 2.2, *3* (2 trials), 3.3, 4, 4.8, 5.2, 6.3, 8.2, 9.9 (3 trials), 12, and 25 mg/kg calculated as chlormequat chloride or 0.37, 0.54, 0.7, 0.93 (2 trials), 1, 1.2, 1.5 (2 trials), 1.7, **2.3** (2 trials), 2.6, 3.1, 3.7, 4, 4.9, 6.4, 7.7 (3 trials), 9.3, and 19 mg/kg calculated as chlormequat cation.

The values in 20 trials with *rye straw* were 0.2, 0.3, 0.48, 2.2, 2.7, 2.8, 3.1, 4.3, 4.5, **4.7**, **4.8**, 5.5, 5.7, 6.9, 7.5, 9, 9.6 (2 trials), and 12 (2 trials) mg/kg calculated as chlormequat chloride or 0.16, 0.23, 0.37, 1.7, 2.1, 2.2, 2.4, 3.3, 3.5, **3.7** (2 trials), 4.3, 4.4, 5.4, 5.8, 7, 7.4 (2 trials), and 9.3 (2 trials) mg/kg calculated as chlormequat cation.

The concentrations in 35 trials with *wheat straw* were 0.5 (2 trials), 0.9, 1.5, 2.3, 2.6, 3.9, 4.8 (2 trials), 5.1, 5.4, 5.8, 6.1, 6.2, 6.6, 7 (2 trials), **7.2**, 8, 10, 11, 12, 13 (3 trials), 14, 15 (2 trials), 17 (2 trials), 18 (2 trials), 20, 21, and 29 mg/kg calculated as chlormequat chloride, or 0.39 (2 trials), 0.7, 1.2, 1.8, 2, 3, 3.7 (2 trials), 4, 4.2, 4.5, 4.7, 4.8, 5.1, 5.4 (2 trials), **5.6**, 6.2, 7.8, 8.5, 9.3, 10 (3 trials), 11, 12 (2 trials), 13 (2 trials), 14 (2 trials), 16 (2 trials), and 22 mg/kg calculated as chlormequat calculated calcula

The 117 values available for *straw* (fresh weight), in rank order, are: 0.16, 0.23, 0.28, 0.37 (2 trials), 0.39 (2 trials), 0.54, 0.7 (3 trials), 0.76, 0.78, 0.85, 0.93 (2 trials), 1, 1, 1.2 (4 trials), 1.4, 1.5 (2 trials), 1.7 (3 trials), 1.8, 1.9 (3 trials), 2, 2.1 (2 trials), 2.2 (2 trials), 2.3 (2 trials), 2.4 (2 trials), 2.6, 3, 3.1 (2 trials), 3.3 (3 trials), 3.4 (3 trials), 3.5 (2 trials), **3.7** (6 trials), 3.8, 4, 4.2 (2 trials), 4.3 (2 trials), 4.4, 4.5 (3 trials), 4.7, 4.8 (2 trials), 4.9, 5, 5.1, 5.4 (3 trials), 5.6, 5.8, 6.2, 6.4, 6.6, 6.8, 6.9, 7 (2 trials), 7.4 (2 trials), 7.7 (3 trials), 7.8, 8.5 (2 trials), 9.3 (6 trials), 10 (3 trials), 12 (3 trials), 13 (2 trials), 14 (2 trials), 16 (2 trials), 19, and 22 mg/kg calculated as chlormequat cation.

Allowing for the standard 89% of dry matter (FAO, 1997) in cereal straw (barley, 89%; oats, 90%; rye, 88%; wheat, 88%), the Meeting estimated a maximum residue level and an STMR value for dry straw and fodder of cereal grains of 30 mg/kg and 4.2 mg/kg (3.7/0.89), respectively, calculated as chlormequat cation. The previously recommended MRL of 20 mg/kg (fresh weight) for dry straw and fodder of barley, oats, rye, and wheat is withdrawn.

The 1994 JMPR estimated a maximum residue level of 20 mg/kg for *oat and rye forage* (*green*) on a fresh weight basis. The current Meeting considered the supervised trials that had been conducted according to current use patterns:

| Country    | No. of | Concentration of residues, calculated as chlormequat             | In accordance with GAP of |
|------------|--------|--|---------------------------|
|            | trials | chloride, mg/kg  |                           |
| Oats       |        |  |                           |
| Germany    | 17     | 1.1, 1.3, 1.5, 1.8, 2.5, 2.9, 3.1, 3.5, 3.7, 4.3, 6.4, 6.9, 7.6, | Belgium, Germany,         |
|            |        | 8.1, 15, 15, 17  | Finland, Netherlands      |
| UK         | 1      | 4.7  | UK                        |
| Summer rye |        |  |                           |
| Germany    | 4      | 11, 12, 12, 13   |                           |
| Belgium    |        |  |                           |
| Winter rye |        |  |                           |
| Germany    | 14     | 1.9, 2.1, 2.2, 3.6, 4.1, 4.2, 4.3, 4.9, 5.9, 9, 17, 18, 20, 28   | Germany, UK, Netherlands  |

A further trial on oats was submitted for consideration by the 2000 JMPR, in which the concentration of residue was 28 mg/kg, expressed as chlormequat chloride, in the whole green plant 30 days after treatment.

The concentrations found in all 37 trials on oat and rye forage (fresh weight) were, in rank order, 1.1, 1.3, 1.5, 1.8, 1.9, 2.1, 2.2, 2.5, 2.9, 3.1, 3.5, 3.6, 3.7, 4.1, 4.2, 4.3 (2 trials), 4.7, **4.9**, 5.9, 6.4, 6.9, 7.6, 8.1, 9, 11, 12 (2 trials), 13, 15 (2 trials), 17 (2 trials), 18, 20, and 28 (2 trials) mg/kg calculated as chlormequat chloride, or 0.85, 1, 1.2, 1.4, 1.5, 1.6, 1.7, 1.9, 2.2, 2.4, 2.7, 2.8, 2.9, 3.2, 3.3 (3 trials), 3.6, **3.8**, 4.6, 5, 5.3, 5.9, 6.3, 7, 8.5, 9.3 (2 trials), 10, 12 (2 trials), 13 (2 trials), 14, 16, and 22 (2 trials) mg/kg calculated as chlormequat cation.

Allowing for the standard 30% of dry matter in cereal forage (FAO, 1997), the Meeting estimated a maximum residue level of 100 mg/kg and an STMR value of 13 mg/kg (3.8/0.3), calculated as chlormequat cation (dry weight), for oat and rye forage. The previous MRL recommendation (20 mg/kg, fresh weight) is withdrawn.

No new data on residues or GAP for maize were submitted. The 1994 JMPR had received the results of nine supervised trials conducted in Germany at rates within the range of Belgium GAP. For green maize plants, including cobs, the following concentrations (fresh weight) were reported (PHI, 13-35 days): 0.39, 0.92, 1.6, 2.4, **3.4**, 4.3, 4.8, 5.0, and 6.2 mg/kg calculated as chlormequat chloride or 0.3, 0.71, 1.2, 1.9, **2.6**, 3.3, 3.7, 3.9, and 4.8 mg/kg calculated as chlormequat cation.

Allowing for the standard 40% of dry matter in maize forage (FAO, 1997), the Meeting estimated a maximum residue level of 15 mg/kg and an STMR value of 6.5 mg/kg (2.6/0.4), calculated as chlormequat cation (dry weight).

For maize fodder, the following concentrations (fresh weight) were reported (PHI, 78-113 days): 0.36, 0.68, 0.8, 2.4, 2.5, 4.1, 4.3, 4.5, 5.1 mg/kg calculated as chlormequat chloride, or 0.28, 0.53, 0.62, *1.9* (2 trials), 3.2, 3.3, 3.5, and 4 mg/kg calculated as chlormequat cation.

Allowing for the standard 83% of dry matter in maize stover (FAO, 1997), the Meeting estimated a maximum residue level of 7 mg/kg and an STMR value of 2.3 mg/kg (1.9/0.83), calculated as chlormequat cation (dry weight).

# Residues in animal and poultry commodities

The Meeting estimated the dietary burden of chlormequat residues in farm animals on the basis of the diets listed in Appendix IX of the FAO Manual. Calculation from the MRLs yields maximum concentrations of residues in feed suitable for estimating MRLs for animal commodities. Calculation from the STMR values for feed allows estimation of STMR values for animal commodities.

| Commodity    | MRL,<br>mg/kg | Group | % dry<br>matter | MRL/<br>dry | % of diet      |               |         | Concentration of residue,<br>mg/kg |               |         |
|--------------|---------------|-------|-----------------|-------------|----------------|---------------|---------|------------------------------------|---------------|---------|
|              |               |       |                 | matter      | Beef<br>cattle | Dairy<br>cows | Poultry | Beef<br>cattle                     | Dairy<br>cows | Poultry |
| Barley grain | 2             | GC    | 88              | 2.3         |                |               |         |                                    |               |         |

Cows

Groups of three lactating cows were given chlormequat chloride in the diet twice daily at a dose of 240, 720, or 2400 mg/animal per day, equivalent to 0.4, 1.3, and 4 mg/kg bw per day or 12, 36, and 120 ppm on a dry weight basis, for 28 consecutive days. Two additional animals were treated at the

high dose for 28 days and slaughtered 2 or 7 days after the last dose. The doses were equivalent to 0.31, 1, and 3.1 mg/kg bw per day (or 9.3, 28, and 93 ppm), calculated as chlormequat cation. At the lowest dose, the average concentrations of chlormequat chloride residues were 0.029 mg/kg in milk, 0.1 mg/kg in liver, and 0.2 mg/kg in kidney. No residues were found in meat or fat. At the medium and high doses, the plateau concentrations of chlormequat chloride residue in milk were 0.1 and 0.2 mg/kg. Concentrations up to 0.11 mg/kg were determined in some meat and fat samples. The concentrations were 0.1 and 0.4 mg/kg in liver and 0.4 and 0.8 mg/kg in kidney at the two doses, respectively, indicating that the values in kidney were at least twice as high as in liver. The concentrations of chlormequat chloride in skimmed milk were similar to those in whole milk.

The concentration of chlormequat residues in milk reached a plateau 10-11 days after the first treatment with the medium dose, but after 3-4 days with the low and high doses. The residues were cleared rapidly from meat, fat, and liver, and none could be determined in these tissues 2 days after the end of dosing. The concentrations in milk and kidney fell to about 20% of their plateau values. After 7 days, the values for milk were below the LOQ of 0.01 mg/kg, but 0.09 mg/kg remained in kidney. Although milk and tissue samples were frozen on the day of sampling, they were analysed in part 1 year later, and no adequate information on stability was received.

According to the recommendation of the 1997 JMPR, the maximum residue level and the STMR value for milk were calculated on the basis of dietary burdens of 65 and 8.1 mg/kg, respectively, for dairy cattle. The maximum residue levels and the STMR values for meat, liver, and kidney were derived from dietary burdens of 35 or 6.3 mg/kg, respectively, for beef cattle. The following table shows the highest and the mean actual and extrapolated concentrations of residues for estimation of MRLs and STMR values for chlormequat.

| Dose, ppm            | Concer | ntration of       | residues | , mg/kg, c | alculated | as chlorn | nequat cat | ion    |        |        |

<sup>1</sup> The mean concentration in milk was calculated from samples taken on days 3-28.

The Meeting estimated maximum residue levels of 0.5 mg/kg for milk, 0.1 mg/kg for liver, 0.5 mg/kg for kidney, and 0.2 mg/kg for meat and recommended that the HR values be 0.35 mg/kg for milk, 0.088 mg/kg for liver, 0.35 mg/kg for kidney, and 0.11 mg/kg for meat. The estimated STMR values are 0.018 mg/kg for milk, 0.042 mg/kg for liver, 0.084 for kidney, and 0.04 mg/kg for meat. No maximum residue level was recommended for fat.

#### Chickens

Three groups of four hens were given capsules containing chlormequat chloride at a dose of 0.72, 2.1, or 7.2 mg/bird per day, equal to 6, 18, and 60 ppm on a dry weight basis, for 28 consecutive days. Two additional groups of 12 hens were treated with the high dose for 28 days and slaughtered 2 or 7

days after the last dose. The doses were equivalent to 4.6, 14, and 46 ppm when calculated as chlormequat cation.

The lowest dose resulted in concentrations of chlormequat chloride residues in eggs at or above the LOQ of 0.05 mg/kg, while 0.05 mg/kg was found in liver and none in meat or fat. Plateau concentrations of 0.06 and 0.1 mg/kg were found in eggs of hens treated with the two higher doses after 1 week of dosing. The concentrations in meat and fat samples were below the LOQ of 0.05 mg/kg, while those in liver were 0.07 mg/kg at the medium dose and 0.18 mg/kg at the high dose.

The residues were cleared rapidly from meat, fat, and liver. No chlormequat chloride was determined in meat or fat. The concentrations in liver had fallen to 0.05 mg/kg 2 days after the end of dosing and to below the LOQ after 7 days. After 2 and 7 days, the residues in eggs had fallen to values below the LOQ of 0.05 mg/kg.

Egg and tissue samples were frozen on the day of sampling but were analysed in part 3 months (tissues) or 10 months (eggs) later. No adequate information on stability was received.

According to the recommendation of the 1997 JMPR, the maximum residue level and the STMR values for eggs and poultry tissues were calculated on the basis of dietary burdens of 9.6 and 1.1 mg/kg, respectively. The following table shows the highest and the mean actual and extrapolated concentrations of residues for estimation of MRLs and STMR values for chlormequat.

| Dose, ppm         | Concentrations of residues, mg/kg, calculated as chlormequat cation |                   |         |        |         |        |         |        |

| Actual: 4.6       | 0.047   |                   |         |        | 0.07    | 0.04   |         |        |

<sup>1</sup> The mean concentration in eggs was calculated from samples taken on days 3-28.

The Meeting recommended an MRL of 0.1 mg/kg for eggs and offal, and 0.04\* mg/kg for meat; no MRL was recommended for fat. The estimated STMR values were 0.04 for eggs, 0.0096 for liver, and 0 for meat. HR values of 0.064 mg/kg for eggs, 0.053 mg/kg for offal, and 0 for meat were estimated.

## Fate of residues during processing

In three studies of the processing of *rape seed* reported by the 1994 JMPR, the mean processing factor for crude rape seed oil was <0.018. On the basis of the STMR value of 2.0 mg/kg for rape seed, an STMR-P value of 0.037 mg/kg was estimated for crude rape seed oil.

One study on the processing of *barley* to barley pearls submitted to the 1994 JMPR indicates a processing factor of 0.06. On the basis of the STMR value of 0.15 mg/kg for barley grain, an STMR-P value of 0.009 mg/kg was estimated for barley pearl. Another study indicated processing factors of 0.69 for malt and 0.015 for beer. On the basis of the STMR value of 0.15 mg/kg for barley, STMR-P values of 0.1 mg/kg and 0.0023 mg/kg were estimated for malt and beer, respectively.

Two studies on the processing of *oats* to oat flakes were submitted to the 2000 JMPR, but only one could be used for evaluation (processing factor, 0.27) because high values were found in samples from untreated plots in the second study. Two further studies were reported by the 1994

JMPR (processing factors, 0.1 and 0.25). On the basis of an STMR value of 1.2 mg/kg for oat grains and a mean processing factor of 0.21, an STMR-P value of 0.25 mg/kg was estimated for oat flakes.

One study on the processing of *rye* was submitted to the 2000 JMPR but could not be used for evaluation because high values were found in samples from untreated plots. In a study reported by the 1994 JMPR, the processing factors were 3.2 for bran, 0.99 for flour, 1.3 for wholemeal, and 0.95 for wholemeal bread. On the basis of the MRL of 3 mg/kg for rye, the following maximum residue levels were estimated: 10 mg/kg for rye bran, 3 mg/kg for rye flour, and 4 mg/kg for rye wholemeal. On the basis of the STMR value of 0.26 mg/kg, STMR-P values were estimated as 0.83 mg/kg for rye bran, 0.26 mg/kg for rye flour, 0.34 mg/kg for rye wholemeal, and 0.25 mg/kg for rye wholemeal bread.

One study on the processing of *wheat* submitted to the 2000 JMPR showed processing factors of 2.5 for wheat bran, 1 for wholemeal, and 0.63 for wholemeal bread. In a study reported by the 1994 JMPR, processing factors of 4.6 for bran, 0.41 for flour, 1.4 for wholemeal, and 0.79 for wholemeal bread were estimated. The following processing factors were estimated: bran, 3.6; flour, 0.41; wholemeal, 1.2; and wholemeal bread, 0.71. On the basis of the MRL of 3 mg/kg for wheat grain, the following maximum residue levels were estimated: 10 mg/kg for wheat bran, 2 mg/kg for wheat flour, and 5 mg/kg for wheat wholemeal. On the basis of the STMR value of 0.26 mg/kg for wheat grain, STMR-P values of 0.94 mg/kg for wheat bran, 0.11 mg/kg for wheat flour, 0.31 mg/kg for wheat wholemeal bread were estimated.

# RECOMMENDATIONS

The Meeting estimated the maximum residue and STMR levels shown below. The maximum residue levels are recommended for use as MRLs.

|         | Commodity                               | MRL, m        | g/kg     | STMR,          | HR, mg/kg |

<sup>1</sup>Now included in recommendation for Straw and fodder (dry) of cereal grains

 $^{2}$  The information provided to the JMPR precludes an estimate that the dietary intake would be below the acute RfD of 0.05 mg/kg bw

<sup>3</sup>Except Maize fodder

### Further work or information

### Desirable

Analytical study of stability in frozen storage of samples of animal products fortified with chlormequat.

### **Dietary risk assessment**

### Chronic intake

STMR or STMR-P values were estimated by the present Meeting for 27 raw and processed food commodities. When data on consumption were available, these values were used to estimate dietary intake. The results are shown in Annex 3.

The IEDIs for the five GEMS/Food regional diets, based on the estimated STMR values, represented 0-3 % of the ADI. The Meeting concluded that long-term intake of residues of chlormequat from uses that have been considered by the JMPR is unlikely to present a public health concern.

#### Short-term intake

The IESTI for chlormequat was calculated for the food commodities (and their processing fractions) for which maximum residue levels and STMR values were estimated and for which data on consumption were available. The results are shown in Annex 4. Pears were the only commodity for

which the IESTI exceeded the acute RfD, with values of 240% for the general population and 700% for children.

The Meeting concluded that short-term intake of residues of chlormequat when used, other than on pears, in ways that have been considered by the JMPR is unlikely to present a public health concern.
